Dania Huggins  
Irrigated Lands Conditional Waiver Program  
Central Valley Regional Water Quality Control Board  
11020 Sun Center Drive, #200  
Rancho Cordova, CA 95670-6114

Dear Dania,

The East San Joaquin Water Quality Coalition is submitting the 2008 irrigation season Semi-Annual Monitoring Report for review by the Central Valley Regional Water Quality Control Board as required by the Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands Resolution Order No. R5-2003-0105, Monitoring and Reporting Program Order No. R5-2005-0833, amended by Monitoring and Reporting Program Order No. R5-2006-0053 and Monitoring and Reporting Program Order No. R5-2006-0077.

The attached documents report on the Coalition monitoring program for the period of April 1, 2008 to September 30, 2008 and covers activities associated with the 2008 irrigation season monitoring, reporting, outreach and education.

In every aspect, the Coalition seeks the best quality in its monitoring program by using the most scientifically reliable field and laboratory protocols, ensuring complete quality control and quality assurance of the data received from laboratories, and reporting on that data accurately and punctually to both the CVRWQCB and to the members of the Coalition. The Coalition and its technical staff process and review an immense quantity of data and provide a large number of reports in a timely manner to the CVRWQCB.

Requirements of the MRP were met with a few exceptions which are described in the attached SAMR. Sampling occurred during all six months of the irrigation season and all data generated are an accurate reflection of conditions in the Coalition region. None of the few exceptions affected the overall completeness, accuracy, or precision of the data. Consequently, the conclusions and recommendations and the Coalition's outreach program are unaffected by these exceptions.

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for knowingly submitting false information, including the possibility of fine and imprisonment for violations."

This letter will be submitted with an original signature when the printed version of the SAMR is submitted to the Regional Board.

Submitted respectfully,

A handwritten signature in black ink, consisting of a stylized 'P' followed by a horizontal line and a vertical stroke, and a large 'K' followed by a horizontal line.

Parry Klassen

## List of Acronyms

---

BMP	Best Management Practice
BOD	Biological Oxygen Demand
BU	Beneficial Use
CDPR	California Department of Pesticide Regulation
CEDEN	California Environmental Data Exchange Network
COC	Chain of Custody
CURES	Coalition for Urban and Rural Environmental Stewardship
CVRWQCB	Central Valley Regional Water Quality Control Board
DDD	Dichlorodiphenyldichloroethane
DDE	Dichlorodiphenyldichloroethylene
DDT	Dichlorodiphenyltrichloroethane
DF	Dilution factor
DFG	California (Department of Fish and Game)
DHS	(California) Department of Health Services
DI	Deionized
DO	Dissolved Oxygen
DQO	Data Quality Objective
DWR	(California) Department of Water Resources
E	Environmental sample
EC	Specific Conductance
EC <sub>50</sub>	Effective Concentration of 50% of the measured endpoint
EPA	Environmental Protection Agency
ESJWQC	East San Joaquin County Water Quality Coalition
FB	Field Blank
FD	Field Duplicate
HDPE	High density polyethylene
ILRP	Irrigated Land and Regulatory Program
IPM	Integrated Pesticide Management
IRIS	Integrated Risk Information System
K <sub>oc</sub>	Organic Carbon Partitioning Coefficient
LABQA	Laboratory Quality Assurance
LC <sub>50</sub>	Lethal Concentration at 50% mortality
LCS	Laboratory Control Spike
MCL	Maximum Contaminant Level
MLJ-LLC	Michael L. Johnson, LLC
MPN	Most Probable Number
MRP	Monitoring and Reporting Program Order No. R5-2005-00833
MS	Matrix Spike
MUN	Municipal and Domestic Supply (beneficial use)
NA	Not Applicable
ND	Not Detected
NiCd	Nickel-cadmium

NM	Normal Monitoring
NONAG	The sample was provided by a project other than the Coalition to the laboratory and was included in the QC report from the laboratory to meet their QC requirements.
OP	Organophosphate
PCA	Pesticide Control Advisor
pH	Power of Hydrogen
PR	Percent Recovery
PTFE	Polytetrafluoroethylene (Teflon™)
PUR	Pesticide Use Report
QA	Quality Assurance
QAPP	Quality Assurance Project Plan
QC	Quality Control
RfD	Reference Dose
RL	Reporting Limit
RPD	Relative Percent Difference
RS	Resample
SAMR	Semi-Annual Monitoring Report
SG	Statistically significantly different from control; Greater than 80% threshold
SL	Statistically significantly different from control; Less than 80% threshold
SOP	Standard operating procedure
SPE	Solid Phase Extraction
SWAMP	Surface Water Ambient Monitoring Program
TDS	Total Dissolved Solids
TIE	Toxicity Identification Evaluation
TKN	Total Kjeldahl Nitrogen
TOC	Total Organic Carbon
TRS	Township, Range, Section
UC	University of California
USEPA	United States Environmental Protection Agency
VOA	Volatile Organic Analyte
WER	Watershed Evaluation Report
WQG	Water Quality Guidelines
WQTL	Water Quality Trigger Limit

## List of Units

---

cfs	cubic feet per second
L	Liter
lbs	pounds
mg	milligram
NTU	Nephelometric Turbidity Units
ppm	parts per million
sec	second
TUa	Toxic Unit (acute)
TUc	Toxic Unit (chronic)
µg	microgram

## List of Terms

---

**Agricultural Commissioner** – County Agriculture Commissioner

**ArcGIS** – Geographic Information Systems mapping software

**Central Valley or Valley** – California Central Valley

**Coalition** – East San Joaquin Water Quality Coalition

**Coalition/ESJWQC region** – The region within the Central Valley that is monitored by the East San Joaquin Water Quality Coalition.

**Constituent of concern** – any constituent that is the focus of monitoring

**Drainage** –water that moves horizontally across the surface or vertically into the subsurface from land

**Landowners** – one or more persons responsible for the management of the irrigated land

**Non project QA sample** – sample results from another project other than the Coalition included to meet laboratory QC requirements.

**Regional Board** – Central Valley Regional Water Quality Control Board

**Site subwatershed** – Starting from the sampling site, all water bodies that drain, directly or indirectly, into the water body before the point where sampling occurs.

**Special study** – a study conducted outside of normal monitoring activities that involves monitoring specific constituents in an effort to determine the mechanism responsible for the exceedances

**Subwatershed** – The topographic perimeter of the catchment area of a stream tributary. (EPA terms of environment: (<http://www.epa.gov/OCEPATERMS/sterms.html>))

**Waiver** – Central Valley Regional Water Quality Control Board Coalition Group Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands, Order No. R5-2006-0077, amending Order No. R5-2006-0053.

**Waterbody** –standing or flowing water of any size that may or may not move into a larger body of water, including lakes, reservoirs, ponds, rivers, streams, tributaries, creeks, sloughs, canals, laterals and drainage ditches.

**Watershed** – The land area that drains into a stream; the watershed for a major river may encompass a number of smaller watersheds that ultimately combine at a common point. (EPA terms of environment: <http://www.epa.gov/OCEPATERMS/wterms.html>)

## Executive Summary

---

The East San Joaquin Water Quality Coalition (ESJWQC) region includes the counties of Stanislaus, Merced, Madera, Tuolumne, and Mariposa and the portion of Calaveras County that drains into the Stanislaus River. Apart from the San Joaquin River which forms the south and east boundary of the Coalition, there are five major rivers in the watershed: the Fresno River, Chowchilla River, Merced River, Tuolumne River and Stanislaus River. In addition, the Eastside Bypass is considered a major water body. These east side tributaries of the San Joaquin River drain the Sierra Nevada range from east to west. Irrigated agriculture is the predominant land use in the Coalition area although the growing urban areas in the Central Valley are also a significant land use. Other non-irrigated land uses include dairies with minor acreage in feedlots.

Water quality monitoring was conducted during 6 months of the irrigation season (April – September 2008). Several sites were dry during several monitoring trips. The primary objective of the monitoring program was to characterize discharge from agriculture during the irrigation season. Field data were recorded during each sampling event unless otherwise noted and ambient water samples were analyzed for pesticides, *E. coli*, metals, bacteria, inorganic and organic parameters, as well as toxicity to three test species: *Ceriodaphnia dubia*, *Pimephales promelas*, and *Selenastrum capricornutum*. During sediment sampling events field parameters were measured and toxicity samples were collected to test for *Hyalella azteca* toxicity. All water and sediment sample analyses are based on requirements specified in Table 1 of the ILRP Monitoring and Reporting Program (MRP). For samples that experienced toxicity, follow-up sampling occurred within 48 hours from the time that the laboratory reported the toxicity.

Samples collected during the 2008 irrigation season included normal monitoring and Management Plan Monitoring. For both types of samples, there were 29 exceedances of pesticides including chlorpyrifos (18), malathion (2), and one each of carbofuran, cyanazine, DDT, DDE, dieldrin, dimethoate, diuron, methyl parathion, and thiobencarb. Water column toxicity was experienced in 37 samples (not including field duplicates). All sites showing toxicity were resampled to determine the persistence of the toxicity. Of the 37 samples that experienced toxicity, 35 were toxic to *Selenastrum*, and two were toxic to *Ceriodaphnia*. Twenty-four sediment samples were found to be toxic to *Hyalella*.

As in the previous irrigation season, exceedances of Specific Conductance (EC) and Total Dissolved Solids (TDS), both measures of salts in the water, often co-occurred during the irrigation monitoring events when both parameters were measured. In total, there were 25 exceedances of TDS and 52 exceedances of the SC WQTLs. There were 86 exceedances of the Dissolved Oxygen (DO) and 17 exceedances of the pH WQTLs. There were 50 exceedances of the *E. coli* WQTL, 28 of the nitrate, and 4 of the ammonia WQTL. Three metals, arsenic (13), copper (31), and lead (10), were found at concentrations above WQTLs in water samples. Among the metals, only copper is currently used by agriculture within the Coalition region. Sources are distinguishable using stable isotopes but the cost of the analyses is substantial and the Coalition does not anticipate using this technique to identify the source(s).

Eleven TIEs were performed during the irrigation season. Four TIEs on *Selenastrum* resulted in no persistent toxicity and the cause of toxicity could not be determined. Results of the other TIEs indicated that toxicity was a result of non polar organics and cationic metals for *Selenastrum* and organophosphate pesticides for *Ceriodaphnia*. TIEs were conducted on all but two samples that had a greater than 50% toxic effect on the test organism. Both samples were resamples for *Selenastrum* toxicity where the original sample did not require a TIE; due to a lab miscommunication the resamples were not saved for TIEs.

Over the 2008 storm season, the Coalition was able to meet its monitoring program objectives by determining the concentration and load of waste in discharges to surface waters, evaluating compliance with existing narrative and numeric water quality triggers to determine if implementation of additional management practices is necessary to improve and/or protect water quality and assessing the impact of storm water discharges from irrigated agriculture to surface water. The Coalition used the results of surveys of management practices to determine the implementation of management practices to reduce discharge of specific wastes that impact water quality in receiving waters of the Coalition region. Survey results were compiled and submitted to the CVRWQCB on January 31, 2009. These results will be used to track effectiveness and will be used as a measure of initial conditions to track the implementation of new practices.

Outreach and education activities continue to be a central component of the Coalition monitoring program. The Coalition provides information and notification of exceedances in person during grower meetings, through the Coalition website, and by mail. The Coalition website ([www.esjcoalition.org](http://www.esjcoalition.org)) includes a general description of the Coalition's mission, member information, recommended best management practices, a schedule of Coalition meetings and presentations, Coalition news and newsletters, maps of sample sites and subwatersheds, and links to other sources of relevant information.

A letter was sent to almond and alfalfa growers on July 1, 2008 reminding members that the 2007 irrigation exceedances of chlorpyrifos had been linked to spray drift and irrigation runoff after application. The letter encouraged growers to implement management practices affecting spray drift and irrigation runoff. The letter also included a list of chlorpyrifos exceedances in all subwatersheds during July 2007.

In mid-July 2008, a mailing of the Watershed Coalition News (newsletter) went out to 6,500 growers containing an ESJWQC-sponsored article on chlorpyrifos exceedances and best management practices to reduce discharge and/or spray drift. Additional outreach occurred as Coalition Executive Director Parry Klassen was invited to give presentations on October 7, 21, 28, and November 4, 2008 at the Merced Community College Pest Management Update Course. The presentations included Coalition monitoring results, sprayer calibrations, and management of organophosphates and pyrethroids for both orchards and row crops.

A mailing was sent out to all 118 Coalition members within the Dry Creek @ Wellsford Rd site subwatershed to announce an upcoming grower meeting. Included in the mailing were a blank general survey (if outstanding) and an exceedance table for all years and seasons. The meeting

with Dry Creek growers was held on November 12, 2008 at the Fruit Yard restaurant in Modesto. MLJ-LLC and Coalition representatives discussed water quality exceedances, management plan requirements and management practices to reduce agricultural discharge.

Conclusions from Coalition monitoring results are:

- The outreach strategy used to date has not been as effective as necessary to reduce exceedances of WQTLs. Exceedances from many of the manageable pesticide applications such as chlorpyrifos and copper have not been eliminated, and toxicity to *Selenastrum* and *Hyalella* remain common.
- The problematic constituents from past years' monitoring remain the primary exceedances experienced in the Coalition region.
- Dairies may play a larger role in causing exceedances of numerous constituents than previously thought.

Greatly elevated concentrations of soluble chemicals such as chlorpyrifos are most likely the result of irrigation return flows; concentrations slightly over the WQTL most likely are the result of spray drift. Increased concentrations of soluble chemicals such as chlorpyrifos generally are associated with increased applications in watersheds indicating that elevated concentrations are the result of numerous growers and/or large acreages contributing to the exceedance. Using these results, individual growers along water bodies can be contacted and the appropriate management practices discussed to more effectively target outreach. Sufficient data now exist to target specific crops and specific times of the year to focus outreach. It is unlikely that additional Management Plan Monitoring will be helpful in providing the Coalition with information critical to discussions with growers. Discharges in priority watersheds have been characterized sufficiently and growers identified for outreach such that additional monitoring will not be cost effective.

## Introduction

---

This document is being submitted by the East San Joaquin Water Quality Coalition (ESJWQC or Coalition) to the Central Valley Regional Water Quality Control Board (CVRWQCB or Regional Board) as required by the Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands Resolution No. R5-2003-0105 (Order), Monitoring and Reporting Program Order No. R5-2005-0833, amended by Monitoring and Reporting Program Order No. R5-2006-0053 and Monitoring and Reporting Program Order No. R5-2006-0077 (hereafter referred to as the Irrigated Lands Regulatory Program or ILRP). The document herein reports on the Coalition monitoring program and covers activities associated with the 2008 irrigation season monitoring, reporting, outreach and education.

Data that are too substantial to include in the body of this report are located in separate appendices. Where appropriate, Semi-Annual Monitoring Report (SAMR) sections refer readers to the appendices relevant to that section.

## Description of Watershed

---

The East San Joaquin Water Quality Coalition (ESJWQC) area includes Stanislaus, Merced, Madera, Tuolumne, and Mariposa Counties and the portion of Calaveras County that drains into the Stanislaus River. The region that drains into the Coalition area is bordered by the crest of the Sierra Nevada on the east and the San Joaquin River on the west, the Stanislaus River on the north to the San Joaquin River on the south. The southern portion of the Coalition area includes the area that was formerly within the Root Creek Coalition. Additionally, there are landholdings in the vicinity of the Lone Willow Slough watershed (west of the Eastside Bypass) that have joined the Westside Coalition.

The only surface water export from the Coalition area is northward via the San Joaquin River. This river drains watersheds on the east and west side of the California Central Valley, though only east side watersheds are relevant with respect to the Coalition area. San Joaquin River water is eventually either exported to the San Francisco Bay through the Delta, or conveyed southward via the State Water Project and the Delta Mendota Canal. The Coalition area also includes within its boundaries all or portions of six irrigation districts: Oakdale Irrigation District, Merced Irrigation District, Turlock Irrigation District, Modesto Irrigation District, Chowchilla Irrigation District and Madera Irrigation District. Water bodies may have both irrigation district and Coalition involvement only when they convey both irrigation supply and agriculture return water. Irrigation districts are covered by individual waivers.

Apart from the San Joaquin River, there are five major rivers in the watershed: Fresno River, Chowchilla River, Merced River, Tuolumne River and Stanislaus River. In addition, the Eastside Bypass is considered a major water body. These east side tributaries of the San Joaquin River drain the Sierra Nevada range from east to west. Typically, only the Stanislaus, Merced, and Tuolumne Rivers maintain flows during the summer months. Flow in the Chowchilla and Fresno Rivers are intermittent to nonexistent as the irrigation season progresses into the fall and remain dry unless major storm events produce sufficient precipitation in the immediate vicinity of the rivers. Intermediate sized water bodies in the Coalition area (e.g. Dry Creek, Duck Slough, and Highline Canal) originate either in the Sierra Nevada foothills or the Valley itself and are tributaries to the major rivers. The remaining water bodies are small in size (e.g. Silva Drain, Mustang Creek) and are primarily agricultural canals and ditches that convey water to one of the larger rivers or intermediate-sized creeks/sloughs.

Although exact acreage is difficult to estimate due to rapidly changing land use, the Coalition area contains 1,186,889 acres that are considered irrigated agriculture (Table 1). For Stanislaus, Merced, Mariposa, Tuolumne, and Madera Counties, the Coalition used the Department of Water Resources (DWR) land use estimates for irrigated agriculture to determine total acreage. DWR does not provide land use data for Calaveras County. Instead, the Coalition used data from the County Agricultural Commissioner's office.

**Table 1. Acreage of irrigated land in ESJWQC counties.**

Data from 2001 California Department of Water Resources  
(<http://www.landwateruse.water.ca.gov/annualdata/landuse/2001/landuselevels.cfm>).

<b>County</b>	<b>Irrigated Land Area (acres)</b>
Calaveras	976
Madera	295,000
Mariposa	297
Merced	510,500
Stanislaus	378,700
Tuolumne	1,416
<b>Total</b>	<b>1,186,889</b>

Note that the estimates of irrigated acres may differ from previous estimates. The Coalition anticipates that as urban development increases over the next several years, the estimates will continue to change.

### ***Land Use***

Irrigated agriculture is the predominant land use in the Coalition area although growth of the urban areas in the San Joaquin Valley has been a significant factor impacting water quality. Non-irrigated land uses include urban and dairy with some acreage in feedlots and impoundments.

A variety of crops are grown and are often found in regions specific to microclimate, soil type, and local farming history. A more detailed discussion of crop type occurs in this report within the Sampling Sites Description section. Over 50 types of commercial crops are produced within the Coalition area (Table 2). The most common crops by acres are almonds, tomatoes, hay, sweet potatoes, cotton, silage, beans, wheat, peaches, melons, and grapes. In general agriculture varies geographically as one travels from the north to south and from east to west. In the eastern foothills, deciduous orchards and grapes are the dominant crops, though there are also considerable amounts of irrigated pastures and dairy farms. Crop type is more diverse in the northern Coalition area and includes row crops (e.g. tomatoes, sweet potatoes, melons, and leafy green vegetables), alfalfa hay, and orchards. In the relatively drier southern area dominate crops include cotton, vineyards, and orchards (almonds and pistachios).

A map of land use in the Coalition region is provided in Figure 1. Information was obtained from the California Department of Pesticide Regulation database which is current through 2004 (<http://calpip.cdpr.ca.gov/cfdocs/calpip/prod/main.cfm>). The map in Figure 1 is provided as a jpeg file; however, due to the size of the Coalition area, the map does not support a reasonable

level of detail. ArcGIS coverage has been provided previously, and can be referred to for more detail on coverage.

**Table 2. Crops grown and monthly pesticide use in the ESJWQC region.**

Crop information was developed from Pesticide Use Reports from the 2004 CDPR PUR database. An "X" in the month column specifying that there were pesticide use permits filed in those months indicating that applications of chemicals to those crops occurred.

Figure 1. Agriculture lands in the ESJWQC region.

## ***Climate***

Summer temperatures are usually hot in the San Joaquin Valley, ranging from the mid 80's to mid 90's (°F) for average daily high temperatures and the mid to upper 50's for average summer daily low temperatures. In the summer the northern area is subject to pulses of cool coastal air that can provide relief from summertime highs and allow for the farming of crops requiring cooler temperatures. The upland areas are slightly cooler at night but generally remain hot throughout the summer. In the winter, temperatures are usually moderate with average daily high temperatures in the mid to upper 50's and average daily low temperatures in the low 40's. Freezing is common; this generally prevents farming of perennial crops susceptible to frost. Annual precipitation on the San Joaquin Valley floor in the Coalition area is variable, averaging 13-15 inches per year (City of Merced). Rainfall occurs predominantly during the winter and is heterogeneously distributed throughout this period (typical for a Mediterranean climate). Winter seasons are characterized by several small storms with one or two major events (increased rain due to larger storms) providing the bulk of the precipitation. December, January and February are historically the months with greatest precipitation. There appears to be no discernible pattern as to when during the winter these large storms occur.

## ***Soils***

Soils maps reveal a complicated mosaic of soil types in the Coalition area. Generally, the Coalition area has sandy, well-drained soils. Soil type interacts with other factors such as slope, soil saturation, rainfall/irrigation water amount, and drainage patterns to control runoff. Soils maps and ArcGIS soils coverages have been delivered to the Central Valley Regional Water Quality Control Board (CVRWQCB) previously and will not be provided as part of this document.

## ***Hydrology***

As indicated above, there are several main rivers that cross the Coalition area from east to west. These rivers have complex hydrologic systems due to both seasonal influence of precipitation, and management systems for water use (reservoirs, basin transfers, hydropower, municipal and irrigation supply, and anadromous fisheries). In general, flows are greatest during the winter and spring due to winter precipitation and subsequent spring snowmelt. Summertime flows are now greater than flows were historically due to reservoir releases. The numerous small creeks that have their headwaters in the foothills and western portion of the Sierra Nevada mountain range are primarily ephemeral with no flow from early summer through the first rains of the winter. Later discussion of hydrology will be specific to each subwatershed.

There is an increased propensity for runoff with increased slope, soil water saturation, and volume of water, conditions that arise primarily due to large amounts of rainfall and the relatively greater sloped valley margins. During the winter, runoff is drained through the myriad of creeks, rivers, and drains developed for flood management. Runoff can also occur during the irrigation season if water entering the field is greater than the amount that can infiltrate the soil. Recent sampling efforts indicate that many of the drainages in the southern

portion of the Coalition region do not carry runoff even during substantial rainfall events. Immediately after a storm in March of 2005, Ash Slough did not maintain sufficient flows to be sampled even when adjacent orchards were flooded. Also, the watersheds throughout the Coalition region tend to be “flashy” in that water from runoff events moves through the systems very quickly leaving very little flow shortly after the storm ends. For example, there was no flow remaining when crews visited the site for persistence sampling in the Lone Willow Slough watershed approximately one week after a winter 2005 storm event.

A complex system for water transfer, use, and re-use is utilized for irrigation purposes. In some cases, the volume of water applied to a field for irrigation may represent not only what is needed by the vegetative crop, but also a greater quantity used either to push the water over the field, or as a method of reducing the negative effects of evapotranspiration and consequent accumulation of salts. The system is designed to allow downstream irrigators to reuse water that was previously used upstream.

### ***Valuable Aquatic Resources***

Aquatic resources of water bodies within the Coalition area are defined in part by the beneficial use (BU) assigned by the CVRWQCB. Using the tributary rule, BUs were applied to upstream tributaries based on the currently assigned BU (Table 3) in downstream water bodies. Important aquatic resources exist in the Coalition area, including cold water and warm water stream aquatic habitat, wetlands and fisheries resources.

Wetlands are an important aquatic resource within the Coalition area. These habitats are associated with riparian areas along many of the water bodies in the region (particularly in the Sandy Mush Country area of southern Merced County) and savannah step region of the lower Sierra Foothills. Because vernal pools are isolated mini-watersheds they are found heterogeneously distributed across the Coalition in upland areas. They receive winter rains and require an aquatard to maintain their characteristic pools into the spring. These wetlands maintain a unique flora and fauna and are protected by the Clean Water Act. Generally, vernal pools and irrigated agriculture are not found together, although there are exceptions.

Several fisheries are considered important in the Coalition area. Steelhead trout (*Oncorhynchus mykiss*) were common in the region prior to the construction of dams on all of the major tributaries of the San Joaquin River. Once the dams were built, historic spawning grounds were eliminated and with them, most of the wild salmonids in the San Joaquin Valley. Currently, no permanent steelhead stocks exist in the drainages of the San Joaquin Valley despite occasional reports of fish in the Tuolumne and Merced Rivers. The California Department of Fish and Game considers the Tuolumne River to have suitable habitat to support a steelhead run if one could become established.

Chinook salmon (*Oncorhynchus tshawytscha*) are present in the San Joaquin system and are found in all major tributaries in the region. All of the major tributaries are considered to be impaired for salmonid spawning and/or migration habitat as is the main stem of the San Joaquin River (Table II-1 of the Sacramento/San Joaquin River Basin Plan).

**Table 3. Primary water bodies that drain directly into the major rivers of the ESJWQC region and the beneficial use for each of the major river reaches.**

Site Subwatershed (site name)	Immediate Downstream River	Beneficial Use of Immediate Downstream River*
Ash Slough @ Avenue 21 <sup>1</sup>	San Joaquin River (Sack Dam to Merced River reach) <sup>3</sup>	1-4, 7-9, 11-15
Bear Creek @ Kibby Rd <sup>1</sup>		
Berenda Slough along Avenue 18 ½		
Black Rascal Creek @ Yosemite Rd		
Cottonwood Creek @ Rd 20 <sup>2</sup>		
Deadman Creek @ Gurr Rd		
Deadman Creek @ Hwy 99		
Dry Creek @ Rd 18 <sup>1</sup>		
Duck Slough @ Gurr Rd		
Duck Slough @ Hwy 99		
Livingston Drain @ Robin Ave		
Miles Creek @ Reilly Rd		
South Slough @ Quinley Rd		
Dry Creek @ Wellsford Rd		
Hatch Drain @ Tuolumne Rd		
Highline Canal @ Hwy 99		
Highline Canal @ Lombardy Rd		
Hilmar Drain @ Central Ave		
Mustang Creek @ East Ave		
Prairie Flower Drain @ Crows Landing Rd		
Westport Drain @ Vivian Ave		
Highline Canal @ Hwy 99	Merced River (McSwain Reservoir to San Joaquin River reach)	1, 3-15
Highline Canal @ Lombardy Rd		
Merced River @ Santa Fe		
Mustang Creek @ East Ave		
Silva Drain @ Meadow Dr		

<sup>1</sup>Surface water flow in these water bodies terminates in subterranean flow except for periods of increased runoff during large winter storms

<sup>2</sup>There is no natural course by which Cottonwood Creek flows to the San Joaquin River. Its course is diverted in several ways, generally through canals or to open areas for percolation, depending upon the current situation

<sup>3</sup>Sack Dam to Merced River reach: all waterbodies that drain to this reach enter via the East Side Bypass with the exception of Livingston Drain

**\* Beneficial Use code list:**

## ***ESJWQC Subwatersheds and Waterbodies***

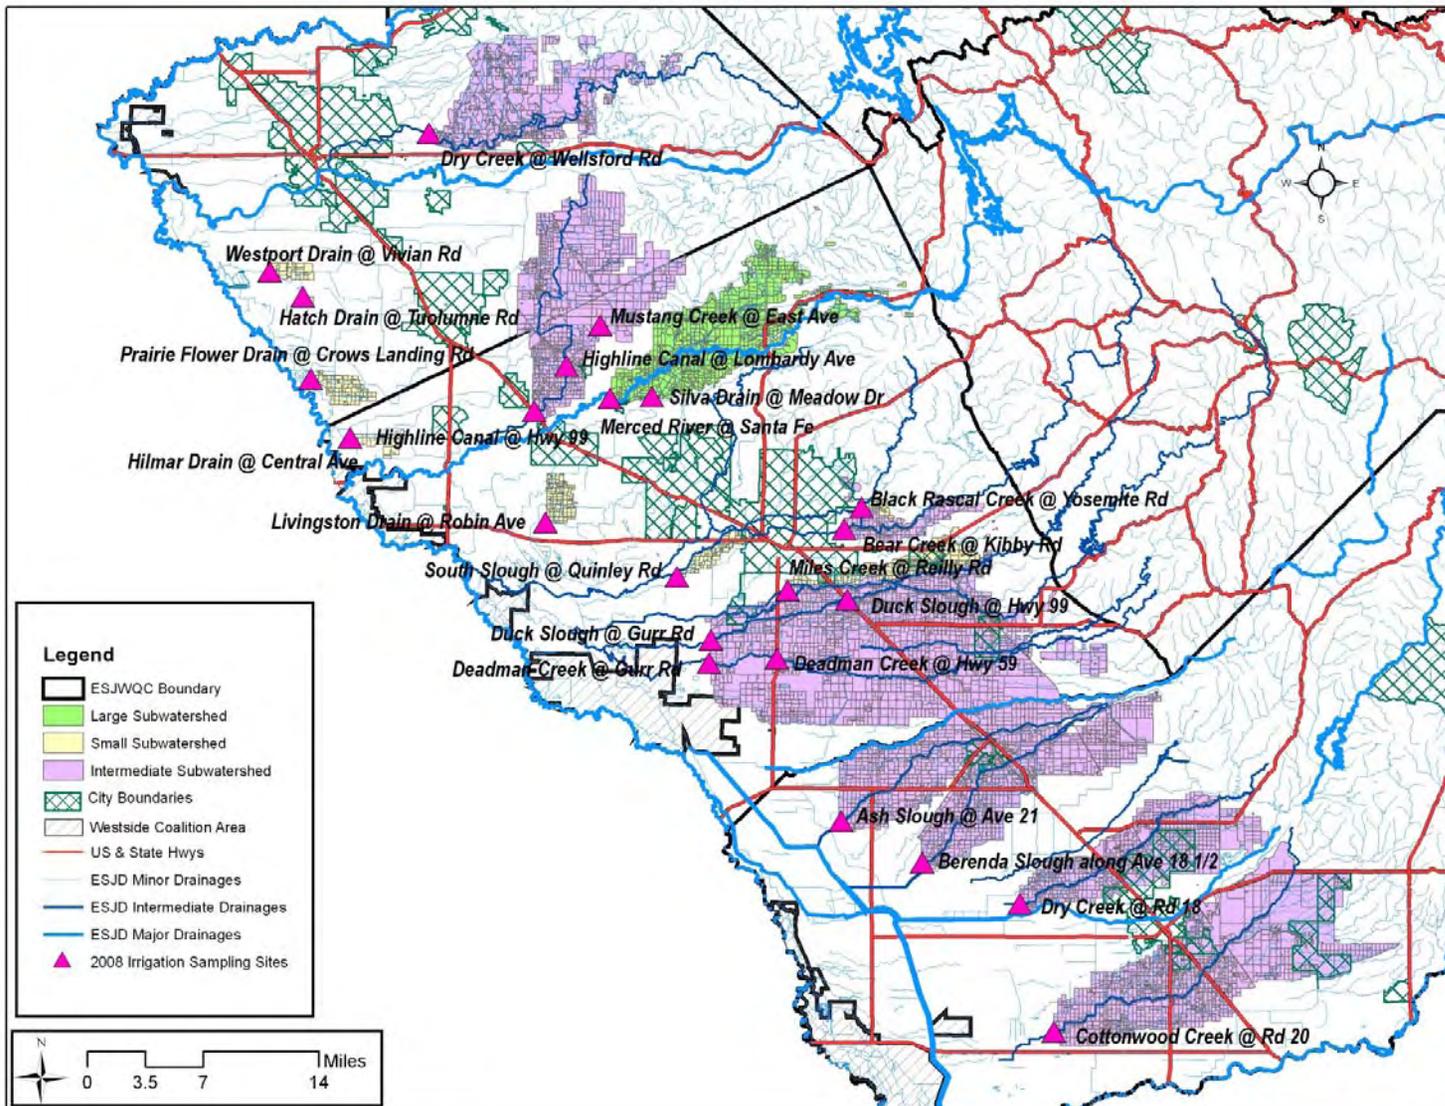

There are approximately 215 water bodies in the Coalition area (Table 5a-5c, East San Joaquin Water Quality Coalition Watershed Evaluation Report, Third Revised Report) that are classified into four categories (large, intermediate, small, or lake/reservoir) based on water flow and water body size. The seven large water bodies within the Coalition region are the Chowchilla River, Eastside Bypass, Fresno River, Merced River, San Joaquin River, Tuolumne River and Stanislaus River. With the exception of the Merced River, none of the large rivers are sampled. The Merced River is sampled but relatively high in the watershed to allow the integration of the sampling results from smaller water bodies that drain into the river. Though the amount of irrigated agriculture within these watersheds is similar or even less than some of the watersheds classified as medium sized, water flow in these relatively larger watersheds is primarily a function of source water originating upstream of irrigated agriculture. These rivers have relatively greater base water flow due to snowmelt and reservoir releases. There are 16 intermediate sized water bodies in the Coalition Region. These are primarily natural creeks and sloughs that drain a large portion of the Coalition area. The 164 smaller water bodies in the Coalition area are small-sized natural creeks, agriculture canals, and/or drains.

## ***Watershed Drainage Maps***

An overall map detailing the Coalition drainage designation for all site subwatersheds is provided in Figure 2. Maps showing drainage designation for each of the subwatersheds in the Merced, Madera and Stanislaus counties are provided in Figure 3 – Figure 5.

A size designation legend is included in Figure 2.

# Monitoring Objectives

---

## *History of Coalition Monitoring*

Coalition ambient water and sediment quality monitoring has been conducted in the ESJWQC region since the inception of the ILRP in 2003. Over the years both the number of sites monitored and the constituents analyzed have grown. In 2004 samples were collected from four sites and were sent to laboratories to test for nine total constituents/analytes as well as toxicity testing. By 2008, 23 monitoring sites were sampled and over 50 total analytes tested in addition to toxicity. Table 4 illustrates the sites monitored during each of the storm and irrigation seasons across years of sampling. A blank cell indicates that no sampling occurred at that site during the specified season. "Dry" indicates that the site was dry during one or more events during the specified monitoring season.

**Table 4. Sample sites and years monitored.**

Station Name	2004	2005		2006		2007		2008

## ***Irrigation Season Monitoring 2008***

### **Monitoring Characterization**

#### *Normal Monitoring*

This report covers monitoring conducted during the irrigation season between the months of April 2008 and September 2008. The irrigation season sampling is designed to characterize the discharge from irrigated agriculture as a result of irrigation return flows. Sampling during the irrigation season occurs once per month per site, or twice per month if a site's management plan specifies additional monitoring.

Irrigation season sediment samples are collected during the month of August. The Coalition collected sediment samples on August 28, 2008.

#### *Management Plan Monitoring*

During the irrigation season of 2007, the Coalition initiated additional monitoring as part of the ESJWQC Management Plan's strategy to identify contaminant sources and evaluate effectiveness of newly implemented management practices. This additional monitoring included monitoring for a constituent/location under a management plan twice during a month for which that constituent exceeded a water quality trigger limit (WQTL). In 2008, for constituent/locations where exceedances continued to occur for a second year under a management plan, the Coalition sampled upstream. Details on the process and the schedule of Management Plan Monitoring are found in the ESJWQC Management Plan submitted September 30, 2008 to the Regional Board.

### **Monitoring Objectives**

The objectives of the ESJWQC monitoring program are to:

- Determine the concentration and load of waste in discharges to surface waters
- Evaluate compliance with existing narrative and numeric water quality objectives to determine if implementation of additional management practices is necessary to improve and/or protect water quality
- Assess the impact of waste discharges from irrigated agriculture to surface water
- Determine the degree of implementation of management practices to reduce discharge of specific wastes that impact water quality in watersheds within the coalition region
- Determine the effectiveness of management practices and strategies to reduce discharges of wastes that impact water quality

In order to achieve the objectives listed above, the ESJWQC monitored water quality at 23 sites in the Coalition region during the 2008 irrigation season. The Coalition sampled for numerous water quality variables and constituents including 39 pesticides, *E. coli*, physical parameters (total dissolved solids, color and turbidity), eight metals, total organic carbon, nutrients, field parameters (dissolved oxygen, pH, electrical conductivity), water toxicity to three test species including *Ceriodaphnia dubia*, *Pimephales promelas* and *Selenastrum capricornutum* and sediment toxicity to *Hyalella azteca*. Monitoring constituents are established by the MRP (Order No. R5-2005-0833) and are discussed in more detail below.

Three sites (Ash Slough @ Ave 21, Berenda Slough @ Rd 18½ and Mustang Creek @ East Ave) were not sampled at all during the 6-month irrigation season due to persistent dry conditions. All dry sites, as well as all sites sampled successfully, were documented by photographs which are available on request.

### ***Pesticides and Toxicity***

Pesticides can be found in the water column or sediment as a result of applications to fields that are subsequently irrigated. Irrigation return flows from fields can move sediment and chemicals to surface waters. The concentrations can be compared to numeric and narrative water quality triggers to determine if exceedances have been experienced. Toxicity testing is complementary to chemical analyses and can provide an independent and more direct assessment of the level of impairment in the water body. The objective of the Coalition is to use the results of toxicity testing along with water chemistry analysis to assess the impact of discharges from irrigated agriculture.

### ***Nutrients and Physical Parameters***

Excessive nutrients can cause eutrophication of surface waters resulting in elevated total organic carbon, color content, and turbidity. All of these factors can independently cause impairment of surface waters. The Coalition's objective is to determine if exceedances are occurring and to determine if potential sources can be identified through analysis of monitoring data. However, sources of nutrients, organic carbon, color, and low dissolved oxygen are difficult to identify. If current monitoring data are not sufficient, the Coalition may conduct further investigations to identify sources. Such investigations may include special studies when they are determined to be cost effective. By understanding the sources of constituents responsible for the exceedances, the Coalition can properly recommend management practices to address exceedances of nutrients and physical parameters.

### ***Field Parameters***

Much like physical parameters, exceedances of water quality objectives for pH, dissolved oxygen (DO), and specific conductance (EC) are difficult to track to sources. All of these parameters are non-conserved meaning that they can increase or decrease in concentration as water moves downstream. These parameters are the result of processes occurring in the water column and sediment and can vary diurnally. As with nutrients and physical parameters, the Coalition's objective is to determine if exceedances are occurring and to investigate potential sources through analysis of monitoring data and special studies where they are cost effective. By understanding the sources of constituents that may affect field parameters, the Coalition can properly recommend management practices to address the exceedances.

## ***E. coli***

*E. coli* inhabits the intestinal tracts of animals and is voided in fecal material. *E. coli* may persist in the presence of oxygen in the environment for periods of time after being voided. The bacteria are also known to reproduce and magnify in the environment. However, conditions under which this occurs are not well understood and require additional research. Any species of vertebrate that voids feces can contribute *E. coli* to surface waters, including humans, companion animals such as dogs and cats, cows, chickens, waterfowl (ducks and geese), raccoons, otters, ground squirrels, feral pigs, and in some locations deer. Consequently, there may be a large amount of bacteria in any environmental sample that is collected.

As a result of *E. coli* detections in samples collected for Coalition monitoring, a special study was conducted in 2006 to identify the contributing sources of *E. coli* in Coalition water bodies. Results from this study indicated that the most prominent source of bacteria being discharged into water bodies is human, with smaller contributions coming from bovine and chicken. A full report of the *E. coli* special study was submitted to the CVRWQCB on September 9, 2007.

*E. coli* from humans can enter aquatic systems from leaky septic systems, leaky sanitary sewer lines, improperly treated discharge from waste water treatment plants, application of biosolids to agricultural land, and direct inputs from individuals who defecate in or near water bodies. Input from cows can occur from dairies, grazing in irrigated pastures, and various manure sources. *E. coli* from chickens can enter from poultry operations or manure sources. Irrigated agriculture is responsible for management if *E. coli* contamination is the result of runoff from irrigated pasture or manure applications for fertilizer.

## ***Metals***

The Coalition samples for four basic classes of metals: 1) those that are naturally present because of underlying geologic materials but generally not applied by agriculture (boron, selenium, 2) those that are naturally present because of underlying geologic materials but are applied by agriculture (copper, zinc, nickel), 3) those that may be legacy pesticides but also have numerous nonagricultural sources (lead, arsenic), and 4) those that are found solely as a result of nonagricultural anthropogenic sources (cadmium). These categories are not all mutually exclusive and in fact, all metals belong to the first category. For example, nickel is a plant micronutrient that may be incorporated into fertilizer mixes, although normally there is a sufficient quantity of nickel in soils to supply the needs of crops. As a result, although it may be applied by agriculture, exceedances would be expected to primarily be a result of natural weathering of soils.

Natural weathering of geologic materials can release to surface waters metals and metalloid elements such as selenium, arsenic, and boron. Selenium salts are naturally elevated in the southwest portion of the San Joaquin Valley and are transported to surface waters during storm runoff. These salts are so problematic that there is a prohibition of discharge of irrigation tail water in some locations in the Valley. Arsenic appears to be naturally elevated in several locations in the San Joaquin Valley. Zinc and nickel are also found in soils and can be found in

surface waters at levels that reflect background concentrations. Both of these metals can be applied during agricultural operations as well, and the difference between applications and natural weathering must be understood to properly manage the amounts reaching surface waters. Understanding background levels of these elements will be an important task for the Coalition when trying to understand the impacts of agricultural inputs to surface waters.

While all other metals can be released as a result of the weathering of geologic materials, elevated levels of most metals are a result of anthropogenic inputs. Lead was used as a pesticide during the last century but was used in declining amounts over the last several decades before being prohibited in the 1990s. Lead was also used in gasoline until the early 1980s when it was replaced by other fuel oxygenates. Lead-based paint was routinely used until the latter parts of the last century but is still present in many old buildings and structures. Lead is also a component of batteries, and is the material in solder in numerous electronic devices including televisions, computers, and cell phones. These sources can be distinguished through sophisticated analytical tests that are beyond the capabilities of the Coalition. Copper is routinely used by agriculture on a number of crops and could be found in surface waters as a result of applications. Additional sources include road surfaces where wearing of brake pads can result in substantial loading to surface waters.

Because fertilizer applications and the micronutrient constituents included in fertilizer mixes are not reported, there is no way the Coalition can distinguish between natural and anthropogenic sources with normal monitoring data. Several of these metals can be identified to source using sophisticated analytical equipment and techniques, but these tests are beyond the capabilities of the Coalition. Consequently, the Coalition will use monitoring data to determine if exceedances are occurring, and will attempt to establish background concentrations of some metals in surface waters to determine if concentrations are a result of natural or anthropogenic inputs to the water. In addition, starting in October 2008, the Coalition will analyze for both dissolved and total metals to determine the amount of metals that are bioavailable.

## Sampling Site Descriptions

The site names, codes and locations of the 23 sites and 11 upstream Management Plan sites monitored during the 2008 irrigation season are provided in Table 5. A narrative description of each site subwatershed with respect to hydrology and agricultural production follows below.

**Table 5. ESJWQC irrigation 2008 sampling locations.**

Site Name	Station Code	Latitude	Longitude
Upstream Management Plan Site Name			
Ash Slough @ Ave 21	545XASAAT	37.0545	-120.4158

Westport Drain @ Vivian Rd	535XWDAVR	37.5368	-121.0486

## ***Site Subwatershed Descriptions***

The Coalition sampled a total of 23 site subwatersheds as part of normal monitoring during the 2008 irrigation season. Eight of the subwatersheds contained one or more upstream management plan sites. Descriptions of the site subwatersheds for all sample sites and all upstream management plan sites are provided below alphabetically. Management Plan monitoring sites are indented after the associated downstream normal monitoring location.

Ash Slough @ Avenue 21 (27,704 irrigated acres) – Agriculture upstream includes vineyards, field crops, and deciduous nuts. Ash Slough flows just north of Chowchilla but there appears to be a buffer of agricultural land between Ash Slough and Chowchilla. Dairies are located upstream.

Bear Creek @ Kibby Road (6,740 irrigated acres) – This site subwatershed drains an eastern portion of the Coalition region in Merced County. Bear Creek originates in the foothills of the Sierras with Burn's Creek as one of the major tributaries. Bear Creek drains to the east just north of the towns of Planada, through Merced and eventually to the San Joaquin River. The primary irrigated agriculture in the site subwatershed includes deciduous nuts, field crops, truck crops, and irrigated pasture.

Berenda Slough along Avenue 18 ½ (26,419 irrigated acres) – Berenda Slough flows through the northern portion of Madera County and empties into the Eastside Bypass. The primary agriculture is orchards and vineyards with small amounts of pasture and field crops.

Berenda Slough @ Rd 19 (10,213 irrigated acres) – This site is upstream of Berenda Slough along Avenue 18 ½ and captures runoff from approximately 41% of the subwatershed. The primary agriculture draining into Berenda Slough is nut trees and orchards, vineyards, and pasture.

Black Rascal Creek @ Yosemite Road (535 irrigated acres) – The headwaters of Black Rascal Creek originate in the Sierra foothills. It is located just to the north of the Bear Creek site subwatershed and to the east of the city of Merced. Citrus and field crops make up the majority of the agriculture in the site subwatershed.

Cottonwood Creek @ Road 20 (40,699 irrigated acres) – This site subwatershed is at the very southern edge of the Coalition region in Madera County and drains into the Eastside Bypass. The immediate upstream agriculture is vineyards and there are deciduous nuts farther to the east. There are only a few dairies in the Cottonwood Creek site subwatershed.

Cottonwood Creek @ Hwy 145 (21,897 irrigated acres) – This site is upstream of Cottonwood Creek @ Rd 20 and captures runoff from 54% of the subwatershed. The primary agriculture draining into the site is vineyard, deciduous fruit and nut orchard, and field crops.

Deadman Creek @ Gurr Rd (51,177 irrigated acres) - This site subwatershed is a downstream site from Deadman Creek @ Hwy 59. The primary agriculture in the site subwatershed is orchards and row crops with some upstream irrigated pasture.

Deadman Creek @ Highway 59 (38,230 irrigated acres) – Deadman Creek flows out of the Sierra foothills and confluences with Dutchman’s Creek in the vicinity of Highway 59. The primary agriculture in the site subwatershed is orchards and row crops with some upstream irrigated pasture.

Dry Creek @ Road 18 (22,086 irrigated acres) – Dry Creek originates in the Sierra foothills and flows to the north of the city of Madera eventually draining into the San Joaquin River through various channels and irrigation ditches. Deciduous crops are the primary irrigated agriculture in the upper portion of the site subwatershed whereas vineyards predominate in the lower portions. There are field crops scattered throughout the site subwatershed.

Dry Creek @ Rd 22 (15,311 irrigated acres) – This site is upstream of Dry Creek @ Rd 18 and collects runoff from approximately 66% of the subwatershed. The primary irrigated agriculture draining into the site is vineyard, deciduous fruit and nut orchards, and row crops.

Dry Creek @ Rd 28 ½ (582 irrigated acres) – This site is upstream of both Dry Creek @ Rd 18 and Dry Creek @ Rd 22 and collects runoff from approximately 3% of the subwatershed. The primary irrigated agriculture draining into the site is deciduous fruit and nut orchards and citrus orchards.

Dry Creek @ Wellsford Road (23,339 irrigated acres) – This site subwatershed is in the northern part of the Coalition region and drains a combination of field crops, deciduous nuts, and vineyards. Dry Creek originates to the east of Modesto and drains into the Tuolumne River. This site subwatershed samples Dry Creek at the furthest downstream location that collects agricultural drainage prior to flowing through the urban areas of Modesto. Dairies are located upstream of this site and the town of Waterford may contribute an urban signal.

Dry Creek @ Waterford Rd (14,348 irrigated acres) – This site is upstream of Dry Creek @ Wellsford and collects runoff from approximately 62% of the irrigated agriculture in the subwatershed. The agriculture drained is of the same composition as Dry Creek @ Wellsford Rd and includes a combination of field crops, deciduous nuts, and vineyards.

Duck Slough @ Gurr Road (28,636 irrigated acres) – This site subwatershed is a monitoring location downstream from Duck Slough @ Hwy 99. Located to the south and west of Merced, this site drains field crops immediately upstream and deciduous nuts further upstream as well as some irrigated pasture. The city of Merced delivers treated water to Duck Slough a few miles upstream of the Gurr Road site. Duck Slough flows west eventually becoming Deadman Creek in the western portion of the Coalition region. The slough eventually flows into the San Joaquin River via Deadman Creek and Deep Slough.

Duck Slough @ Hwy 59 (14,036 irrigated acres) – This site is upstream of Duck Slough @ Gurr Rd halfway between Gurr Rd and Hwy 99. The area drained is approximately 59% of the irrigated agriculture in the subwatershed. Like Duck Slough @ Gurr Rd this site drains field crops immediately upstream and deciduous nuts further upstream as well as some irrigated pasture. At the bridge where the water crosses Hwy 59 a sign identifies the water body as Mariposa Creek, but its location between McNamara Rd and Owens Creek as well as aerial photographs of the region indicate otherwise.

North Slough @ Hwy 59 (16,762 irrigated acres) – This site is upstream of Duck Slough @ Gurr Rd. North Slough is fed by water from Lingard Lateral and it drains into Duck Slough 2 miles west of Hwy 59, but its flow is intermittent. It did not flow during the irrigation season of 2008 and it is unclear under what circumstances water would drain into Duck Slough. This site collects runoff from approximately 59% of the irrigated agriculture in the subwatershed, including field crops immediately upstream and deciduous nuts further upstream as well as some irrigated pasture.

Duck Slough @ Hwy 99 (15,622 irrigated acres) – This site subwatershed is located upstream of the Duck Slough @ Gurr Road site and was selected to determine relative contribution of water quality impairments in the upstream portion of the Duck Slough subwatershed. Duck Slough originates in the Sierra foothills and flows west eventually joining with Deadman Creek in the western portion of the coalition region. The monitoring site is located just east of Highway 99 south of Planada and Merced. Irrigated agriculture in this site subwatershed is primarily deciduous nuts, with truck crops and irrigated pasture the next most common land uses.

Duck Slough @ Whealan Rd (7,417 irrigated acres) – This site is upstream of Duck Slough @ Hwy 99. The drained area is approximately 47% of the subwatershed above Hwy 99 and includes deciduous nuts, truck crops and irrigated pasture.

Hatch Drain @ Tuolumne Rd (259 irrigated acres) – This small site subwatershed is located in the western portion of the Coalition region in Stanislaus County. The two major crops are citrus and field crops.

Highline Canal @ Highway 99 (35,220 irrigated acres) – The Highline Canal is a conveyance of the Turlock Irrigation District and carries both clean irrigation water and irrigation return flow during the summer, and storm water runoff during the winter. This site was selected as a downstream companion site to the Highline Canal @ Lombardy Road site. This site subwatershed is monitored to determine the relative contribution of the upstream and downstream site subwatersheds to water quality impairments. The sampling site is located just south of Delhi as the canal crosses the highway. The irrigated agriculture is primarily deciduous nuts, and these are located at the lower end of the site subwatershed. A small number of vineyards are also present.

Highline Canal @ Lombardy Road (30,154 irrigated acres) – The Highline Canal is a conveyance of the Turlock Irrigation District and carries both clean irrigation water and irrigation return flow during the summer, and storm water runoff during the winter. The main upstream tributary of the Highline Canal is Mustang Creek. The Highline Canal flows west and eventually

drains into the Merced River. Dairies are present upstream and Mustang Creek (described below), a major tributary during the dormant season, passes immediately to the southeast of the Turlock Airport. The main agricultural crop upstream is deciduous nuts.

Hilmar Drain @ Central Ave (2,718 irrigated acres) – This site subwatershed is located toward the western edge of the Coalition region near the San Joaquin River. This is a small site subwatershed containing primarily field crops and a large number of dairies with irrigated pasture. Hilmar Drain originates at Williams Ave and Washington Road and eventually drains into the San Joaquin River. At this location the Turlock Irrigation District refers to the water body as “Reclamation Drain”.

Reclamation Drain @ Williams Ave (141 irrigated acres) – This site is upstream of Hilmar Drain @ Central Ave and immediately upstream of the confluence with Hilmar Drain @ Mitchell Rd. It collects runoff from approximately 5% of the entire subwatershed, primarily irrigated pasture and field crops.

Hilmar Drain @ Mitchell Rd (2,147 irrigated acres) – This site is upstream of Hilmar Drain @ Mitchell Rd and immediately upstream of the confluence with Reclamation Drain @ Williams Ave. It collects runoff from approximately 79% of the irrigated agriculture in the subwatershed, primarily field crops and a large number of dairies with irrigated pasture.

Livingston Drain @ Robin Ave (3,656 irrigated acres) – Livingston Drain is located in the west central portion of the Coalition region in Merced County. It is located west of Atwater and Livingston. The agriculture is almost entirely citrus.

Merced River @ Santa Fe Drive (27,796 irrigated acres) – This water body is designated as a major water body and is 303d listed. It was selected as an integrator site for several of the drains and tributaries in the vicinity. The Merced River originates in the high Sierra encountering several dams and impoundments as it flows west. The Merced River eventually drains into the San Joaquin River near Hatfield State Park. Upstream agriculture includes some field crops in the immediate vicinity of the river and deciduous nuts, primarily almonds.

Miles Creek @ Reilly Rd. (9,664 irrigated acres) – Miles Creek is located just north of Duck Slough and drains into Owen’s Creek. The primary agriculture includes field crops, deciduous nuts and fruit, pasture and truck, nursery and berry. Within the subwatershed are also urban drainages, dairies and hay and pasture lands.

Mustang Creek @ East Ave (12,113 irrigated acres) – Mustang Creek originates in the foothills of the Sierra Nevada and flows into the upper portion of the Highline Canal. Mustang Creek is ephemeral with flow found primarily during winter runoff events. Summer flows are intermittent as the upstream orchards utilize microspray irrigation. Citrus and deciduous nut crops are the main agriculture with smaller amounts of field crops and grains and hay.

Prairie Flower Drain @ Crows Landing Road (4,080 irrigated acres) – Relative to other drains in the western portion of the Coalition region, Prairie Flower Drain is longer and appears to drain mostly irrigated agriculture. Dairies and feedlots are ubiquitous in this part of the Coalition

region and this drain may receive runoff from several dairies immediately upstream. Upstream agriculture is field crops.

Prairie Flower Drain @ Morgan Ave (1,199 irrigated acres) – This site is upstream of Prairie Flower Drain @ Crows Landing Rd. It collects runoff from approximately 29% of the irrigated agriculture in the subwatershed, including irrigated pasture, feedlots, and dairies.

Silva Drain @ Meadow Drive (67 irrigated acres) – This is a very small site subwatershed that confluences with Jones Drain just upstream of the confluence of Jones Drain with the Merced River. The primary agriculture is citrus orchards with small amounts of field crops and irrigated pasture. Large dairies are found in the site subwatershed.

South Slough @ Quinley Road (2,352 irrigated acres) – South Slough begins just west of Merced and eventually flows into Bear Creek. Pasture, deciduous nuts, and citrus are the primary crops in the site watershed.

Westport Drain @ Vivian Road (1,474 irrigated acres) – This site subwatershed is located adjacent to the Hatch Drain subwatershed in the western portion of the Coalition region. The primary agriculture in this site subwatershed is citrus and field crops.

## **Monitoring and Analysis**

### **Normal Monitoring**

Table 6 specifies the constituents monitored at each site subwatershed. The Coalition monitoring program previously consisted of a mix of Phase I and Phase II monitoring elements at various sites, but was homogenized for the irrigation 2008 season to monitor all constituents at all sites, with several exceptions. Constituents listed in Table 6 include field parameters (pH, DO, EC and temperature), metals, nutrients, physical parameters (color, turbidity, total dissolved solids), total organic carbon (TOC), *E. coli*, pesticides (organophosphates, pyrethroids, carbamates, herbicides, organochlorines, and glyphosate/paraquat), water column toxicity (water flea, algae and fathead minnow) and sediment toxicity.

On November 19, 2007 the Coalition submitted a proposal to the Regional Board to drop constituents at sites that had been monitored for two or more full years which did not have a single exceedance of a water quality trigger limit. On December 14, 2007 the Coalition was notified by the Executive Officer that the Coalition would no longer need to monitor at the listed locations for the following constituents:

- Bear Creek @ Kibby Rd: pyrethroids and *Selenastrum capricornutum* toxicity,
- Cottonwood Creek @ Rd 20: pyrethroids and *Selenastrum capricornutum* toxicity,
- Dry Creek @ Wellfsford Rd: pyrethroids,
- Duck Slough @ Hwy 105: pyrethroids,
- Merced River @ Santa Fe: pyrethroids,
- Prairie Flower Drain @ Crows Landing Rd: pyrethroids.

During the first irrigation season event of 2008 toxicity to *S. capricornutum* was tested as a result of lab error for both Bear Creek @ Kibby Rd and Cottonwood Creek @ Rd 20. Both were found to be toxic, therefore the Coalition resumed monitoring for toxicity to algae for the remainder of the season.

Additionally, because two years of sampling resulted in no exceedances of *E. coli* or sediment toxicity at the Merced River @ Santa Fe sample site, both of these tests were withdrawn from the suite of analytes monitored at that site in 2006. It was brought to the attention of the Coalition after the 2008 storm season that the Coalition was not approved by the Executive Officer of the Regional Board to drop this constituent and therefore the Coalition resumed monitoring for *E. coli* during the irrigation season of 2008.

**Table 6. ESJWQC irrigation 2008 sampling constituents.**

Constituents listed below include field parameters (pH, DO, EC and temperature), metals, nutrients, physical parameters (color, turbidity, and total dissolved solids), total organic carbon (TOC), *E. coli*, pesticides (organophosphates, pyrethroids, carbamates, herbicides, organochlorines, and glyphosate/paraquat), water column toxicity (water flea, algae and fathead minnow) and sediment toxicity.

## Management Plan Monitoring

Management Plans develop a strategy to identify agriculture sources of water quality impairments, identify management practices currently in place in the subwatersheds, identify potential management practices that could be implemented to further improve water quality, develop a monitoring framework to assess improvements, and establish the performance goals that are used to track progress. Management Plans were developed for all sites with two or more exceedances of a single constituent were detected in two years of monitoring (Table 7). Site subwatersheds could have management plans for one or more constituents.

Monitoring was conducted beyond that required by the MRP and are categorized into Tier I and Tier II. Tier I sampling is one additional sample from the site collected at a separate time during the month in which exceedances occur. Tier II sampling involves moving upstream in an attempt to identify additional sources. Management Plan samples were collected in the same calendar month as the exceedances that triggered the Management Plan and are analyzed only for the constituent(s) that triggered the Management Plan. Management Plans specify Tier 1 or Tier 2 monitoring, depending on the frequency and intensity of exceedances detected in the water body. If exceedances continue to occur additional actions are taken, including an attempt to locate the source with upstream sampling. Upstream samples are collected during the same event as normal monitoring yielding results from two or more locations along the length of a water body during a single sampling event.

Additional sampling took place 40 times at 11 sites and upstream sampling took place 38 times at 11 sites. Upstream Management Plan sites are indented in the above tables and site descriptions. The complete Management Plan sampling schedule for the 2008 irrigation season identifying the site and target constituent is in the table below.

**Table 7. Management Plan sampling schedule. U = upstream sampling; A = additional sampling.**

Sample Site	Month	Type	Chlorpyrifos	Bifenthrin	Diuron	Ammonia	Nitrate	Copper	<i>Ceriodaphnia dubia</i>	<i>Selenastrum capricornutum</i>	<i>Pimephales promelas</i>

## Location Maps of Sample Sites and Land Use

---

All site subwatersheds listed in Table 8 and Table 9 drain agricultural land in the Coalition region. The tables provided include the acreage for each major crop or land use type and indicate whether the land area is irrigated or non-irrigated. Land use maps are provided in Figure 6 – Figure 9 for locations involved in normal monitoring. The maps include parcel specific land use data in each of the site subwatersheds as well as the hydrology that drains those parcels. Not included are roadside ditches that may drain fields to the nearest surface water body. Ditches are constructed to move water draining from roads adjacent to the fields and are not generally constructed or used to move water draining from agricultural fields. Land use information was obtained from data provided by California Department of Water Resources (<http://www.landwateruse.water.ca.gov/annualdata/landuse/2001/landuselevels.cfm>). Land use maps for upstream sampling locations can be found in the ESJWQC Management Plan. A narrative description of each site subwatershed monitored during the 2008 irrigation season is provided in the previous section, Sampling Sites Descriptions.

**Table 8. Land use acreage of site subwatersheds monitored during the 2008 irrigation season.**

The land uses are designated as irrigated/non-irrigated (I/NI). Sites are listed alphabetically from Ash Slough to Hatch Drain.

Land Use	I/NI	Ash Slough @ Ave 21	Bear Creek @ Kibby Rd	Beranda Slough along Ave 18 1/2	Black Rascal Creek @ Yosemite Rd	Cottonwood Creek @ Rd 20	Deadman Creek @ Gurr Rd	Deadman Creek @ Hwy 59	Dry Creek @ Wellsford Rd	Dry Creek @ Rd 18	Duck Slough @ Gurr Rd	Duck Slough @ Hwy 99	Hatch Drain @ Tuolumne Rd

# Monitoring Results

---

## *Sample Details*

Full monitoring results from the 2008 irrigation season are included in Appendix I. The results include field parameters, organic (pesticides), inorganics including metals, and *E. coli*, toxicity and loads for any detectable analyte with corresponding site flow. Loads have been calculated for all detections (Appendix I, Table I-6) according to the following formula:

Instantaneous Load ( $\mu\text{g}/\text{sec}$ ) = Discharge (cfs) X 28.317L x Concentration (milligram/L x 1,000 or  $\mu\text{g}/\text{L}$ ).

The load values calculated and presented for pesticides or other constituents in this report represent instantaneous loads only. These values should not be used to extrapolate loading over any period of time (e.g. weekly, monthly, seasonal or annual). The primary purpose for reporting instantaneous loads is to provide the Regional Water Board with a context for the concentrations of various constituents at the time that samples were collected.

Monitoring data include results from samples taken for normal monitoring and sediment toxicity monitoring including resampling due to toxicity. Each sampling location, sampling date, sampling time and type of monitoring is listed in Table 10. A detailed schedule of Management Plan Monitoring can be found in the ESJWQC Management Plan submitted on September 30, 2008.

**Table 10. Sample details for all 2008 irrigation season sorted by station name, sample date and monitoring event.**

NM = Normal Monitoring (water column). RS = Resampling due to toxicity. MPM = Management Plan Monitoring. SED = Sediment sampling including resampling due to toxicity.

## Sampling and Analytical Methods Used

---

Sample collection criteria and field instruments are provided in Table 11 and Table 12 respectively. Analytical methods and reporting limits are provided in Table 13. All field sampling methods were performed as outlined in the standard operating procedures (SOPs) provided in the ESJWQC Quality Assurance Project Plan (QAPP). All analytical methods were performed as described in the QAPP. No deviations from these procedures occurred during the monitoring.

**Table 11. Sampling procedures, containers, sample volumes, preservation and storage techniques, and holding times.**

Parameter	Sample Container	Sample Volume <sup>(1)</sup>	Immediate Processing and Storage	Holding Time <sup>(2)</sup>
<b>Physical Parameters<sup>(3)</sup></b>				
Color	Glass or polyethylene	500 mL	Store at 4°C	48 hours
Turbidity	Glass or polyethylene	150 mL	Store at 4°C	48 hours
Total Dissolved Solids	Polyethylene	500 mL	Store at 4°C	7 days
<b>Drinking Water</b>				
<i>E. coli</i> (pathogens)	Polyethylene (sterile)	100 mL	Store at 4°C	24 hours <sup>(4)</sup>
Total Organic Carbon	Amber Glass VOA, PTFE-lined cap	125 mL	Preserve w/HCL; Store at 4°C	28 days
<b>Toxicity</b>				
Aquatic bioassays	Amber glass	5 gallons	Store at 4°C	36 hours
Sediment bioassays	Glass	1 liter (x2)	Store at 4°C	14 days
<b>Pesticides</b>				
Carbamates	Amber Glass	1 liter	Store at 4°C; Extract within 7 days	40 days
Organochlorines	Amber Glass	1 liter		
Organophosphates	Amber Glass	1 liter		
Pyrethroids	Amber Glass	1 liter		
Herbicides (general)	Amber Glass	1 liter		
Herbicides (paraquat)	Polyethylene	1 liter		
Herbicides (glyphosate)	Amber Glass VOA	40 ml (x2)	Store at 4°C, freeze within 2 weeks	6 months
<b>Nutrients</b>				
TKN, Ammonia, and Total Phosphorus	Polyethylene	500 mL	Preserve to ≤ pH 2 with H <sub>2</sub> SO <sub>4</sub> ; Store at 4°C	28 days
Nitrate as NO <sub>3</sub> , Nitrite as N, and Soluble Ortho-Phosphate	Polyethylene	1000 mL	Store at 4°C	48 hours
<b>Metals/Trace Elements</b>				
Trace elements <sup>(5)</sup>	Polyethylene	500 mL	Filter as necessary; Preserve to ≤ pH 2 with HNO <sub>3</sub>	40 days

1. Additional volumes may be required for QC analyses; NA = Not Applicable
2. Holding time after initial preservation or extraction.
3. Volume of water necessary to analyze the physical parameters is typically combined in multiple 1L polyethylene bottles, which provides sufficient volume for re-analyses and lab spike duplicates. This is only possible when the same laboratory provides the analyses for all of the physical parameters.
4. Samples for bacteria analyses should be set up as soon as possible.
5. To include arsenic, boron, cadmium, copper, lead, nickel, selenium, and zinc.

**Table 12. Field parameters and instruments used to collect measurements.**

<b>Parameter</b>	<b>Instrument</b>
Dissolved oxygen	YSI Model 556
Temperature	YSI Model 556
pH	YSI Model 556
Specific Conductance	YSI Model 556
Discharge	Marsh-McBirney Flow Mate 2000

## Copy of Chain of Custody Forms

---

Original Chain of Custody (COC) forms have been scanned and converted to pdf. Pdf copies of the COCs are provided in Appendix II. COCs were faxed by the contract laboratories to Michael L. Johnson, LLC after the receipt of samples by the laboratory. As such, they are complete and accurate records of sample handling and processing and reflect the timing of sample collection and delivery to the laboratories. Sample collection and delivery was performed according to the ESJWQC QAPP. If there were any discrepancies between the COC and sample delivery, the issues were resolved and documented either directly on the COC or on an anomaly form filled out by the laboratory. Documentation of COC anomalies can be found in Table II-1 of Appendix II.

## Lab and Field QC Results

---

Laboratory and field quality control (QC) results are included in Appendix III. Field duplicate and field blank results are included for organics, inorganics (including metals, physical parameters, and nutrients), *E. coli*, and field duplicates for toxicity. Laboratory QC results include matrix spikes (MS) performed on both Coalition samples and samples from other projects, laboratory control spikes (LCS), laboratory blanks and laboratory duplicates. All quality control criteria are listed with the result and samples not meeting quality control criteria are flagged.

## Precision and Accuracy

---

Normal surface water monitoring occurred six times during the irrigation season of 2008 for 23 sites with the following exceptions due to lack of water:

- Ash Slough @ Ave 21 (all sampling events)
- Berenda Slough along Ave 18 ½ (all sampling events)
- Cottonwood Creek @ Rd 20 (9/30/08)
- Dry Creek @ Rd 18 (9/30/08)
- Mustang Creek @ East Ave (4/22/08, 5/20/08, 7/22/08, 8/19/08, 9/23/08)
- South Slough @ Quinley Rd (5/27/08, 9/30/08)

Resampling to test for water column toxicity persistence occurred at the following sites:

- Bear Creek @ Kibby Rd (5/7/08)
- Cottonwood Creek @ Rd 20 (5/7/08)
- Deadman Creek @ Hwy 59 (5/7/08)
- Duck Slough @ Hwy 99 (5/7/08)
- Hatch Drain @ Tuolumne Rd (4/29/08, 5/27/08, 7/29/08, 8/26/08)
- Highline Canal @ Hwy 99 (5/27/08)
- Highline Canal @ Lombardy Rd (5/27/08)
- Hilmar Drain @ Central Ave (9/30/08)
- Hilmar Drain @ Mitchell Rd (7/29/08)
- Livingston Drain @ Robin Ave (4/29/08, 5/27/08)
- Miles Creek @ Reilly Rd (5/7/08)
- Prairie Flower Drain @ Crows Landing Rd (4/29/08, 5/27/08)
- Silva Drain @ Meadow Dr (6/24/08, 7/29/08)
- South Slough @ Quinley Rd (5/7/08)
- Westport Drain @ Vivian Rd (4/29/08)

Sediment sampling occurred once during the irrigation season during the month of August. Sediment from the following sites was not submitted due to the sites being dry on August 28, 2008:

- Ash Slough @ Ave 21
- Berenda Slough along Ave 18 ½
- Mustang Creek @ East Ave
- South Slough @ Quinley Rd

Resampling to test for persistence of sediment toxicity occurred at the following sites on October 2, 2008:

- Bear Creek @ Kibby Rd
- Black Rascal Creek @ Yosemite Rd
- Deadman Creek @ Hwy 59
- Dry Creek @ Rd 18
- Dry Creek @ Wellsford Rd
- Duck Slough @ Gurr Rd
- Duck Slough @ Hwy 99

- Hatch Drain @ Tuolumne Rd
- Highline Canal @ Hwy 99
- Highline Canal @ Lombardy Rd
- Hilmar Drain @ Central Ave
- Miles Creek @ Reilly Rd
- Prairie Flower Drain @ Crows Landing Rd
- Silva Drain @ Meadow Dr
- Westport Drain @ Vivian Rd

During the irrigation season, 11 Management Plan Monitoring sites were sampled in addition to the 23 Normal Monitoring sites. Management Plan Monitoring was either upstream of the normal monitoring site or an additional sample collected on a different day than normal monitoring (see site subwatershed management plans for details). The following Management Plan sites were not sampled due to a lack of water:

- Ash Slough @ Ave 21 (all sampling events)
- Berenda Slough @ Rd 19 (5/27/08, 9/30/08)
- Cottonwood Creek at Highway 145 (9/30/08)
- Dry Creek @ Rd 28 1/2 (9/30/08)
- North Slough @ Hwy 59 (7/29/08, 9/30/08)

## **Chemistry**

The constituents sampled during the 2008 irrigation season are listed by site in Table 6. For Normal and Management Plan Monitoring, not including laboratory or field quality control (QC) samples, 115-117 carbamate, organochlorine, and herbicide, 115-137 organophosphate, 80 pyrethroid, 115 *E. coli* and physical parameter, 115-149 nutrient and 117-149 metal samples were collected and analyzed for the irrigation event in 2008. There was 100% completeness for environmental samples collected for chemistry analyses.

For each irrigation event, one field duplicate and field blank were collected for each constituent to meet the field QC requirement of 5%. Field blanks and duplicates comprised 15-23% of organic samples, 17% of *E. coli* and physical parameter samples, and 14-17% of nutrient samples and metal samples.

For some constituents the environmental sample may exceed the amount that the instrument is calibrated to detect and therefore the sample requires dilution. The result reported is the amount found in the diluted sample multiplied by the dilution factor to represent the amount of the analyte present in the original sample. The dilution factor is recorded and the RL is generally increased by multiplying the RL for that analyte by the dilution factor. There are times that the RL is increased higher than this value based on method requirements. Therefore, for each dilution that occurs, there is a corresponding increase in the limit of quantification.

For pesticides such as paraquat, co-elution, also referred to as matrix interference, may cause the RL to be raised and the sample is flagged. In such cases the dilution factor (DF) is recorded for each sample.

All results are reported in the Monitoring Results section of this report (Appendix I). Each result is flagged if it does not meet data quality objectives (acceptability criteria) using SWAMP codes and can also be found in the SWAMP comparable database managed by the Coalition. The Coalition works with the University of California, Davis Data Center to ensure that all data remains SWAMP comparable and that all data are suitable to be uploaded to the California Environmental Data Exchange Network (CEDEN). An electronic copy of the database has been submitted to the Regional Board with the hardcopy of this report. A review of the number of samples analyzed and the percentage per analyte that meets acceptability criteria are listed in the tables following this section. A brief overview is provided below to assess overall precision and accuracy per analyte. All pesticides are grouped and discussed together.

- Color: Ninety-two percent of field blanks met acceptability criteria ( $< RL$  or  $< 1/5$  the environmental sample). Seventy-five percent of field duplicates had relative percent differences (RPDs) less than 25%. Laboratory control spikes and lab blanks were run with each color batch and 100% met laboratory QC criteria. Laboratory duplicates were recorded by the lab to assess precision and all met acceptability criteria. Due to laboratory error, one color batch in May was run without a lab duplicate and the batch was flagged. Matrix spikes and matrix spike duplicates cannot be performed for color.
- Hardness: One hundred percent of field blanks were below the reporting limit. Sixty seven percent of field duplicates met acceptability criteria. All laboratory blank and laboratory control spikes met laboratory QC criteria. Ninety-four percent of matrix spikes and 100% of matrix spike duplicates met acceptability criteria.
- Dissolved Solids (TDS): Field blanks met acceptability criteria in 92% of the samples analyzed. Eighty-three percent of field duplicates had RPDs less than 25%. Lab blanks, laboratory control spikes and laboratory duplicates were run with every batch and met acceptance criteria for 100% of samples. Matrix spikes cannot be performed for TDS.
- Turbidity: One hundred percent of field blanks and 75% of field duplicates met acceptability criteria. Laboratory blanks were run with every batch and 100% were less than the reporting limit. Lab control spikes and laboratory duplicates were analyzed with each batch and all of the samples met acceptance criteria. Matrix spikes cannot be performed for turbidity.
- Nitrate as N: One hundred percent of field blanks met acceptability criteria. One hundred percent of field duplicates had RPDs below 25%. Laboratory blanks and laboratory control spikes were run with each batch and 100% of the samples met acceptance criteria. Seventy-six percent of matrix spikes were within the acceptability criteria due to possible matrix interference in the QC samples (26 of 34). All matrix spikes were recovered above the quality control limit of 110%, and all laboratory control spikes were within range; therefore matrix spikes were not re-analyzed. One hundred percent of matrix spike duplicates met the acceptability requirement for precision.

- Ammonia as N: One hundred percent of field blanks met acceptability criteria. Eighty-three percent of field duplicates had RPDs below 25% (10 of 12). One hundred percent of laboratory blanks and laboratory control spikes met acceptability criteria. Matrix spikes and matrix spike duplicates were run with each batch and 100% met acceptability criteria.
- Nitrogen, Total Kjeldahl (TKN): Seventy-five percent of field blanks (9 of 12) were below the RL of 0.1. Three field blanks had detectable amounts of TKN in April (0.13 mg/L), June (0.11 mg/L) and August (0.16 mg/L). Seventy five percent of field duplicates (9 of 12) met acceptance criteria. Lab blanks were run with every batch and 100% were less than the minimum detection limit. Laboratory control spikes were within acceptance criteria for all batches. Matrix spikes were performed in each batch with 72% meeting acceptability requirements (33 of 46). Of the 13 matrix spikes not meeting the requirements, 10 were due to possible matrix interferences in the QC sample collected by ESJWQC and three were due to possible matrix interferences in a QC sample collected from another project. Twelve of the 13 samples were matrix spike/matrix spike duplicate combinations affecting six batches and the 13<sup>th</sup> sample was a single matrix spike from another project affecting one batch. For all batches, the LCS was within control limits. Ninety-five percent of matrix spike duplicates met the requirements for precision.
- Nitrite as N: Ninety-two percent of field blanks met acceptance criteria. All field blanks had RPDs less than 25%. One hundred percent of laboratory blanks and laboratory control spikes met acceptance criteria. Matrix spikes and matrix spike duplicates were within acceptability criteria for all batches.
- Orthophosphate as P: One hundred percent of field blanks and 92% of field duplicates collected met acceptance criteria. Lab blanks were run with every batch and 100% were less than the RL. Laboratory control spikes were within acceptability criteria for all batches. Matrix spikes were performed in each batch with 92% meeting acceptability criteria and 100% of matrix spike duplicates meeting the requirements of accuracy and precision.
- Phosphate as P: Field blanks met acceptance criteria in 75% of the samples collected (9 of 12). Of the 12 field blanks, three were non-detect and nine were detected above the reporting limit of 0.01 mg/L. Of those nine, six were less than 1/5 of the associated environmental sample. The three field blanks that had detections greater than the RL and greater than 1/5 the environmental sample occurred once in June (0.047 mg/L) and twice in August (0.014 and 0.017 mg/L). Eighty-three percent of field duplicates had RPDs less than 25%. Laboratory blanks and laboratory control spikes were within acceptability criteria for all batches. One hundred percent of matrix spikes and matrix spike duplicates met acceptability criteria for accuracy and precision.
- Total Organic Carbon (TOC): One hundred percent of field blanks and field duplicates met acceptability criteria. Laboratory blanks and lab control spikes met acceptance criteria for 100% of the samples. Ninety-four percent of matrix spikes met acceptability

criteria, and 100% of matrix spike duplicates performed met acceptability requirements for precision.

- Total Metals: On July 22<sup>nd</sup> the field crews began using Caltest de-ionized water, in low-density polyethylene (LDPE) containers, exclusively for field blanks. The field blanks were filled previously from de-ionized water collected from UC Davis and stored in a high-density polyethylene (HDPE) carboy. One hundred percent of the metals field blanks met field precision criteria except for two zinc field blank samples. The zinc field blank samples exceeded the reporting limit and were greater than one fifth of the environmental samples collected on August 19 and 26 (environmental sample = 3 µg/L, field blank = 2 µg/L for both sets of samples). Contamination in the field may be due to contamination of the field blank water, the field blank storage container, the field blank bottle, or contamination from the sampler. The field blank bottle came directly from the laboratory and is certified pre-clean. The bottle was not opened until immediately before filling it with DI water. Clean gloves were used when filling the bottle with DI water from the LDPE container and neither the lid nor the opening of the bottle was touched. The cap was immediately returned to the bottle and screwed on tightly after filling. All sampling SOPs (which include the above steps to prevent contamination) were followed. Other sources of contamination may have occurred during transport from the field to the laboratory (all bottles were closed tightly and only touched when being put in the cooler by the sampler and taken from the cooler by the laboratory with gloved hands) and/or during the laboratory extraction process. In response to the zinc detections in the blank water Caltest collected a series of blank samples in and around their lab starting in August, and found sporadic low level zinc detections as high as 1.3 µg/L. After placing various controls around their lab the blank zinc level was 0.3 µg/L, less than the reporting limit of 1 µg/L, which leads Caltest to believe that their controls are helping. Caltest plans to continue this monitoring on an ongoing basis.

Due to past detections in field blanks, travel blanks were sent from the lab and traveled with the sampling crew from beginning to end. A single copper detection, 1.1 µg/L, was reported in April; the field blank collected during the same trip was non-detect for copper. Laboratory blanks were run with each metals batch and 99.8% met acceptability criteria. The single lab blank detection was a zinc sample whose result equaled the RL (detected prior to the new control Caltest put in place).

All field duplicates, except for copper, lead, selenium and zinc, met the acceptability criteria (RPDs < 25%). The copper RPDs outside the acceptance limits were 153, 30.7 and 93.3. The largest copper RPD was calculated from an environmental result of 45 and a field duplicate result of 6. Due to the large variation between the environmental and duplicate sample results, as well as the high copper environmental sample result, the lab re-ran the samples in triplicate and received similar results. In addition, all COCs were verified and samplers noted no anomalies in sampling procedures. No further actions were taken. Of the two lead RPDs above the quality control limits one of the environmental and duplicate pairs was at a concentration below the RL. The selenium RPDs outside the acceptance limits were 66.6, 26.5, 89, 80.8, 88, and 124, and the zinc RPDs were 50, 28.5, 35.29, and 90.9. Of the selenium field duplicate and environmental

samples associated with the RPDs above 25% all had concentrations below reporting limits and were considered estimates. The zinc concentration levels were all above the reporting limit value of 1. All field SOPs were followed by the field crew including collecting the environmental and field duplicate samples at the same time near one another in the water column. A water body that is not well mixed across the width of the channel can result in unequal concentrations of metals and pesticides, as can a channel with high flow and turbid waters due to increased sediment mobilization. Of the sites associated with elevated RPDs, over half were from murky or cloudy brown water, with a mud or sand substrate, and had low to moderate flow with moderate turbidity. As the analyses involve total metals (no filtration in the field), elevated amounts of suspended sediment in the sample could account for the differences between the copper, lead, selenium and zinc environmental and field duplicate samples.

Laboratory control spikes were within acceptable recovery limits for 100% of samples run. Matrix spikes recoveries were within control limits for 96% of all metals samples analyzed. Seventy-seven percent of boron matrix spikes were within control limits (PR 85-115). Eleven of 37 boron matrix spikes were outside of the quality control limits with seven recovering below control limits (all non-project matrix spikes) and four were above quality control limits. For each batch with a matrix spike that recovered outside of recovery criteria, the samples were spiked with an amount less than half of what was detected in the environmental sample. Poor recoveries are most likely due to the amount of boron in the sample being detected at a level over twice the amount with which the sample was spiked. In all cases, laboratory control spikes extracted and run in the same batch were within acceptable recovery limits. All matrix spike duplicates analyzed met acceptability criteria for precision (RPD < 25%).

- *E. coli*: Sterility checks of laboratory blanks, negative control and positive control samples were run for each batch. One hundred percent of laboratory blanks met acceptability criteria. One hundred percent of field blanks collected had *E. coli* numbers less than the reporting limit of 1.  $R_{log}$ s were performed on *E. coli* lab duplicates by Caltest Laboratories. The mean  $R_{log}$  for the laboratory was calculated to be 0.40. This value multiplied by 3.27 resulted in a precision criterion of 1.30. All laboratory duplicates had  $R_{log}$ s below the criteria acceptance level. Due to the nature of the analysis method and *E. coli* distribution within the water column, it is not possible to use RPDs to assess precision; however, field duplicate RPDs have been recorded to monitor the variation in duplicates over time analyzed by the lab.
- Pesticides: Field blanks met the acceptance criteria for 99.7% of all pesticides (Table 14). The single pesticide detected in a field blank was DDT at 0.018 µg/L (0.008 µg/L above the RL), and the associated environmental sample was non-detect. All field duplicates met acceptance criteria except for a cyanazine (RPD 63.4%) and chlorpyrifos (RPD 176%) sample. The environmental and duplicate cyanazine results were both below the reporting limits and considered estimates. The chlorpyrifos environmental result was below the RL and differed by more than 40% from the confirmation column, both of which may have resulted in a larger RPD result.

For the irrigation season, pesticides were analyzed in eight different groups: pyrethroids (EPA 8081A), organochlorines (EPA 8081A), organophosphates (EPA 8141A), carbamates (EPA 8321A), methamidophos (EPA 8141A), paraquat (EPA 549.2), glyphosate (EPA 547M) and triazines (EPA 619). Lab blanks were run with each batch and 100% met acceptability criteria. Matrix spikes and laboratory control spikes were performed for each batch to assess precision and accuracy as well as possible matrix interference. Either a matrix spike duplicate and/or a laboratory control spike duplicate were performed per batch to assess precision. Ninety-five percent of matrix spike samples run were within acceptability criteria. The individual pesticides with less than 90% of samples within acceptable recoveries for matrix spikes include methomyl (87.5%), cyanazine (87.5%), paraquat (25%) and phosmet (79%). Three matrix spike and/or matrix spike duplicates were above control limits for methomyl and cyanazine but their associated laboratory control spikes were within the acceptability criteria and all environmental samples were non-detect. Phosmet had matrix spike and matrix spike duplicates above control limits in one batch and a matrix spike below control limits in another, but the laboratory control spikes were within the criteria range and all environmental samples were non-detect. In another batch, phosmet had zero recovery in both the matrix spike and matrix spike duplicate. The lab has since prepared a new spike solution to use in the phosmet matrix spike procedure and this analysis is being closely monitored to be sure the problem does not re-occur. The lab control spike in the same batch was recovered within the acceptable criteria and all other samples in the batch were non-detect. Paraquat analysis is difficult to perform in water samples due to matrix interferences; paraquat tends to bind to suspended solids in the sample and therefore recoveries of matrix spike samples are consistently low. In two paraquat batches the MS/MSD were below the control limits (PR 43-102). The LCS was within the acceptable range, all samples were non-detect and the MS/MSD samples were not re-analyzed for one of the batches. In the other batch, the LCS was above the control limits, all samples were non-detect, and the re-injection of the matrix spike and matrix spike duplicate yielded similar results. Of the nine paraquat batches with matrix spikes above the control limit, five batches had the LCS outside of the quality control limits, and four batches had re-injections performed with similar results. Two of the batches with high MS/MSD/LCS recoveries were due to bad solid phase extraction (SPE) cartridges. The batches were re-extracted and the analyses were performed. Only one batch had a single detection, and in that batch the LCS was within acceptability criteria.

Laboratory precision assessed by the RPD of laboratory duplicates, met acceptability criteria in 95% of matrix spike duplicates (Table 15). Carbofuran, methiocarb, diuron and paraquat all had 83% of MSDs within acceptable criteria (RPD > 25%). None of the carbofuran, methiocarb or diuron matrix spike and matrix spike duplicates with high RPDs were outside of percent recovery limits, and all had non-detect samples in their batches. In one of the paraquat batches one matrix spike was recovered above quality control limits (PR 112%) while the duplicate experienced a lower recovery but was within control limits (PR 61.3%). All samples in the batch were non-detect so no re-extraction was performed. The second MS/MSD RPD that was greater than 25% was due to one matrix spike that had zero recovery. The matrix spikes were re-analyzed with similar results and all samples were non-detect. Laboratory control spikes were

within acceptability criteria for 98% of samples analyzed, and 100% of laboratory control spike duplicates had RPDs less than 25%.

Surrogates were run for each analysis except for glyphosate and paraquat. Surrogate recoveries were within specific acceptance criteria for 99.2% of all samples analyzed. All batches with laboratory QC analyses outside of acceptability criteria were flagged as was the specific sample in the batch. When a surrogate is recovered outside of the acceptability criteria, the associated environmental sample is flagged as well. Batches are approved by evaluating all measures of precision and accuracy such that although a single QC sample may be outside of acceptability criteria, the entire batch may be accepted due to the other QCs analyses/procedures associated with that batch meeting acceptability criteria. Due to laboratory error, triphenyl phosphate and tributylphosphate were run with a single EPA 8081A batch. The batch was re-extracted past hold time and re-analyzed with the correct surrogates, yielding the same results. The original batch, with the incorrect surrogates, was reported since it was analyzed within hold time and the recoveries for both sets of surrogates were similar (and within recovery criteria).

Four batches this season were run without matrix spike and matrix spike duplicate samples, causing the batches to be flagged as having "incomplete QC". All of the batches were run with a laboratory control spike duplicate meeting precision requirements. The Management Plan Monitoring batches, one each month from May through August, were missing MS/MSD due to a miscommunication with the laboratory. It was not noted on the COC that a matrix spike was to be run, and therefore the lab did not run the spike analyses. The issue was resolved mid-August and the matrix spike analysis is now noted on all COCs for all Management Plan samples in addition to the collection of extra water. In addition, one color batch in May was run without a laboratory duplicate due to laboratory error.

Hold times for all chemistry analysis were met, except for two paraquat batches. The two batches run in May were originally extracted and run within hold time. Due to lack of recovery of paraquat in the matrix spike, matrix spike duplicate, and LCS due to bad SPE cartridges, the batches were re-extracted and samples reanalyzed past the 7-day hold time. The lab has subsequently switched cartridge suppliers as a corrective action.

## ***Toxicity***

For aquatic toxicity testing, the acceptability of test results is determined primarily by performance-based criteria for test organisms, culture and test conditions, and the results of control bioassays. Control bioassays include monthly reference toxicant testing and negative and solvent controls (for TIEs). Test acceptability requirements are documented in the method documents for each bioassay method and are included in the ESJWQC QAPP. In addition to the QA requirements for the toxicity testing methods, a minimum of 5% of the samples collected are required to be collected as field duplicates. Field duplicates were collected every sampling event such that the overall rate of field duplicates would be at least 5% of all samples including management plan samples and resamples due to toxicity occurring during normal monitoring.

The overall percentage of field duplicates are as follows: *Ceriodaphnia* 9%, *Pimephales* 9%, *Selenastrum* 8% and *Hyalella* 6%.

- **Water Column Toxicity:** Field duplicates were collected during each irrigation event and were tested for toxicity to *Ceriodaphnia*, *Selenastrum* and *Pimephales* (Table 25). For these three species RPDs for all field duplicates were within acceptability criteria (RPD < 25%) except for *Selenastrum*, which had 83.3% of field duplicate samples meeting the acceptability criteria. Two of the 12 field duplicates had RPDs greater than 25% (RPD 60.7% and 46%) however neither the field duplicates nor the associated environmental samples exhibited toxicity. Due to laboratory error Cottonwood Creek @ Rd 20 and Bear Creek @ Kibby Rd were tested for algae toxicity in April. Since the samples were found to be toxic, the Coalition decided to follow protocols and had TIEs conducted and the sites were resampled. The algal toxicity was persistent for both samples. Also in April, Deadman's Creek @ Hwy 59 and Duck Slough @ Hwy 99 both had a >50% toxic effect in algae cell growth in the resamples collected due to toxicity in the original sample. Phase I algae TIEs were scheduled for the resamples, but due to error the samples were discarded prior to the TIE initiation. All tests met holding time requirements (< 36 hours), water quality requirements and control requirements (as listed in the EPA method guidelines).
  
- **Sediment Toxicity:** Sediment was collected on August 28, 2008 and resampled on October 2, 2008. Two field duplicates were collected and both had RPDs less than 25% (Table 25) One hundred percent of the sediment samples had laboratory controls within acceptability criteria. All sediment samples met holding time criteria.

**Table 14. ESJWQC summary of field blank quality control sample evaluations.**

Samples were collected during the irrigation season of 2008 and are sorted by method and analyte.

Method	Analyte	Data Quality Objective	Number of Samples	Samples Within Control Limits	Percent Samples Acceptable
EPA 8321A CARB	Aldicarb	<RL or < (env sample/5)	12	12	100.00

## Pesticide Use Information

---

All exceedances for the 2008 irrigation sampling are provided in the next section of this report, Data Interpretation. Pesticide use reports (PUR) for January 2008 – September 2008 were requested from all the counties within the Coalition region and applications relevant to exceedances are included in Appendix IV. It should be noted that PUR data are considered preliminary and may include errors and/or omissions.

For each sampling period in which chemicals, metals or toxicity were detected, all reported pesticide use for one to six months prior to sampling (depending on the exceedance, see Table 26) was collected for the specific site subwatershed based on Township-Range-Section (TRS). All pesticide products that contained the detected chemicals and metals are listed by their active ingredients and application method and are provided in maps in Appendix IV. Pesticide use is reported as amount of product used. Some products may have more than one active ingredient and in this case the product appears more than once with the name of the chemical ingredient. Data are not available for individual fields or parcels except where they coincide with complete sections. If necessary, PURs can be tentatively assigned to individual parcels by matching the size of the parcel and crop from the land use data with the number of acres and the commodity to which the product was applied and also using land ownership information and matching to user information on the PUR tables. Where exceedances in consecutive monitoring periods require pesticide use reports, only the additional pesticide use from the date of the previous exceedance are provided for the later exceedance. If there were no applications within the specified PUR collection period (Table 26), PUR data for an additional month back was reviewed. If no applications were made during this additional month, the last application was noted.

Cyanazine, dieldrin, endrin, DDT and DDE exceedances are not queried since there are no registered products that contain these chemicals. Nitrate/nitrite exceedances are not listed since the use of these products are not reported.

**Table 26. Pesticide use data collected for reported exceedances.**

Exceedance Type	Pesticides Use Data Collected
Pesticides in water column	1 month with 6 months for pyrethroids
Metals in water column	3 months
Sediment Toxicity – <i>Hyalella azteca</i>	3 months with 6 months for pyrethroids
Water column toxicity – <i>Selenastrum capricornutum</i> , <i>Pimephales promelas</i> and <i>Ceriodaphnia dubia</i>	1 month with 6 months for pyrethroids

## Data Interpretation

---

Discrepancies occurred between exceedances reported in this document and those submitted as exceedance reports to the CVRWQCB during the 2008 irrigation monitoring season (Table 27). These discrepancies include detections that were either not reported in official exceedance reports or were reported incorrectly for various reasons described below.

Exceedances of cadmium, lead and nickel have been reported in Exceedance Reports that are not included in the following tables due to increased WQTLs (revised WQTL list received on September 16, 2008). Therefore 10 cadmium exceedances (WQTL raised from 0.04 to 5 µg/L), five lead exceedances (WQTL raised from 2 to 15 µg/L) and one nickel exceedance (WQTL raised from 12 to 100 µg/L) were reported to the Regional Board that are no longer considered exceedances.

In addition, discrepancies occurred between the initial percentages reported for *Selenastrum capricornutum* toxicity and those included in this report. *Selenastrum* toxicity test results are reported from the laboratory in both absorbance units and cells/mL (calculated based on absorbance). Initially a percent cell growth relative to the control was calculated based on the reported absorbance; however the percent relative to the control values entered into the Coalition database were calculated based on cell counts. Because of the nature of the calculations, the percentages reported in the initial exceedance reports may vary slightly from the final exceedances listed in Table 32.

pH exceedances for Highline Canal @ Hwy 99 and Livingston Drain @ Robin Ave (sampled on June 3, 2008) were reported incorrectly on June 4, 2008 as 8.54 and 8.61, respectively. The true results are 8.61 for Livingston Drain @ Robin Ave and 8.54 for Highline Canal @ Hwy 99 (Table 27).

A dissolved oxygen exceedance was not reported for Black Rascal Creek @ Yosemite Rd sampled on September 30, 2008 (Table 27).

In an Exceedance Report submitted on October 2, 2008, exceedances of DDE and DDT were reported for Highline Canal @ Lombardy Rd. It was not noted that both of these were detected in the field blank; the associated field duplicate and environmental sample both had no DDE and DDT. The other three exceedances (chlorpyrifos, malathion and methyl parathion) reported for Highline Canal @ Lombardy Rd were results from the field duplicate, not the environmental sample. The Highline Canal @ Lombardy Rd environmental sample collected on August 19 had no pesticide exceedances. In the same table, malathion concentration was reported as 0.012 µg/L for Prairie Flower Drain @ Crows Landing; the correct value was 0.12 µg/L (Table 27).

All samples that were toxic were resampled within 48 hours of receiving laboratory results. All samples that experienced toxicity greater than 50% of the control underwent toxicity identification evaluations (TIEs) except for two samples collected as resamples due to toxicity in

the original sample. In April, Deadman's Creek @ Hwy 59 and Duck Slough @ Hwy 99 both had a >50% reduction in algae cell growth in the resamples. Phase I algae TIEs were scheduled for the resamples, but due to lab error the samples were discarded prior to the initiation of the TIE. Complete TIE results are included Appendix VI and summarized in Table 32.

Water quality trigger limits (WQTLs) used to determine exceedances are provided in Table 28. A summary of exceedances that occurred during monitoring over the 2008 irrigation season is presented in Table 29 - Table 32.

**Table 27. Exceedance discrepancies that occurred during the 2008 irrigation season.**

Station Name	Sample Date	Analyte	Unit	Exceedance Report	Current Report
Highline Canal @ Hwy 99	06/03/08	pH	none	8.54	8.61
Livingston Drain @ Robin Ave	06/03/08	pH	none	8.61	8.54
Highline Canal @ Lombardy Rd (FD)	08/19/08	Chlorpyrifos	µg/L	Reported as the environmental sample	0.031
Highline Canal @ Lombardy Rd (FB)	08/19/08	DDE	µg/L	Not Reported	0.0089
Highline Canal @ Lombardy Rd (FB)	08/19/08	DDT	µg/L	Not Reported	0.018
Highline Canal @ Lombardy Rd (FD)	08/19/08	Malathion	µg/L	Reported as the environmental sample	0.14
Prairie Flower Drain @ Crows Landing Rd	08/19/08	Malathion	µg/L	0.012	0.12
Highline Canal @ Lombardy Rd (FD)	08/19/08	Methyl parathion	µg/L	Reported as the environmental sample	0.18
Black Rascal Creek @ Yosemite Rd	09/30/08	Oxygen, Dissolved	mg/L	Not Reported	3.75

**Table 28. Water Quality Triggers Limits (WQTLs) for constituents and parameters measured during Coalition monitoring (updated on September 16, 2008).**

Constituent	Water Quality Trigger Limit (WQTL)	Standard Type	Beneficial Use (BU) with most protective limit	Reference for the Trigger Limit	Category (see footnotes)
<b>Field and Physical Parameters</b>

Orthophosphate, soluble	NA				
TKN	NA				

Category 1: Constituents that have numeric water quality objectives in the Sac-SJR Basin Plan or other WQO listed by reference such as MCLs (Page III-3.0)\*, CTRs (Page III-10.1)\*, and chlorinated hydrocarbon pesticides (Page III-6.0, third bullet)\*. Other numeric objectives may only apply to specific water bodies sections, or during specified time periods (see Basin Plan for more details).

Category 2: Pesticides with discharge prohibitions. Prohibitions apply to any discharges not subject to board-approved management practices (Page IV-25.0)\*.

Category 3: Constituent does not have numeric WQO, and does not have a primary MCL. WQ Trigger Limit exceedance is based on implementation of narrative objective. All detections should be tracked. None are default exceedances.

Category 4: Coalitions may propose alternative triggers for specific water bodies. The coalition must provide the documentation that supports their proposed alternative trigger.

(\*) Water Quality Control Plan for the Sacramento and San Joaquin River Basins. Revised on October 2007. Narrative WQTLs are based on Water Quality Goals Database. Updated by Jon Marshack on 16 July 2008

NA = Not Available. Until completion of evaluation studies and MRP Plan submittals with site specific information on beneficial uses.  
ND = Non Detect.

## Interpretation of Results

---

Monitoring of ambient waters is conducted by the Coalition for the purpose of characterizing agricultural discharges in the Coalition area. Over the long term, monitoring data provide insight on general trends in water quality at each of the sample sites. To understand the source of exceedances, the Coalition can perform any of the following:

1. An analysis of associated toxicity data (for chemistry exceedances) to prioritize the search for biologically relevant chemical exceedances, or the evaluation of chemistry data (for toxicity exceedances) to determine possible sources of toxicity
2. An analysis of relevant Toxicity Identification Evaluation (TIE) results to determine possible causes of toxicity in sample water including constituents for which the Coalition does not test
3. The use of PURs to identify relevant applications that occurred upstream of the sample site prior to the sampling event
4. An analysis of monitoring data to determine the potential mechanism associated with exceedances of physical and field parameters such as DO, pH, and TDS
5. Special studies where appropriate and cost-effective, to determine the sources of constituents such as *E. coli* or the potential causes of exceedances such as low DO
6. Additional sampling as listed in the ESJWQC Management Plan submitted September 30, 2008

These actions were implemented on a case by case basis over the course of the 2008 irrigation monitoring season. All PUR data for exceedances that occurred during the 2008 irrigation season can be found in Appendix IV.

Both normal monitoring (NM) and Management Plan Monitoring (MPM) exceedances of WQTLs from the 2008 irrigation season are discussed in this section. All site subwatersheds are listed alphabetically and include a site subwatershed table of exceedances under the subsection, *Site Subwatershed Analysis*. A summary of the constituents analyzed for NM (Table 6) and MPM (Table 7) is provided in the Monitoring and Analysis section of this document. All monitoring results can be found in Appendix I. A full analysis of MPM results will be included in the ESJWQC Management Plan update to be submitted on April 1, 2009 for priority site subwatersheds. The Management Plan update will also review any new site/constituent requiring a management plan due to exceedances that have occurred in 2008. A general discussion of exceedances of pH, DO, SC/TDS, nutrients, ammonia, *E. coli*, arsenic and lead are provided at the end of this section.

## Site Subwatershed Analyses

### Ash Slough @ Ave 21

Ash Slough @ Ave 21 was dry during all six irrigation sampling events.

### Bear Creek @ Kibby Rd

**Table 33. Bear Creek @ Kibby Rd sample site - 2008 irrigation season exceedances.**

\*WQTL based on hardness and shown in parenthesis

Toxicity to *Selenastrum* occurred in samples collected during the first irrigation monitoring event on April 29, 2008 (Table 33). Resampling occurred one week later (May 7, 2008) and samples were again toxic to *Selenastrum*. This is the first time that samples from Bear Creek have been toxic to algae since monitoring began in 2004. A TIE was conducted on the original sample (collected on April 29), however toxicity did not persist through the treatments and the cause of toxicity could not be determined. Copper was detected in the sample water during the same event at a concentration below the WQTL (1.1 µg/L) indicating that this amount is unlikely to account for the toxicity to algae. There were no other detections of any pesticides at this site during this event. It is possible that a constituent that was not analyzed for in the water chemistry samples was the cause of toxicity. PUR data show 73 pesticide applications in the site subwatershed that may be relevant to the toxicity. The active ingredients in these applications include 2,4-D dimethylamine salt, amino ethoxy vinyl glycine hydrochloride, copper hydroxide, copper oxide (ous), copper sulfate (basic), diuron, glufosinate-ammonium, glyphosate (various products), midacloprid, MCPA dimethylamine salt, MSMA, nicosulfuron, oxyfluorfen, rimsulfuron, sethoxydim and simazine. Of these, copper, diuron, glyphosate and simazine are analyzed for by the Coalition. Only copper was detected in the chemistry analysis. *Selenastrum* toxicity occurred for the first time at the Bear Creek @ Kibby Rd site and therefore does not require a Management Plan. Bear Creek @ Kibby Rd is currently under a Management Plan for chlorpyrifos and *Ceriodaphnia dubia* toxicity. Management practices implemented to

reduce exceedances of these constituents (i.e. holding basins, retention ponds, filter strips) will most likely reduce incidences of algae toxicity as well.

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (91% survival relative to the control, Table 33). Samples with an average survival above 80% but statistically different from the control are considered toxic but not ecologically relevant. This sediment toxicity was a first-time exceedance at this site and therefore has not been addressed in the Coalition Management Plan. Sediment samples do not undergo chemical analysis or TIE treatments, and the cause of toxicity in the sediment is uncertain. In the water column, samples collected two days prior to sediment sampling resulted in one exceedance of copper (7.1 µg/L). Due to the tendency of copper to bind to sediment (the  $K_{oc}$  for copper sulfide pentahydrate is 16720, however other copper compounds do not have known  $K_{oc}$  values), the exceedance level detection of copper in the water column may be an indication of elevated levels of copper in the sediment at that site. There were no other pesticide or metal exceedances in water samples during the month of August. PUR data show no applications of copper within three months of the sediment toxicity event. There were 129 pesticide applications containing active ingredients other than copper that may be relevant to the *Hyalella* toxicity. These active ingredients include lambda-cyhalothrin, (s)-cypermethrin, permethrin, bifenthrin, cyfluthrin, fenpropathrin, esfenvalerate, propargite, indoxacarb, abamectin, spiromesifen, chlorpyrifos, glyphosate, paraquat dichloride, ethephon and pyraclostrobin. As mentioned above, *Hyalella* toxicity has not yet been addressed in the Coalition Management Plan. If samples from this site test toxic to *Hyalella* again, then the exceedances will be included in an updated management plan.

One exceedance of the copper WQTL occurred at Bear Creek in a sample collected on August 26, 2008 (Table 33). Previous exceedances of copper at this site occurred in samples collected during both storm monitoring events of 2008 on January 24 (8.6 µg/L) and February 25, 2008 (7.2 µg/L) and also during one of the storm monitoring events from the previous year on February 12, 2007 (12 µg/L). There were no applications of copper within three months of the exceedance date in the site subwatershed. Copper applications only occurred between the months of February and April in 2008. As a result of the 2008 storm and irrigation season exceedances, copper will be included as a Management Plan constituent for Bear Creek in the Management Plan update.

One exceedance of the arsenic WQTL occurred in samples collected during the June 24, 2008 sampling event (Table 33). Samples from this site have been tested for metals since the irrigation season of 2006 and this was the first detection of arsenic above the WQTL (10 µg/L). There were no other exceedances of metals during this event. However, most of the metals tested were detected at higher concentrations than during any other event of that season. Boron was detected at 40 µg/L, compared to an average detection of 7.3 µg/L in samples from the other irrigation events. Copper was detected at approximately twice the concentration of other events (at 3 µg/L). These results indicate that metals were remobilized from a reservoir in the creek, such as contaminated sediment, resulting in elevated concentrations in the water column. Prior to this event, arsenic had not been detected above 3.4 µg/L. Arsenic is not currently applied by agriculture in the Coalition region. Refer to the explanation provided below, under *Constituent Specific Analyses/Special Studies*, for details on the historical use of

arsenic in agriculture. At this point the source of arsenic in the Bear Creek site subwatershed is unclear although it is likely that the native soils in the creek contain arsenic.

### Berenda Slough along Ave 18 ½

**Table 34. Berenda Slough along Avenue 18 ½ and Berenda Slough @ Rd 19 (upstream) sample sites - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L
Berenda Slough @ Rd 19	7/29/2008	MPM	1.10

MPM – Management Plan monitoring

The Berenda Slough along Ave 18 ½ sample site was dry during every sampling event of the irrigation season. Current Management Plan constituents for Berenda Slough include chlorpyrifos, *Selenastrum* toxicity, dissolved oxygen, and *E. coli*. The upstream MPM site, Berenda Slough @ Rd 19, contained water during two of three MPM sampling events. Samples were collected from the MPM site on May 27, 2008 for analysis of chlorpyrifos and water column toxicity to *Selenastrum capricornutum*, and on July 29, 2008 for water column toxicity to *Selenastrum*. Field parameters were also measured during each sampling event. The only exceedance at this site was of the dissolved oxygen (DO) WQTL which occurred during the July 29, 2008 MPM sampling event (Table 34). Exceedances of the DO WQTL have occurred at the Berenda Slough site during previous monitoring events, all during irrigation months. Two exceedances occurred during the 2006 irrigation season in June and July, and six exceedances occurred during the irrigation season of 2007 in all months between May and August. DO is a Management Plan constituent for the Berenda Slough site subwatershed. Possible sources of DO in Coalition surface waters are discussed further below, under *Constituent Specific Analyses/Special Studies*.

### Black Rascal Creek @ Yosemite Rd

**Table 35. Black Rascal Creek @ Yosemite Rd sample site - 2008 Irrigation season exceedances.**

Sample Site	Sample Date	Sample Type	DO, mg/L	pH	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, µg/L	Lead*, µg/L

NM – normal monitoring; MPM – Management Plan monitoring; Sediment – Sediment monitoring; RS – Resample

\*WQTL based on hardness and shown in parenthesis

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (63% survival as compared to the control, Table 35). This was the first sediment toxicity to occur at this site and does not require a management plan. Sediment samples do not undergo chemical analysis or toxicity identification evaluations; therefore the cause of toxicity in the sediment is uncertain. In the water column, there were no exceedance level detections of any pesticides or metals during the same month of sampling. Four months prior to sediment sampling (April 29, 2008), one exceedance each of the copper and lead WQTLs occurred at this site (Table 35). No other pesticides or metals exceedances occurred at this site during the irrigation season. Low level concentrations of metals, however, were found at this site during every monitoring event of this irrigation season as well as during previous sampling seasons. The concentrations of metals detected in the water column during these events are not sufficient to have a toxic effect on *Hyalella*. For example, the highest concentration of copper, 14 µg/L, occurred in water samples collected on May 17, 2008 (the WQTL based on the 290 mg/L hardness for that sample was 23 µg/L). The average LC<sub>50</sub> of copper for *Hyalella* is 33.7 µg/L (Pesticide Action Network Database). There were also four detections of pesticides at concentrations below WQTLs. In samples collected on April 29, 2008, chlorpyrifos was detected at a concentration of 0.0078 µg/L. In samples collected on May 27, 2008, paraquat was detected at 0.61 µg/L, cyanazine at 0.96 µg/L and simazine at 0.68 µg/L. The source of sediment toxicity in the creek is unknown. PUR data show 53 pesticide applications that may be relevant to the *Hyalella* toxicity. The active ingredients in these applications include lambda-cyhalothrin, permethrin, bifenthrin, esfenvalerate, (s)-cypermethrin, cyfluthrin, abamectin, glyphosate, and propargite. If additional sediment toxicity is detected in future sampling events, then the toxicity will be addressed in a management plan for this site subwatershed.

Exceedances of the lead WQTL occurred during the first and sixth irrigation sampling events on April 29 and September 30, 2008 (Table 35). One exceedance of the copper WQTL also occurred during the April 29, 2008 sampling event. These exceedances were the first to occur for copper and lead at this site. During both of these events, low concentrations (below the WQTLs) of all other metals tested were also measured at this site. Neither of these metals has been addressed in a Management Plan. Metals in a water body have a tendency to bind to

sediment and do not degrade. As a result, metals can accumulate in a stream bed over time from natural or anthropogenic sources. Copper enter surface waters as a result of weathering of rocks and soils that contain metals or from runoff due to agricultural applications. PUR data indicate that the use of copper-containing products was limited to four applications during the entire 2008 irrigation season. Eight hundred pounds of product containing copper hydroxide were applied across 100 acres of walnut orchards between mid-March and early April. Without knowing how much of the total copper detected was dissolved, it is difficult to determine if the source of this exceedance was due to copper applications or copper bound to sediment in the water column. Lead predominately resides in the sediments and could have become mobilized in the water during the sampling event as a result of disturbance of the stream bed. Currently, there are no pesticides applied that contain lead. Possible sources of lead in the Coalition region are discussed in more detail below under *Constituent Specific Analyses/Special Studies*.

Three exceedances of *E. coli* were detected during the first three monitoring events at Black Rascal Creek (Table 34). Exceedances of the *E. coli* WQTL have occurred most frequently and at the highest levels during the storm runoff seasons. For example, during 2008 storm monitoring, *E. coli* was measured during both events above the maximum detection limit (>2400 MPN/100mL). The 2007 monitoring results are similar, with *E. coli* levels at or above the maximum detection limit during both storm events and ranging between 84 and 770 MPN/100mL during the irrigation season events. Upstream of the sample site, land use includes dairies and pasture (comprising approximately half of the upstream site subwatershed), and discharge running off of these lands during the storm season may contain bacteria from dairy or animal waste. Other sources of *E. coli* at the site are described further under *Constituent Specific Analyses/Special Studies*, below. *E. coli* is a priority E constituent in the management plan for Black Rascal Creek @ Yosemite Rd.

Dissolved oxygen was detected below the minimum WQTL of 7 at the Black Rascal Creek sample site during July, August, September and October (Table 35). The environmental factors that contribute to low concentrations of DO in a water body were investigated by the Coalition and results from this special evaluation are provided under *Constituent Specific Analyses/Special Studies*. DO is currently addressed in the Black Rascal Creek site subwatershed management plan.

Two pH exceedances occurred during the first and sixth irrigation season monitoring events (Table 35). The first exceedance, measured on April 29, 2008, was the first pH exceedance to occur at this site and was addressed in a Communication Report submitted on July 3, 2008. This exceedance was measured above the upper WQTL, whereas the exceedance detected on September 30, 2008 was below the lower pH limit. pH can vary diurnally with photosynthetic rates and changes in the concentration of CO<sub>2</sub> and O<sub>2</sub> in the water, and it is difficult to determine the relative role of the various factors influencing pH fluctuations. Further explanation of pH dynamics in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. As a result of the two 2008 irrigation season exceedances, pH will be addressed in the updated Site Subwatershed Management Plan (April 1, 2009).

## Cottonwood Creek @ Rd 20

**Table 36. Cottonwood Creek @ Rd 20 and Cottonwood Creek @ Hwy 145 (upstream) sites - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, µg/L	Cyanazine, µg/L
Cottonwood Creek @ Rd 20	4/29/2008	NM		5	580	8 (6.9)	
Cottonwood Creek @ Rd 20	5/7/2008	RS		4			
Cottonwood Creek @ Rd 20	5/27/2008	NM			250		1.1
Cottonwood Creek @ Hwy 145	6/24/2008	MPM				39 (5.5)	
Cottonwood Creek @ Rd 20	6/24/2008	NM			1300		
Cottonwood Creek @ Rd 20	7/29/2008	NM			1000		
Cottonwood Creek @ Hwy 145	8/26/2008	MPM	6.45				
Cottonwood Creek @ Rd 20	8/26/2008	NM	6.83		390	4.4 (3.7)	

NM – normal monitoring; MPM – Management Plan monitoring; RS – Resample

\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Selenastrum capricornutum* (5% survival as compared to the control) occurred for the first time at Cottonwood Creek in samples collected on April 29, 2008 (Table 36). Resampling one week later again resulted in toxicity, indicating that the source of toxicity at this site was persistent. A TIE was conducted for this sample and results from the evaluation indicated that the source(s) of toxicity were non-polar organic and cationic compound(s). Low concentrations (below the WQTL) of diuron (0.63 µg/L) and simazine (0.11 µg/L) were detected in water samples from this event. Metals detected in the sample water were arsenic (2 µg/L), boron (32 µg/L), copper (8 µg/L), lead (0.82 µg/L), nickel (1.7 µg/L), selenium (0.3 µg/L) and zinc (10 µg/L). The Phase III TIE analysis indicated that diuron and zinc were present at toxic concentrations (diuron = 0.3 TUC and total metals = 1.5 TUC, Appendix VI). It is possible that additive effects of metals and pesticides in the creek caused *Selenastrum* toxicity at this site. PUR data include 280 applications that may be relevant to the *Selenastrum* toxicity. The active ingredients in these applications include 1,3-dichloropropene, 2,4-D, dimethylamine salt, copper, copper hydroxide, copper oxide(ous), diuron, flumioxazin, glufosinate-ammonium, glyphosate, imidacloprid, oryzalin, oxyfluorfen, paraquat dichloride, pendimethalin, pyraflufen-ethyl and simazine. *Selenastrum* toxicity has not been addressed in a management plan for this site (the second exceedance on May 7, 2008 is due to a resample and is considered part of the same event of the first exceedance). If another exceedance occurs, the Cottonwood Creek Site Subwatershed Management Plan will be updated to include *Selenastrum* toxicity.

Exceedances of the copper WQTL occurred during the first and fifth irrigation monitoring events at the normal monitoring site, Cottonwood Creek @ Rd 20. Copper is a management plan constituent for Cottonwood Creek and due to exceedances during the first year of

Management Plan monitoring, the Coalition sampled upstream at Cottonwood Creek @ Hwy 45 during the 2008 irrigation season. Upstream Management Plan monitoring occurred at Cottonwood Creek @ Hwy 145 during the third irrigation event and exceedance levels of copper were detected (39 µg/L, Table 36). Between March 26 and April 26, there were 139 applications of copper hydroxide in the site subwatershed, all for pest control on wine and table grapes. Within three months prior to the August 26 exceedance, copper sulfate was applied across 700 acres of raisin grapes, almonds and pistachios. PUR data for the upstream site subwatershed include 22 applications of copper hydroxide between April 1 and 17, predominantly on wine grapes, and 21 applications of copper sulfate between June 3 and 9 on raisin grapes. PUR data will be reviewed on a parcel level in the ESJWQC Management Plan update to more specifically identify possible agricultural sources of copper. Exceedances of the copper WQTL and follow up actions to address the exceedances are described further in the Coalition Management Plan, submitted September 30, 2008 which will be updated on April 1, 2009.

One exceedance of cyanazine was detected during the May 27, 2008 sampling event for the first time at this site (1.1 µg/L, Table 36). Cyanazine is a triazine herbicide that is not currently registered for agricultural use. Due to the pesticide's long hydrolysis half-life (3,680 days according to the Pesticide Action Network Database), it is possible that the detection was a result of applications in the past. Cyanazine was classified as a Restricted Use Pesticide between 1995 and 2002 and during that time production of the herbicide was phased out. The sale and use of cyanazine stocks were prohibited after September 30, 2002. PUR data indicate that the last application of cyanazine within the Cottonwood Creek site subwatershed was in July of 1995. Approximately 32 lbs of active ingredient were applied across 40 acres of corn crops on July 18 and 19, 1995. With over ten years between the last application and the detection in the water column, it is unlikely that this application is the source of the exceedance.

Exceedances of the *E. coli* WQTL occurred in all normal monitoring samples from Cottonwood Creek during the irrigation season ranging from 250 – 1300 MPN/100 mL with the highest values occurring in June and July (Table 36). Samples collected during the first 2008 storm monitoring event also resulted in an exceedance (1200 MPN/100mL) however there were no exceedances of the *E. coli* WQTL at this site in 2007. Prior to 2008, the last irrigation season *E. coli* exceedance occurred on August 16, 2005. Possible sources of *E. coli* in Coalition water bodies are described below under *Constituent Specific Analyses/Special Studies*. Land use within the Cottonwood Creek site subwatershed is predominantly vineyards and orchards. Some land is also allocated for dairies and pasture, and runoff from these parcels may be contributing to elevated levels of *E. coli* at the sample site. *E. coli* is a priority E constituent in the management plan for Cottonwood Creek @ Rd 20.

Exceedances of the DO WQTL occurred at both the normal monitoring and the upstream Management Plan sites on August 26, 2008 (6.45 and 6.83 mg/L, Table 36). DO exceedances are common in the Coalition region, particularly during the warmer summer months. Low DO occurred at the Cottonwood Creek site during numerous events since the irrigation season of 2005, when monitoring began at this site. A further discussion of parameters that may affect

DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the management plan for Cottonwood Creek @ Rd 20.

### Deadman Creek @ Gurr Rd

**Table 37. Deadman Creek @ Gurr Rd sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	SC, µS/cm	E. coli, MPN/100 ml	TDS, mg/L	Arsenic, µg/L	Dieldrin, µg/L
Deadman Creek @ Gurr Rd	4/29/2008	NM			>2400		18	0.028
Deadman Creek @ Gurr Rd	5/27/2008	NM		801		520		
Deadman Creek @ Gurr Rd	6/24/2008	NM	4.85					
Deadman Creek @ Gurr Rd	7/29/2008	NM	6.87					
Deadman Creek @ Gurr Rd	8/26/2008	NM	5.21		330			
Deadman Creek @ Gurr Rd	8/28/2008	Sediment	5.9					
Deadman Creek @ Gurr Rd	9/30/2008	NM	5.46					
Deadman Creek @ Gurr Rd	9/30/2008	FD			330			

NM – normal monitoring; Sediment – Sediment monitoring; FD – Field Duplicate sample

Dieldrin was detected at a concentration of 0.028 µg/L in the sample from Deadman Creek @ Gurr Rd during the April 29, 2008 monitoring event. This concentration is above the drinking water criteria of 0.00014 µg/L but below the Sacramento/San Joaquin Basin Plan objective of 0.056 µg/L (Table 37). Dieldrin is an organochlorine insecticide that is not currently registered for agricultural use. Dieldrin was widely used in the past to control insects on cotton, corn and citrus crops, however it was banned from agricultural use in 1974. The insecticide was also used to control locusts and mosquitoes, as a wood preserve, and for termite control. All products containing dieldrin were banned from use in 1987. Dieldrin is a persistent, bioaccumulative pollutant. Dieldrin does not undergo hydrolysis once introduced to water, but photolysis will slowly degrade the chemical. Dieldrin also has a very long half-life in soils (up to 7 years) and as a result, it is possible that the detection in the creek is a legacy of past use. There was no toxicity detected in samples collected at the same time as this exceedance.

One exceedance of arsenic was detected in samples collected during the April 29, 2008 sampling event (Table 37). Prior exceedances of arsenic occurred during both storm sampling events in 2007 and 2008 at this site. Arsenic detected in water samples on April 29, 2008 is likely from the same source as the arsenic exceedances from the two prior months of storm sampling. It is possible that storm runoff from the upstream site subwatershed is introducing elevated levels of arsenic to surface waters, which persist into the early irrigation season. The source of arsenic in the Deadman Creek site subwatershed is uncertain. Arsenic was used by agriculture in the past for broadleaf weed control and as a cotton defoliant. Currently there is limited use of arsenic in California and it is not applied by agriculture anywhere in the Coalition region. Further explanation of plausible sources of arsenic in the Coalition region is provided

below under *Constituent Specific Analyses/Special Studies*. Arsenic is a priority E constituent in the management plan for Deadman Creek @ Gurr Rd.

Detections of *E. coli* above the WQTL occurred in April, August and September (field duplicate sample only) normal monitoring events (Table 37). *E. coli* exceedances have occurred at this site since monitoring began in 2004 and do not appear to be related to a particular season or month. Possible sources of *E. coli* in the creek include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. Though dairies are not abundant in the Deadman Creek site subwatershed, some land upstream of the sampling site is used for dairies and pasture. It is unknown if agriculture in the area applies manure or biosolids as fertilizer on crops. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* is a priority E constituent in the management plan for Deadman Creek @ Gurr Rd.

Exceedances of the DO WQTL occurred during the last four irrigation monitoring events at this site (Table 37). DO exceedances are common in the Coalition region, particularly during the warmer summer months. DO concentrations below the WQTL in the Deadman Creek @ Gurr Rd site have occurred during irrigation events since 2004. DO at this site was not below the WQTL of 7 mg/L during any storm monitoring event. A discussion of parameters that may affect DO concentration in surface waters is provided at the end of this section, under *Constituent Specific Analyses/Special Studies*. Exceedances from the 2008 irrigation season will be addressed further in the updated Coalition Management Plan.

Exceedances of the total dissolved solids (TDS) and specific conductivity (SC) WQTLs were detected for the first time in samples collected on May 27, 2008 (Table 37). TDS describes all solids (usually mineral salts) that are dissolved in water and are frequently associated with exceedances of SC. Potential sources of TDS and SC are minerals leached from soils by upstream surface water and ground water, or drain water from irrigated agriculture. These sources are described further below under *Constituent Specific Analyses/Special Studies*. The shallow ground water appears to be the cause of elevated salinity in many ESJWQC water bodies close to the San Joaquin River. It is unknown if shallow ground water is the cause of the elevated TDS and SC detected at Deadman Creek @ Gurr Rd. If additional SC or TDS exceedances occur at this site, then these constituents will be address in the Site Subwatershed Management Plan.

## Deadman Creek @ Hwy 59

**Table 38. Deadman Creek @ Hwy 59 sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Arsenic, µg/L	Chlorpyrifos, µg/L

Deadman Creek @ Hwy 59	9/30/2008	NM	4.45				13	
Deadman Creek @ Hwy 59	10/2/2008	Sediment RS	4.22					

NM – normal monitoring; Sediment – Sediment Monitoring; RS – Resample

Water column toxicity to *Selenastrum capricornutum* occurred in the sample collected during the first irrigation monitoring event on April 29, 2008 as well as the resample collected on May 7, 2008 (Table 38). A TIE was scheduled for the resample due to less than 50% cell growth relative to the control, however due to a miscommunication error in the laboratory, a TIE was not conducted. There were no exceedances of constituents known to be toxic to green algae during this event. Two herbicides, diuron and simazine, were detected in water samples but at concentrations below their respective EC<sub>50</sub>s for *Selenastrum* (diuron = 0.7 µg/L, EC<sub>50</sub> = 2.4 µg/L; simazine = 0.45 µg/L, EC<sub>50</sub> = 100 µg/L). Detections of metals in the sample water included all of the metals (arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc), however only arsenic was detected at a concentration above the WQTL (Table 38). The EC<sub>50</sub> for arsenic acid is 690 µg/L (EPA ECOTOX website) and therefore the amount detected in the water sample accounts for less than 0.1 TU<sub>c</sub>. The concentrations of the other metals were relatively low, and were not likely the source of toxicity. PUR data include 158 pesticide applications that may be relevant to the *Selenastrum* toxicity. The active ingredients in these pesticides include 2,4-D, dimethylamine salt, amino ethoxy vinyl glycine hydrochloride, carfentrazone-ethyl, copper, glufosinate-ammonium, glyphosate, imidacloprid, oryzalin, oxyfluorfen, paraquat dichloride, rimsulfuron, sethoxydim, s-metolachlor. Water samples from the Deadman Creek @ Hwy 59 site have been tested for water column toxicity since the irrigation season of 2005. Since that time, *Selenastrum* toxicity has occurred once prior to the April 29, 2008 sampling event, on January 25, 2008. As a result of the second toxicity exceedance, *Selenastrum* toxicity will be addressed in the ESJWQC Management Plan update.

Sediment toxicity to *Hyalella azteca* was detected in samples collected for the irrigation sediment sampling event on August 28, 2008 (90% survival compared to the control, Table 38). This was the first sediment toxicity to occur at this site. The percent survival of organisms in the sample was above 80% and although significantly different from the control, is not considered to be ecological significant. Toxicity resampling occurred on October 2, 2008 and results from this site indicated that sediment toxicity was not persistent. Sediment samples do not undergo chemical analyses or TIEs and therefore the cause of toxicity is unknown. Water samples were collected from this site two days prior to sediment sampling and chemistry results include one exceedance (11 µg/L) of the arsenic WQTL. With the exception of cadmium, all of the metals were detected at concentrations below the WQTLs for each irrigation monitoring event. The highest concentration of copper occurred in a sample collected on May 27, 2008, which was measured at 4.3 µg/L (the WQTL based on the 262 mg/L hardness for that sample was 21 µg/L). The copper LC<sub>50</sub> for *Hyalella* in hard water (124 mg/L) is 90 (82-99) µg/L and in soft water (18 mg/L) is 36 (21-61) µg/L (EPA ECOTOX website Ref# 80935). Chlorpyrifos was also detected in the water column during the August sampling event, at a concentration of 0.015 µg/L (LC<sub>50</sub>=0.086 µg/L, EPA ECOTOX website Ref# 14907). PUR data contain 458 pesticide applications including 50 applications of chlorpyrifos that may be relevant to the *Hyalella* toxicity. Besides chlorpyrifos, the active ingredients reported include lambda-cyhalothrin, (s)-cypermethrin, cyfluthrin, pyrethrins, permethrin, esfenvalerate, fenpropathrin, bifenthrin, indoxacarb, paraquat dichloride, glyphosate, spiromesifen, propargite, abamectin, pyraclostrobin, etoxazole, pyriproxyfen, malathion and trifloxystrobin. If additional sediment toxicity is detected in future sampling events, then the toxicity will be addressed in a Coalition Management Plan update.

Management Plan Monitoring was conducted at Deadman Creek @ Hwy 59 in August and September for chlorpyrifos. Samples collected on August 5 and September 9 contained concentrations of chlorpyrifos above the WQTL (0.14 and 0.069 µg/L, Table 38). Chlorpyrifos was not detected above 0.015 µg/L in any other samples collected during the 2008 irrigation season. Two previous chlorpyrifos exceedances occurred at this site in September 2006 and August 2007 however none of the exceedances have been associated with *Ceriodaphnia* toxicity. PUR data prior to August 5 include 43 pesticide applications with approximately 378 gallons of product containing chlorpyrifos applied on alfalfa. Between August 5 and September 9 an additional 20 applications of chlorpyrifos were applied on alfalfa (131 gallons of product). Chlorpyrifos exceedances will be included in the ESJWQC Management Plan update.

Arsenic was detected at concentrations exceeding the WQTL during five of the six normal monitoring events during the irrigation season (Table 38). Metals were sampled for the first time during the irrigation season of 2008 at this Deadman Creek site and, as a result, these arsenic exceedances were the first to occur at Deadman Creek @ Hwy 59. The downstream site (Deadman Creek @ Gurr Rd) also experienced one exceedance of arsenic during the first irrigation monitoring event on April 29, 2008 (Table 37). After April, there were no arsenic exceedances experienced at the downstream Gurr Rd site for the remainder of the irrigation season. These results indicate that the sources of arsenic at these two sites either differ or are present only in the upstream site subwatershed. Future monitoring may provide better insight on whether exceedances of arsenic are connected to a specific source. There is currently no agricultural use of arsenic within the Deadman Creek @ Hwy 59 site subwatershed. Further

information on arsenic in the Coalition region is provided below under *Constituent Specific Analyses/Special Studies*.

Exceedances of the *E. coli* WQTL occurred during the first four normal monitoring events of the irrigation season (Table 38). *E. coli* was also detected at exceedance levels throughout much of the 2007 irrigation and storm seasons, but there were no exceedances in 2006. Possible sources of *E. coli* in the creek include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids and liquid dairy waste, and a large array of wildlife. As mentioned previously, dairies are not abundant in the vicinity of the Deadman Creek sampling sites, but there are some scattered parcels of land within the site subwatershed that contain dairies and irrigated pasture. It is unknown if agriculture in the area applies manure, biosolids or liquid dairy waste as fertilizer on crops. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*.

Exceedances of the DO WQTL occurred during the last four monitoring months at this site (Table 38). DO exceedances are common in the Coalition region, particularly during the warmer summer months. DO concentrations below the WQTL in the Deadman Creek @ Hwy 59 site have occurred intermittently across irrigation events since 2006. The WQTL for DO has not been exceeded during any storm monitoring events. A discussion of parameters that may affect DO in surface waters is provided at the end of this section, under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the Deadman Creek @ Hwy 59 subwatershed Management Plan.

### Dry Creek @ Rd 18

**Table 39. Dry Creek @ Rd 18 normal monitoring and Dry Creek @ Rd 22 Management Plan Monitoring sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	pH	<i>Hyalella azteca</i> , Survival: % of Control	Copper*, µg/L	Lead*, µg/L
Dry Creek @ Rd 22	4/29/2008	MPM		8.8		5.2 (3.0)	
Dry Creek @ Rd 18	4/29/2008	NM				6.8 (3.0)	
Dry Creek @ Rd 18 (FD)	4/29/2008	NM				6.9 (4.1)	
Dry Creek @ Rd 22	5/27/2008	MPM				5.7 (4.1)	
Dry Creek @ Rd 18	5/27/2008	NM				5 (3.5)	
Dry Creek @ Rd 22	6/24/2008	MPM				6.5 (2.6)

Dry Creek @ Rd 18	8/26/2008	FD				4.8 (1.5)	0.3 (0.21)
Dry Creek @ Rd 18	8/28/2008	Sediment	5.62		89		

Site Name	Sample Date	Sample Type	DO, mg/L	pH	<i>Hyaella azteca</i> , Survival: % of Control	Copper*, µg/L	Lead*, µg/L
Dry Creek @ Rd 22	9/30/2008	MPM	3.97			36 (8.2)	

FD – Field Duplicate sample; NM – normal monitoring; MPM – Management Plan monitoring; Sediment – Sediment Monitoring  
 \*WQTL based on hardness and shown in parenthesis

Sediment toxicity to *Hyaella azteca* occurred in samples collected on August 28, 2008 (Table 39). Survival in the sample water was 89% compared to the control and although statistically significant, survival above 80% is not considered ecologically significant. Sediment resampling occurred on October 2, 2008 and results from this site indicated that the toxicity was not persistent. Sediment samples were not analyzed for pesticides or metals, however water samples collected two days prior to sediment sampling resulted in exceedances of the copper and lead WQTLs. Metals detected in the sample water may be an indication of metals concentrated in the sediment, and if so, copper and lead could have contributed to the *Hyaella* toxicity. Other possible sources of sediment toxicity are constituents or parameters not tested by the Coalition. PUR data show 346 applications of pesticides relevant to this toxicity. Active ingredients applied include pyrethrins, cyfluthrin, permethrin, bifenthrin, esfenvalerate, lambda-cyhalothrin, hexythiazox, glyphosate, glyphosate, isopropylamine salt, oxyfluorfen, paraquat dichloride, thiamethoxam, malathion, abamectin, chlorpyrifos, azoxystrobin, piperonyl butoxide, propargite, glyphosate, potassium salt, tau-fluvalinate, buprofezin, spiromesifen, cyprodinil, pyraclostrobin and fludioxonil.

Copper was detected at concentrations exceeding the WQTL in all samples analyzed for this constituent during the irrigation season (Table 39). Copper is under the Dry Creek Site Subwatershed Management Plan and upstream sampling occurred at Dry Creek @ Rd 22 during each irrigation season. An additional upstream site, Dry Creek @ Rd 28 ½, was sampled in July and September to further source copper exceedances. In September both Dry Creek @ Rd 18 and Rd 28 ½ were dry and the exceedance at Rd 22 was 36 µg/L. Copper concentrations at Dry Creek @ Rd 18 averaged 26.5 µg/L during the 2007/2008 storm season compared to the average 5.36 µg/L copper concentrations detected over the irrigation months of 2008. The highest load of copper detected at Dry Creek @ Rd 18 in 2008 occurred in July even though concentrations of copper were greater during the storm season. Analysis of PUR data from 2004-2007 indicate that applications of copper tend to peak during the month of July (ESJWQC Management Plan). PUR data for each of the copper exceedances detected during the 2008 irrigation season are provided in Appendix IV and will be evaluated further in the Coalition Management Plan update. Applications of various copper containing products occurred in January, February, March, April, June, and August with a majority of the applications occurring on grape and almond crops.

Lead was detected above the WQTL during the August 23, 2008 sampling event in both the grab and the duplicate sample (Table 39). Detections of lead in the creek occurred during every irrigation season event and ranged between 0.15 – 0.36 µg/L. Most of the detections fell below the laboratory reporting limit and therefore are considered estimated values. Lead in surface waters is not a result of current agricultural applications and there are a number of possible

sources of lead in the Coalition region. These sources are described in detail below, under *Constituent Specific Analyses/Special Studies*. Lead is currently being addressed for Dry Creek @ Rd 18 in the ESJWQC Management Plan.

Exceedances of the DO WQTL occurred at Dry Creek @ Rd 18 on August 26 and 28, 2008 and at the upstream MPM site on September 30, 2008 (Table 39). DO exceedances are common in the Coalition region, particularly during the warmer summer months. Dry Creek @ Rd 18 has had only one previous exceedance, which occurred on September 12, 2006. DO will be addressed in the Coalition Management Plan update. One exceedance of the pH upper WQTL was also detected at the Dry Creek @ Rd 22 (MPM) site on April 29, 2008. There have been two prior exceedances of pH at the Dry Creek @ Rd 18 site. These two exceedances occurred on August 16, 2005 (6.48) and August 28, 2007 (8.53) and are currently addressed in the Coalition Management Plan for this site subwatershed. A discussion of parameters that may affect DO and pH in surface waters is provided below under *Constituent Specific Analyses/Special Studies*.

### Dry Creek @ Wellsford Rd

**Table 40. Dry Creek @ Wellsford Rd sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Chlorpyrifos, µg/L
Dry Creek @ Wellsford Rd	4/22/2008	NM			>2400	
Dry Creek @ Wellsford Rd	5/20/2008	NM	5.67		330	
Dry Creek @ Wellsford Rd	6/17/2008	NM	6.31		>2400	
Dry Creek @ Waterford Rd	7/22/2008	MPM	6.08			0.02

Dry Creek @ Wellsford Rd	9/23/2008	NM			290	
Dry Creek @ Wellsford Rd	10/2/2008	Sediment RS	5.83			

NM – normal monitoring; MPM – Management Plan monitoring; Sediment – Sediment monitoring; RS – Resample

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (73 % survival as compared to the control, Table 40). Sediment samples were not analyzed for pesticides or metals. Water samples were collected at the site one week prior to sediment sampling on August 19, 2008. There were no exceedances of pesticides or metals in the water column during this event. The only organic detected in the water column during the August 19 sampling event was dimethoate at a concentration of 0.25 µg/L (below the WQTL). Total copper in the water column was detected at a concentration of 5.6 µg/L. The upstream sampling site, Dry Creek @ Waterford Rd, experienced an exceedance of chlorpyrifos (0.023 µg/L) during the August 19, 2008 event however chlorpyrifos was not detected in samples from

the downstream Wellsford Rd site during the same event. Without sediment chemistry analysis it is unknown how much copper is bound to sediment collected from this site and therefore contributing to the *Hyalella* toxicity. PUR data do not show any applications of products containing copper in the site subwatershed between January and September of 2008. Other pesticides that were applied in the Dry Creek @ Wellsford Rd site subwatershed that may be relevant to this toxicity include lambda-cyhalothrin, permethrin, esfenvalerate, cyfluthrin, cypermethrin, bifenthrin, abamectin, glyphosate, oxyfluorfen, paraquat dichloride, propargite, chlorpyrifos, etoxazole, trifloxystrobin and pyriproxyfen.

Chlorpyrifos is currently included in the Dry Creek @ Wellsford Rd Site Subwatershed Management Plan as a priority A constituent. Upstream monitoring for chlorpyrifos occurred at Dry Creek @ Waterford in July, August and September. Chlorpyrifos exceedances occurred twice at the upstream Management Plan site, Dry Creek @ Waterford Rd and once at the normal monitoring site, Dry Creek @ Wellsford Rd (Table 40). Samples collected at the upstream site in September were also tested for toxicity to *Ceriodaphnia dubia* resulting in no toxicity. Chlorpyrifos exceedances have occurred at the normal monitoring site five times previous to the 2008 irrigation season. All of the chlorpyrifos exceedances at this site have occurred during irrigation season monitoring in the months between July and September. PUR data from 2004-2008 indicate that applications of chlorpyrifos occurred predominantly during the months of May, June, July and August. In sections of land upstream of the normal monitoring site, reported pesticide use in 2008 was the greatest during July when 36 chlorpyrifos applications occurred on 1294 acres of almonds, walnuts and corn. Of the 36 July applications that occurred, 23 were applied in the upstream site subwatershed of the Management Plan monitoring site. An additional nine applications occurred in the Management Plan site subwatershed, prior to the August 12 exceedance. Further analysis and action to address chlorpyrifos exceedances at this site will occur through the Site Subwatershed Management Plan.

Exceedances of the *E. coli* WQTL occurred in all samples during the irrigation season (Table 40). Possible sources of *E. coli* in the creek include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids and liquid dairy waste, and a large array of wildlife. Dairies and pasture are relatively abundant in the Dry Creek @ Wellsford Rd site subwatershed. Runoff from these lands may be contributing *E. coli*. It is unknown if agriculture in the area applies manure or biosolids as fertilizer on crops. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*.

Exceedances of the DO WQTL occurred at both the normal monitoring and Management Plan monitoring sites during May, June, July, August and October (Table 40). DO exceedances are common in the Coalition region, particularly during the warmer summer months and DO is currently included in the Site Subwatershed Management Plan for Dry Creek. Exceedances of the DO WQTL occurred at Dry Creek @ Wellsford during the irrigation season since 2005, most likely due to low flows and high temperatures. Only one exceedance has occurred during the storm season (February 11, 2007). A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. Exceedances from the 2008 irrigation season will further be addressed in the Coalition Management Plan update.

## Duck Slough @ Gurr Rd

**Table 41. Duck Slough sample sites - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	SC, $\mu$ S/cm	<i>Hyalella azteca</i> , Survival: % of Control	Carbofuran, $\mu$ g/L
Duck Slough @ Gurr Rd	4/29/2008	NM				0.052
Duck Slough @ Hwy 59	6/24/2008	MPM	4.22	841		
Duck Slough @ Hwy 59	7/29/2008	MPM	4.83			
Duck Slough @ Gurr Rd	8/28/2008	Sediment			63	
Duck Slough @ Hwy 59	9/30/2008	MPM	3.33			
Duck Slough @ Gurr Rd	10/2/2008	Sediment RS			93	

NM – normal monitoring; MPM – Management Plan monitoring; RS – Resample; Sediment – Sediment Monitoring

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (Table 41). Survival in the sample water was 63% and 93% in the resamples collected on October 2, 2008. Sediment samples were not analyzed for pesticides or metals. Water samples collected at the site two days prior to sediment sampling, on August 26, 2008, did not contain concentrations of any pesticides or metals that would be exceedances of their respective WQTLs. PUR data include 361 applications that may be relevant to this toxicity. Active ingredients applied include lambda-cyhalothrin, cyfluthrin, (s)-cypermethrin, esfenvalerate, permethrin, bifenthrin, indoxacarb, abamectin, clofentezine, glyphosate, chlorpyrifos, spiromesifen, paraquat dichloride, propargite, etoxazole, malathion, pyraclostrobin and thiamethoxam. *Hyalella* toxicity is a priority D constituent in the Management Plan for Duck Slough @ Gurr Rd.

Carbofuran was detected above exceedance concentrations for the first time during the April 29, 2008 monitoring event (0.052  $\mu$ g/L, Table 41). Carbofuran is a prohibited discharge pesticide and any detection of the constituent in a water sample is considered an exceedance. It is a restricted use pesticide and has minimal use in California on crops such as artichokes, grapes and ornamentals. A systemic, broad spectrum N-methyl carbamate insecticide and nematocide, carbofuran is highly toxic to *Ceriodaphnia dubia*. There was no toxicity detected in samples from this event. PUR data indicates that applications of carbofuran occurred during the month of March. Between March 8 and March 24, 2008 approximately 54 gallons of carbofuran were applied on 792 acres of irrigated alfalfa. If additional exceedances of carbofuran occur at this site, then actions will be taken to address the exceedances through the Coalition Management Plan.

Exceedances of the DO WQTL occurred at the upstream MPM site, Duck Slough @ Hwy 59, during all events (Table 41). Low DO is common across water bodies within the Coalition region, particularly during the warmer summer months. There have been three previous exceedances of the DO WQTL at the (downstream) Duck Slough @ Gurr Rd site. These exceedances occurred on July 12, 2006, September 13, 2006 and June 19, 2007. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific*

*Analyses/Special Studies.* DO is a priority E constituent in the management plan for Duck Slough @ Gurr Rd.

One exceedance of the SC WQTL occurred at the upstream MPM site on June 24, 2008 (Table 41). Potential sources of SC include minerals leached from soils by upstream surface water and ground water, or drain water from irrigated agriculture. The 2008 irrigation season was the first season of sampling for the MPM site; therefore there have not been any previous exceedances at this site. There has been only one exceedance of the SC WQTL in the past at the normal monitoring site, Duck Slough @ Gurr Rd. This exceedance occurred during sampling on September 29, 2004 and SC was measured at 701  $\mu\text{S}/\text{cm}$  (WQTL = 700  $\mu\text{S}/\text{cm}$ ). Further discussion on parameters that may affect SC in surface waters is provided below under *Constituent Specific Analyses/Special Studies.*

### Duck Slough @ Hwy 99

**Table 42. Duck Slough @ Hwy 99 Rd and Duck Slough @ Whealan Rd sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, $\mu\text{g}/\text{L}$	Lead*, $\mu\text{g}/\text{L}$	Chlorpyrifos, $\mu\text{g}/\text{L}$
Duck Slough @ Hwy 99	4/29/2008	NM	86		280			
Duck Slough @ Hwy 99	5/7/2008	RS	5					
Duck Slough @ Whealan Rd	6/24/2008	MPM				73 (5.0)

Duck Slough @ Hwy 99	10/2/2008	Sediment RS		90				

NM – normal monitoring; MPM – Management Plan monitoring; Sediment – Sediment Monitoring; RS - Resample  
\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Selenastrum capricornutum* occurred in samples collected during the first irrigation monitoring event on April 29, 2008 (Table 42). Resampling occurred at this site on May 7, 2008 and sample tested toxic again, indicating that the source of toxicity was persistent at the site. Toxicity in the resample was greater than that experienced during the original sampling event (5% compared to the control). A TIE was not conducted on the resample due to a laboratory miscommunication. Prior to this event, *Selenastrum* toxicity occurred in a sample collected on July 12, 2005. There were no exceedances of constituents known to be toxic to green algae in the sample collected on April 29, 2008. Chemistry results

indicate the presence of metals at concentrations below WQTL for arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc. It may be that the toxicity was a result of constituents or parameters not tested by the Coalition. PUR data include applications in April 2008 of a variety of active ingredients that are known to be toxic to *Selenastrum*. These include copper, glyphosate, 2,4-d, carfentrazone-ethyl, simazine, paraquat dichloride, glufosinate-ammonium, oryzalin, oxyfluorfen, amino ethoxy vinyl glycine, sethoxydim, imidacloprid and s-metolachlor. There were 29 reported pesticide applications between the original sampling event and the date of resampling. Relevant pesticides applied between these two dates included paraquat dichloride and glyphosate. It is uncertain whether either of these applications contributed to the toxicity experienced in any of the samples collected on either date. All PUR data and maps of applications relevant to exceedances are provided in Appendix IV. *Selenastrum* toxicity has not yet been addressed in a Management Plan for the Duck Slough site subwatershed. As a result of the toxicity experienced during the 2008 irrigation season these exceedances will be addressed in the ESJWQC Management Plan update.

Sediment toxicity to *Hyalella azteca* occurred for the first time at this site in samples collected on August 28, 2008 (Table 42). Survival in the sample water was 86% compared to the control which is greater than the 80% threshold indicating that this toxicity is not ecologically significant. Resampling occurred at the site on October 2, 2008 resulting in 90% survival compared to the control. Sediment samples were not analyzed for pesticides or metals. Water samples collected at the site two days prior to sediment sampling, on August 26, 2008, contained exceedance levels of only lead (0.72 µg/L). There were no detections of any pesticides in these samples, however low concentrations (below the WQTL) of most of the tested metals were detected in these water samples. Low level concentrations of metals are common in Coalition water bodies. These are considered background levels and are not known to cause toxicity. The concentration of metals in the sediment, however, may differ (may be more concentrated) from that detected in the water column, and as a result it is unknown if metals are a source of sediment toxicity in the slough. Water samples collected at the upstream site, Duck Slough @ Whealan Rd, contained exceedance level concentrations of copper in both the August and September water samples. Without knowing the concentration of copper in the sediment it is difficult to know if copper was in part responsible for the sediment toxicity at the downstream site. There were 187 applications of pesticides that may be relevant to the sediment toxicity. Pesticides applied include cyfluthrin, esfenvalerate, permethrin, lambda-cyhalothrin, (s)-cypermethrin, glyphosate, clofentezine, paraquat, dichloride, chlorpyrifos, bifenthrin, indoxacarb, abamectin, malathion, etoxazole, pyraclostrobin, propargite and spiromesifen. If additional toxicity occurs at the site then *Hyalella* will be addressed in the Duck Slough @ Hwy 99 Site Subwatershed Management Plan.

Chlorpyrifos is currently addressed in the Site Subwatershed Management Plan and upstream monitoring occurred during May and July, 2008. One exceedance of the chlorpyrifos WQTL occurred at Duck Slough @ Hwy 99 in a sample collected on September 30, 2008, however no chlorpyrifos was detected in the sample from the upstream monitoring location at Whealan Rd (Table 42). Chlorpyrifos is known to cause *Ceriodaphnia dubia* toxicity, but no toxicity was experienced during this event. Chlorpyrifos exceedances have occurred at the normal monitoring site during three events previous to the 2008 irrigation season. All of the chlorpyrifos exceedances at this site have occurred during irrigation season. PUR data indicate

elevated chlorpyrifos use during the months of July and August, however there is no reported use during the month of September. In July, 256 pounds of chlorpyrifos (active ingredient) were applied on 523 acres of alfalfa, corn and walnuts. Use during the month of August was less, amounting to 146 pounds of product applied on 427 acres of agriculture. Chlorpyrifos is a priority A constituent in the Duck Slough @ Hwy 99 site subwatershed. Further analyses and actions to address chlorpyrifos exceedances at this site will occur through the Site Subwatershed Management Plan.

Copper is also included in the Duck Slough @ Hwy 99 Site Subwatershed and upstream monitoring was conducted in April, June, July, August and September, 2008. Three exceedances occurred at the MPM site, Duck Slough @ Whealan Rd, on June 24, 2008 (73 µg/L), August 26, 2008 (3.4 µg/L) and September 30, 2008 (3.7 µg/L) (Table 41). The NM site, Duck Slough @ Hwy 99, experienced one exceedance in samples collected on July 29, 2008 (2.7 µg/L). PUR data indicate four applications of copper pesticides within three months prior to this exceedance. These applications totaled 357 pounds of product applied on 121 acres of walnuts and processing tomatoes. Prior to the June 24 copper exceedance at the upstream Duck Slough @ Whealan Rd site, there were six applications of copper hydroxide. These applications totaled 417 lbs of fungicide applied across 136 acres of walnuts and processing tomatoes. Exceedances from the 2008 irrigation season will be addressed in the ESJWQC Management Plan update.

Lead was detected above the WQTL during the July 29, 2008 and August 26, 2008 sampling events (Table 42). Lead in surface waters is not a result of current agricultural practices; and there are a number of possible alternative sources of lead in the Coalition region. These sources are described in detail below, under *Constituent Specific Analyses/Special Studies*. Lead is currently a priority E constituent in the Site Subwatershed Management Plan for Duck Slough @ Hwy 99. The exceedances of the lead WQTL that occurred during the 2008 irrigation season will be addressed further in the ESJWQC Management Plan update.

One exceedances of the *E. coli* WQTL occurred during the first irrigation monitoring event at the Duck Slough @ Gurr Rd site (280 MPN/100 mL, Table 42). Possible sources of *E. coli* in the creek include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. Dairies and pasture are relatively abundant in the Duck Slough @ Hwy 99 site subwatershed. Runoff from these lands may be contributing the level of *E. coli* at the sample site. It is unknown if agriculture in the area applies manure, biosolids or liquid dairy waste as fertilizer on crops. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*.

## Hatch Drain @ Tuolumne Rd

FD – field duplicate; NM – normal monitoring; Sediment – Sediment Monitoring; RS - Resample

Water column toxicity to *Selenastrum capricornutum* occurred in samples collected during four out of the six irrigation monitoring events (Table 43). This is the first irrigation season that samples from Hatch Drain have tested toxic to *Selenastrum*. Resampling occurred after each of the toxicity events and all but one resample was toxic. TIEs were conducted on three of the samples (April 29, July 22 and August 19). The first TIE, conducted on samples collected during the April 29, 2008 event, indicated that the sample toxicity was due to non-polar organics and cationic compounds. Samples collected on July 22 and August 19 resulted in no baseline toxicity and therefore the TIEs were inconclusive for those samples. Exceedance level concentrations of arsenic and/or lead occurred in all of the normal monitoring samples that experienced toxicity. Arsenic and lead are not considered to be acutely toxic to *Selenastrum* especially at the low concentrations detected during these events. Besides DDT, there were no exceedance level concentrations of any other pesticides during the irrigation season. There were low concentrations (between 0.44 and 0.75  $\mu$ g/L) of cyanazine and simazine during two of the sampling events (May 27 and June 24, 2008), and one detection of chlorpyrifos (0.0067  $\mu$ g/L) during the July 22, 2008 event. Toxicity to *Selenastrum* was also detected in the samples collected during both 2008 storm monitoring events. PUR data indicates applications of pesticides that are known to be toxic to green algae, including copper hydroxide, glyphosate, s-metolachlor, paraquat dichloride, and carfentrazone-ethyl. It is uncertain if any of these applications contributed to the toxicity at this site. *Selenastrum* toxicity has not yet been addressed in a Management Plan for Hatch Drain. Toxicity experienced during the 2008 storm and irrigation seasons will be addressed in the ESJWQC Management Plan update.

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 resulting in complete mortality (Table 43). Resamples collected on October 2, experienced 5% survival relative to the control, indicating that the sediment toxicity was persistent at this site. Sediment toxicity has previously occurred in samples collected from this site and is currently included in the Hatch Drain Site Subwatershed Management Plan. Sediment samples were not analyzed for pesticides or metals. Water samples collected at this site have consistently resulted in detections or exceedances of lead and arsenic. These detections may be an indication of the existence of metals in the sediment. There may also be constituents in the sediment that are not detected in the sample water. PUR data include 17 pesticide applications that may be relevant to this toxicity. Active ingredients of the applied pesticides include lambda-cyhalothrin, esfenvalerate, bifenthrin, glyphosate, spiromesifen and chlorpyrifos. The toxicity experienced during the 2008 monitoring events will be addressed in the ESJWQC Management Plan update.

DDT was detected at an exceedance concentration for the first time at the Hatch Drain @ Tuolumne Rd sample site during the April 22, 2008 monitoring event (Table 43). Laboratory analyses of water samples detected DDT in the field duplicate sample but not in the grab sample. DDT has an extremely high  $K_{oc}$ . It is possible that the field duplicate could have been contaminated with sediment mobilized from the drain during collection of the grab sample. DDT is an organochlorine pesticide that was used abundantly in the past, but is not currently registered for agricultural use. Due to the long half-life, DDT and its breakdown products, DDD and DDE, are still found in Coalition water bodies. Since DDT is no longer used by agriculture, current agricultural pesticide applications are not the source of these exceedances. If additional exceedances of DDT occur at this site, then the exceedances will be addressed through actions stated in the ESJWQC Management Plan.

Exceedances of *E. coli* occurred during most of the irrigation monitoring events (April, May, June, July and August, Table 43). Possible sources of *E. coli* include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. The Hatch Drain @ Tuolumne Rd site subwatershed is relatively small, encompassing only a few sections of land. Within the small subwatershed, approximately half of the land-use is for pasture and dairy. It may be that irrigation runoff from these lands is contributing to the *E. coli* in the drain. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* is a priority E constituent for this site. Exceedances experienced during the 2008 irrigation season will be included in the ESJWQC Management Plan update.

Exceedances of the nitrate WQTL occurred in all samples analyzed for this constituent during the irrigation season (Table 43). Potential sources of nitrate in surface waters include runoff of fertilizers or organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from dairies. These sources can move to surface waters through surface water runoff or shallow subsurface flows. There are no wastewater treatment plants upstream of the Hatch Drain sample site. As mentioned above, approximately half of the site subwatershed is made up of pasture land or dairies and runoff containing animal waste upstream of the Hatch Drain site could be the source of nitrate in the drain. Additional

information regarding possible sources of nitrate in the Coalition region is provided under *Constituent Specific Analyses/Special Studies* below. It is not certain which particular source is responsible for these exceedances. Nitrate is a priority E constituent at this site, and further analysis and a description of actions that will be taken to address the exceedances will be provided in the ESJWQC Management Plan update.

Arsenic was detected at exceedance concentrations during all of the six irrigation monitoring events (Table 43). Past monitoring results from this site include arsenic exceedances in 12 of the 14 collected water samples. There is currently no agricultural use of arsenic within the Hatch Drain @ Tuolumne Rd site subwatershed, however detections may be a legacy of historical use. Further information on arsenic in the Coalition region is provided below under *Constituent Specific Analyses/Special Studies*. Arsenic is a priority E constituent at this site.

Exceedances of the TDS and SC WQTLs were also detected during all of the irrigation sampling (Table 43). TDS describes all solids (usually mineral salts) that are dissolved in water and are frequently associated with exceedances of SC. Potential sources of TDS and SC are minerals leached from soils by upstream surface water and ground water, or drain water from irrigated agriculture. Possible sources of these exceedances in the drain are described further below under *Constituent Specific Analyses/Special Studies*. Exceedance level concentrations of SC and TDS have occurred at the Hatch Drain site during most monitoring events. As a result, these constituents were included as priority E constituents in the management plan for this site.

Exceedances of the DO WQTL occurred during every sampling event during the irrigation season at the Hatch Drain site (Table 43). Similar DO concentrations were measured during all storm season events as well as the previous irrigation season events. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the management plan for Hatch Drain @ Tuolumne Rd.

## Highline Canal @ Hwy 99

Highline Canal @ Hwy 99	10/2/2008	RS			92		

NM – normal monitoring; Sediment – Sediment Monitoring; MPM – Management Plan monitoring; RS - Resample

Water column toxicity to *Selenastrum capricornutum* occurred in samples collected during the first and second irrigation monitoring events on April 22 and May 20, 2008 (63% and 76% survival compared to the control, Table 44). Resampling occurred after each of the toxicity exceedances and there was no toxicity in either resample indicating that the toxicity at the site was not persistent. There were no exceedance level concentrations of any metals or pesticides during either of the toxicity events. Metals detected below the WQTL in the sample water include arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc; all detections were at low concentrations not known to have an effect on algae. There were no detections of any pesticides during the April 22, 2008 sampling event. Samples collected during the May 20, 2008 event resulted in a detection of cyanazine measured below the laboratory reporting limit at 0.26 µg/L. Toxicity to *Selenastrum* was also detected during a storm monitoring event in both 2007 and 2008. However, prior to this irrigation season, there has been no *Selenastrum* toxicity in irrigation samples over three years of sampling. The source of toxicity at the site may be due to a combination of constituents in the canal. The upstream site, Highline Canal @ Lombardy Rd, has had multiple instances of toxicity to *Selenastrum* including May 20, 2008. It is possible that the source of toxicity is the same for both sites during the May sampling event. PUR data indicate 204 applications that may be relevant to the *Selenastrum* toxicity that occurred on April 22. Pesticides applied include copper, glyphosate, paraquat dichloride, methyl bromide, 2,4-d, dimethylamine salt, glufosinate-ammonium, oryzalin, carfentrazone-ethyl, simazine, pendimethalin, 2,4-d, diethanolamine salt, and s-metolachlor. Prior to the May 20 toxicity event, there were 345 relevant applications of pesticides including copper oxide, copper hydroxide, copper sulfate (basic), simazine, pendimethalin, paraquat dichloride, oxyfluorfen, glyphosate, isopropylamine salt, 2,4-d, dimethylamine salt, norflurazon, glyphosate, glyphosate, potassium salt, methyl bromide, glufosinate-ammonium, oryzalin, carfentrazone-ethyl, 2,4-d, diethanolamine salt, s-metolachlor, imidacloprid and sethoxydim. It has not been determined if any of these products may be a source of toxicity. Toxicity experienced during the 2008 storm and irrigation seasons will be included in the updated Coalition Management Plan.

Sediment toxicity to *Hyalella azteca* occurred in the sample collected on August 28, 2008 (Table 44). Survival in the sample water was 94% compared to the control and although the survival is significantly different from the control because the survival is greater than 80% it is not considered ecologically relevant. Resamples resulted in 92% survival compared to the control. Sediment samples were not analyzed for pesticides or metals, and there were no exceedances of any pesticide or metals WQTLs in water samples collected one week prior to sediment sampling. PUR data indicate 496 applications of pesticides known to be toxic to *Hyalella*. The active ingredients in the pesticides applied include lambda-cyhalothrin, esfenvalerate,

bifenthrin, permethrin, cyfluthrin, abamectin, glyphosate, glyphosate, isopropylamine salt, chlorpyrifos, oxyfluorfen, paraquat dichloride, spiromesifen, propargite, glyphosate, potassium salt, pyraclostrobin, trifluralin, etoxazole, piperonyl butoxide, chlorophacinone and pyriproxyfen. *Hyalella* toxicity is addressed in the ESJWQC Management Plan for Highline Canal @ Hwy 99 as a priority D constituent.

One chlorpyrifos exceedance occurred at this site in a sample collected on July 22, 2008 (Table 44). Chlorpyrifos is known to cause *Ceriodaphnia dubia* toxicity, but no toxicity was experienced during this event. Exceedances have occurred during both the irrigation and storm seasons of previous years and is currently addressed as a priority A constituent in the Highline Canal @ Hwy 99 Site Subwatershed Management Plan. PUR data indicate elevated chlorpyrifos use during the months of July and August in 2008. In July, 385 lbs of chlorpyrifos was applied on 1073 acres of walnuts, almonds and corn. Further analyses and discussion of chlorpyrifos exceedances will be included in the ESJWQC Management Plan update.

Exceedances of the *E. coli* WQTL occurred during the second irrigation monitoring event at this site (Table 44). Possible sources of *E. coli* in the canal include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. Scattered sections of land within the Highline Canal @ Hwy 99 site subwatershed are used for pasture and dairy, particularly to the northwest of the sample site. It may be that irrigation runoff from these lands is contributing to the *E. coli* in the canal. *E. coli* was also detected at the upstream site, Highline Canal @ Lombardy Rd on May 20, 2008 (Table 45). Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Coalition Management Plan as a priority E constituent.

Exceedances of the pH WQTL occurred at this site in May, June, August and September (Table 44). Prior to this irrigation season, elevated pH occurred at this site intermittently across both the storm and irrigation seasons. A discussion of parameters that may affect pH in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. The Management Plan for Highline Canal @ Hwy 99 addresses pH as a priority E constituent.

## Highline Canal @ Lombardy Rd

Table 45. Highline Canal @ Lombardy Rd sample site - 2008 Irrigation season exceedances.

Site Name	Sample Date	Sample Type	pH	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, µg/L	Lead*, µg/L	Chlorpyrifos, µg/L	Malathion, µg/L	Methyl parathion, µg/L

\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Selenastrum capricornutum* occurred in samples collected for the second irrigation monitoring event on May 20, 2008 (Table 45). Resamples collected one week later were not toxic. There were no exceedance level concentrations of any metals or pesticides during the toxicity event. Metals detected below the WQTL in the sample water include arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc; detections were at concentrations not known to have an effect on algae. During the May 20, 2008 event, the only detection was of cyanazine measured at 0.29 µg/L; below the laboratory reporting limit. Toxicity to *Selenastrum* also occurred on the same date at the downstream location, Highline Canal @ Hwy 99 co-occurring with a detection of cyanazine (0.26 µg/L). The cyanazine concentrations were not sufficient to be the cause of the algae toxicity; however, cyanazine may have contributed to the toxicity in combination with another constituent for which the Coalition does not analyze. Cyanazine is not currently registered for use in the United States. Toxicity to *Selenastrum* has occurred three times prior to this event, on August 17, 2005, March 16, 2006 and February 28, 2007. The source of toxicity at the site may be due to a combination of factors or constituents in the canal. PUR data show 252 applications of pesticides relevant to the *Selenastrum* toxicity including copper, oxyfluorfen, paraquat dichloride, glufosinate-ammonium, oryzalin, 2,4-d, arfentrazone-ethyl, simazine, pendimethalin, s-metolachlor and glyphosate. *Selenastrum* toxicity is a priority D constituent under the Highline Canal @ Hwy Lombardy Site Subwatershed.

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (62% survival relative to the control, Table 45). Resamples collected on October 2 experienced 82% survival relative to the control. Sediment toxicity has occurred during four previous sampling events (as well as one resample toxicity), across irrigation and storm seasons. Sediment

samples were not analyzed for pesticides or metals; however there were multiple exceedances of pesticides and metals in water samples collected one week prior to sediment sampling, including copper, lead, and chlorpyrifos (Table 45). The LC<sub>50</sub> for chlorpyrifos to *Hyalella* is 0.086 µg/L (ECOTOX Ref#14907) and the 0.031 µg/L in the water column a week earlier may have contributed to the 38% mortality of *Hyalella*. There may also be constituents apparent in the sediment not detected in the sample water. PUR data indicate that there were 423 applications of pesticides that are known to be toxic to *Hyalella* and have a tendency to bind to sediment, including esfenvalerate, lambda-cyhalothrin, permethrin, bifenthrin, cyfluthrin, chlorpyrifos, spiromesifen, abamectin, paraquat dichloride, pyraclostrobin and propargite. The toxicity experienced during the 2008 monitoring seasons will be addressed in the ESJWQC Management Plan update.

The chlorpyrifos WQTL was exceeded in the sample collected on August 19, 2008 (0.013 µg/L, Table 45). Both a grab and a field duplicate sample were collected from this site during the August 19, 2008 event and chlorpyrifos was detected only in the field duplicate sample. Chlorpyrifos is an organophosphate pesticide, commonly applied for pest control on alfalfa and orchard crops, among others. Chlorpyrifos is mostly applied as a dormant spray on orchard crops during the winter season, and prior to harvest during the late irrigation season on field crops such as alfalfa. Detections of chlorpyrifos in the canal have occurred previously during both the irrigation and storm seasons. Chlorpyrifos is currently addressed in the Site Subwatershed Management Plan for Highline Canal @ Lombardy Rd. Chlorpyrifos is toxic to *Ceriodaphnia dubia*, however there was no toxicity detected in these samples. PUR data for the Highline Canal @ Lombardy Rd site subwatershed include ten applications of chlorpyrifos during the month of August 2008. Between August 1 and 14, 815 acres of almond, walnuts and corn were treated with products containing chlorpyrifos. In addition there was one 50 gallon application that occurred on July 31, applied to 200 acres of almonds.

Copper was detected above the WQTL in the field duplicate sample collected on August 19, 2008 (3.3 µg/L, Table 45). The associated environmental sample contained 1.2 µg/L which was below the WQTL based on hardness. There have been four exceedances of the copper WQTL prior to this event occurring during the storm and irrigation seasons of 2007 and the storm season of 2008. The highest detections measured at this site occurred during the 2008 storm monitoring, January 24 and February 26, at 28 µg/L and 32 µg/L respectively. The copper load was highest during the January 24, 2008 event (43 mg/s). PUR data indicate one application of copper within three months prior to the exceedance. On May 25, 2008, 20 pounds of chlorpyrifos were applied on five acres of walnuts. Copper is currently addressed in the Highline Canal @ Lombardy Rd Site Subwatershed Management Plan.

Exceedances of the malathion and methyl parathion WQTLs occurred for the first time at this site in samples collected on August 19 (Table 45). These pesticides were only detected in the field duplicate sample. Methyl parathion is an organophosphate pesticide and is used to control insects in a wide range of crops, including walnuts, corn, onion, and wine grapes, among others. It is generally applied as a spray, mainly as an emulsifiable concentrate formulation. However, emulsifiable concentrate formulations were canceled voluntarily by the registrants of the product. This came into effect on 30 April 1997. Currently, methyl parathion is still applied in California; however there was no reported use of the product in the Highline Canal site

subwatershed in 2008. As a result, the source of the exceedance in the canal is unknown. Malathion is a prohibited discharge pesticide and any detection is considered an exceedance. Malathion is an organophosphate insecticide that is predominantly used on alfalfa, field crops, walnuts, and for structural pest control (in California). PUR data for the Highline Canal do not include any applications of malathion in the site subwatershed in 2008. Though malathion is known to be toxic to *Ceriodaphnia dubia* (LC<sub>50</sub> = 3.35 µg/L, ECOTOX Ref# 95923), there was no toxicity in samples collected at the same time. If additional exceedances of malathion or methyl parathion occur in the canal, then these constituents will be addressed in the ESJWQC Management Plan update.

Exceedances of the DDE and DDT WQTL occurred in the field blank samples collected on August 19. There were no detections of either constituent in the grab or field duplicate samples collected from Highline Canal @ Lombardy Rd. Field blank detections do not reflect the water quality in the canal and are only used to assess field contamination. Further information regarding field blank detections can be found in the section *Precision and Accuracy*.

Lead was detected 0.01 µg/L above the WQTL during the August 19, 2008 sampling event (Table 45). This concentration was lower than those of all previous samples during the irrigation season, but was an exceedance due to lower water hardness in the sample. Lead in surface waters is not a result of current agricultural practices, however there are a number of possible alternative sources of lead in the Coalition region. These sources are described in detail below, under *Constituent Specific Analyses/Special Studies*. Lead is a priority E constituent in the management plan for Highline Canal @ Lombardy Rd.

Exceedances of the *E. coli* WQTL occurred during the second irrigation monitoring event at this site (Table 45). A similar level of *E. coli* was also detected at the downstream sample location at Hwy 99 (Table 44). Possible sources of *E. coli* in the canal include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. Scattered sections of land within the Highline Canal site subwatershed are used for pasture and dairy, particularly to the northwest of the sample site. It may be that irrigation runoff from these lands is contributing to the *E. coli* in the canal. The *E. coli* WQTL was not exceeded in samples collected from the upstream site, Highline Canal @ Lombardy Rd, during the same event. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Coalition Management Plan as a priority E constituent.

Exceedances of the pH WQTL occurred at this site above the upper WQTL during the fourth and fifth irrigation monitoring events (Table 45). Prior to this irrigation season, elevated pH was detected once on March 21, 2005 and pH was detected once below the lower WQTL on August 17, 2005. A discussion of parameters that may affect pH in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. The Site Subwatershed Management Plan for Highline Canal @ Lombardy Rd addresses pH as a priority E constituent.

## Hilmar Drain @ Central Ave

Table 46. Hilmar Drain @ Central Ave sample site - 2008 Irrigation season exceedances.

FD – field duplicate; NM – normal monitoring; MPM – Management Plan monitoring; RS – Resample; Sediment – Sediment Monitoring

Water column toxicity to *Selenastrum* is currently under the Site Subwatershed Management Plan for Hilmar Drain @ Central Ave. In July 2008, upstream monitoring was conducted at two locations; Hilmar Drain @ Mitchell Ave (drains area to the west) and Reclamation Drain @ Williams Ave (drains area to the north) to test for *Selenastrum* toxicity, ammonia, nitrate and copper. Two samples were analyzed for diuron during the month of April as part of the Management Plan (April 22 and 29). *Selenastrum* toxicity occurred in samples collected at Hilmar Drain @ Central Ave in April and September and at the upstream Management Plan monitoring site (Hilmar Drain @ Mitchell) in July (Table 46). Samples collected on April 22 contained 0.23 µg/L of diuron which is below the laboratory reporting limit and is therefore an estimated concentration. Copper was also detected in the sample at a concentration (4.3 µg/L) below the WQTL. PUR data include applications of pesticides that could have contributed to the April toxicity, including copper, carfentrazone-ethyl and MCPA. During the April 29, 2008 resample event, diuron samples were also collected as part of the EJSWQC Management Plan. There was a detection of diuron on April 29 coinciding with the resample toxicity to *Selenastrum* (diuron = 3.43 µg/L, *Selenastrum* = 59% growth as compared to the control). The EC<sub>50</sub> of diuron to *Selenastrum* is 2.4 µg/L (ECOTOX website), indicating that the diuron was present at toxic levels. PUR data include one application of diuron in 2008 prior to the April 29 toxicity. On February 7, 16.1 gallons of diuron were applied on 43 acres of alfalfa. On July 22, samples were tested for *Selenastrum* toxicity at Hilmar Drain @ Central Ave, Hilmar Drain @ Mitchell Ave and Reclamation Drain @ Williams Ave. Only samples from Mitchell Ave were

toxic to *Selenastrum* (70% growth as compared to the control). Samples were also tested for copper with 5.5 µg/L, 5.9 µg/L and 10 µg/L detected for Hilmar Drain @ Central Ave, Hilmar Drain @ Mitchell Ave and Reclamation Drain @ Williams Ave, respectively. None of the copper concentrations were above the WQTL. The last copper application reported occurred on March 13 on 15 acres of almonds. PUR data from the Hilmar Drain @ Mitchell Rd site includes 59 applications of pesticides that may have contributed to the toxicity. Pesticides applied include glyphosate, oxyfluorfen, carfentrazone-ethyl, glyphosate, 2,4-d, nicosulfuron, rimsulfuron, halosulfuron-methyl, dicamba, 3,6-dichloro-o-anisic acid, paraquat dichloride and sethoxydim. On September 23 both the grab and field duplicate samples were toxic to *Selenastrum* (73% and 83% growth as compared to the control). The resample collected on September was also toxic (75% growth as compared to the control). During the September toxicity events, there were no metal or pesticide exceedances (Table 46). Metals detected at concentrations below the WQTL include arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc. All of these metals were detected at low concentrations not known to have an effect on algae. PUR data include one application each of glyphosate and 3,6-dichloro-o-anisic acid. *Selenastrum* toxicity has been addressed in the Site Subwatershed Management Plan for Hilmar Drain.

Sediment toxicity to *Hyalella* occurred in samples collected on August 28, 2008 (Table 46), resulting in complete mortality. Resampling occurred at the site on October 2, 2008, and again resulted in complete mortality of *Hyalella*. Sediment toxicity occurred during two previous sampling events, during the 2008 storm season (March 4, 2008) and the 2005 irrigation season (September 21, 2005). Sediment samples are not analyzed for pesticides or metals; however there was one exceedance of DDE in water samples collected one week prior to sediment sampling (0.0056 µg/L). DDE is a breakdown product of the organochlorine, DDT and has a high tendency to bind to sediment. As a result, DDE in the water column is an indication that DDE may be concentrated in the drain sediment. There were also metals in the August water samples at concentrations similar to those detected in other events. Metals also have a tendency to bind to organic matter and these detections in the water column are an indication of the existence of metals in the drain sediment. Pesticides applied in the site subwatershed that may have contributed to this sediment toxicity include lambda-cyhalothrin, esfenvalerate, bifenthrin, chlorpyrifos, spiromesifen, paraquat dichloride, oxyfluorfen, propargite and glyphosate. *Hyalella* toxicity has not yet been addressed in a Management Plan for the Hilmar Drain site. The toxicity experienced during the 2008 monitoring seasons will be addressed in the ESJWQC Management Plan update.

Detections of diuron in the drain have occurred in the past in April and June of 2007. As part of the ESJWQC Management Plan, additional monitoring was conducted at Hilmar Drain @ Central on April 29 and June 3 for diuron. The only exceedance of diuron occurred during the April 29, 2008 Management Plan sampling event (Table 46). Diuron is a broad spectrum, carbamate herbicide, commonly applied for weed control on alfalfa and walnuts, among others crops. Diuron is also used for weed control on state highway rights of way (<http://pesticideinfo.org/>). Applications typically occur as a preemergent in the spring. As mentioned above, PUR data indicate that the most recent application of diuron prior to the April 29, 2008 exceedance occurred on February 7, 2008. Sixteen gallons of active ingredient were applied across 43 acres of alfalfa within the Hilmar Drain site subwatershed. Diuron is included in the Site Subwatershed Management Plan for Hilmar Drain as a priority C constituent. Diuron is highly

toxic to *Selenastrum*, and toxicity was detected in the samples from the April 29, 2008 event, as described above.

One exceedance of the DDE WQTL occurred in Hilmar Drain during the August 19, 2008 sampling event (Table 46). The WQTL for DDE is below the laboratory reporting limit; therefore any detection of the pesticide in sample water is considered an exceedance. Due to its long half-life, DDT and its breakdown products, DDD and DDE, are still found in Coalition water bodies. DDT is not currently applied by agriculture; therefore PUR data are not available for this detection. If DDE is detected in the Hilmar Drain again, then the exceedances will be addressed in the ESJWQC Management Plan.

As part of the Site Subwatershed Management Plan, upstream monitoring for nitrate occurred at the Hilmar Drain @ Mitchell Rd and Reclamation Drain @ Williams Ave on July 22, 2008. Nitrate was detected above exceedance levels in samples collected from Hilmar Drain @ Central Ave in May, July, and September (Table 46). An exceedance of the nitrate WQTL occurred at the upstream Management Plan site, Hilmar Drain @ Mitchell Ave, but not at the Reclamation Drain @ Williams Ave location. Nitrate exceedances are common in the Hilmar Drain during summer irrigation months, and were experienced during most irrigation monitoring events in 2006 and 2007. Potential sources of nitrates in surface waters include runoff of fertilizers or organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from dairies. These sources can move to surface waters through surface water runoff or shallow subsurface flows. Almost half of the Hilmar Drain site subwatershed is made up of pasture land or dairies and runoff containing animal waste upstream of the sample site could be the source of nitrate in the drain. Upstream sampling may aid the Coalition in determining the source of the nitrate exceedances and focusing outreach to those growers. Additional information on nitrate and possible sources is described under *Constituent Specific Analyses/Special Studies* below. It is not certain which source is responsible for these exceedances. Hilmar Drain nitrate exceedances will be discussed further in the ESJWQC Management Plan update.

Exceedances of the *E. coli* WQTL occurred during three of the irrigation monitoring events at this site on May 20, June 17 and July 22, 2008 (Table 46). Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. As mentioned above, a large portion of farmland in the upstream subwatershed is designated for dairies or pasture. It may be that irrigation runoff from these lands is contributing to the *E. coli* in the drain. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Site Subwatershed Management Plan for Hilmar Drain.

Exceedances of the TDS and SC WQTLs occurred at least once from April to September (Table 46). TDS was not measured at the upstream Management Plan site, however SC was measured in the field above the WQTL during every visit. Measurements of SC and concentrations of TDS at this site have been consistently elevated since monitoring was initiated. Sources of SC in Coalition water bodies are further discussed under *Constituent Specific Analyses/Special Studies*, below. These constituents are also addressed in the Site Subwatershed Management Plan for Hilmar Drain.

Exceedances of the DO WQTL occurred on April 29 and August 28 at Hilmar Drain @ Central Ave (Table 46). DO exceedances also occurred at Hilmar Drain @ Mitchell Ave on July 22 and 29 (Table 46). DO exceedances have occurred in the drain four times prior to the 2008 irrigation monitoring season. Three of those exceedances occurred during the 2005 and 2006 irrigation seasons, and the fourth exceedance occurred during the storm season of 2008. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is currently addressed in the Site Subwatershed Management Plan for Hilmar Drain @ Central Ave.

### Livingston Drain @ Robin Ave

**Table 47. Livingston Drain @ Robin Ave sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	pH	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, µg/L	Nitrate, µg/L	Chlorpyrifos, µg/L

\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Selenastrum* occurred in samples collected during the April and May sampling events (Table 47). Prior to this irrigation season, one sample tested toxic to *Selenastrum* on February 26, 2008. There were no exceedance level concentrations of any pesticides or metals during the April or May sampling events. Metals that were detected below the WQTL during both of these events were arsenic, boron, copper, lead, nickel, selenium and zinc. All of these metals were detected at low concentrations not known to have an effect on algae. Copper in the sample water collected on April 22 and May 20, 8.7 µg/L and 7.1 µg/L, respectively, may have contributed to the toxicity. In samples collected on May 20, there was also a small amount of simazine (1.0 µg/L). The EC<sub>50</sub> of simazine for *Selenastrum* is 100 µg/L

(ECOTOX, Ref#56747). PUR data include applications of pesticides that may be relevant to the toxicity events, including copper, 1,3-dichloropropene, 2,4-d, carfentrazone-ethyl, glufosinate-ammonium, glyphosate, norflurazon, oxyfluorfen, paraquat dichloride, pendimethalin, potassium n-methyldithiocarbamate, rimsulfuron and simazine. *Selenastrum* toxicity has not yet been addressed in a management plan for Livingston Drain. Toxicity exceedances from the 2008 irrigation season will be included in the ESJWQC Management Plan update.

Chlorpyrifos was detected at exceedance concentrations during the June 17 and July 22, 2008 monitoring event (Table 47). Chlorpyrifos is highly toxic to *Ceriodaphnia dubia*, however there was no toxicity detected in these samples. PUR data indicate that within one month prior to the June 17 exceedance, 290 pounds of chlorpyrifos were applied on 65 acres of sweet potatoes. During the month prior to the July 22 exceedance, there were two applications of chlorpyrifos that occurred on 38 acres of almonds (the first application included 1152 ounces of product and the second, 40 quarts). Previous chlorpyrifos exceedances occurred in samples collected for the first storm sampling event on January 24, 2008 and in samples collected during the 2007 irrigation season on August 14, 2008. Chlorpyrifos has not yet been addressed in a management plan for Livingston Drain, but will be included in the ESJWQC Management Plan update.

As per the ESJWQC Management Plan, additional monitoring for copper occurred at Livingston Drain @ Robin Ave in May, June, July and September. Copper was detected above the WQTL in samples collected in June and July (Table 47). Exceedances of the copper WQTL occurred in almost all samples collected at this site prior to this event, including the 2007 irrigation season and the 2008 storm season. The highest concentrations measured at this site occurred in samples collected in the early 2007 irrigation season (May 15, 2007) and the second 2008 storm event (February 26, 2008). Copper concentrations were identical for each sampling event (18 µg/L). PUR data indicate one copper application that occurred on March 25, in which 50 lbs of product (Nordox 75 WG) was applied to 40 acres of wine grapes. There were no agricultural applications of copper after March 25 (prior to the June and July exceedances). There are a number of possible sources of copper in water bodies within the Coalition region, and these exceedances may be a result of drain inputs other than agriculture. Copper is commonly applied by dairies and can also become available to water bodies through the weathering of rocks and soils that naturally contain metals. Automobile components may also contain copper and wearing of brakes can add substantial amounts of copper to surface waters that pass through or near urban areas. Copper is a priority C constituent in the Site Subwatershed Management Plan for Livingston Drain.

The WQTL for nitrate was exceeded for the first time at the Livingston Drain site in samples collected on June 17, 2008 (Table 47). Nitrate was detected at 11 µg/L in both the grab and field duplicate samples. Potential sources of nitrates in surface waters include runoff of fertilizers or organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from dairies. Additional information on sources of nitrate in the Coalition region is described below under *Constituent Specific Analyses/Special Studies*. The Livingston Drain site drains only a small portion of land (approximately 69 irrigated acres), however, a pasture is located adjacent to the sample site. Runoff from the pasture could be the source of nitrate in the drain either through direct runoff or through movement in shallow

ground water. If additional nitrate exceedances occur at this site, then the exceedances will be addressed in the Coalition Management Plan.

One exceedance of the *E. coli* WQTL occurred during the July 22, 2008 monitoring event (Table 47). Prior to this exceedance, *E. coli* was detected above the WQTL only during the January 24, 2008 monitoring event. Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. As mentioned above, a pasture is located just adjacent to the sample site along Livingston Drain. It may be that irrigation runoff from this land is contributing to the *E. coli* in the drain. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has not yet been addressed in the Site Subwatershed Management Plan for Livingston Drain. However, as a result of the second exceedance, this constituent will be addressed in the ESJWQC Management Plan update.

Exceedances of the pH WQTL were detected above the upper WQTL during the majority of irrigation monitoring events at this site (Table 47). Exceedances of the pH WQTL occurred three times during the 2007 irrigation season. It is uncertain what factors may be involved in the persistently elevated pH levels in the Livingston Drain. A discussion of parameters that may affect pH in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. The Site Subwatershed Management Plan for Livingston Drain @ Robin Ave addresses pH as a priority E constituent.

### Merced River @ Santa Fe

**Table 48. Merced River @ Santa Fe sample site - 2008 Irrigation season exceedance.**

Site Name	Sample Date	Sample Type	DO, mg/L
Merced River @ Santa Fe	4/22/2008	NM	6.06

NM – normal monitoring

DO was the only constituent for which there was an exceedance of the WQTL at the Merced River @ Santa Fe sample site during the 2008 irrigation season. During the first irrigation monitoring event, DO was 6.06 mg/L (Table 48). Low DO occurred at this site previously during sampling on June 14, 2006. It is apparent that low DO is not a persistent problem at the Merced River site. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is not included in the Site Subwatershed Management Plan for Merced River @ Santa Fe. As a result of the second exceedance, DO will be addressed in the ESJWQC Management Plan update.

## Miles Creek @ Reilly Rd

**Table 49. Miles Creek @ Reilly Rd sample site - 2008 Irrigation season exceedances.**

FD – field duplicate; NM – normal monitoring; RS – Resample; Sediment – Sediment Monitoring; MPM – Management Plan monitoring

\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Selenastrum* occurred in samples collected on April 29, 2008 (25% growth as compared to the control, Table 49). Resampling for toxicity occurred one week later, on May 7, and toxicity was experienced again. Prior to this irrigation season, one sample tested toxic to *Selenastrum*, on June 26, 2007. There were no exceedance level concentrations of any pesticides or metals during the April toxicity event. Phase III TIE analysis indicated that paraquat, copper and zinc were present at toxic concentrations (paraquat = 0.1 TUC, total metals = 0.8 TUC, Appendix VI). PUR data include 41 applications of pesticides relevant to the *Selenastrum* toxicity, including amino ethoxy vinyl glycine hydrochloride, bromoxynil heptanoate, bromoxynil octanoate, carfentrazone-ethyl, glufosinate-ammonium, glyphosate, nicosulfuron, oxyfluorfen, paraquat dichloride and sethoxydim. *Selenastrum* toxicity has not yet been addressed in the Site Subwatershed Management Plan for Miles Creek @ Reilly Rd. As a result of the second exceedance, *Selenastrum* toxicity will be included in the ESJWQC Management Plan update.

Sediment toxicity to *Hyalella* occurred in samples collected on August 28, 2008 (Table 49). *Hyalella* survival was 95% of the control (91% in the field duplicate sample), indicating a statistically significant difference between the sample and the control. The survival in the sample was greater than 80% and the toxicity is not considered ecologically relevant. Resampling occurred at the site on October 2, 2008, and again resulted in toxicity to *Hyalella* (91% survival compared to the control). Sediment toxicity occurred once at this site prior to this sampling event during the 2007 irrigation season (August 23, 2007). Sediment samples are not analyzed for pesticides or metals, however exceedances of chlorpyrifos, copper and lead

occurred in water samples collected one week prior to sediment sampling (Table 49). Detections of these constituents in the sample water may be an indication of levels in the sediment, particularly for those constituents that have a tendency to bind to sediment. Metals have a high tendency to bind to sediment, and the properties of chlorpyrifos allow the constituent to both bind to sediment and dissolve in the water column (estimates of  $K_{oc}$  ranging from below 1000 to 6040), [www.wsi.nrcs.usda.gov/products/w2q/pest/data/aidata.xls](http://www.wsi.nrcs.usda.gov/products/w2q/pest/data/aidata.xls)). PUR data indicate 119 applications of pesticides that may have contributed to the toxicity at this site. The active ingredients applied include permethrin, cyfluthrin, esfenvalerate, (s)-cypermethrin, lambda-cyhalothrin, bifenthrin, paraquat dichloride, clofentezine, azoxystrobin, chlorpyrifos, and indoxacarb. *Hyalella* toxicity has not yet been addressed in the Site Subwatershed Management Plan for Miles Creek @ Reilly Rd; however, as a result of the exceedance during the 2008 monitoring season, *Hyalella* toxicity will be addressed in the ESJWQC Management Plan update.

Chlorpyrifos was detected at concentrations above the WQTL during the July 29 and August 26, 2008 monitoring events (Table 49). Chlorpyrifos is toxic to *Ceriodaphnia dubia*, however there was no toxicity detected in either of these samples. PUR data for the Miles Creek @ Reilly Rd site subwatershed indicate that during the 2008 irrigation season, applications of chlorpyrifos began in mid-June and continued through August. Eight applications occurred within one month prior to the July 29, 2008 exceedance during which time 148 gallons of product were applied to 592 acres of corn, alfalfa and almonds. Ten applications occurred within one month prior to the August 26, 2008 exceedance, when 83 gallons of product were applied to 511 acres of alfalfa, almonds and walnuts. Prior to 2008, one chlorpyrifos exceedance occurred in samples collected on September 18, 2007. Chlorpyrifos is not addressed in Site Subwatershed Management Plan for this site and will be included in the ESJWQC Management Plan update.

Copper and lead were also detected above their respective WQTLs (calculated based on hardness) in samples collected on July 29 and August 26, 2008 (Table 49). Previous exceedances of the copper WQTL occurred during both of the 2008 storm season events and three of the six 2007 irrigation season events (May 29, June 26 and August 21, 2007). The highest detection measured at this site occurred during the second storm season event in February 2008 (34 µg/L). As a result of previous copper exceedances, Miles Creek was sampled twice during May, June and August of 2008 as part of the ESJWQC Management Plan monitoring. Exceedances during the irrigation season of 2008 occurred only during July and August sampling. Prior exceedances of lead also occurred during the two 2008 storm monitoring events and during the June 26, 2007 irrigation monitoring event. Lead is not applied by agricultural, however copper is an active ingredient in a number of fungicides used on a variety of crops in the Coalition region. PUR data indicate that the most recent prior applications reported were in January 2008. Copper exceedances were addressed as a priority C constituent in the Site Subwatershed Management Plan for Miles Creek @ Reilly Rd; 2008 exceedances will be further discussed in the ESJWQC Management Plan update.

DO was measured below the WQTL at this site during all sampling events between June and August of 2008. There were no exceedances of the DO WQTL prior to these events at the Miles Creek site. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO has not yet been addressed in the Site

Subwatershed Management Plan for this site, but will be included in the ESJWQC Management Plan update.

### Prairie Flower Drain @ Crows Landing Rd

NM – normal monitoring; MPM – Management Plan monitoring; RS – Resample ; Sediment – Sediment Monitoring

Water column toxicity to *Selenastrum* occurred in samples collected on April 22 and May 20, 2008 at the Prairie Flower Drain @ Crows Landing Rd site (Table 50). Resampling occurred one week after each of these toxicity events, on April 29 and May 27, and toxicity was experienced again in both of the resamples. Samples collected during the 2008 storm season (during both events) also tested toxic to *Selenastrum*. Prior to 2008, one sample from this site tested toxic to *Selenastrum* on May 15, 2007. There were no detections of exceedance level concentrations of any pesticides or metals in any of these samples. Metals detected below the WQTL concentrations during these events were arsenic, boron, cadmium, copper, lead, nickel, selenium and zinc. Phase III TIE analysis indicates that copper, nickel and zinc were present at toxic concentrations (total metals = 1.3 TUC, Appendix VI). PUR data include only two applications of relevant pesticides within one month prior to the initial toxicity on April 22. One of these applications was 1674 gallons of potassium n-methyldithiocarbamate applied across 279 acres of processing tomatoes. Also known as metam potassium, this product is used as a fumigant, fungicide, microbiocide, algacide and nematicide on a variety of crops in California. It is not certain whether this product was responsible for the *Selenastrum* toxicity on April 22, or those experienced thereafter; the Coalition does not currently analyze for fungicides. Two

additional applications of the same quantity of metam potassium were applied on April 22, 2008. Between April 22 and May 27, 2008 there were 24 applications of other pesticides relevant to *Selenastrum* toxicity. The active ingredients of these pesticides include nicosulfuron, halosulfuron-methyl, dicamba, glyphosate, foramsulfuron, and rimsulfuron. *Selenastrum* toxicity has not yet been addressed in the management plan for Prairie Flower Drain @ Crows Landing Rd. As a result of the 2008 storm and irrigation exceedances *Selenastrum* toxicity will be included in the next ESJWQC Management Plan update.

Sediment toxicity to *Hyalella azteca* occurred in samples collected on August 28, 2008 (Table 50). Survival in the sample water was 90% of the control, indicating a level of toxicity in the sediment below the LC<sub>50</sub> for *Hyalella*. Resampling occurred at the site on October 2, 2008, and again resulted in toxicity to *Hyalella*. Prior to this event, sediment toxicity occurred in samples collected during the 2005 and 2007 irrigation seasons. Sediment samples are not analyzed for pesticides or metals, however each of the sediment toxicities that occurred at this site were preceded by (or in close proximity to) exceedance level detections of chlorpyrifos in sample water. During the 2008 Irrigation season, there were exceedances of both chlorpyrifos (0.024 µg/L) and malathion (0.012 µg/L). Chlorpyrifos is moderately soluble, with estimates of K<sub>oc</sub> ranging from under 1000 to 6040, making the constituent capable of dissolving in the water column or binding to sediment. Malathion, is more soluble and less likely to bind to sediment. PUR data includes 47 applications of various active ingredients that have the potential to cause *Hyalella* toxicity including bifenthrin, chlorpyrifos, esfenvalerate, glyphosate, lambda-cyhalothrin and spiromesifen. *Hyalella* toxicity is a priority D constituent in the management plan for Prairie Flower Drain.

Chlorpyrifos was detected at exceedance levels during the August 19, 2008 monitoring event (Table 50). PUR data for the Prairie Flower Drain @ Crows Landing Rd site subwatershed is provided in Appendix IV. There have been three previous chlorpyrifos exceedances. Two exceedances occurred on August 17 and September 21 2005, and one exceedance occurred on August 28, 2007. Exceedances in August appear to correlate with the amount of active ingredient applied in the site subwatershed, which is greatest during the month of August (refer to the Prairie Flower Drain Site Subwatershed Management Plan). PUR data include two applications on July 25 and four applications on August 5 on corn. Chlorpyrifos is a priority A constituent in the Site Subwatershed Management Plan for Prairie Flower Drain.

One exceedance of the malathion WQTL also occurred in samples collected during the August 19, 2008 monitoring event (Table 50). Malathion is an organophosphate insecticide that is predominantly used on alfalfa, field crops, walnuts, and for structural pest control (in California). Malathion is also known to be toxic to *Ceriodaphnia dubia*, however as mentioned above there was no toxicity in these samples. This was the first detection of malathion in the Prairie Flower Drain. There were no applications of malathion one month prior to the sample date; the most recent application was on March 5, 2008 on alfalfa. If there are additional exceedances of malathion at this site, then the exceedances will be addressed in the ESJWQC Management Plan.

One exceedance of the dimethoate WQTL occurred in a sample collected during the July 22, 2008 monitoring event (Table 50). Dimethoate is an organophosphate insecticide that is

predominantly used in California on alfalfa, tomatoes, oranges, and corn. Like chlorpyrifos and malathion, dimethoate is known to be toxic to *Ceriodaphnia dubia*, however, there was no toxicity in these samples. This exceedance was the first of dimethoate in the Prairie Flower Drain. PUR data indicate 17 applications occurring between July 1 and July 21, 2008. Approximately 110 gallons of dimethoate were applied on 895 acres of corn and processing tomatoes. If there are additional exceedances of dimethoate at this site, then the exceedances will be addressed in the ESJWQC Management Plan.

One exceedance of the ammonia WQTL occurred in samples collected from the Prairie Flower Drain @ Crows Landing Rd on June 17, 2008 (Table 50). Ammonia can enter a water body through two sources, direct discharge from agricultural fertilizers or animal waste, or from discharges from waste water treatment plants. Additionally, ammonia can be generated in the stream as a result of the breakdown of organic nitrogen. Possible sources of ammonia in Coalition water bodies are described below, under *Constituent Specific Analyses/Special Studies*. There are no waste water inputs to Prairie Flower Drain, however there are several dairies upstream of the sample site that may have contributed to this exceedance. Ammonia has been detected at exceedance concentrations once prior to this event, on July 13, 2007. As a result, ammonia exceedances will be addressed in the next ESJWQC Management Plan update.

Exceedances of the nitrate WQTL were experienced in all samples analyzed for this constituent during the irrigation season (Table 50). Upstream monitoring for nitrate at the Prairie Flower Drain @ Morgan Rd occurred during every sampling event and exceedances were detected above the WQTL in all samples except those collected on July 22, 2008. Nitrate was detected at a concentration of 0.053 µg/L during this event. Potential sources of nitrates in surface waters include runoff of fertilizers or organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from dairies. Additional information on sources of nitrates is provided under *Constituent Specific Analyses/Special Studies*. As mentioned previously, a large portion of the Prairie Flower Drain site subwatershed is made up of pasture land or dairies, and runoff containing animal waste upstream of the sample site could be the source of nitrate in the drain. Nitrate has been addressed in the Site Subwatershed Management Plan for Prairie Flower Drain as a priority D constituent.

Exceedances of the *E. coli* WQTL also occurred in all samples analyzed for this constituent during the irrigation season (Table 50). There was no upstream monitoring for *E. coli* at the Prairie Flower Drain @ Morgan Rd site. Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids and liquid dairy waste, and a large array of wildlife. Irrigation runoff from pasture land or dairies may be contributing to the *E. coli* in the drain. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Site Subwatershed Management Plan for Prairie Flower Drain as a priority E constituent.

Exceedances of the TDS and SC WQTLs also occurred in all samples (Table 50). TDS was not measured at the upstream Management Plan site; however during each sampling event SC was measured above the WQTL. TDS describes all solids (usually mineral salts) that are dissolved in water and are frequently associated with exceedances of SC. Potential sources of TDS and SC

are minerals leached from soils by upstream surface water and ground water, or drain water from irrigated agriculture. Sources of SC and TDS in Coalition water bodies are described further under *Constituent Specific Analyses/Special Studies*. Measurements of SC and TDS at this site have been consistently high since monitoring was initiated. These constituents are addressed in the Site Subwatershed Management Plan for Prairie Flower Drain as priority E constituents.

Exceedances of the DO WQTL occurred during eight of the 16 irrigation season sampling events at the Prairie Flower Drain sites (Table 50). Similar concentrations of DO were measured during previous irrigation seasons, and only one DO measurement has fallen below the WQTL during storm season monitoring (March 22, 2005). A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the Site Subwatershed Management Plan for Prairie Flower Drain.

### Silva Drain @ Meadow Dr

**Table 51. Silva Drain @ Meadow Dr sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	pH	<i>Ceriodaphnia dubia</i> , Survival: % of Control	<i>Pimephales promelas</i> , Growth: % of Control	<i>Hyalella azteca</i> , Survival: % of Control	<i>E. coli</i> , MPN/100 ml	Ammonia, mg/L	Copper*, µg/L	Lead*, µg/L	Chlorpyrifos, µg/L

FD – Field Duplicate; NM – normal monitoring; MPM – Management Plan monitoring; RS – Resample; Sediment – Sediment Monitoring

\*WQTL based on hardness and shown in parenthesis

Water column toxicity to *Ceriodaphnia dubia* occurred in samples collected on July 22, 2008 at the Silva Drain @ Meadow Dr site (Table 51). Complete mortality occurred in the environmental sample as well as the field duplicate sample at this site. Chlorpyrifos was also detected in samples collected during the same event at 0.43 µg/L. A dilution series and TIE was conducted on these samples. The dilution series resulted in 5.2 acute toxic units, and the results of the TIE indicated that the source of toxicity was an organophosphate pesticide (such as chlorpyrifos). Phase III TIE analysis indicates that chlorpyrifos accounted for all of the toxicity detected in the sample (chlorpyrifos = 5.4 TUA, Appendix VI). Resampling occurred one week later, on July 29 and toxicity was experienced again. The reoccurrence of toxicity is an

indication that the source of toxicity was persistent at that site. Prior to 2008, one sample tested toxic to *Ceriodaphnia* on August 9, 2006. That toxicity also corresponded to a chlorpyrifos exceedance at the site. PUR data indicate that there were three applications of chlorpyrifos reported during the months of June and July. In total, 4.38 gallons of chlorpyrifos were applied on 23 acres of almonds and corn between June 24 and July 18, 2008. There were no other applications of chlorpyrifos reported in the site subwatershed between January and October, 2008. Other relevant applications that occurred within the site subwatershed include the active ingredients, permethrin, esfenvalerate, paraquat dichloride, fluazifop-p-butyl and propargite. *Ceriodaphnia* toxicity has not yet been addressed in the management plan for Silva Drain @ Meadow Dr. As a result of the 2008 storm and irrigation exceedances *Ceriodaphnia* toxicity will be included in the next ESJWQC Management Plan update for this site.

Toxicity to *Pimephales* occurred in a sample collected from Silva Drain @ Meadow Dr (Table 51). The level of toxicity did not drop below 50% and therefore did not trigger a TIE. Follow-up sampling for toxicity occurred one week after the initial samples were collected and toxicity was not persistent at this site. Ammonia (13 mg/L) was detected in the Silva Drain @ Meadow Dr sample water during this event. *Pimephales* is known to be sensitive to ammonia in water, and it is likely that the toxicity detected at this site is due to the elevated level of ammonia. *E. coli* was also detected at this site at the highest concentration detectable (>2400 MPN/100mL), indicating that the source of ammonia may be dairy waste. There is irrigated pasture just adjacent to the sample site and dairies are also found upstream. Drainage water from the pasture is a possible source of fecal contamination at the sample site.

Sediment toxicity to *Hyalella* occurred in a sample collected on August 28, 2008 (Table 51). Survival was 85% of the control. Resampling occurred at the site on October 2, 2008, and again resulted in toxicity to *Hyalella*. Prior to this event, sediment toxicity occurred in samples collected on August 9 and September 6, 2006 (initial sample and resample). Sediment samples are not analyzed for pesticides or metals, however each of the sediment toxicities that occurred at this site were preceded by (or in close proximity to) exceedance level detections of chlorpyrifos in sample water. Chlorpyrifos is moderately soluble, with estimates of  $K_{oc}$  ranging from under 1000 to 6040, making the constituent capable of dissolving in the water column or binding to sediment. Detections of chlorpyrifos in the sample water may be an indication of levels in the drain sediment. Applications of chlorpyrifos during the 2008 irrigation season are described above, and all PUR data relevant to this toxicity are provided in Appendix IV. Other pesticides applied in the site subwatershed that may be relevant to sediment toxicity include permethrin, esfenvalerate, paraquat dichloride and spiromesifen. *Hyalella* toxicity is a priority D constituent in the Site Subwatershed Management Plan for Silva Drain @ Meadow Dr.

Chlorpyrifos was detected at exceedance concentrations during the July 22, August 5 (MPM) and August 19, 2008 monitoring events (Table 51). Chlorpyrifos is an organophosphate pesticide, commonly applied for pest control on alfalfa and orchard crops, among others. Samples collected during these events tested toxic to *Ceriodaphnia*. As mentioned previously, there were three applications of chlorpyrifos reported during the months of June and July, totaling 4.38 gallons of product applied on 23 acres of almonds and corn. There were no other applications of chlorpyrifos reported in the site subwatershed between January and October, 2008. There were chlorpyrifos exceedances on August 9, 2006, and July 17 and August 28, 2007

that were positively correlated with the quantity of applied pesticide in the site subwatershed (see the ESJWQC Management Plan). Chlorpyrifos has been addressed as a priority B constituent in the Site Subwatershed Management Plan for the Silva Drain site.

Copper was detected at exceedance level concentrations for the first time at this site on June 17, 2008 and again in samples collected on August 19 and September 23, 2008 (Table 51). Copper is commonly applied as a fungicide, algicide and pesticide throughout the Coalition region. Copper is known to contribute to the toxicity of *Selenastrum*, reducing growth of the algae, however algae toxicity did not occur during any of these events. Copper occurs as an active ingredient in pesticides such as copper, copper hydroxide, copper sulfate and copper sulfate pentahydrate. Copper can also become available to water bodies through the weathering of rocks and soils that naturally contain metals. Copper is found in automobile components and wearing of brakes and can move to surface waters that pass through or near roadways. Since copper does not degrade, it is possible that applications can cause exceedances several months after application. Only three applications of copper in the site subwatershed were reported between January and October, 2008. These occurred on January 4 and January 11, totaling 584 pounds of product applied on 103 acres of almonds. During the first four monitoring events there was no water flow measured in the drain, and during the August and September events flow was measured at 0.53 cfs and 0.14 cfs, respectively. As a result, the detections of copper in the drain may reflect concentrations localized in the drain sediment rather than those from active sources upstream. Exceedances of copper have not yet been addressed in the Site Subwatershed Management Plan for Silva Drain @ Meadow Dr. As a result of the 2008 irrigation exceedances, copper will be included in the next ESJWQC Management Plan update.

Lead was detected at exceedance level concentrations for the first time at this site during the fifth irrigation sampling event on August 18, 2008 (Table 51). An exceedance of the lead WQTL also occurred during this event. There were also detections of other metals (below the WQTL limits). Both the copper and lead exceedances had not occurred prior to the 2008 irrigation season. Metals in a water body have the tendency to bind to sediment and do not degrade. As a result, a variety of metals can accumulate in a stream bed over time from natural or anthropogenic sources. The concentrations of both lead and copper point to the possibility that mobilized sediment could be the source of these exceedances. Sediment can be mobilized as a result of disturbance; however the cause of mobilization during this event is unknown. Field sheet notes recorded in the field indicate that on the day of sampling the site water was brown and murky (<4 inches of visibility), with low flow (0.53 cfs), and that the stream bed substrate was mud. Additional information on sources of lead in the Coalition region are discussed in more detail below under *Constituent Specific Analyses/Special Studies*. Exceedances of lead have not yet been addressed in the Site Subwatershed Management Plan for Silva Drain @ Meadow Dr. As a result of the 2008 irrigation exceedance, lead will be included in the next ESJWQC Management Plan update.

Ammonia was detected at exceedance level concentrations for the first time at this site on April 22, 2008. Ammonia exceedances occurred again during the June 17 and September 23, 2008 events. Ammonia can enter a water body through two sources, direct discharge from agricultural fertilizers or animal waste, or from discharges from waste water treatment plants.

Additional information on sources of ammonia in the Coalition region can be found under *Constituent Specific Analyses/Special Studies*, below. There are no waste water inputs to Silva Drain, however runoff from pasture upstream of the sample site may have contributed to these exceedances. Exceedances of ammonia have not yet been addressed in the Site Subwatershed Management Plan for Silva Drain @ Meadow Dr. As a result of the 2008 irrigation exceedances, ammonia will be included in the next ESJWQC Management Plan update.

Exceedances of the *E. coli* WQTL occurred at this site during irrigation monitoring events on June 17, July 22, August 19 and September 23, 2008 (Table 51). Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. The Silva Drain site subwatershed consists of a small portion of land allocated for agricultural field crops and pasture. Irrigation runoff from pasture land may be contributing to the *E. coli* in the drain. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Site Subwatershed Management Plan for Silva Drain as a priority E constituent.

One exceedance of the pH WQTL occurred at this site during the sediment resample event on October 2, 2008 (Table 51). During this event, pH was measured at the site at 0.01 pH units above the upper WQTL. A discussion of parameters that may affect pH in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. Exceedances of pH have not yet been addressed in the management plan for Silva Drain @ Meadow Dr. As a result of the 2008 irrigation exceedance, pH will be included in the ESJWQC Management Plan update.

Exceedances of the DO WQTL occurred during all but one sampling event during the irrigation season at the Silva Drain site (Table 51). Exceedances of the DO WQTL have occurred throughout irrigation seasons since 2006, when monitoring began at this site. There have been no DO exceedances at this site during storm season events. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the Site Subwatershed Management Plan for Silva Drain @ Meadow Dr.

### South Slough @ Quinley Rd

**Table 52. South Slough Quinley Rd sample site - 2008 Irrigation season exceedances.**

Site Name	Sample Date	Sample Type	DO, mg/L	<i>Selenastrum capricornutum</i> , Growth: % of Control	<i>E. coli</i> , MPN/100 ml	Copper*, µg/L	Lead*, µg/L	Chlorpyrifos, µg/L

South Slough @ Quinley Rd	7/29/2008	NM						0.029

NM – normal monitoring

\*WQTL based on hardness and shown in parenthesis

Toxicity to *Selenastrum* occurred at this site in samples collected on April 29, 2008 (Table 52). Results from the TIE indicated that the majority of toxicity was caused by cationic metals, while non-polar organics may have been responsible for a portion of the toxicity. Follow-up re-sampling for toxicity occurred one week after the initial samples were collected and toxicity did not occur in the re-samples. There were no exceedance-level detections of pesticides or metals relevant to the toxicity in these samples. Low concentrations of metals were detected (below the WQTL). Phase III TIE analysis indicates that copper and zinc were present at toxic concentrations (total metals = 0.7 TUc) and unknown non-polar organics may be present in the sample (Appendix VI). It is possible that a constituent not tested by the Coalition is the cause of toxicity. PUR data show six applications of pesticides in the site subwatershed relevant to algae toxicity. Pesticides applied include copper hydroxide, s-metolachlor, glyphosate, oxyfluorfen and oryzalin. *Selenastrum* toxicity has not yet been addressed in the Site Subwatershed Management Plan for South Slough @ Quinley Rd. As a result of the toxicity during the 2008 irrigation season, this exceedance will be included in the ESJWQC Management Plan update.

Chlorpyrifos was detected at exceedance levels in samples from South Slough @ Quinley Rd for the first time during the July 29, 2008 monitoring event (Table 52). Chlorpyrifos is an organophosphate pesticide, commonly applied for pest control on alfalfa and orchard crops, among others. Chlorpyrifos is highly toxic to *Ceriodaphnia dubia*, however samples collected during this event did not result in toxicity. PUR data include three applications of chlorpyrifos occurring during the month of July, prior to the sampling event. All three applications occurred on July 20, when 51 gallons of product (Lorsban 4E-HF) were applied on 275 acres of corn. These were the only applications to occur between January and October, 2008. Chlorpyrifos has not been addressed in the Site Subwatershed Management Plan for South Slough. As a result of this exceedance, chlorpyrifos will be included in the ESJWQC Management Plan update.

One exceedance of the copper WQTL occurred at this site for the first time during the third irrigation monitoring event on June 24, 2008 (Table 52). Copper is commonly applied throughout the Coalition region and is considered an organic herbicide, fungicide, and algicide. Copper is known to contribute to the toxicity of *Selenastrum*. Copper active ingredients include copper, copper hydroxide, copper sulfate and copper sulfate pentahydrate. Copper can also become available to water bodies through the weathering of rocks and soils that naturally contain metals. Copper is found in automobile components and wearing of brakes can add substantial amounts of copper to surface waters that pass through or near urban areas. Since copper does not degrade, it is possible that applications can cause exceedances several months after application. PUR data indicate that there was no use of copper within three months prior to the exceedance. The most recent application occurred on February 29, 2008. This application amounted to 140 pounds of product applied on 35 acres of almonds. This is the only application of copper reported between January and October, 2008. Copper had not yet been addressed in the Site Subwatershed Management Plan for South Slough. Exceedances that occurred during the 2008 irrigation season will be included in the ESJWQC Management Plan update.

Lead was also detected at exceedance level concentrations for the first time at this site during the third irrigation season sampling event on June 24, 2008 (Table 52). Lead is not an active

ingredient in any currently applied pesticide and the detection in the Slough is likely a legacy of any number of anthropogenic or natural sources. Possible sources of lead in the Coalition region are discussed in more detail below under *Constituent Specific Analyses/Special Studies*. Metals in a water body have the tendency to bind to sediment and do not degrade. As a result, a variety of metals can accumulate in a stream bed over time, and can be remobilized into the water column. Sediment can be mobilized as a result of disturbance; however the cause of mobilization during this event is unknown. Field sheet notes indicate that on the day of sampling the site water was brown and murky (<4 inches of visibility), with moderate flow (8.49 cfs), and that the stream bed substrate was mud. Exceedances of lead have not yet been addressed in the Site Subwatershed Management Plan for South Slough. If additional exceedances of lead occur at this site, then the constituent will be included in the Site Subwatershed Management Plan.

One exceedance of the *E. coli* WQTL occurred during the first irrigation monitoring event at this site on April 22, 2008 (Table 52). Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids and liquid dairy waste, and a large array of wildlife. Land allocated to dairies and pasture is abundant in the South Slough site subwatershed. Irrigation runoff from these lands may be contributing to the *E. coli* in the slough. Sources of *E. coli* are described further below under *Constituent Specific Analyses/Special Studies*. *E. coli* has been addressed in the Site Subwatershed Management Plan for South Slough as a priority E constituent, and will further be addressed in the ESJWQC Management Plan update.

One exceedance of the DO WQTL occurred during the first irrigation season event on April 29, 2008 (Table 52). Exceedances of the DO WQTL also occurred throughout the 2007 irrigation season, but not during monitoring in 2006. There have been no DO exceedances at this site during storm season events. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the Site Subwatershed Management Plan for South Slough.

### Westport Drain @ Vivian Rd

Toxicity to *Selenastrum* occurred in a sample collected on April 22, 2008 (58% growth compared to the control, Table 53). Follow-up sampling for toxicity occurred one week after the initial samples were collected and toxicity did not occur again in the re-samples. There were no exceedance level concentrations of pesticides or metals relevant to the toxicity in these samples. Metals were detected at low concentrations (below the WQTL) and it is possible that these detections combined may have contributed to algae toxicity including a copper detection of 2.7 µg/L (EC<sub>50</sub> = 30 µg/L, ECOTOX website). Since a TIE was not triggered, it is unknown what class of chemical is responsible for toxicity and it is possible that a non-polar organic not tested by the Coalition contributed to the toxicity. PUR data include 32 applications of pesticides that may be relevant to this toxicity which contain the active ingredients, copper hydroxide, 2,4-d, oxyfluorfen, paraquat dichloride, carfentrazone-ethyl and glyphosate. *Selenastrum* toxicity occurred in samples collected on May 15, 2007 and February 26, 2008 as well as in the resample on March 4, 2008. *Selenastrum* toxicity has not been addressed in the Site Subwatershed Management Plan for Westport Drain @ Vivian Rd. As a result of the toxicity experienced during the 2008 storm and irrigation seasons these exceedances will be included in the ESJWQC Management Plan update to be submitted April 1, 2009.

Sediment toxicity to *Hyalella azteca* occurred for the first time in the field duplicate sample collected on August 28, 2008 (Table 53). Survival in the sample water was 94% of the control, indicating a level of toxicity that is not ecologically relevant (>80% survival). In addition, the associated environmental sample had the same amount of survival as field duplicate sample; however, due to less variation between the replicates, the environmental sample was not significantly different from the control and therefore not toxic. Resampling was conducted on October 2, 2008, and there was no toxicity in the resample. Sediment samples are not analyzed for pesticides or metals, and in the water column there were no exceedance level detections of any pesticides or metals known to cause toxicity. PUR data include 61 applications of pesticides that may be relevant to *Hyalella* toxicity which contain the active ingredients, lambda-cyhalothrin, fenpropathrin, esfenvalerate, bifenthrin, permethrin, glyphosate, oxyfluorfen, chlorpyrifos and paraquat dichloride. If *Hyalella* toxicity is experienced again at this site, the toxicity will be addressed in the Site Subwatershed Management Plan for Westport Drain.

Chlorpyrifos was detected above the exceedance level concentration in samples from Westport Drain @ Vivian Rd during the July 22, 2008 monitoring event (0.016 µg/L, Table 53). The chlorpyrifos concentration is below the reporting limit for this analyte and is considered an

estimate. There was no toxicity to *Ceriodaphnia* during this event. PUR data for the Westport Drain @ Vivian Rd site subwatershed indicate that within one month prior to the exceedance date there were nine applications of products containing chlorpyrifos. In that time, 128 lbs of these pesticides (various products) were applied on 359 acres of walnuts, alfalfa and almonds. Chlorpyrifos was detected at exceedances level concentrations at this site one time prior to this event. Chlorpyrifos will be included in the ESJWQC Management Plan update for Westport Drain.

Exceedances of the nitrate WQTL occurred during every monitoring event of the irrigation season (Table 53). Potential sources of nitrates in surface waters include runoff of fertilizers or organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from dairies. Additional information regarding sources of nitrate in the Coalition region can be found below under *Constituent Specific Analyses/Special Studies*. Both pasture and dairies are located close to the sampling site in the small Westport Drain site subwatershed, and runoff containing animal waste could be a source of the detected nitrate. It is also possible that the drain is intercepting shallow ground water that has elevated nitrate concentrations. Nitrate is addressed in the Site Subwatershed Management Plan for Westport Drain as a priority D constituent.

Exceedances of the *E. coli* WQTL occurred during four of five irrigation monitoring events at this site (Table 53). Possible sources of *E. coli* in the drain include irrigated pasture, dairies, leaky sewer lines or septic systems, applied manure, biosolids, liquid dairy waste, and a large array of wildlife. As mentioned above, dairies and pasture are located adjacent to the Westport Drain sample site, and irrigation runoff from these lands may be contributing to the *E. coli* in the drain. Sources of *E. coli* are described further under *Constituent Specific Analyses/Special Studies* below. *E. coli* has been addressed in the Site Subwatershed Management Plan for Westport Drain as a priority E constituent.

Exceedances of the TDS and SC WQTLs occurred during every monitoring event in which analyses for these constituents were conducted (Table 53). TDS describes all solids (usually mineral salts) that are dissolved in water and are frequently associated with exceedances of SC. Sources of salts in the Coalition region are described below under *Constituent Specific Analyses/Special Studies*. Exceedances of the SC or TDS WQTLs have occurred at this site during every event since monitoring was initiated at this site in 2007. SC and TDS are addressed in the Site Subwatershed Management Plan for Westport Drain as priority E constituents.

Exceedances of the DO WQTL occurred during the first five irrigation monitoring events at this site (Table 53). Exceedances of the DO WQTL occurred throughout the 2007 irrigation season, and during the second 2008 storm season event. A discussion of parameters that may affect DO in surface waters is provided below under *Constituent Specific Analyses/Special Studies*. DO is a priority E constituent in the Site Subwatershed Management Plan for Westport Drain.

### ***Constituent Specific Evaluations/Special Studies***

## pH

The determinants of pH in surface waters are not well understood and pH can vary diurnally with changes in photosynthetic rates and the resulting changes in the concentration of CO<sub>2</sub> and O<sub>2</sub> in the water. Control of pH in surface waters is a function of the balance between the buffering capacity of the water, inputs of organic acids from soil leaching, and the relative amount of photosynthesis. In an attempt to understand the underlying mechanism behind the pH in Coalition surface waters, a preliminary analysis was undertaken to determine the statistical relationship between pH and dissolved oxygen (DO), hardness, temperature and specific conductance (SC). Multiple regression analyses were performed using pH as the response variable and DO, hardness, temperature, and SC as the predictor variables. Neither hardness nor SC were statistically significant predictors of pH. DO and temperature were significant predictors of pH. However, the adjusted coefficient of determination was only 0.23 indicating that 23% of the variation in pH was accounted for by the variation in DO or temperature. The estimated model is:

$$\text{pH} = 6.3395 + .0899 * \text{DO} + 2.4807\text{E-}02 * \text{Temp}$$

The equation indicates that raising temperature or the concentration of dissolved oxygen raises pH. This result, coupled with the lack of significance of hardness, suggests that pH dynamics in surface waters in the Coalition region are controlled by photosynthetic rate and the production of dissolved oxygen. Interestingly, SC was predictable from hardness indicating that the levels of SC in the surface waters in the Coalition region are primarily a function of CaCO<sub>3</sub>, which dissociates to Ca<sup>2+</sup> and CO<sub>3</sub><sup>2-</sup>. These analyses suggest that the primary cation in the surface water is Ca<sup>2+</sup> which is from natural sources.

## DO

Exceedances of the dissolved oxygen (DO) water quality objective are common and have been present throughout the Coalition region since monitoring was implemented. DO and pH are expected to vary diurnally and can exceed the standards as a result of natural processes in the water column such as changing water temperature, photosynthesis and respiration. Changes in DO can be exacerbated by the addition of nutrients which stimulate production of organic material which eventually dies and is released into the water column and sediment where it is broken down by microbial activity. The respiration of the bacteria during the breakdown process is termed Biological Oxygen Demand (BOD).

The Coalition conducted a special study which attempted to determine if BOD was the cause of low DO concentrations. The results of this study were included in Appendix VIII of the December 30, 2007 Semi Annual Monitoring Report. The majority of the samples contained no measurable BOD. The reasons for this could be the long holding time prior to initiation of the test or already depleted dissolved oxygen concentrations in the water column. BOD and Total Organic Carbon (TOC) were positively correlated and TOC was used as a surrogate for BOD in a multiple regression analysis. Water temperature, BOD, and nitrate in the water column were all significant predictors of dissolved oxygen. As water temperature and BOD increased, dissolved oxygen decreased. As nitrate increased, dissolved oxygen increased although the explanation for this latter relationship is not clear. It is clear that both water temperature and

BOD are significant factors causing the decrease in DO although other, as yet unknown factors are also important.

### **SC/TDS**

Potential sources of TDS (and by extension, the determinants of SC) are minerals leached from soils by upstream surface water and ground water, or drain water from irrigated agriculture. The two general sources of minerals/salts in agricultural landscapes are fertilizers and native soils. A commercial fertilizer can be made up of dozens of different chemicals, each of which ionize and contribute to the SC of the solution. Different brands of fertilizer can use different chemicals to make up the total formula suggesting that there will not be a universal signal for fertilizer-generated SC or TDS.

Water bodies in close proximity to the San Joaquin River have a depth to ground water that tends to be very shallow. Data developed by the Modesto and Turlock Irrigation Districts suggests that the exceedances of TDS/SC in this region are a function of ground water. Geologically, the ground water from both the east and west side of the Valley moves toward the San Joaquin River trough, the low point in the Valley that is naturally high in salts. The movement of water down gradient toward the San Joaquin River creates a shallow ground water table, as evidenced by the numerous wetlands that are in the vicinity of the river. This shallow ground water appears to be the cause of the salinity problems in many ESJWQC water bodies close to the river.

### **Nitrate**

Potential sources of nitrate in surface waters include runoff of fertilizers, organic matter from irrigated pasture, leaking septic systems, waste-treatment facility effluent, and inputs from animal waste. These sources can move to surface waters through above ground runoff or shallow subsurface flows. Animal waste that enters surface waters can be converted to nitrate by nitrifying bacteria. Possible sources of animal waste in a water body include dairies, poultry facilities, pasture and/or wildlife. From years of movement of nitrate from dairies into ground water, there is a significant amount of nitrate in the aquifers beneath the Coalition region. Many of these aquifers are very shallow and many of the drains in the western portion of the Coalition were constructed in the 1800s to lower the water table and allow farming. More recently, tile drains have been placed in some areas of the Coalition, and these further remove shallow ground water from the subsurface and move it to surface drainages. As a result, nitrate from dairies is now intercepted by field and surface drains resulting in consistent exceedances of the nitrate WQTL. Because of its extreme solubility, it is likely that any applications of nitrate fertilizers would result in immediate runoff to surface waters and it is unlikely that applications in the spring would result in exceedances of the WQTL throughout the irrigation season.

### **Ammonia**

Ammonia can enter a water body through two sources, direct discharge from agricultural fertilizers or animal waste, or from discharges from waste water treatment plants. Ammonia in fertilizer is typically converted to nitrite and then nitrate in soils over a short period of time and discharge of fertilizer would have to be immediate to detect ammonia in the receiving water

body. Previous exceedances of the ammonia WQTL have been attributed to discharge from dairies.

### **E. coli**

*E. coli* is an indicator of fecal contamination in surface waters. Potential sources of *E. coli* include runoff from irrigated pasture, dairies, leaky sewer lines, leaky septic systems, runoff from applications of manure, biosolids and liquid dairy waste, and direct deposition of fecal material from a large array of wildlife. A study designed to identify the source of fecal contamination in Coalition water bodies was initiated in August 2006. Obligate anaerobic bacteria of the genus *Bacteroides* were extracted from water samples and their DNA analyzed to determine the source(s) of the fecal matter. Anaerobic *Bacteroides* were used because they persist in the environment for only a short period of time (days), meaning any detection of *Bacteroides* DNA in the sample is from a recent contamination event. As a facultative anaerobe, *E. coli* can reproduce and persist in an oxygenated environment for an unknown period of time, thus detecting *E. coli* in a water sample is an indicator of fecal contamination but the timing of the contamination is not possible to determine.

For the study, water sampling occurred at 27 sites (4 baseline and 23 monitoring) within the Coalition region during non-monitoring events. Results of the study indicate that the source of the fecal contamination is a combination of human, cows, and chickens depending on the location. The sampling occurred only during late summer low flow conditions and should be repeated during winter storm events. Samples can be analyzed for additional molecular markers and chemical markers that can confirm the contamination by human sewage, but those analyses will require a much larger research effort that is outside the capabilities of the Coalition.

### **Arsenic**

The registrations on many products with this active ingredient have been cancelled. However, there are four products currently registered for use on citrus, for weed control around ditches, for use on ornamental plants, for nonagricultural weed control, and for weed control around buildings, driveways, sidewalks, rights-of-way, and fencerows. Several products are available for use by homeowners and nonagricultural users (e.g. county road maintenance) ([http://www.pesticideinfo.org/List\\_Products.jsp?Rec\\_Id=PC34358&Chem\\_Name=Sodium%20cacodylate&PC\\_Code=012502](http://www.pesticideinfo.org/List_Products.jsp?Rec_Id=PC34358&Chem_Name=Sodium%20cacodylate&PC_Code=012502)) and the product may have been purchased for use by local homeowners for use on their property. Arsenic is found in sodium cacodylate which is applied by agriculture for broadleaf weed control and as a cotton defoliant. California Department of Pesticide Regulation records indicate no agricultural use of sodium cacodylate across the Coalition region between 1998 and 2008.

### **Lead**

Lead is a legacy of any of a number of potential sources including deposition from leaded gasoline, disposal of lead-containing products such as paints, electronic components, and batteries, and old applications of lead arsenate pesticides. Currently, there are no pesticides applied that contain lead, although lead arsenate was used in the past. Lead arsenate was used generally only until the 1960s and has been banned on all food crops since 1991. Currently, the

most probable source is contaminated soils that originated from old pesticide applications, disposal of products containing lead, aerial deposition of particulate lead from industrial processes, or the deposition of automobile exhaust. Lead is predominantly particulate bound and not bioavailable in that form. Major roads and highways within subwatersheds may contribute to the leaching of lead into waterways. In addition, disposal of lead paint in the vicinity, burial of old buildings with lead paint, or leaching lead from lead arsenate deposition could all contribute to lead detections. The Coalition is currently not able to identify the specific source(s) of individual detections at sample sites, but lead in surface waters is not likely a result of agricultural management practices.

## Summary of Management Practices

---

One of the primary goals of the Coalition is to gather information on management practices that are demonstrated to benefit water quality and to provide this information and support to growers to facilitate the implementation of these management practices. Over the last several years, the Coalition has collaborated with groups such as the Natural Resources Conservation Service (NRCS), University of California Agricultural Cooperative Extension (UC Extension), the Coalition for Urban and Rural Environmental Stewardship (CURES), pesticide registrants and pest control advisors (PCAs) to gather information on the most up-to-date management practices to reduce the potential for pesticide runoff. Information is provided to growers regularly throughout the year by means of Coalition outreach meetings, mailings, personal communication with growers, and the Coalition website. Each management practice is viewed as one tool in a collective tool box and the management practices (tools) that are most beneficial to a particular farming operation will depend on factors including (but not limited to) the size of the farm, the drainage system, soil type, crop type and the crop pests that must be controlled.

A working list of management practices is provided in Table 54 below. Management practices are described based on the goal (e.g. water conservation, waste discharge reduction) and the mechanism of the practice. The ESJWQC Management Plan will include specific information on management practices that have been provided to the Coalition members and growers. Management practices are continually developing and changing and therefore the information will be updated in the ESJWQC Management Plan as new data become available.

**Table 54. Table of best management practices (BMPs), target constituents, mechanism and possible improvements to water quality.**

BMP	BMP Endpoint	BMP Target(s)	BMP Mechanism	Effectuated water/sediment quality monitoring parameter(s)
Sediment basin	Reduce discharge	PI, PS, K, S, NP	Removal of sediment, pesticides bound to sediments; allow time for biodegradation of pesticides	Color, turbidity, EC, TDS, metals, short half-life pesticides, high K <sub>oc</sub> pesticides, total phosphorous
Vegetated buffers	Reduce discharge	PI, PS, K, S, NP, NN	Remove sediment, nutrients, pesticides bound to sediments, or any contaminants with low solubility	Color, turbidity, EC, TDS, metals, pesticides, nutrients
Cover crop, dormant season vegetation	Reduce discharge	K, S, NP	Remove sediment, pesticides bound to sediments, or any contaminants with low solubility; protect soils and soil nutrients for growing season	Color, turbidity, EC, TDS, metals, pesticides, nutrients
Sprayer calibration	Reduce discharge	D	Reduce potential for spray drift	All pesticides
Polyacrylamide (PAM)	Reduce discharge	PI, K, S, NP	Removes sediment from the water column, removing pesticides bound to sediments	Color, turbidity, metals, pyrethroid pesticides, total phosphorous
Dormant season field retainers	Reduce discharge	PS, S	Reduce/eliminate storm runoff	Color, turbidity, EC, TDS, copper, pyrethroid pesticides, organophosphate pesticides
Microspray and drip irrigation	Reduce water use & discharge	D,W	Increase water use efficiency, eliminate potential for spray drift	All pesticides, copper
Tail water return	Reduce water use & discharge	PI, PS, K, S, W, NP, NN	Re-use of irrigation water, eliminate discharge completely	Color, turbidity, EC, TDS, metals, all pesticides, all nutrients

**BMP Targets Code:**

D: Chemical (pesticide) drift

PS: Dormant spray pesticide storm runoff

S: Sediment runoff

NP: Nutrients: phosphorous

PI: Pesticide runoff from irrigation

K: High K<sub>oc</sub> pesticide runoff

W: Water use efficiency

NN: Nutrients: nitrate, nitrite or Kjeldhal nitrogen

## ***Management Practice Implementation***

When an exceedance(s) of water quality trigger limits (WQTLs) occur at a sample site more than once, the Coalition is required to develop a Management Plan to address those exceedances. In addition, if a single exceedance of either chlorpyrifos or diazinon (TMDL constituents) occurs the Coalition will address those exceedances in the ESJWQC Management Plan. The ESJWQC Management Plan contains goals and actions that are designed to address problems specific to a subwatershed. Performing grower outreach and encouraging the implementation of management practices are important components of the plan. The Management Plan provides a prioritization scheme and process by which management actions can be adopted. Based on this plan, growers are encouraged to adopt management practices through presentations at county and/or subwatershed meetings and in higher priority subwatersheds, through contacts on an individual grower and/or grower group basis. In some cases, Coalition representatives visit individual farms to investigate potential sources of exceedances and to personally speak with growers or applicators about practices. All the growers with whom the Coalition has met have expressed willingness to cooperate and change practices to avoid contributing to problems in the future.

The Coalition is in the process of documenting implementation of management practices in the Coalition region. This is being done by asking growers to complete a management practices survey if they operate in watersheds under Management Plans. Conversations with growers indicate that they are changing practices but often do not report the changes to the Coalition. Changing chemicals, application methods (e.g. timing of application, calibrating nozzles), or implementing structural management practices are occurring in the Coalition region but are difficult to track. Data obtained from general surveys sent to members of the Coalition have been summarized to a parcel level and a General Survey Summary Report was submitted to the Regional Board on January 30, 2009.

## **Actions Taken to Address Water Quality Impacts**

---

Monitoring of ambient surface waters is conducted by the Coalition for the purpose of characterizing discharges from agriculture. Over the long term, monitoring data provide insight on the general trends in water quality at each of the sample sites. Results from each event within a monitoring season can identify constituents, agricultural lands, crops and/or particular pesticides that need to be managed to reduce or eliminate input from agriculture. A series of actions taken to determine the potential sources of exceedances include 1) the use of PURs to identify relevant applications that occurred upstream of the sample site and within a specified time period prior to the sampling event, 2) an analysis of monitoring data to determine the potential mechanism associated with exceedances of physical and field parameters such as DO, pH, and TDS, and 3) special studies where appropriate and cost effective to determine the sources of constituents such as *E. coli* or the potential causes of exceedances such as low DO.

As follow-up to exceedances, the Coalition notified the Regional Board of all exceedances in Exceedance and Communication Reports (Table 55). In addition, the Coalition creates an annual report for members to review all exceedances to date. Results are also disseminated at grower outreach meetings and, in some cases, by personal communication when evidence such as PUR indicates the likely contributor to a detection or exceedance. The Coalition also provides growers with information on management practices to reduce storm water runoff, and discharge of irrigation water and sediments into receiving water bodies. Additional relevant management practices are presented at meetings, such as alternative products, structural changes to manage drain water or pesticide application practices for minimizing spray drift. Appendix VII includes meeting handouts and agendas.

### ***Outreach and Education***

Based on the results of the monitoring, the Coalition held workshops, meetings and presentations to provide useful information to all growers in the Coalition region. Outreach and education activities are an important component of the Coalition monitoring program. The Coalition continues to make a strong effort to provide information to growers at regular meetings, as well as at meetings conducted by the County Agricultural Commissioner, and by personal contact. Coalition presentations during the 2008 irrigation season provided members with general information, site subwatershed specific monitoring results, and management practices that have proven to be effective to reduce the discharge of pesticides to water bodies. All outreach and education activities are documented in Table 56.

In November and December of 2007, the staff from the Stanislaus County Ag Commissioner's office walked four creeks that the Coalition currently monitors: Dry Creek (Stanislaus County), Hatch Drain, Westport Drain and Prairie Flower Drain. While walking the creeks the Ag Commissioner's staff photo-documented and using GPS marked the locations where there was the possibility for direct discharge into the stream. This information was matched with member parcel information and letters were sent inviting land owners to a meeting to discuss the impacts of direct discharge. On June 18, 2008 the Coalition held a meeting at the Stanislaus

Farm Bureau to discuss the creek walks and relevant exceedances of WQTLs. ILRP compliance requirements were also discussed with growers.

A letter was sent to almond and alfalfa growers on July 1, 2008 reminding members that the 2007 irrigation exceedances of chlorpyrifos had been linked to spray drift and irrigation runoff after application. The letter encouraged growers to implement management practices affecting spray drift and irrigation runoff. The letter also included a list of chlorpyrifos exceedances in all subwatersheds during July 2007. Surveys were included in mailings to members who had not previously completed a survey.

In mid-July 2008, a mailing of the Watershed Coalition News (newsletter) went out to 6,500 growers containing an ESJWQC-sponsored article on chlorpyrifos exceedances and best management practices to reduce discharge and/or spray drift. Additional outreach occurred as Coalition Executive Director Parry Klassen was invited to give presentations on October 7, 21, 28, and November 4, 2008 at the Merced Community College Pest Management Update Course. The presentations included Coalition monitoring results, sprayer calibrations, and management of organophosphates and pyrethroids for both orchards and row crops.

A mailing was sent out to all 118 Coalition members within the Dry Creek @ Wellsford Rd site subwatershed to announce an upcoming grower meeting. Included in the mailing were a blank general survey (if outstanding) and an exceedance table for all years and seasons. The meeting with Dry Creek growers was held on November 12, 2008 at the Fruit Yard restaurant in Modesto. MLJ-LLC and Coalition representatives discussed water quality exceedances, management plan requirements and management practices to reduce agricultural discharge.

In late November, the Modesto Pesticide Applicator Professional Association Seminar, a grower and PCA meeting, took place and Coalition Executive Director Parry Klassen presented Coalition monitoring results from sites within Stanislaus County, and information on best management practices for organophosphate and pyrethroid pesticides.

The 2008 Annual Grower Meetings were held on December 16, 17, and 18 in Stanislaus, Merced, and Madera Counties, respectively. Coalition representatives and MLJ-LLC personnel discussed ESJWQC Coalition activities, 2008 monitoring results, and priority subwatershed management plans. Annual reports were available for members and general surveys were available for members to fill out at the meeting.

The Coalition also hosts a Coalition website: <http://www.esjcoalition.org/home.asp>. This website serves as a clearing house for Coalition activities and outreach on management practices. Information provided on the website functions as a useful supplement to regular grower contacts and meetings.

### ***Pest Control Advisors, Agricultural Commissioners, and Registrants***

For the Coalition to be most effective in providing recommendations on management practices that will reduce or eliminate discharge, collaboration with County Agricultural Commissioners,

PCAs and pesticide registrants is critical. During the 2008 irrigation season the Coalition worked with each of these entities as needed to follow-up on exceedances. Agricultural Commissioners from the various counties are active participants as non-voting members of the ESJWQC Board of Directors. The Stanislaus Agricultural Commissioner's office has been active in the last year with the initiation of creek walks within the Stanislaus County. Merced and Madera County Agricultural Commissioners in 2009 are planning to perform similar creek walks of waterways sampled by the Coalition in their counties.

## Activities, Events and Deliverables

---

Table 55 and Table 56 provide Coalition activities, events and deliverables that have occurred during the 2008 irrigation monitoring season. Table 55 includes the Exceedance and Communication report date (by constituent group) in association with the sample date for which the exceedance occurred (see also Appendix V). Table 56 lists Coalition activities chronologically including the activity category (Grower Notification, BMP Outreach and Education, or General Surveys), description, constituents addressed and the individual responsible for conducting the activity (see also Appendix VII).

**Table 55. Calendar of sampling events and associated deliverables for the ESJWQC relevant to the 2008 irrigation season.**

Sample Event	Sample Date	Monitoring Type	Field		Toxicity		Pesticides		Metals	
			Exceedance Report	Communication Report						
Irrigation1	4/22/2008	NM	4/23/2008	-	4/28/2008	-	5/23/2008	7/29/08	5/30/2008	8/4/08

MPM = Management Plan Monitoring; NM = Normal Monitoring (water column); SED = Sediment sampling including resampling due to toxicity; RS = Resampling due to toxicity

**Table 56. Table of ESJWQC actions and deliverables dealing with grower notification of exceedances and management practices relevant to the 2008 irrigation monitoring season.**

County	Date	Category	Description	Constituents Addressed	Who
Dry Creek, Hatch Drain, Westport Drain, and Prairie Flower Drain subwatersheds	May 12, 2008	Grower Notification	Mailing to 27 members and non-members that had drains identified announcing grower meeting on June 18, 2008 and notification that permission has been obtained to "walk the creeks" and map locations of drainage into waterways.	All Constituents	Parry Klassen
Stanislaus	June 18, 2008	BMP Outreach and Education	Grower meeting at Farm Bureau inviting all direct dischargers (identified in creek walks) in the upstream subwatershed to discuss compliance with ILRP.	All Constituents	Parry Klassen, Mike Johnson
Almond and alfalfa growers in all counties	July 1, 2008	Grower Notification	Letter sent only to members who claimed to farm almonds and/or alfalfa within subwatersheds that had chlorpyrifos during the 2007 irrigation season.	Chlorpyrifos	Parry Klassen
All	Mid-July, 2008	Grower Notification	Mailing of Watershed Coalition News (newsletter) to 6,500 growers containing ESJWQC sponsored article on chlorpyrifos exceedances and BMPs to reduce discharge and/or spray drift.	Chlorpyrifos and all applied pesticides	Parry Klassen
All	October, 2008	BMP Outreach and Education	Binder of information on BMPs sent out to all Coalition members. Developed by CURES, funded by Westside Coalition Prop 50 grant.	All Constituents	Parry Klassen
All	October 1, 2008	Grower Notification	Mailing to all Coalition members including information on the EQIP funding approaching deadline (Oct. 31) for BMP implementation.	Organophosphates, pyrethroids, and carbamates	Parry Klassen, Wayne Zipser
All	October 2, 2008	Grower Notification	Mailing to announce NRCS Funds are available.	Pesticides	Parry Klassen
Merced	October 7, 2008	BMP Outreach and Education	Merced Community College Pest Management Update Course: grower, PCA meeting to discuss Coalition results.	All Constituents	Parry Klassen
Merced	October 21, 2008	BMP Outreach and Education	Merced Community College Pest Management Update Course: grower, PCA meeting to discuss sprayer calibrations.	All Constituents	Parry Klassen

County	Date	Category	Description	Constituents Addressed	Who
Merced	October 28, 2008	BMP Outreach and Education	Merced Community College Pest Management Update Course: grower, PCA meeting to discuss organophosphates and pyrethroids relating to orchards.	Organophosphates, pyrethroids	Parry Klassen
Dry Creek @ Wellsford subwatershed	October 29, 2008	Grower Notification	Mailing to all 118 members within Dry Creek subwatershed to announce grower meeting on November 14, 2008; included cover letter, agenda, survey (if outstanding), and exceedances chart for all years and seasons.	All Constituents	Parry Klassen
Merced	November 4, 2008	BMP Outreach and Education	Merced Community College Pest Management Update Course: grower, PCA meeting to discuss organophosphates and pyrethroids relating to row crops.	Organophosphates, pyrethroids	Parry Klassen
Dry Creek @ Wellsford subwatershed	November 12, 2008	BMP Outreach and Education	Meeting with Dry Creek growers at the Fruit Yard in Modesto regarding water quality exceedances, Management Plan requirements and management practices to reduce agricultural discharge.	All Constituents	Parry Klassen, MLJ-LLC
Modesto	November 20, 2008	BMP Outreach and Education	Pesticide Applicator Professional Association grower meeting to discuss Stanislaus County coalition results, BMPs for OPs and pyrethroids.	Organophosphates, pyrethroids	Parry Klassen
All	December 3, 2008	Grower Notification	Mailing to all growers announcing a deadline extension for membership renewal and the 2008 Annual Meetings.	Organophosphates, pyrethroids	Parry Klassen
Stanislaus Area	December 16, 2008	BMP Outreach and Education	2008 Annual Growers Meeting: discussed ESJ Coalition activities, 2008 monitoring results, priority management plans specifically pesticides drive water quality challenge, and filled out BMP surveys.	All Constituents	Parry Klassen, MLJ-LLC
Merced County	December 17, 2008	BMP Outreach and Education	2008 Annual Growers Meeting: discussed ESJ Coalition activities, 2008 monitoring results, priority management plans specifically pesticides drive water quality challenge, and filled out BMP surveys.	All Constituents	Parry Klassen, MLJ-LLC
Madera County	December 18, 2008	BMP Outreach and Education	2008 Annual Growers Meeting: discussed ESJ Coalition activities, 2008 monitoring results, priority management plans specifically pesticides drive water quality challenge, and filled out BMP surveys.	All Constituents	Parry Klassen, MLJ-LLC

County	Date	Category	Description	Constituents Addressed	Who
All	January 30, 2009	General Surveys	General survey results linked to parcels and summarized in the ESJWQC General Survey Summary Report.	Not Applicable	MLJ-LLC

# Exceedance, Communication, and Evaluation Reports

---

## ***Exceedance and Communication Reports***

All Exceedance and Communication Reports are included in Appendix V. If any errors occurred in the original communication, an updated report was emailed to the Regional Board; all communications are documented in Appendix V. The following errors were not noticed until the submission of this SAMR:

1. Exceedance Report submitted on July 28, 2008 for metals, *E. coli*, nutrients and physical parameters indicated that sampling occurred on "June 17 and 24, 2008". Sampling actually occurred on June 17 and 25, 2008.
2. The Communication Report submitted on December 4, 2008 for sediment toxicity noted that sampling occurred on "August 18, 2008". Sampling actually occurred on August 28, 2008.
3. Incorrect reporting of 2 pH results (Exceedance Report submitted on June 4, 2008) and six pesticide results (Exceedance Report submitted on October 2, 2008). See *Data Interpretation* section for details (Table 27).
4. One dissolved oxygen exceedance was not reported in the Exceedance Report submitted on October 2, 2008. See *Data Interpretation* section for details (Table 28).

## ***Evaluation Reports***

Evaluation Reports were not required for exceedances experienced during the 2008 irrigation season events. Management Plans have superseded Evaluation Reports and an ESJWQC Management Plan was submitted on September 30, 2008 reviewing all exceedances up to 2008. The ESJWQC Management Plan will be updated on a yearly basis (to be submitted on April 1 of each year) to incorporate results from the previous years sampling and special studies. An updated Management Plan that will address exceedances that occurred in 2008 will be submitted on April 1, 2009.

## Conclusions and Recommendations

---

Over the 2008 irrigation season, the Coalition was able to meet its monitoring program objectives:

- Determine the concentration and load of waste in discharges to surface waters.
  - The completeness of the analytical data was sufficient to determine concentration and load for all samples collected.
  - Quality control issues were present for a small number of samples, but the batches were evaluated using all LABQA results and were determined to be acceptable.
- Evaluate compliance with existing narrative and numeric water quality triggers to determine if implementation of additional management practices is necessary to improve and/or protect water quality.
  - The data for all constituents for which criteria exist were compared to the appropriate water quality trigger.
  - Exceedances resulted in notification of the CVRWQCB within the time period specified in the MRP.
  - If samples existed in which the constituent exceeded the objective, it was determined that outreach would be performed and growers were encouraged to implement additional management practices as described in the ESJWQC Management Plan.
  - A series of meetings with growers was held in which additional management practices were presented and growers were encouraged to implement the practices to protect water quality.
- Assess the impact of water discharges from irrigated agriculture to surface water.
  - Comparisons of monitoring data with water quality trigger limits allowed a determination that several water bodies in the Coalition region were impacted by irrigated agriculture.
  - The data collected are insufficient to determine the relationship between toxicity, the presence of chemicals, and the level of biological impairment.
- Determine the degree of implementation of management practices to reduce discharge of specific wastes that impact water quality in receiving waters of the Coalition region.
  - The Coalition compiled responses from its general surveys in a General Survey Summary Report (submitted January 30, 2009).
  - The ESJWQC Management Plan describes the process by which the Coalition will track management practices.
- Determine the effectiveness of management practices and strategies to reduce discharges of wastes that impact water quality.
  - While the Coalition still does not have adequate data to evaluate the effectiveness of management practices implemented in the Coalition region, positive steps are being taken to obtain the necessary data. These steps include:
    - Obtain Coalition region-specific information on management practice effectiveness.

- Create Coalition region-specific management practice handbooks for Coalition members.
- Obtain information from growers in regards to implemented management practices and when they were implemented in high priority subwatersheds.
- Create a database to track implemented management practices.
- Link implemented management practices to changes in water quality as outlined in the Management Plan.
- The Coalition initiated development of a member/parcel/crop relational database whose goal is to enable tracking of members by parcel, TRS, and crop on a real-time basis.
  - Classifying growers by location or crop will facilitate more immediate notification of exceedances and tracking of potential sources.
  - Knowledge of current crops grown by members allows the Coalition to provide growers with crop specific management practices.

To meet the Coalition's monitoring and reporting objectives, it is necessary for the monitoring data collected during the irrigation 2008 season to meet completeness objectives as outlined in the MRP.

- Six months of irrigation season monitoring were conducted.
- Chemical testing met the Regional Board's Reporting Limit requirements.
- Discharge measurements were collected from all sites at which it was possible to collect measurements.

The monitoring program provided the following technical conclusions:

- The most common exceedances were dissolved oxygen, *E. coli*, TDS/SC, copper, chlorpyrifos, *Selenastrum* and *Hyalella* toxicity.
  - Exceedances of chlorpyrifos will trigger management plans for the Livingston Drain @ Robin Ave, Miles Creek @ Reilly Rd, South Slough @ Quinley Ave, and Westport Drain @ Vivian Ave watersheds.
  - *Selenastrum* toxicity will trigger management plans for Deadman Creek @ Highway 59, Duck Slough @ Highway 99, Hatch Drain @ Tuolumne Rd, Highline Canal @ Highway 99, Livingston Drain @ Robin Ave, Miles Creek @ Reilly Rd, Prairie Flower Drain @ Crows Landing Rd, South Slough @ Quinley Ave, and Westport Drain @ Vivian Ave.
  - *Ceriodaphnia* toxicity will trigger management plans for Silva Drain @ Meadow Rd.
  - *Hyalella* toxicity will trigger a management plan at Duck Slough @ Highway 99, Hatch Drain @ Tuolumne Rd, Highline Canal @ Lombardy Rd, and Miles Creek @ Reilly Rd.
  - Exceedances of the copper WQTL will trigger management plans for Bear Creek @ Kibby Rd, Silva Drain @ Meadow Rd, and South Slough @ Quinley Ave
  - Other exceedances triggering management plans are lead at Black Rascal Creek @ Yosemite Ave, Duck Slough @ Highway 59, Miles Creek @ Reilly Rd, and Silva Drain @ Meadow Rd, pH at Black Rascal Creek @ Yosemite Rd and Silva Drain @ Meadow

Rd, DO at Merced River @ Santa Fe Dr and Miles Creek @ Reilly Rd, *E. coli* at Livingston Drain @ Robin Rd, and ammonia at Prairie Flower Drain @ Crows Landing Rd and Silva Drain @ Meadow Rd.

- Additional exceedances of management plan constituents include:
  - Chlorpyrifos at Dry Creek @ Wellsford Road, Deadman Creek @ Highway 59, Duck Slough @ Highway 99, Highline Canal @ Highway 99, Highline Canal @ Lombardy Rd, Prairie Flower Drain @ Crows Landing Rd, Silva Drain @ Meadow Ave..
  - Diuron at Hilmar Drain @ Central Ave.
  - *Hyalella* toxicity at Duck Slough @ Gurr Rd, Highline Canal @ Highway 99, Hilmar Drain @ Central Ave, Prairie Flower Drain @ Crows Landing Rd, and Silva Drain @ Meadow Ave.
  - *Selenastrum* toxicity at Highline Canal @ Lombardy Rd and Hilmar Drain @ Central Ave.
  - Copper at Cottonwood Creek @ Rd 20, Dry Creek @ Rd 18, Duck Slough @ Highway 99, Highline Canal @ Lombardy Rd, Livingston Drain @ Robin Rd, Miles Creek @ Reilly Rd.
  - Lead at Highline Canal @ Lombardy Rd and Dry Creek @ Rd 18.
  - Arsenic at Deadman Creek @ Gurr Rd and Hatch Drain @ Tuolumne Rd.
  - Nitrate at Hilmar Drain @ Central Ave, Hilmar Drain @ Mitchell Rd, Prairie Flower Drain @ Crows Landing Rd, Prairie Flower Drain @ Morgan Rd, Westport Drain @ Vivian Rd and Hatch Drain @ Tuolumne Rd.
  - *E. coli* at Highline Canal @ Highway 99, Prairie Flower Drain @ Crows Landing Rd, Deadman Creek @ Gurr Rd, Deadman Creek @ Highway 59, Silva Drain @ Meadow Ave, Highline Canal @ Lombardy Rd, South Slough @ Quinley Rd, Westport Drain @ Vivian Ave, Hilmar Drain @ Central Ave, Black Rascal Creek @ Yosemite Rd, Cottonwood Creek @ Road 20, Dry Creek @ Road 22, Dry Creek @ Wellsford Rd, and Hatch Drain @ Tuolumne Rd.
  - pH at Dry Creek @ Road 22, Highline Canal @ Highway 99, Highline Canal @ Lombardy Rd and Livingston Drain @ Robin Rd.
  - DO at Berenda Slough along Ave 18 ½, Black Rascal Creek @ Yosemite Rd, Cottonwood Creek @ Road 20, Deadman Creek @ Gurr Rd, Deadman Creek @ Highway 59, Dry Creek @ Rd 18, Dry Creek @ Wellsford Ave, Duck Slough @ Gurr Rd, Hatch Drain @ Tuolumne Rd, Hilmar Drain @ Central Ave, Prairie Flower Drain @ Crows Landing Rd, Silva Drain @ Meadow Rd, South Slough @ Quinley Ave, and Westport Drain @ Vivian Rd.
  - TDS/SC at Duck Slough @ Gurr Rd, Hatch Drain @ Tuolumne Rd, Hilmar Drain @ Central Ave, Prairie Flower Drain @ Crows Landing Rd, and Westport Drain @ Vivian Rd.
- Cyanazine, a nonregistered product was detected in at least five samples; Highline Canal @ Highway 99, Highline Canal @ Lombardy Rd, Black Rascal Creek @ Yosemite Rd, Hatch Drain @ Tuolumne Rd, and Cottonwood Creek @ Road 20.
- Dieldrin, a nonregistered product was detected once at Deadman Creek @ Gurr Rd.
- The large numbers of additional exceedances at management plan sites suggest that the Coalition has characterized the discharge at these sites adequately.
- Of the 39 pesticides for which the Coalition analyzes, only nine were detected at concentrations that exceeded WQTLs. Six of these exceedances occurred only once

during the irrigation season. Only exceedances of the chlorpyrifos, malathion, and DDT/DDD/DDE WQTLs were observed more than once.

Outreach during the irrigation season is necessarily reduced because growers are busy with their farming operations and do not have time to attend meetings. Outreach during the 2008 irrigation season included one grower meeting and three member contacts. The single meeting held during the irrigation season involved discussions with growers who were determined to potentially discharge into the four water bodies that were the focus of the creek walks. Because of the immediate potential for discharge into the water bodies, the Coalition made the decision to contact growers during the irrigation season and request the meeting. After the group meetings during the irrigation season, the Coalition determined that individual grower contacts should be investigated as a more efficient way to discuss implementation of management practices that could affect change in water quality. The individual contacts were initiated in the Dry Creek @ Wellsford Rd site subwatershed during the winter of 2008-09 and the Coalition will await the results of the monitoring in the 2009 irrigation season to determine the effectiveness of those contacts. The three grower notifications targeted the entire Coalition, specific geographic locations within the Coalition (water bodies with creek walk data), and specific commodities (alfalfa and almonds) in an attempt to maximize the efficiency of the outreach. Despite the notifications, additional exceedances occurred in these regions and most probably from applications to these commodities. Again, these results suggest that individual grower contacts will be more effective in convincing growers to change/augment management practices on their farming operation. However, it also indicates that changing practices could be a long process. If each grower must be contacted individually and provided with information implicating them as contributors to exceedances, the process of individual contacts could be slow.

Conclusions from these results are:

- The outreach strategy used to date has not been as effective as necessary to reduce exceedances of WQTLs. Exceedances from many of the manageable pesticide applications such as chlorpyrifos and copper have not been eliminated, and toxicity to *Selenastrum* and *Hyaella* remain common.
- The problematic constituents from past year's monitoring remain the primary exceedances experienced in the Coalition region.
- Dairies may play a larger role in causing exceedances of numerous constituents than previously thought.

The Coalition performed several analyses during the preparation of the Management Plan submitted during the fall of 2008. These analyses were designed to determine the potential sources (parcels) and potential methods of application that resulted in exceedances of WQTLs. These analyses will not be reviewed here but generally:

- Greatly elevated concentrations of soluble chemicals such as chlorpyrifos are most likely the result of irrigation return flows, concentrations slightly over the WQTL most likely are the result of spray drift.

- Increased concentrations of soluble chemicals such as chlorpyrifos generally are associated with increased applications in watersheds indicating that elevated concentrations are the result of numerous growers and/or large acreages contributing to the exceedance.
- Using these results, individual growers along water bodies can be contacted and the appropriate management practices discussed to more effectively target outreach.
- Sufficient data now exist to target specific crops and specific times of the year to focus outreach.
- It is unlikely that additional Management Plan monitoring will be helpful in providing the Coalition with information critical to discussions with growers. Discharges in priority watersheds have been characterized sufficiently and growers identified for outreach such that additional monitoring will not be cost effective.

During the 2008 irrigation season the Coalition finished the development of the baseline survey of management practices currently used in the Coalition region. The results were summarized and provided to the CVRWQCB on January 31, 2009. These results will allow the Coalition to track new practices implemented over the next several years.

### ***Recommendations***

Based on the results of the monitoring and outreach efforts during the 2008 irrigation season, the Coalition makes the following recommendations:

- Although large group notifications and meetings are the only way to fulfill MRP requirements that growers must be notified of exceedances, they do not serve as a process by which the Coalition can track the adoption of new management practices. Large group notifications and meetings should continue as a means of educating growers about Coalition monitoring results.
- Creek walks should occur in Merced and Madera Counties as a means of identifying drains that serve as potential sources of exceedances along the water bodies in those areas.
- Growers in all high priority watersheds should be identified for individual contacts.
- Although continued monitoring will be conducted, intensive monitoring in all watersheds will not provide sufficient information to justify the expense. New monitoring results have not revealed any additional problems and have not always provided sufficient information to identify the sources of the exceedances. Additional management plan monitoring should be evaluated on a case by case basis to determine if the monitoring effort should be reduced.
- It is important for the Coalition to focus on tracking implementation of new management practices and identifying locations where adoption of additional practices are lagging. These high risk areas should be targeted for additional outreach efforts.

**Table I - 2. ESJWQC environmental sample results for organic analysis.**

Samples are sorted by station name, analyte, and sample date.

Station Name	Sample Type Code	Sample Date	Sample Time	Method Name	Analyte	Result	Unit	Qualifier Code	MDL	RL	Expected Value	Quality Assurance	Data Acceptability Criteria	Lab Comments
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8321A	Aldicarb	<0.2	µg/L	ND	0.2	0.4		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 619	Atrazine	<0.07	µg/L	ND	0.07	0.5		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8141A	Azinphos methyl	<0.02	µg/L	ND	0.02	0.1		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8321A	Carbaryl	<0.05	µg/L	ND	0.05	0.07		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8321A	Carbofuran	<0.05	µg/L	ND	0.05	0.07		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8141A	Chlorpyrifos	<0.003	µg/L	ND	0.003	0.02		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 619	Cyanazine	<0.09	µg/L	ND	0.09	0.5		None		
Bear Creek @ Kibby Rd	E	4/29/08	16:20	EPA 8081A	DDD (p,p')	<0.003	µg/L	ND	0.003	0.01		None

**Table I - 4. ESJWQC water toxicity testing results.**

Results for *Ceriodaphnia dubia*, *Pimephales promelas* and *Selenastrum capricornutum* samples collected during the 2008 irrigation season. Re-samples (RS) were collected within 72 hrs of being notified that the original sample was toxic. Toxicity tests are initiated within 36 hours of sampling. Data are sorted by station name, species and sample date.

Station Name	Sample Type Code	Sample Date	Sample Time	Matrix	Toxicity Start Date	Species	Toxicity End Point	Control Mean	Sample Mean	Percent Control	Toxicity Significance	Toxicity Test Comments

**Table I - 5. ESJWQC sediment toxicity testing results.**

Results for *Hyalella azteca* samples collected during the 2008 irrigation season. Re-samples (RS) were collected within 7 days of being notified that the original sample was toxic. Toxicity tests are initiated within 14 days of sampling. Data are sorted by station name, species and sample date.

Station Name	Sample Type Code	Sample Date	Sample Time	Matrix	Toxicity Start Date	Species	Toxicity End Point	Control Mean	Sample Mean	Percent Control	Toxicity Significance	Toxicity Test Comments

### ESJWQC COC anomalies

Anomaly descriptions include date sampled, affected laboratory, affected sites, a brief description of anomaly and corrective action.

Sample Date	APPL	Caltest	NCL	AQUA-Science	Site IDs Affected	Description	Resolution	Resolution Date
08/19/08	X				535XDCWF	Sample labels and COC listed sample ID as 535XDCAWF-GR	Samples logged in at lab as 535XDCWF-GR, COC changed to match	8/20/08
