R0074226

VII.C. Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VII.C.1. Review of Major Cases

As indicated in EPA's *Enforcement Accomplishments Report, FY1995 and FY1996* publications, about 17 significant enforcement actions were resolved between 1995 and 1996 for the Fertilizer, Pesticide, and Agricultural Chemical Industry.

American Cyanamid Company On June 28, 1995, Region II issued an administrative complaint against American Cyanamid Company for violations at its Lederle Laboratories facility located in Pearl River, New York. The complaint proposed assessment of a $272,424 fine for the company's failure to submit timely TRI Form Rs for 1,1,1-trichloroethane, naphthalene, phosphoric acid, toluene, manganese compounds and zinc compounds for the reporting years 1990, 1991, 1992, and 1993.

Precision Generators, Inc. The Regional Administrator signed a consent order in the *Precision Generators, Inc.*, a FIFRA case, in which the respondent agreed to pay the proposed penalty of $4,000. The administrative complaint cited the respondent's sale and misbranding of its unregistered pesticide product ethylene fluid used to accelerate the ripening of fruits and vegetables. Such a product is a "plant regulator" falling within the definition of "pesticide" in FIFRA.

E.C. Geiger, Inc. On August 18, 1995, the Regional Administrator signed a consent agreement and consent order finalizing settlement of the administrative proceeding against E.C. Geiger, Inc. of Harleysville, Pennsylvania, for violations of sections 12(a)(1)(A) and (B) of FIFRA, 7 U.S.C. section 136j(a)(1)(A) and (B). The complaint alleged that during 1992, Geiger sold or distributed an unregistered and misbranded pesticide product, a rooting hormone called "Indole-3-butyric Acid-Horticultural Grade." For these violations the complaint sought a $14,000 penalty. Geiger has agreed to pay a penalty of $8,900.

Rhone-Poulenc, Inc. Region III reached a settlement with Rhone-Poulenc, Inc., in a Part II administrative action brought for violations of RCRA boiler and industrial furnace (BIF) regulations at Rhone-Poulenc's Institute, West Virginia plant. The settlement calls for Rhone-Poulenc to pay a penalty of over $244,000 and to undertake numerous compliance tasks.

IMC-Agrico Company On November 8, 1994, the Regional Administrator ratified a consent decree between the United States and IMC-Agrico Company concerning IMC's violations of section 301(a) of the CWA. IMC owns and operates phosphate rock mines and associated processing facilities in Florida and Louisiana. Eight of its mineral extraction operations located throughout Florida and its Port Sutton Phosphate Terminal located in Tampa, Florida, were the subject of this referral. The action arose out of IMC's violation of its permit effluent limits for a variety of parameters including dissolved oxygen, suspended solids, ammonia, and phosphorous, as well as non-reporting and stormwater violations at the various facilities-over 1,500 permit violations total. The case was initiated following review of the facility discharge monitoring reports and EPA and state inspections of the sites. The consent decree settlement involved an up-front payment of $835,000 and a $265,000 Supplemental Environmental Project (SEP). The pollution prevention SEP involved converting IMC's scrubber discharge and intake water systems into a closed loop system, greatly reducing pollution loading at the Port Sutton facility, by April 1995.

J.T. Eaton & Company, Inc. J.T. Eaton & Company, Inc. distributed and sold at least 13 unregistered pesticides (mostly rodenticides). These unregistered pesticides resulted from varying the form of the rodent bait and the packaging of several of Eaton's registered products (e.g., registered as a bulk product) but sold in ready-to-use place packs. The company also distributed and sold a misbranded pesticide product and made inaccurate claims in advertising for another product. A stop sale, use, or removal order and an administrative complaint were issued simultaneously on March 23, 1995. The penalty assessed in the complaint was $67,500. The complaint was settled on August 25, 1995, for $40,000.

Citizens Elevator Co., Inc. Citizens Elevator Co. repackaged and distributed and sold the pesticide "Preview" in five gallon buckets, many bearing pie filling labels, to at least 24 customers, constituting the distribution and sale of an unregistered pesticide. The complaint, issued June 30, 1994, assessed a penalty of $108,000. In supplemental environmental projects for the prevention of spills of pesticides and fertilizers and the safer, more efficient storage and application of pesticides and fertilizer. The respondent spent $184,771. A consent agreement signed June 30, 1995, settled the case for $8,400.

Nitrogen Products, Inc. On September 25, 1995, a joint stipulation and order of dismissal was filed in the United States District Court for the Eastern District of Arkansas. Nitrogen Products, Inc. (NPI), agreed to pay a civil penalty of $243,600 to the United States for violations of the Clean Air Act, and Subparts A and R of 40 CFR Part 61. The foreign parent corporation, Internationale Nederlanden Bank, N.V., acquired the facility through foreclosure and expended over $2 million to cover the phosphogypsum stack and regrade.

Micro Chemical, Inc. The illegal transportation of hazardous waste by a Louisiana pesticide formulation company, Micro Chemical, Inc., to an unpermitted disposal facility in violation of RCRA resulted in a $500,000 fine. five years of probation, and compliance with corrective action measures contained in a corrective action administrative order on consent. In March 1990. Micro Chemical transported 100 cubic yards of hazardous waste from its facility to a field in Baskin, Louisiana-a location that did not have a RCRA permit. After its discovery, it was removed under the Louisiana Department of Agriculture's guidance. Micro Chemical has taken measures to stabilize and prevent the spread of pesticide contamination from the Micro Chemical facility site, as required by a RCRA 3008(h) corrective action administrative order on consent. The order will result in the removal of all contaminated soil at the site, and the remediation of all off-site contamination that has migrated into a drainage basin located adjacent to the site.

Chempace Corporation On September 26, 1996, Region V PTES filed a civil administrative complaint against Chempace corporation of Toledo, Ohio alleging 99 counts for the distribution or sale of unregistered and misbranded pesticides, and pesticide production in unregistered establishments. The total proposed penalty in the complaint is $200,000. The case is significant in that Chempace had, previous to the complaint, canceled all of the company's pesticide product registrations pursuant to section 4 of FIFRA, as well as their establishment registration pursuant to section 7. However, the company continued to produce and sell those canceled pesticides in a facility that was not registered.

Northrup King Co. On September 30, 1996, as a result of a FIFRA inspection conducted by Region V on March 27-28, 1996, Region V issued a FIFRA civil complaint to Northrup King Co. of Golden Valley, Minnesota. The pesticide involved in the case is a genetically engineered corn seed that protects against the corn borer. Because this case is the first FIFRA complaint involving a genetically engineered pesticide, the case is nationally significant. The complaint alleged 21 counts of sale and distribution of an unregistered pesticide, 21 counts for failure to file a Notice of Arrival for pesticide imports, and 8 counts of pesticide production in unregistered establishments, for a total proposed penalty of $206,500. A consent agreement and consent order was filed simultaneously with, and in resolution of the complaint. The respondent agreed to pay $165,200, which is the largest penalty collected by Region V under FIFRA.

Micro Chemical. Micro Chemical is a pesticide formulating, mixing, and packaging facility 3,000 feet up gradient of the Winnsboro's groundwater well complex. In March 1990, a release from the facility was reported by a citizen. Investigations revealed that the company had attempted to dump 100 cubic yards of pesticide contaminated soil offsite. People living near the dump site became ill from the fumes and the state ordered the soil to be returned to Micro Chemical. Ultimately a criminal case was initiated for the midnight dumping. Other storage violations detected were the subject of an administrative complaint issued in September 1992. A RCRA 3008(h) order on consent was entered into on September 1994 to remediate the site. In resolving the September 1992 complaint, a final order was issued on March 28, 1996. Micro Chemical agreed to pay a penalty of $25,000 and agreed to fund a SEP valued at $25,000. The SEP established collection events for household waste and waste pesticides in the Franklin Parish area. During FY96, the SEP enabled about 100 tons of waste to be collected and properly disposed.

Terra Industries, Inc. At the request of the Chemical Emergency Prevention and Preparedness Office (CEPPO), and in accordance with section 112(r) of the CAA, EPA released the results of its investigation into the cause of an explosion of the ammonium nitrate plant at this nitrogen fertilizer manufacturing facility. The report released in January 1996 identifies numerous unsafe operating procedures at the plant as contributing factors to the explosion, and recommends certain standard operating procedures which would help prevent similar occurrences at ammonium nitrate production facilities.

The Terra explosion occurred on December 13, 1994, killing four individuals and injuring 18 others. It also resulted in the release of approximately 5,700 tons of anhydrous ammonia to the air and approximately 25,000 gallons of nitric acid to the ground and required evacuation over a two-state area of over 2,500 persons from their homes.

In a subsequent action, an administrative civil complaint alleging violations of EPCRA sections 213 and 313, and section 8(a) of TSCA, was filed citing that Terra International failed to submit Toxic Release Inventory (TRI) information to EPA in a timely manner, and data submitted to EPA by Terra failed to include releases of more than 17 million pounds of toxic chemicals to the environment on-site.

Pfizer/AgrEvo Reporting of unreasonable adverse effects information is required under FIFRA section 6(a)(2), and failure to submit such reports has resulted in a $192,000 settlement involving AgrEvo Environmental Health, Inc. and Pfizer, Inc. The case arose in early 1994 after an individual reported disabling neurological symptoms and chemical sensitivity after using RID products to kill lice. The ensuing EPA investigation revealed numerous additional unreported incidents involving RID which is manufactured by AgrEvo and distributed by Pfizer. EPA amended the complaint charging 24 counts against each company. FIFRA 6(a)(2) requires pesticide registrants to submit to EPA any additional information (beyond that submitted in the pesticide registration process) that they have regarding unreasonable adverse effects of their pesticides on human health or the environment. The information is used by the Agency in the determination of risks associated with pesticides.

Rohm and Haas Company This complaint cited Rohm and Haas for 66 violations under FIFRA section 12(a)(1)(c), for the distribution or sale of a registered pesticide the composition of which differed from the composition as described in its registration under FIFRA section 3. EPA registers pesticides based upon the accurate assessment of components used in the manufacture of the product. Use of an unapproved formula can lead to production of a pesticide for which no assessment of risk has been determined or result in unknown synergistic effects. Following settlement negotiations, and in accordance with the FIFRA Enforcement Response Policy, the original penalty of $330,000 was reduced to $118,800, based on a 20% reduction to the gravity level, a 40% reduction for immediate self-disclosure, mitigation, and corrective actions, and a 15% reduction for good attitude, cooperation, and efforts to comply with FIFRA.

VII.C.2. Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the Internet at http://es.epa.gov/oeca/sep.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Activities

National Agricultural Compliance Assistance Center (Ag Center)

EPA's Office of Compliance, with the support from the United States Department of Agriculture (USDA), developed EPA's National Agriculture Compliance Assistance Center (Ag Center). The Ag Center offers comprehensive, easy-to-understand information about approaches to compliance that are both environmentally protective and agriculturally sound.

The Ag Center focuses on providing information about EPA's own requirements. In doing so, the center relies heavily on existing sources of agricultural information and established distribution channels. Educational and technical information on agricultural production is provided by the USDA and other agencies, but assistance in complying with environmental requirements has not traditionally been as readily available. The Ag Center is currently working with USDA and other federal and state agencies to provide the agricultural community, including regional and state regulatory agencies, with a definitive source for federal environmental compliance information. The Ag Center offers information on a variety of topics, including the following:

- Pesticides
- Animal waste management
- Emergency planning and response
- Groundwater and surface water
- Tanks / containment
- Solid / hazardous waste

Through a toll-free telephone number and a website that is regularly updated and expanded, the Ag Center offers a variety of resources including:

- current news, compliance policies and guidelines, pollution prevention information, sources of additional information and expertise, and summaries of regulatory initiatives and requirements

- user-friendly materials that consolidate information about compliance requirements, pollution prevention, and technical assistance resources for use by regional and state assistance and educational programs, trade associations, businesses, citizens, and local governments

- agriculture-related information on reducing pollution and using the latest pollution prevention methods and technologies

- information on ways to reduce the costs of meeting environmental requirements, including identification of barriers to compliance

The Ag Center's toll-free number is 1-888-663-2155 and the website address is: http://es.epa.gov/oeca/ag/

National Pesticide Information Retrieval System (NPIRS)

Purdue University has developed a collection of databases through their Center for Environmental and Regulatory Information Systems, one of which is the National Pesticide Information Retrieval System. NPIRS is a collection of six databases related to pesticides, including product registration document information, data submitter information, residue tolerances, fact sheets, material safety data sheets, and the daily federal register. Full search access to the NPIRS databases is by annual subscription.

Association of American Plant Food Control Officials (AAPFCO) Label Recommendations

The AAPFCO is considering a set of recommendations issued by a task force of fertilizer producers and state officials. These recommendations call for labeling and standards for non-nutrient constituents in fertilizer and directions that will allow users to apply fertilizers at a rate that will not exceed these standards. One proposed addition to labels is to list all raw materials, including recycled wastes; however, the concentration of these materials will not be required (ARA, 1997).

Agricultural Research Institute

ARI was founded in 1951 as a part of the National Academy of Sciences, then incorporated separately in 1973. ARI analyzes agricultural problems and promotes research by its members to solve them. ARI publishes annual meeting minutes, a directory, books, pamphlets, and newsletters.

National Association of State Departments of Agriculture (NASDA)

NASDA was founded in 1916 by directors of state and territorial departments of agriculture to coordinate policies, procedures, laws, and activities between the states and federal agencies and Congress. NASDA conducts research, holds a trade show, and distributes several bulletins, newsletters, and directories.

ChemAlliance

EPA's Office of Compliance developed ChemAlliance, a new Compliance Assistance Center for the chemical industry. Among its features is an exciting "expert help," which offers an interactive guide to finding compliance resources specific to a user's needs. Take a "virtual plant tour" to find out which regulations apply to your company's operations by clicking on a detailed chemical plant illustration. ChemAlliance can be reached at 1-800-672-6048; its web site is located at . *http://www.chemalliance.org,*

VIII.B. EPA Voluntary Programs

Pesticide Environmental Stewardship Program (PESP)

The Pesticide Environmental Stewardship Program (PESP) is a broad effort by EPA, USDA, and the FDA to reduce pesticide use and risk in both agriculture and nonagricultural settings. In September 1993, the three agencies announced a federal commitment to two major goals: 1) developing specific use/risk reduction strategies that include reliance on biological pesticides and other approaches to pest control that are thought to be safer than traditional chemical methods, and 2) by the year 2000, having 75 percent of United States agricultural acreage adopt integrated pest management programs.

A key part of the PESP is the public/private partnership which began when EPA, USDA, and FDA announced the partnership and more than 20 private organizations signed on as charter members. All organizations with a commitment to pesticide use/risk reduction are eligible to join the PESP, either as Partners or Supporters. The PESP program has 35 partners. Together, these partners represent at least 45,000 pesticide users. The program has a goal of adding 35 new partners per year.

33/50 Program

The 33/50 Program is a ground breaking program that has focused on reducing pollution from seventeen high-priority chemicals through voluntary partnerships with industry. The program's name stems from its goals: a 33% reduction in toxic releases by 1992, and a 50% reduction by 1995, against a baseline of 1.5 billion pounds of releases and transfers in 1988. The results have been impressive: 1,300 companies have joined the 33/50 Program (representing over 6,000 facilities) and have reached the national targets a year ahead of schedule. The 33% goal was reached in 1991, and the 50% goal -- a reduction of 745 million pounds of toxic wastes -- was reached in 1994. The 33/50 Program can provide case studies on many of the corporate accomplishments in reducing waste (Contact 33/50 Program Director David Sarokin -- 202-260-6396).

Table 30 lists those companies participating in the 33/50 program that reported the

R0074234

SIC codes 2873, 2874, 2875, and 2879 to TRI. Some of the companies shown also listed facilities that are not producing agricultural chemicals. The number of facilities within each company that are participating in the 33/50 program and that report SIC codes 2873, 2874, 2875, and 2879 is shown. Where available and quantifiable against 1988 releases and transfers, each company's 33/50 goals for 1995 and the actual total releases and transfers and percent reduction between 1988 and 1995 are presented. Eleven of the seventeen target chemicals were reported to TRI by agricultural chemical facilities in 1995.

Table 30 shows that 24 companies comprised of 78 facilities reporting SIC 287 participated in the 33/50 program. For those companies shown with more than one agricultural chemical facility, all facilities may not have participated in 33/50. The 33/50 goals shown for companies with multiple facilities, however, were company-wide, potentially aggregating more than one facility and facilities not carrying out agricultural chemical operations. In addition to company-wide goals, individual facilities within a company may have had their own 33/50 goals or may have been specifically listed as not participating in the 33/50 program. Since the actual percent reductions shown in the last column apply to only the companies' agricultural chemical facilities, direct comparisons to those company goals incorporating non-agricultural chemical facilities or excluding certain facilities may not be possible. For information on specific facilities participating in 33/50, contact David Sarokin (202-260-6907) at the 33/50 Program Office.

Table 30: Fertilizer, Pesticide, and Agricultural Chemical Industry Participation in the 33/50 Program

Parent Company (Headquarters Location)	Company-Owned Facilities Reporting 33/50 Chemicals	Company-Wide % Reduction Goal[1] (1988 to 1995)	1988 TRI Releases and Transfers of 33/50 Chemicals (pounds)[2]	1995 TRI Releases and Transfers of 33/50 Chemicals (pounds)[2]	% of Change per Facility (1988-1995)

1 Company-Wide Reduction Goals aggregate all company-owned facilities which may include facilities not producing agricultural chemicals.

2 Releases and Transfers are from facilities only. 1995 33/50 TRI data were not available at time of publication.

* = Reduction goal not quantifiable against 1988 TRI data. ** = Use reduction goal only. *** = No numeric reduction goal.

R0074236

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups.

There have been at least two Project XL proposals relating to fertilizer production, however both of these have been either rejected or withdrawn. PCS Nitrogen (formerly Arcadian Fertilizer) had proposed to reuse stockpiled phosphogypsum as an ingredient in a soil enhancer. Another proposal by Dow Chemical Company in Louisiana was to trade off equipment leak reductions for relief from some emissions control, monitoring, reporting and record-keeping requirements.

EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline 202-260-8590, Web: http://www.epa.gov/ProjectXL, or Christopher Knopes at EPA's Office of Policy, Planning and Evaluation 202-260-9298)

Climate Wise Program

EPA's ENERGY STAR Buildings Program is a voluntary, profit-based program designed to improve the energy-efficiency in commercial and industrial buildings. Expanding the successful Green Lights Program, ENERGY STAR Buildings was launched in 1995. This program relies on a 5-stage strategy designed to maximize energy savings thereby lowering energy bills, improving occupant comfort, and preventing pollution -- all at the same time. If implemented in every commercial and industrial building in the United States, ENERGY STAR Buildings could cut the nation's energy bill by up to $25 billion and prevent up to 35% of carbon dioxide emissions. (This is equivalent to taking 60 million cars of the road). ENERGY STAR Buildings participants include corporations; small and medium sized businesses; local, federal and state governments; non-profit groups; schools; universities; and health care facilities. EPA provides technical and non-technical support including software, workshops, manuals, communication tools, and an information hotline.

EPA's Office of Air and Radiation manages the operation of the ENERGY STAR Buildings Program. (Contact: Green Light/Energy Star Hotline at 1-888-STAR-YES or Maria Tikoff Vargas, EPA Program Director at 202-233-9178 or visit the ENERGY STAR Buildings Program website at http://www.epa.gov/appdstar/buildings/)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging United States institutions to use energy-efficient lighting technologies. The program saves money for businesses and organizations and creates a cleaner environment by reducing pollutants released into the atmosphere. The program has over 2,345 participants which include major corporations, small and medium sized businesses, federal, state and local governments, non-profit groups, schools, universities, and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. As of March 1997, participants had lowered their electric bills by $289 million annually. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and an information hotline. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Green Light/Energy Star Hotline at 1-888-STARYES or Maria Tikoff Vargar, EPA Program Director, at 202-233-9178)

WasteWiSe Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1997, the program had about 500 companies as members, one third of whom are Fortune 1000 corporations. Members agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports. To member companies, EPA, in turn, provides technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne Oxley, EPA Program Manager, 703-308-0199)

NICE³

The United States Department of Energy is administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE³). By providing grants of up to 45 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, and demonstrate new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the forest products, chemicals, petroleum refining, steel, aluminum, metal casting and glass manufacturing sectors. (Contact: http//www.oit.doe.gov/access/ nice3, Chris Sifri, DOE, 303-275-4723 or Eric Hass, DOE, 303-275-4728)

Design for the Environment (DfE)

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202)-260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at http://es.inel.gov/dfe.

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. State Advisory Groups

Association of American Pesticide Control Officials (AAPCO)
P.O. Box 1249 Members: 55
Hardwick, VT 05843 Staff: 1
Phone: 802-472-6956
Fax: 802-472-6957
E-mail: aapco@plainfield.bypass.com

Formed in 1947, the Association of American Pesticide Control Officials (AAPCO) consists of state and federal pesticide regulatory officials. All federal and provincial Canadian officials, officials of all North American countries involved with the regulation of pesticides may be members of AAPCO as well. AAPCO holds meetings twice a year and publishes an annual handbook that contains uniform policies and model pesticide legislation that the association has adopted.

AAPCO aims to promote uniform and effective state legislation and pesticide regulatory programs. Its other objectives are to develop inspection procedures, to promote labeling and safe use of pesticides, to provide opportunities for members to exchange information, and to work with industry to promote the usefulness and effectiveness of pesticide products.

Members:
10 state representatives

The State FIFRA Issues Research and Evaluation Group evolved in 1978 out of a cooperative agreement between the EPA's Office of Pesticide Programs (OPP) and the Association of American Pesticide Control Officials (AAPCO). SFIREG is an independent but related body of AAPCO that provides state comments to the Office of Pesticide Programs on issues relating to the manufacture, use and disposal of pesticides. Its membership is comprised of ten state representatives, who represent and are selected by the states in each of the ten EPA Regions.

R0074240

VIII.C.2. Trade Associations

Association of American Plant Food Control Officials (AAPFCO)
University of Kentucky — Members: 200
Division of Regulatory Services
103 Regional Services Building
Lexington, KY 40546-0275
Phone: 606-257-2668
606-257-2970
Fax: 606-257-7351

The AAPFCO is an organization of state fertilizer control officials from the United States and Canada who are involved in the administration of fertilizer regulations and laws. The AAPFCO's purpose is to achieve uniformity throughout their membership with regards to promoting effective legislation, adequate sampling, accurate labeling, and safe use of fertilizers, as well as to study and discuss relevant issues.

Agricultural Retailers Association (ARA)
11701 Borman Dr., Ste. 110 — Members:1,100
St. Louis, MO 63146 — Staff: 17
Phone: 800-844-4900
Fax: 314-567-6808

The Agricultural Retailers Association was founded in 1954 and is made up of dealers, manufacturers, and suppliers of fluid fertilizers and agrichemicals, as well as equipment manufacturers, retail affiliations, and state association affiliates. ARA was formerly known as the National Nitrogen Solutions Association. Their publications include *Agricultural Retailers Association-Membership Directory and Buyer's Guide* (annual), *Connections*, a bimonthly newsletter, and the *Fluid Fertilizer Manual.*

Fertilizer Industry Round Table (FIRT)
5234 Glen Arm Rd. — Nonmembership
Glen Arm, MD 21057
Phone: 410-592-6271
Fax: 410-592-5796

The Fertilizer Industry Round Table was founded in 1951. Participants include production, technical, and research personnel in the fertilizer industry. FIRT acts as a forum for discussion of technical and production problems. They hold an annual meeting and publish the proceedings.

R0074241

The Fertilizer Institute (TFI)
501 2nd St., NE
Washington, DC 20002
Phone: 202-675-8250
Fax: 202-544-8123

Members: 300
Staff: 22

The Fertilizer Institute was founded in 1970 and now has 48 affiliated groups. Members include producers, manufacturers, retailers, trading firms, and equipment manufacturers. TFI represents members in various legislative, educational, and technical areas, and provides information and public relations programs. Publications include: *Directory of Fertilizer References*, annual; *Fertilizer Facts and Figures*, annual; *Fertilizer Institute--Action Letter*, monthly; *Fertilizer Record*, periodic.

Chemical Manufacturers Association (CMA)
1300 Wilson Blvd.
Arlington, VA 22209
Phone: 703-741-5000
Fax: 703-741-6000

Members: 185
Staff: 280

The Chemical Manufacturers Association was founded in 1872 and now has a budget of $36 million. CMA conducts advocacy and administers research areas of broad import to chemical manufacturing, such as pollution prevention and other special research programs. CMA also conducts committee studies, operates the Chemical Emergency Center (CHEMTREC) for guidance to emergency service on handling emergencies involving chemicals and the Chemical Reference Center which offers health and safety information about chemicals to the public. Publications include semi-monthly newsletters, *ChemEcology* and *CMA News*, and the *CMA Directory and User's Guide.*

Chemical Specialties Manufacturers Association (CSMA)
1913 Eye St., NW
Washington, DC 20006
Phone: 202-872-8110
Fax: 202-872-8114

Members: 425
Staff: 31

The Chemical Specialties Manufacturers Association was founded in 1914 and is made up of manufacturers, marketers, formulators, and suppliers of household, industrial, and personal care chemical specialty products such as pesticides, cleaning products, disinfectants, sanitizers, and polishes. CSMA serves as a liaison to federal and state agencies and public representatives, provides information and sponsors seminars on governmental activities and scientific developments.

American Crop Protection Association (ACPA)
1156 15th St., NW, Ste. 400 Members: 82
Washington, DC 20005 Staff: 29
Phone: 202-296-1585
Fax: 202-463-0474

The American Crop Protection Association was founded in 1933 and now has a budget of $7 million. Members include companies involved in producing or formulating agricultural chemical products including agricultural fumigants, agricultural scalicides, chemical plant sprays and dusts, defoliants, soil disinfectants, weed killers, and others. It is comprised of legislative, regulatory and science departments and publishes a periodic bulletin, manuals, *Growing Possibilities*, quarterly, and *This Week and Next*, weekly.

Western Crop Protection Association (WCPA)
3835 N. Freeway Blvd. Ste. 140 Members: 170
Sacramento, CA 95834 Staff: 6
Phone: 916-568-3660
Fax: 916-565-0113

The WCPA is a regional organization of manufacturers, formulators, distributors, and dealers of basic pesticide chemicals and suppliers of solvents, diluents, emulsifiers, and containers. They are affiliated with the American Crop Protection Association. They publish several bulletins and periodicals.

National Pest Control Association (NPCA)
8100 Oak St. Members: 2,300
Dunn Loring, VA 22027 Staff: 21
Phone: 703-573-8330
Fax: 703-573-4116

The National Pest Control Association was founded in 1933 and now has a budget of $2.8 million. Members include companies engaged in control of insects, rodents, birds, and other pests. NPCA provides advisory services on control procedures, new products, and safety and business administration practices. NPCA sponsors research at several universities, furnishes technical information and advice to standards and code writing groups, and maintains an extensive library on pests. NPCA publishes many titles including manuals, newsletters, membership guides, technical releases, and reports.

International Fertilizer Development Center (IFDC)
PO Box 2040 Nonmembership
Muscle Shoals, AL 35662 Staff: 180
Phone: 205-381-6600
Fax: 205-381-7408

The International Fertilizer Development Center was founded in 1974 and includes participants such as scientists, engineers, economists and specialists in market research and development and communications. IFDC uses a $13.5 million budget to try to alleviate world hunger by increasing agricultural production in the tropics and subtropics through development of improved fertilizers. IFDC sponsors and conducts studies in fertilizer efficiencies and offers courses on fertilizer production, environmental issues, and crop sustainability. They maintain greenhouses and laboratories, and publish several periodicals and manuals.

United Products Formulators and Distributors Association(UPFDA)
1 Executive Concourse No. 103 Members: 102
Duluth, GA 30136 Staff: 1
Phone: 404-623-8721
Fax: 404-623-1714

The United Products Formulators and Distributors Association was founded in 1968 and is made up of companies engaged in formulating and distributing pesticide products. The UPFDA works to solve problems of member companies and promote sound and beneficial legislation and to cooperate with allied industries.

North American Horticultural Supply Association (NAHSA)
1790 Arch St. Members: 135
Philadelphia, PA 19103 Staff: 3
Phone: 215-564-3484
Fax: 215-564-2175

The North American Horticultural Supply Association was founded in 1988 and represents horticultural supplies such as greenhouse building materials and supplies, pesticides, and fertilizers. The NAHSA works to strengthen and enhance the relationship between manufacturers and distributors and promotes distribution in the market. They publish a quarterly newsletter, *NAHSA News*, and an annual *Industry Calendar*.

American Agricultural Economics Association (AAEA)
1110 Buckeye Ave. Members: 4,500
Ames, IA 50010-8063 Staff: 6
Phone: 515-233-3202
Fax: 515-233-3101

The American Agricultural Economics Association, founded in 1910, is a professional society of state, federal, and industrial agricultural economists, teachers, and extension workers. The AAEA works to further knowledge of agricultural economics through scientific research, instruction, publications, meetings, and other activities. They publish a bimonthly newsletter, a semi-bimonthly *American Journal of Agricultural Economics*, a quarterly magazine *Choices*, and a biennial *Handbook Directory*.

Institute for Agriculture and Trade Policy (IATP)
1313 5th St., SE, No. 303
Minneapolis, MN 55414
Phone: 612-379-5980
Fax: 612-379-5982

The IATP was founded in 1986 and has an annual budget of $1.15 million. They maintain a speakers bureau and conduct research programs on trade agriculture, global institutions, North-South relations, and the Third World. They publish several periodical bulletins.

California Fertilizers Association (CFA)
1700 I St., Ste. 130
Sacramento, CA 95814
Phone: 916-441-1584
Fax: 916-441-2569

The CFA represents fertilizer manufacturers, distributors, wholesalers, and retail dealers that sell products within California. They maintain a legislative hotline and publish studies and handbooks on issues pertaining to fertilizers.

American Society of Agronomy (ASA)
677 S. Segoe Rd.
Madison, WI 53711
Phone: 608-273-8080
Fax: (608) 273-2021

Members: 12,500
Staff: 30

The ASA was founded in 1907 and presently operates on a budget of 2.5 million dollars per year. ASA is a professional society of plant breeders, soil scientists, chemists, educators, technicians, and other concerned with crop production and soil management. ASA sponsors fellowship programs and provides placement service. ASA publishes annual, bimonthly, and monthly periodicals as well as special publications.

Potash and Phosphate Institute (PPI)
655 Engineering Drive No. 110
Norcross, GA 30092
Phone: 770-447-0335
Fax: 770-448-0439

Members: 14
Staff: 30

PPI supports scientific research in the areas of soil fertility, soil testing, plant analysis, and tissue testing. PPI participates in farmers meetings, workshops, and training courses and publish a quarterly magazine, *Better Crops with Plant Food.*

GENERAL INFORMATION

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by GeoLogics Corporation (Alexandria, VA), Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). A listing of available Sector Notebooks is included on the following page.

Obtaining copies:

Electronic versions of all sector notebooks are available via Internet on the EnviroSenSe World Wide Web at **www.epa.gov/oeca/sector**. EnviroSenSe is a free, public, environmental exchange system operated by EPA's Office of Enforcement and Compliance Assurance and Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization. Direct technical questions to the "Feedback" button on the bottom of the web page.

Purchase printed bound copies from the **Government Printing Office (GPO)** by consulting the order form at the back of this document or order via the Internet by visiting the on-line GPO Sales Product Catalog at **http://orders.access.gpo.gov/su_docs/sale/prf/prf.html**. Search using the exact title of the document "Profile of the XXXX Industry" or simply "Sector Notebook." When ordering, use the GPO document number found on the order form at the back of this document.

Complimentary volumes are available to certain groups or subscribers, including public and academic libraries; federal, state, tribal, and local governments; and the media from EPA's National Service Center for Environmental Publications at **(800) 490-9198.** When ordering, use the EPA publication number found on the following page.

The Sector Notebooks were developed by the EPA's Office of Compliance. Direct general questions about the Sector Notebook Project to:

Seth Heminway, Coordinator, Sector Notebook Project
US EPA Office of Compliance

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution (such as economic sector, and community-based approaches) are becoming an important supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these interrelationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies addressing all media for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach by the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several interrelated topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above alone could be the subject of a lengthy volume. However, to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be explored further based upon the references listed at the end of this profile. As a check on the information included, each notebook went through an external document review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be sent via the web page.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the relative national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or repackage the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers also may want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks, please contact the Office of Compliance at 202-564-2310.

II. INTRODUCTION TO THE AGRICULTURAL PRODUCTION INDUSTRIES: CROPS, GREENHOUSES/NURSERIES, AND FORESTRY

This section provides background information on three types of agricultural production industries:

- Establishments that produce crops, including oilseed and grains, vegetables and melons, fruit and tree nuts, and other crops
- Greenhouses and nurseries
- Establishments engaged in forestry and logging.

> The Office of Management and Budget (OMB) has replaced the Standard Industrial Classification (SIC) system, which was used to track the flow of goods and services within the economy, with the NAICS. The NAICS, which is based on similar production processes to the SIC system, is being implemented by OMB.

This section defines these industries in terms of their North American Industrial Classification System (NAICS) codes. According to NAICS, establishments that produce crops and greenhouses/nurseries are classified in ***NAICS code 111 (Crop Production)***. Because greenhouses/nurseries comprise a large number of the entities in NAICS 111 and are somewhat different in actual practices, this notebook presents data and information on them separately from crop production. Greenhouse, nursery, and floriculture production is classified as ***NAICS code 1114.*** Establishments engaged in forestry are classified in ***NAICS code 113 (Forestry and Logging)***. The forestry production industry has practices that differ significantly from those used for crops and greenhouses/nurseries.

Establishments primarily engaged in crop production and forestry are classified in subgroup(s), up to six digits long, based on the total value of sales of agricultural products. An establishment would be placed in the group that represents 50 percent or more of its total sales. For example, if 51 percent of the total sales of an establishment is wheat, then it would be classified under NAICS codes 1111 (Oilseed and Grain Farming) and 11114 (Wheat Farming).

Data for the notebook, specifically in this chapter, were obtained from the U.S. Department of Agriculture (USDA) and the 1997 Agriculture Census (Ag Census). All data are the most recent publicly available data for the source cited.

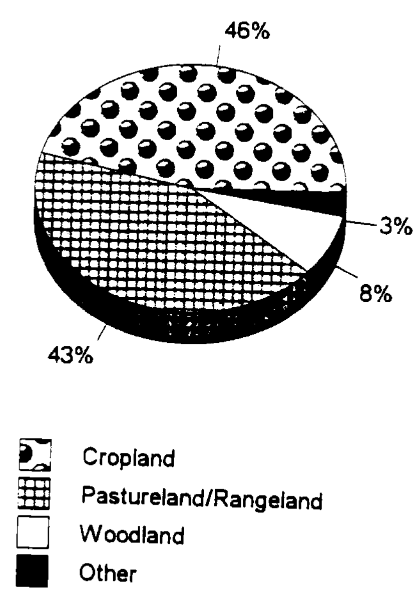
II.A. General Overview of Agricultural Establishments

This section presents a general overview of agricultural establishments to provide background information regarding the number of such establishments and production data. The USDA's National Agricultural Statistics Service (NASS) defines an *agricultural establishment* (i.e., farm) based on production. It defines a farm as a place which produced or sold, or normally would have produced or sold, $1,000 or more of agricultural products during the year. Agricultural products include all products grown by establishments described in this profile, which are classified under NAICS codes 111, 113, and 1114, as well as those in NAICS code 112 - Animal Production, which are covered in the *Profile of the Agricultural Livestock Production Industry*.

According to the 1997 Ag Census, there were more than 1.9 million farms (i.e., agricultural establishments) in the United States. Of these, approximately 47 percent (902,372 farms) were classified as NAICS code 111 - Crop Production. The other 53 percent (1,009,487 farms) were classified as NAICS code 112 - Animal Production. These 1.9 million agricultural establishments represent nearly 932 million acres of land, with the average agricultural establishment consisting of 487 acres. (Note: 1 acre is approximately the size of a football field.) Both of these numbers--932 million acres and 487 acres--are smaller than those for 1992, which were 946 million acres and 491 acres, respectively.

As shown in Exhibit 1, of the 932 million acres of agricultural land, the overwhelming majority (89%) consists of cropland and pastureland/rangeland.

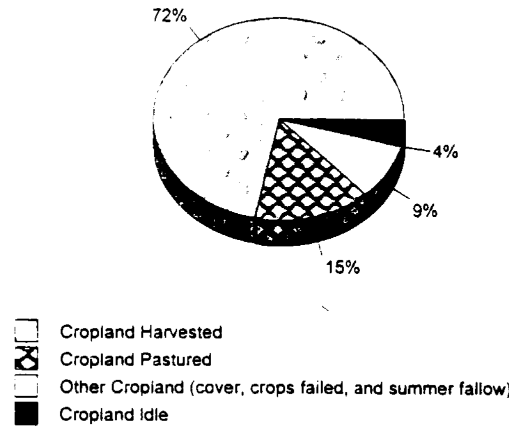
Exhibit 1. Agricultural Land Use in the U.S. (1997 Ag Census)



R0074270

As presented in Exhibit 2, the 1997 Ag Census describes cropland as:

Exhibit 2. Types of Cropland (1997 Ag Census)



- *Harvested cropland* -- Includes all acreage from which crops are harvested, such as: (1) corn, wheat, barley, oats, sorghum, soybeans, cotton, and tobacco; (2) wild or tame harvested hay, silage, and green chop; and (3) vegetables. It also includes land in orchards and vineyards; all acres in greenhouses, nurseries, Christmas trees, and sod; and any other acreage from which a crop is harvested even if the crop is considered a partial failure and the yield is very low.

- *Cropland used only for pasture or grazing* -- Includes land pastured or grazed which could be used for crops without any additional improvement, and land in planted crops that is pastured or grazed before reaching maturity.

- *Cropland used for cover crops* -- Includes land used only to grow cover crops for controlling erosion or to be plowed under for improving the soil.

- *Cropland on which all crops failed* -- Includes: (1) all land from which a crop failed (except fruit or nuts in an orchard, grove, or vineyard being maintained for production) and no other crop is harvested and which is not pastured or grazed, and (2) acreage not harvested due to low prices or labor shortages.

- *Cultivated summer fallow* -- Includes cropland left unseeded for harvest, and cultivated or treated with herbicides to control weeds and conserve moisture.

- *Idle cropland* -- Includes any other acreage which could be used for crops without any additional improvement and which is not included in one of the above categories of cropland.

The 1997 Ag Census describes pastureland and rangeland as land, other than cropland or woodland pasture, that is normally used for pasture or grazing. This land, sometimes called "meadow" or "prairie," may be composed of bunchgrass, shortgrass, buffalo grass, bluestem, bluegrass, switchgrass, desert shrubs, sagebrush, mesquite, greasewood, mountain browse, salt brush, cactus, juniper, and pinion. It also can be predominantly covered with brush or browse.

As shown in Exhibit 3, approximately 82 percent of agricultural establishments in 1997 consisted of fewer than 500 acres; only 4 percent consisted of 2,000 or more acres.

According to the 1997 Ag Census, all agricultural establishments combined to produce approximately $197 billion worth of agricultural products.

Exhibit 3. Acreage of Agricultural Establishments in the U.S. (1997 Ag Census)

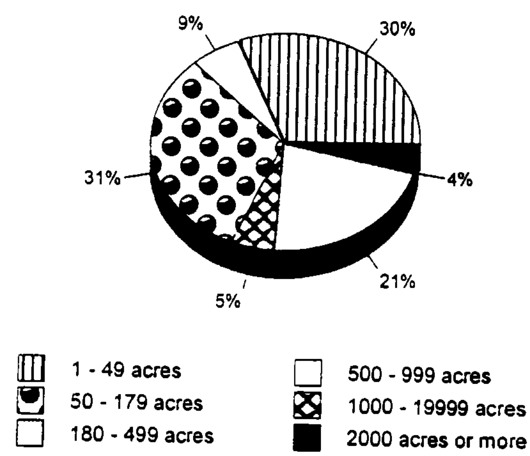


Exhibit 4. Agricultural Establishments by Value of Sales (1997 Ag Census)

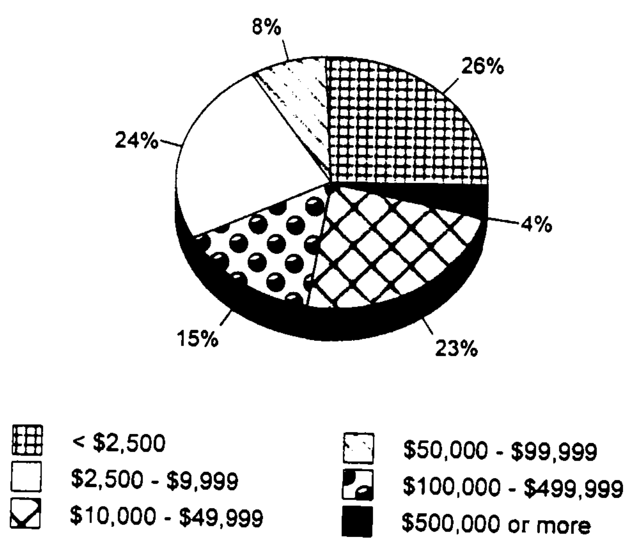


The market value of the agricultural products sold was split almost evenly between crop production, including nursery and greenhouse crops (49.6%) and livestock production (50.4%).

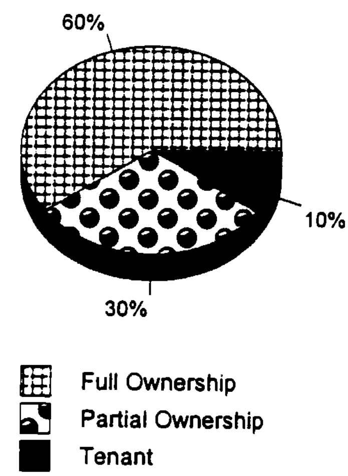
As shown in Exhibit 4, approximately 73 percent of all agricultural establishments produced less than $50,000 worth of agricultural products.

R0074272

In addition to tracking the number of agricultural establishments and the value of products sold, the Ag Census tracks and identifies other characteristics of agricultural establishments, such as ownership and organization. Exhibit 5 presents a breakdown of the ownership status of agricultural establishments in the U.S. The Ag Census basically identifies the ownership status of agricultural establishments by one of three categories:

- Full ownership, in which full owners operate only the land they own.
- Partial ownership, in which partial owners operate land they own and also land they rent from others.
- Tenant/rental arrangement, in which tenants operate only land they rent from others or work on shares for others.

Exhibit 5. Ownership Status of Agricultural Establishments in the U.S. (1997 Ag Census)



The Census further classifies agricultural establishment ownership by the person or entity who owns the establishment. There are four distinct types of organization: (1) individual or family (sole proprietorship); (2) partnership, including family partnership; (3) corporation, including family corporation, and (4) other, including cooperatives, estate or trust, and institutional. Approximately 86 percent of all establishments are owned and operated by individuals or families. Partnerships account for another 9 percent of the establishments and corporations own just more than 4 percent of the establishments. Fewer than 1 percent of all farms are owned by other organizations. (1997 Ag Census).

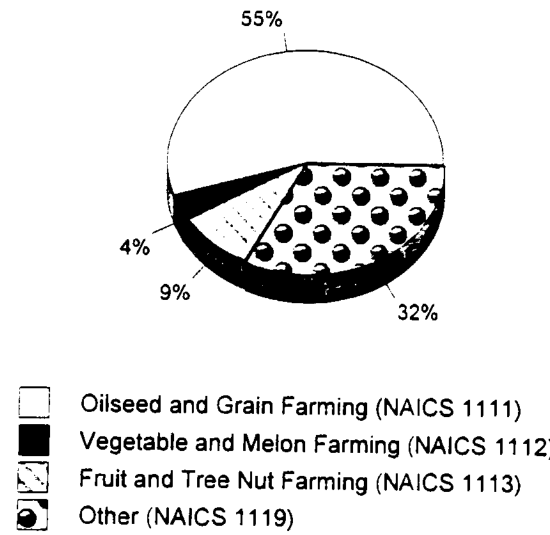
II.B. Characterization of the Crop Production Industry

This section provides data and information on the crop production industry. For the purposes of this profile, crop production includes the four categories of commodities presented in Exhibit 6. This notebook follows the structure provided by the 1997 Ag Census, which classifies all of these commodity production operations within NAICS code 111. Because the notebook is addressing greenhouse, nursery, and floriculture products separately in the next section, they are not included within this discussion.

Exhibit 6. 1997 NAICS Descriptions for Crop Production (NAICS 111)

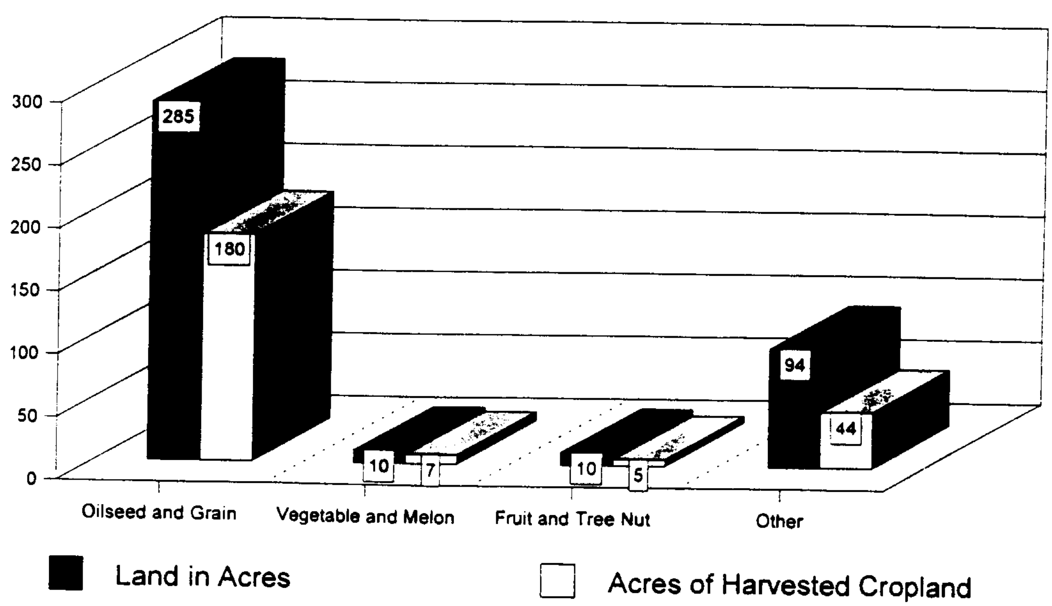
Type of Establishment	NAICS Code	SIC Code	Description
Oilseed and Grain	1111	0116, 0119	Establishments primarily engaged in: 1) growing oilseed and/or grain crops and/or 2) producing oilseed and grain seeds. These crops have an annual growth cycle and are typically grown in open fields.
Vegetables and Melons	1112	0134, 0139, 0161	Establishments primarily engaged in growing root and tuber crops (except sugar beets and peanuts) or edible plants and/or producing root and tuber or edible plant seeds. The crops included in this group have an annual growth cycle and are grown in open fields.
Fruits and Tree Nuts	1113	0171, 0172, 0173, 0174, 0175, 0179	Establishments primarily engaged in growing fruit and/or tree nut crops. The crops included in this industry group are generally not grown from seeds and have a perennial life cycle.
Other Crops	1119	0131, 0132, 0133, 0139, 0191, 0831, 2099	Establishments primarily engaged in: 1) growing crops (other than those listed previously), such as tobacco, cotton, sugarcane, hay, sugar beets, peanuts, agave, herbs and spices, and hay and grass seeds, or 2) growing a combination of these crops.

Exhibit 7. Number of Farms
(1997 Ag Census)



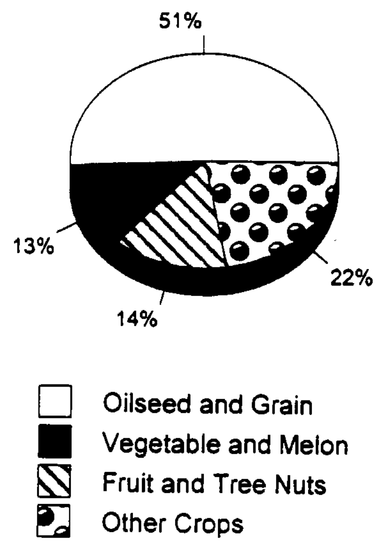
In 1997, there were 845,180 establishments producing the four categories of commodities referenced above. All these establishments combined covered nearly 400 million acres, of which more than half (236 million acres) was harvested cropland. The average crop producing establishment in 1997 was approximately 473 acres in size and averaged approximately 279 acres of harvested cropland. Of the 845,180 crop producing establishments, more than 50 percent (462,877) were classified as oilseed and grain farming (see Exhibit 7). Also, as shown in Exhibit 8, oilseed and grain farming accounted for the majority of the land in acres as well as harvested cropland.

Exhibit 8. Land in Acres vs. Acres of Harvested Cropland (in millions of acres)
(1997 Agriculture Census)



R0074275

Exhibit 9. Percent of Sales by Type of Establishment (1997 Ag Census)



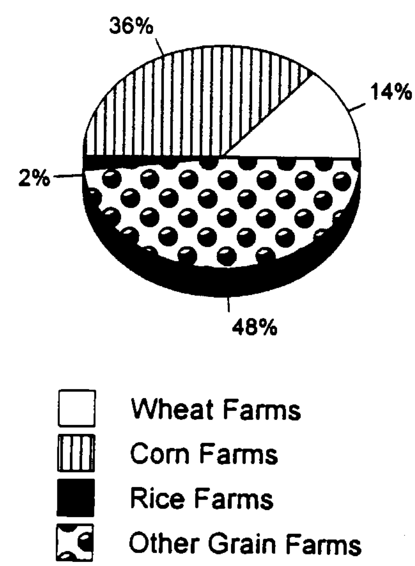
The four types of crop-producing establishments defined above accounted for approximately $87 billion worth of products sold in 1997. Exhibit 9 presents the distribution of those sales among the four types of establishments.

II.B.1. Oilseed and Grain

Oilseed and grain accounted for the majority of agricultural sales in the U.S. in 1997. For the purposes of the 1997 Ag Census, oilseed includes primarily soybeans, but also dry peas and beans, canola, flaxseeds, mustard seeds, oilseeds, rapeseeds, safflower, sesame seeds, and sunflowers. Grain includes wheat, corn, rice, and other grains such as barley, broomcorn, buckwheat, milo, oats, rye, sorghum, and wild rice. These grains are considered both food and feed grains, meaning they may be used either in food production or as feed for livestock.

In 1997, there were 462,877 oilseed and grain establishments in the U.S.; 94,481 were oilseed establishments and 368,396 were grain establishments. As shown in Exhibit 10, corn-producing establishments comprise the majority of the grain establishments in the U.S. On average, each grain-producing establishment is approximately 671 acres. Of those, approximately 407 acres are harvested cropland.

Exhibit 10. Types of Grain Farms (1997 Ag Census)



R0074276

II.B.2. Vegetables and Melons

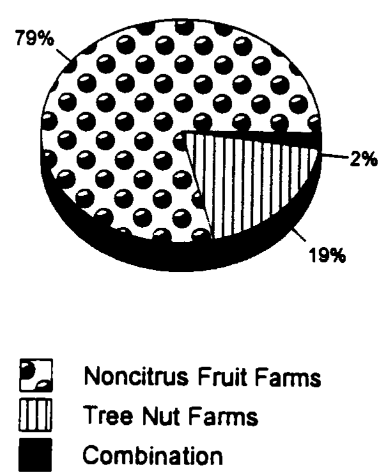
Vegetable and melon farming accounts for 31,030 establishments, or just less than 4 percent of the total crop-producing establishments in the U.S. An average vegetable and melon establishment consists of approximately 330 acres, of which approximately 170 acres are harvested cropland. Potato farming is the largest subgroup within vegetable and melon farming. It comprises nearly 12 percent of all vegetable and melon farms. The average potato-producing establishment has approximately 981 acres; approximately 730 of these acres are harvested cropland.

II.B.3. Fruit and Tree Nuts

Fruit and tree nut farming comprised the third largest group of crop-producing establishments combining for 81,956 establishments. This category is basically broken into two categories: 1) citrus fruits, and 2) noncitrus fruits and tree nuts. Citrus-producing establishments (i.e., groves) accounted for 12,275 establishments, or approximately 15 percent of all fruit and tree nut establishments. Noncitrus fruits and tree nuts, which include apples, grapes, strawberries, other berries, tree nuts, and other noncitrus fruits, comprised the remainder of the establishments (69,681) in 1997. (Tree nuts include almonds, hazelnuts, walnuts, macadamia nuts, pecans, and pistachios.) The percentages of noncitrus fruit and tree nut establishments are presented in Exhibit 11.

In 1997, the average fruit and tree nut establishment was 127 acres, with approximately half of those acres being harvested. Orange groves accounted for more than 75 percent of all citrus fruit establishments. Florida dominates citrus fruit production, except for lemons. Noncitrus fruits are grown across the country. Tree nuts are grown primarily in California and Hawaii.

Exhibit 11. Noncitrus Fruit and Tree Nut Farms (1997 Ag Census)



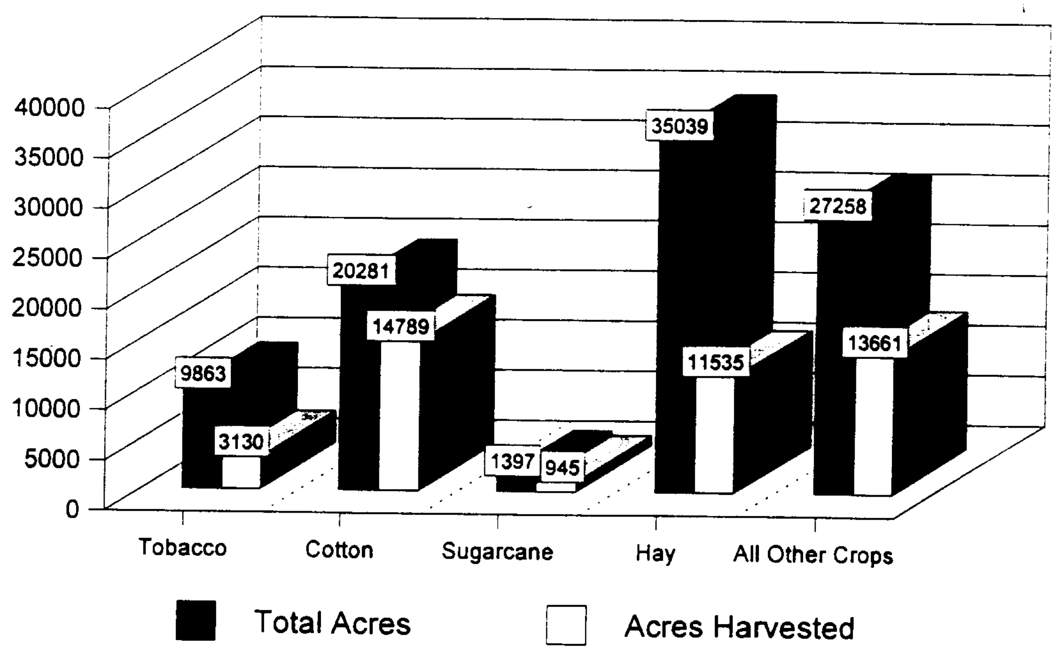
R0074277

II.B.4. Other Crops

The category of Other Crops comprised the second largest group of crop-producing establishments in the U.S. in 1997. A total of 269,317 farms were classified as NAICS code 1119 - Other Crops Farming. These other crops include tobacco, cotton, sugarcane, and hay, as well as other specialty crops such as honey and sugarbeets. Of the 269,317 other crop farms, 52 percent were classified as hay farms. Tobacco farms accounted for 24 percent of these establishments and cotton-producing establishments represented 7 percent. Sugarcane farms accounted for less than 1 percent of all establishments in this category. The remaining 17 percent were classified in the All Other Crops category.

These establishments combined for a total land area of approximately 94 million acres, or approximately 349 acres per establishment. The average number of acres harvested was 164 acres. Exhibit 12 provides a comparison of total acres to acres harvested for other crops.

Exhibit 12. Total Acres vs. Acres Harvested of Other Crops (in thousands of acres) (1997 Ag Census)



R0074278

II.C. Characterization of the Greenhouse, Nursery, and Floriculture Production Industry

Although the greenhouse, nursery, and floriculture industry is classified under NAICS code 111, this profile separates it into its own section because its practices and environmental impacts are different from those associated with the crops discussed in Section II.B.

In 1997, according to the Ag Census, there were 57,192 farms classified as NAICS code 1114, which is Greenhouse, Nursery, and Floriculture Production. This industry group consists of establishments that primarily grow crops of any kind under cover and/or grow nursery stock and flowers. "Under cover" is generally defined as in greenhouses, cold frames, cloth houses, and lath houses. The crops grown are removed at various stages of maturity and have annual and perennial life cycles. The nursery stock includes short rotation woody crops that have growth cycles of 10 years or less.

Of the 57,192 establishments classified as NAICS 1114, 97 percent were nursery and floriculture production (NAICS code 11142). The remaining 3 percent were classified as NAICS code 11141 - food crops grown under cover. Within the nursery and floriculture classification, there are two distinct categories:

- ***Nursery and tree production***, which consists of establishments primarily engaged in growing nursery products, nursery stock, shrubbery, bulbs, fruit stock, and sod, and those engaged in growing short rotation woody trees with a growth and harvest cycle of 10 years or less for pulp or tree stock, such as Christmas trees, under cover or in open fields.

- ***Floriculture production***, which consists of establishments primarily engaged in growing and/or producing floriculture products, such as cut flowers, cut cultivated greens (e.g., leatherleaf ferns, chamaedorea, etc.), potted flowering and foliage plants, and flower seeds, under cover or in open fields.

In 1997, there were 33,935 nursery and tree production establishments and 21,824 floriculture establishments. These establishments combined for total sales of nearly $10 billion, or approximately 10 percent of the total value of all crops sold in 1997. The average size of nursery and tree production establishments is nearly 92 acres, with an average of approximately 35 acres being harvested cropland. Floriculture production establishments average 35 acres in size with approximately one-third of that acreage being harvested cropland. California and Florida account for the majority of the establishments, as well as sales, in the floriculture industry.

Exhibits 13 and 14 show the value of greenhouse, nursery, and floriculture production compared to total crop production, and the value of greenhouse, nursery, and floriculture production sales, respectively.

Exhibit 13. Value of Greenhouse, Nursery, and Floriculture Production Compared to Total Crop Production (1997 Ag Census)

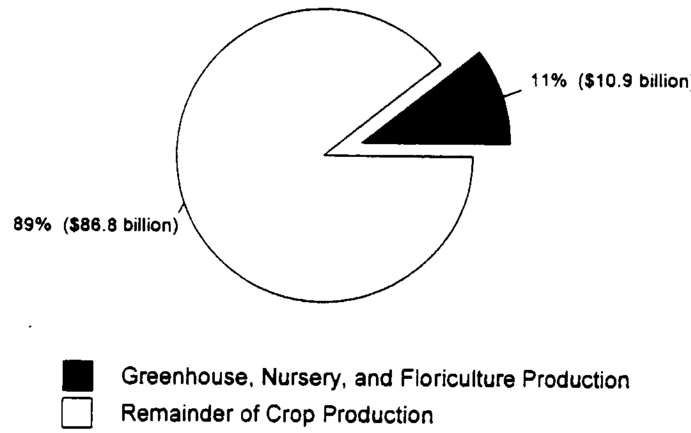


Exhibit 14. Values of Greenhouse, Nursery, and Floriculture Production Sales (1997 Ag Census)

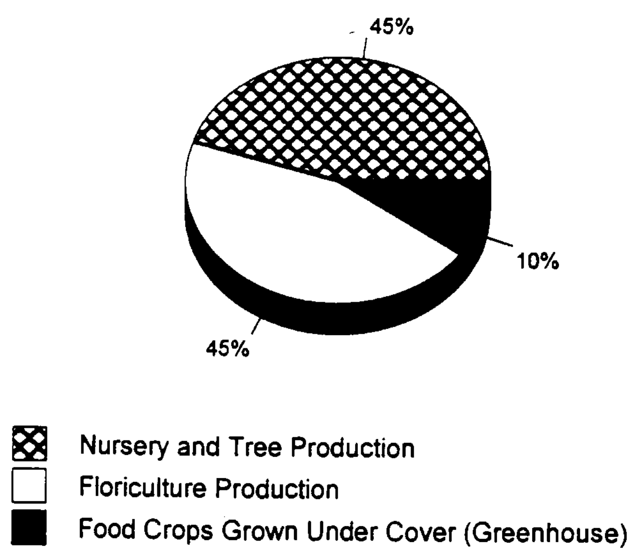


R0074280

II.D. Characterization of the Forestry Production Industry

This section pertains to the forestry industry as classified within ***NAICS code 113 - Forestry and Logging***. As defined by NAICS, industries in this sector grow and harvest timber on a long production cycle (i.e., 10 years or more). Long production cycles use different production processes than short production cycles, which require more horticultural interventions prior to harvest, resulting in processes more similar to those found in the previous sections of this profile. The three subsectors included within NAICS code 113 are:

- ***Timber tract operations (NAICS code 1131)***, which consist of establishments engaged in operating timber tracts for the purpose of selling standing timber.

- ***Forest nurseries and gathering of forest products (NAICS code 1132)***, which primarily engage in growing trees for reforestation and gather forest products, such as gums, barks, balsam needles, rhizomes, fibers, Spanish moss, ginseng, and truffles.

- ***Logging (NAICS code 1133)***, which consists of establishments primarily engaged in cutting timber, cutting and transporting timber, and producing wood chips in the field.

Industries usually specialize in different stages of the production cycle, as indicated by the three NAICS codes. Reforestation requires production of seedlings in specialized nurseries. Timber production requires natural forest or suitable areas of land that are available for a long duration. The harvesting of timber (except when done on an extremely small scale) requires specialized machinery unique to the industry. Establishments gathering forest products, such as gums, barks, balsam needles, rhizomes, fibers, Spanish moss, and ginseng and truffles, are also included in this industry.

II.D.1. Definition of Forest Land

The U.S. Forest Service defines a forested area as "forest land" if it is at least one acre in size and *at least 10 percent occupied by forest trees of any size or formerly having had such tree cover and not currently developed for non-forest use.* (Examples of non-forest uses include areas for crops, improved pasture, residential areas, and other similar areas.) Forest land includes transition zones, such as areas between heavily forested and nonforested lands that are at least 10 percent stocked with forest trees and forest areas adjacent to urban and built-up lands (36 CFR 219).

In the United States, there are approximately 736.7 million acres of forest land. The distribution of this forest land among geographic regions is presented in Exhibit 15.

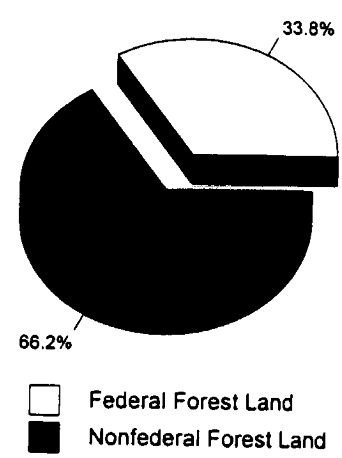
Exhibit 15. Distribution of U.S. Forested Land Area

Geographic Region	Total Land Area (in thousands of acres)	Forested Acres (in thousands)	Percent Forested
Northeast	126,816	85,380	67
North Central	286,764	83,108	29
Pacific Northwest	469,093	177,611	38
Pacific Southwest	103,934	39,011	38
Great Plains	194,299	4,232	2
Southeast	147,419	88,078	60
South Central	387,104	123,760	32
Rocky Mountains	547,918	135,499	25
Total	**2,263,347**	**736,679**	
Source: American Forest and Paper Association (AFPA), 1995			

Federal Versus Nonfederal Forest Lands

Of the 736.7 million acres, approximately 249.1 million acres (or 33.8 percent) are owned by the federal government. The remaining 487.6 million acres are owned by nonfederal entities, such as state or local governments, private citizens, or companies (see Exhibit 16).

Exhibit 16. Federal vs. Nonfederal Forest Lands (AFPA 1995)



R0074282

Approximately 57 percent of all productive forest land in the U.S. is owned by 9.3 million non-industrial private landowners. These 353 million acres of land produce more than half of the nation's wood supply (AFPA, 1995).

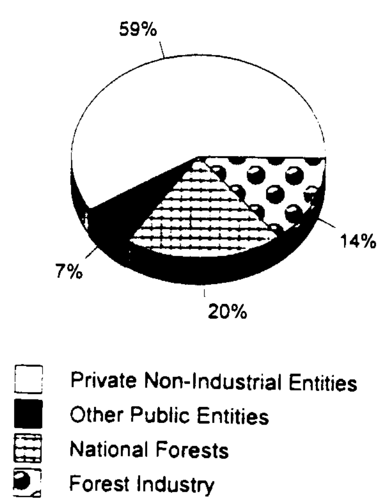
The majority of federal forest land is managed as the national forest system (NFS). The NFS includes:

- National forest lands reserved from the U.S. public domain.
- National forest lands acquired through purchase, exchange, donation, or other means.
- National grasslands.
- Other lands, waters, or interests administered by the U.S. Forest Service (FS) or designated for administration through the FS as part of the system.

The NFS contains 191 million acres, or 77 percent, of federal forest lands. (The remaining federal forest lands are managed by the Bureau of Land Management, the National Park Service, and other federal agencies.) The NFS is contained in 43 states and creates about 500,000 private sector jobs. Of the remaining nonfederal forests, privately held commercial forest lands make up the largest portion accounting for 347 million acres (71 percent).

Timberlands. Two-thirds of U.S. forest lands, or almost 490 million acres, are classified as timberlands. Timberlands are defined as forest lands used for the production of commercial wood products. Commercial timberland can be used for repeated growing and harvesting of trees. Seventy percent of timberlands are located in the East (AFPA, 1995). Exhibit 17 presents additional information about timberland ownership. Of the 490 million acres of timberland, federal, state, and local governments own 131 million acres (27 percent) and non-industrial private entities own 288 million acres (59 percent).

Exhibit 17. Timberland Ownership (AFPA 1995)



R0074283

Private timberlands are mostly on small tracts of forest land. Only 600,000 landowners have holdings larger than 100 acres (AFPA, 1995). The forest products industry owns about 70 million acres (14 percent) of commercial timberland. One-third of the nation's annual timber harvest is from these forests (AFPA, 1995).

II.D.2. Consumption and Regeneration of Forest Products

The United States is the world's leading producer and consumer of forest products (e.g., paper products) and accounts for approximately one-fourth of the world's production and consumption (AFPA, 1995). The United States is also the world's largest producer of softwood and hardwood lumber. Specifically for timber, in 1996, total annual sales for commercial (i.e., nonfederal) timber and nontimber forest products were approximately $3.8 billion. Timber alone accounted for approximately 69 percent of those sales.

In fiscal year 1998, the NFS sold approximately174 million cubic feet (or 870 million board feet) of timber valued at approximately $80 million. NFS timber sales from the past 6 years are presented in Exhibit 18. Also in fiscal year 1998, BLM sold 43.7 million cubic feet (or 261 million board feet) of timber. (A value was not provided for the BLM timber sales.)

Exhibit 18. NFS Timber Sales, FY 1993-1998
(from U.S. Forest Service)

Fiscal Year	Approx. Volume (million cubic feet)	Value
1993	250	$192,942,739
1994	177	$125,340,385
1995	240	$140,460,250
1996	212	$125,226,853
1997	195	$123,681,846
1998	174	$80,195,720

Exhibit 19. Acres Seeded and Acres of Tree Planting (FY 1996)

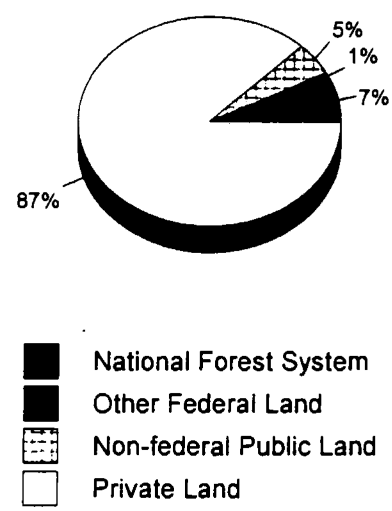


Exhibit 19 provides a breakout of where regeneration efforts occurred. To replenish the forests, more than 2.4 million acres in the U.S. were either seeded or planted with trees in government fiscal year 1996 (October 1995 - September 1996). The overwhelming majority of the regeneration efforts occurred on private lands where nearly 2.1 million acres were seeded or planted.

II.E. Geographic Distribution and Economic Trends

According to the 1997 National Resource Inventory (NRI), some changes have occurred in land use. Since 1982, federal land increased by 4.6 million acres, nonfederal rural land decreased by 36.7 million acres, and developed land increased by nearly 30 million acres. Cropland acreage, classified as irrigated, non-irrigated, cultivated, or non-cultivated acreage, nationally decreased by 45.9 million acres between 1982 and 1997. Rangeland decreased by 12.4 million acres and pastureland decreased by almost 14 million acres. Generally, a shift has occurred in irrigated agriculture from west to east across the country.

The distribution of prime farmland by land cover/use has also changed in the past 15 years. There were 330.6 million acres of prime farmland in 1997, which was down 11.7 million acres from 1982. Most (64 percent) of the prime farmland is in cropland, but large amounts are in pastureland (35.5 million acres) and forest land (47.7 million acres).

R0074285

For more information from the 1997 NRI, please visit the website http://www.nhq.nrcs.usda.gov/NRI/1997. Additional information on the geographic distribution of the crop production industries and their economic trends is very extensive and available through many sources. National and state-specific information can be accessed through the Internet from the 1997 Agriculture Census at http://www.nass.usda.gov/census/ and the National Agriculture Statistics Service at http://www.usda.gov/nass/.

III. Summary of Operations, Impacts, and Pollution Prevention Opportunities for the Agricultural Production Industries: Crops, Greenhouses/Nurseries, and Forestry

This section provides an overview of commonly employed operations and maintenance activities in the agricultural production industries of crops, greenhouses/nurseries, and forestry. This discussion is not exhaustive; the operations and maintenance activities discussed are intended to represent the material inputs, major pollution outputs, and associated environmental impacts from these agricultural production practices. General pollution prevention and waste minimization opportunities are also discussed in the context of each of the operations and maintenance activities.

The choice of practices or operations influences the material used and the resulting pollution outputs and environmental impacts. Keep in mind that environmental impacts are relative, as some kinds of pollution outputs have far greater impacts than others.

Impact of Agriculture on the Environment

> The Clean Water Act Plan of 1998 called for the development of the EPA/USDA Unified National Strategy for AFOs to minimize the water quality and public health impacts of AFOs.

According to the *EPA/USDA Unified National Strategy for Animal Feeding Operations* (March 9, 1999), despite progress in improving water quality, 40 percent of the Nation's waterways assessed by States do not meet goals for fishing, swimming, or both. While pollution from factories and sewage treatment plants has been dramatically reduced, the runoff from city streets, agricultural activities, including AFOs, and other sources continues to degrade the environment and puts environmental resources (i.e., surface water, drinking water) at risk. According to EPA's 1996 305(b) water quality report, the top two pollutants from agriculture were identified as sediment and nutrients, respectively. Additional agricultural pollutants, such as animal wastes, salts, and pesticides, were identified by EPA[1]. The following presents a brief discussion of the environmental impacts or effects of agricultural pollutants.

(1) ***Nutrients***. Excess nutrients in water (i.e., phosphorus and nitrogen) can result in or contribute to low levels of dissolved oxygen (anoxia),

[1] *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, U.S. Environmental Protection Agency, January 1993.

eutrophication, and toxic algal blooms. These conditions may be harmful to human health and ecosystems; may adversely affect the suitability of the water for other uses; and, in combination with other circumstances, have been associated with outbreaks of microbes such as *Pfiesteria piscicida*.

- Phosphorus. Phosphorus determines the amount of algae growth and aging that occurs in freshwater bodies. Runoff and erosion can carry some of the applied phosphorus to nearby water bodies.

- Nitrogen. In addition to eutrophication, excessive nitrogen causes other water quality problems. Dissolved ammonia at concentrations above 0.2 mg/L may be toxic to fish. Biologically important inorganic forms of nitrogen are ammonium, nitrate, and nitrite. Ammonium becomes adsorbed to the soil and is lost primarily with eroding sediment. Even if nitrogen is not in a readily available form as it leaves the field, it can be converted to an available form either during transport or after delivery to water bodies. Nitrogen in the form of nitrate, can contaminate drinking water supplies drawn from groundwater. Nitrates above 10 ppm in drinking water are potentially dangerous, especially to newborn infants.

(2) ***Sediment.*** Sediment affects the use of water in many ways. Suspended solids reduce the amount of sunlight available to aquatic plants, cover fish spawning areas and food supplies, clog the filtering capacity of filter feeders, and clog and harm the gills of fish. Turbidity interferes with the feeding habits of fish. These effects combine to reduce fish and plant populations and decrease the overall productivity of waters. In addition, recreation is limited because of the decreased fish population and the water's unappealing, turbid appearance. Turbidity also reduces visibility, making swimming less safe.

(3) ***Animal Wastes.*** Animal waste includes the fecal and urinary wastes of livestock and poultry; process water (such as from a milking parlor); and the feed, bedding, litter, and soil with which fecal and urinary matter and process water become intermixed. Manure and wastewater from animal feeding operations have the potential to contribute pollutants such as nutrients (e.g., nitrogen and phosphorus), organic matter, sediments, pathogens, heavy metals, hormones, antibiotics, and ammonia to the environment. Decomposing organic matter (i.e., animal waste) can reduce oxygen levels and cause fish kills. Solids

deposited in water bodies can accelerate eutrophication through the release of nutrients over extended periods of time.

Contamination of groundwater can be a problem if runoff results from the misapplication or over application of manure to land or if storage structures are not built to minimize seepage. Because animal feed sometimes contains heavy metals (e.g., arsenic, copper, zinc), the possibility for harmful accumulations of metals on land where manure is improperly or over applied is possible.

(4) ***Salts***. Salts are a product of the natural weathering process of soil and geologic material. In soils that have poor subsurface drainage, high salt concentrations are created within the root zone where most water extraction occurs. The accumulation of soluble and exchangeable salts (i.e., metal compounds in the soil that can chemically change) leads to soil dispersion (i.e., movement of soil in air and water), structure breakdown, decreased infiltration, and possible toxicity; thus, salts often become a serious problem on irrigated land, both for continued agricultural production and for water quality considerations. High salt concentrations in streams can harm freshwater aquatic plants just as excess soil salinity damages agricultural crops.

(5) ***Pesticides.*** The primary pollutants from pesticides are the active and inert ingredients, diluents, and any persistent degradation products. Pesticides and their degradation products may enter groundwater and surface water in solution, in emulsion, or bound to soils. Pesticides may, in some instances, cause impairments to the uses of surface waters and groundwater. Both the degradation and sorption characteristics of pesticides are highly variable. Some types of pesticides are resistant to degradation and may persist and/or accumulate in aquatic ecosystems. Pesticides may harm the environment by eliminating or reducing populations of desirable organisms, including endangered species.

At a crop production establishment, pesticides may be applied directly to crops or to structures (e.g., barns, housing units) to control pests, including parasites, vectors (i.e., an organism, such as a mosquito or tick, that carries disease-causing microorganisms from one host to another), and predators. Potential contamination from pesticides is generally greatest when rainfall is intense and occurs shortly after pesticide application, a condition during which water runoff and soil losses are also greatest. Pesticides can be transported to receiving waters either in dissolved form or attached to soil. Dissolved pesticides may be leached into groundwater supplies.

People, wildlife, and the environment can also be exposed to pesticide residues in the form of spray drift. Spray drift is the physical movement of a pesticide through air at the time of application or soon thereafter, to any site other than that intended for application. A number of factors influence spray drift including weather conditions, topography, the crop or area being sprayed, and application equipment and methods.

Pesticides are both suspected and known for causing immediate and delayed-onset health hazards for humans. If exposed to pesticides, humans may experience adverse effects, such as nausea, respiratory distress, or more severe symptoms up to and including death. Animals and birds impacted by pesticides can experience similar illnesses or develop other types of physical distress.

Pollution Prevention/Waste Minimization Opportunities in Crop Production, Greenhouses/Nurseries, and Forestry

The best way to reduce pollution is to prevent it in the first place. Industries have creatively implemented pollution prevention techniques that improve operations and increase profits while minimizing environmental impacts. This can be done in many ways such as reducing material inputs, reusing byproducts, improving management practices, and employing substitute toxic chemicals.

To encourage these approaches, this section provides general descriptions of some pollution prevention advances that have been implemented within the agricultural production industries for crops, greenhouses/nurseries, and forestry. While the list is not exhaustive, it does provide core information that can be used as the starting point for establishments interested in beginning their own pollution prevention projects. This section provides information from real activities that may be or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land, and water pollutant releases.

The use of pollution prevention technologies and environmental controls can substantially reduce the volume and concentration of the contaminants released/discharged into the surrounding environment. In some cases, these pollution prevention approaches may be economically beneficial to the agricultural production industries because they decrease the amount of chemicals needed, and therefore the cost of maintaining operations.

Waste minimization generally encompasses any source reduction or recycling that results in either the reduction of total volume or the toxicity of hazardous waste. Source reduction is a reduction of waste generation at the source, usually within a process. Source reduction can include process modifications, feedstock (raw material) substitution, housekeeping and management processes, and increases in efficiency of machinery and equipment. Source reduction includes any activity that reduces the amount of waste that exits a process. Recycling refers to the use or reuse of a waste as an effective substitute for a commercial product or as an ingredient or feedstock in an industrial process.

It should be noted that as individual practices, these pollution prevention and waste minimization practices can significantly reduce the environmental impacts of agricultural operations. However, to get the full effect of the practices and maximize pollution prevention potential, an agricultural operation must consider its individual practices in the context of a system. The practices, ranging from preparing the soil for planting to harvest and post-harvest activities, combine to form an integrated system in which each practice interacts with the others and is affected by the others. That is, outputs from one practice may be inputs into one of the other practices, in effect creating a closed-loop system that both maximizes profits and minimizes environmental impacts. By considering their establishments as systems, operators will be better able to evaluate and implement pollution prevention or waste minimization opportunities.

III.A. Crop Production: Operations, Impacts, and Pollution Prevention Opportunities

The production of crops generally includes the following activities:

- Preparing the site/soil for crops
- Planting/tending crops
- Applying and storing nutrients
- Pest control
- Irrigating crops
- Harvesting crops and post-harvesting activities
- Crop field residue destruction
- Maintaining equipment and vehicles
- Fuel use and fueling activities
- Maintaining the site

The additional activities of planning and management are required for all of the above processes to occur. Exhibit 20 presents the raw material inputs and pollution outputs from each of these processes.

Exhibit 20. Crop Production Activities, Raw Material Inputs, and Potential Pollution Outputs

Activity	Raw Material Input	Potential Pollution Output
Preparing the site/soil, including tilling, drainage and erosion control structures, and adjusting soil pH	– Mulch, seeds, and water – Alkaline material – Water	– Air emissions (e.g., smoke and dust) – Sediment, nutrient and pesticide runoff from soil erosion – Spilled material or excessively applied material
Planting/tending	– Seed, seedlings	– Air emissions (e.g., dust, emissions from planting equipment) – Sediment, nutrient, pesticide runoff from soil erosion – Plants, branches, leaves, etc.
Applying and storing nutrients (e.g., fertilizers, manure, biosolids)	– Organic nutrients – Chemicals – Water	– Runoff and leaching of unused or misapplied nutrients – Chemical air emissions – Odor
Applying pesticides and pest control	– Pesticides (including insecticides, rodenticides, fungicides, and herbicides)	– Runoff and leaching of unused or misapplied pesticides – Chemical air emissions
Irrigating (not including nutrient application)	– Water – Chemicals	– Air emissions – Potential runoff and leaching of materials (e.g., manure, chemicals, pesticides) from saturated areas
Harvesting/post-harvesting activities, including harvesting; washing, processing, packaging, loading, and transporting products; and destroying crop residue	– Water – Corrugated cardboard – Paper – Plastic and fabric packaging materials	– Unusable or spilled products – Worker exposure to pesticides – Organic- and pesticide-contaminated wastewater – Discarded packaging materials

Exhibit 20. Crop Production Activities, Raw Material Inputs, and Potential Pollution Outputs

Activity	Raw Material Input	Potential Pollution Output
Maintaining and repairing agricultural machinery and vehicles	– Oil – Lubricating fluid – Fuel – Coolants – Solvents – Tires – Batteries – Equipment parts	– Used oil – Spent fluids – Spent batteries – Metal machining wastes – Spent organic solvents – Tires – Air, surface water, and soil pollution resulting from spills and/or releases of fluids – Groundwater pollution resulting from spills or releases of fluids and discharges to Class V wells
Fuel use and fueling activities	– Fuel	– Air emissions from machinery – Air, water, soil, and groundwater pollution resulting from spills
Maintaining the site:		
(1) Providing water, including drinking water and water used for personal hygiene	– Water	– Contaminated water supply
(2) Managing PCBs (i.e., PCBs in generators and equipment)	– PCB-containing oils and equipment	– Spills or releases of PCBs
(3) Renovation/demolition	– Asbestos – Lead	– Airborne asbestos fibers – Lead-based paint, dust, and chips – Soil contamination

III.A.1. Preparing the Site/Soil for Crops

Prior to planting crops, the site/soil must be prepared. Site/soil preparation can involve tilling the soil or chemical cultivation, building drainage and erosion control structures, and adjusting soil pH.

Preparing the Soil by Tilling or Chemical Cultivation

Tilling aerates the soil, allows seeds/seedlings to be placed in the soil, and helps roots take hold of the soil. It also improves drainage and allows for better assimilation of nutrients and pesticides into the soil. Tillage methods generally consist of intensive/conventional, reduced tillage, and conservation tillage. The difference in the tillage methods is the amount of soil disturbed and the amount of crop residue allowed to remain during the current planting.

- Intensive/conventional tillage is sometimes conducted in two phases – primary tillage with a moldboard plow followed by secondary tillage with a power tiller or disc harrow. Intensive/conventional tillage can range from complete tillage of the entire field to tillage that allows 15 percent of the crop residue to remain.

- Reduced tillage consists of disturbing from 15 to 30 percent of the soil and crop residue.

- Conservation tillage methods are designed to reduce the loss of soil erosion caused by wind and water. Conservation tillage methods allow 30 percent or more of the soil and crop residue to remain undisturbed and thus reduce soil erosion by water and/or maintain at least 1,000 pounds per acre of flat, small grain residue to reduce soil erosion by wind. Common conservation tillage methods are no-till, strip-till, ridge-till, and mulch till.

  - No-till has minimal soil disturbance since the seed is planted with essentially no tillage of the soil and no disturbance of the crop residue.

  - Strip-till involves tillage of a narrow strip of soil and planting of the seed or seedling in that tilled area.

  - Ridge-till methods disturb a narrow strip of soil that was created during previous cultivation. The crop is planted on the ridge and the crop residue remains between each ridge.

  - Mulch-till involves disturbing the entire soil surface and then applying a crop protection product and/or cultivation[2].

In addition to tilling, soil may be prepared for planting by chemical cultivation. Chemical cultivation includes the application of a systematic herbicide to kill weeds and grasses.

[2] 1998 Crop Residual Management Survey Executive Summary, Top 10 Conservation Tillage Benefits, Conservation Tillage Information Center.

Potential Pollution Outputs and Environmental Impacts

The primary pollution output from preparing soil for planting is soil erosion. Erosion can reduce the productivity of the soil and increase the need for additional fertilizer and other inputs. Sediments and other pollutants (e.g., nutrients, pesticides) that are transported offsite may eventually enter surface waters, settle out, and cause degradation of the water quality. When it settles, the sediments fill interstitial spaces in lake bottoms or streambeds. They can eliminate essential habitat, cover food sources and spawning sites, smother bottom-dwelling organisms, and be detrimental to many species of fish. Sediment deposition also reduces the capacity of stream channels to carry water and of reservoirs to hold water. This decreased flow and storage capacity can lead to increased flooding and decreased water supplies.

Sediments can also be suspended in surface waters, which causes increased water turbidity. Water turbidity limits the depth to which light can penetrate and adversely affecting aquatic vegetation photosynthesis. Suspended sediments can also damage the gills of some fish species, causing them to suffocate. Turbid waters tend to have higher temperatures and lower dissolved oxygen concentrations. Decreased dissolved oxygen levels can kill aquatic vegetation, fish, and benthic invertebrates.

Pollution Prevention/Waste Minimization Opportunities

The primary pollution prevention opportunities arise from the use of reduced or conservation tillage methods, which reduce soil erosion and maintain the existing soil structure (the way the soil particles clump together into larger, almost crystalline, units). Advantages of conservation tillage include:

- ✓ Greater water retention/reduced water usage and energy used for pumping (by increasing the water retention capacity of irrigated soils, there may be opportunities to lengthen periods between irrigation events, thereby saving energy that would otherwise have been used for pumping irrigation water).
- ✓ Reduced erosion of sediment and runoff of nutrients.
- ✓ Reduced fuel use due to reduced equipment use.
- ✓ Reduced wind erosion resulting in less dust.

✓ Shading which reduces weed growth and subsequent herbicide use. The effectiveness of shading is dependent on the type of crop and distance between plants.

✓ Prevention of the growth of some molds that have a much lower overwinter survival if not incorporated into the soil.

✓ Crop residues left undisturbed provide habitats for many beneficial insects and spiders that help control crop predators (e.g., cereal leaf beetle), thereby reducing the need for insecticides. In addition, crop residues help speed the decomposition process and aid plant nutrient cycling.

One possible disadvantage of conservation tillage methods is the carryover of pests (e.g., weeds, diseases, and some insects) in the crop residue. This may result in a subsequent increased use of pesticides and increased level of pesticides in runoff.

Building Drainage and Erosion Control Structures

Erosion control practices are necessary for agricultural operations to control runoff and reduce the amount of soil erosion caused by that runoff. In areas with good drainage, crops are better able to use nutrients and chemicals and will benefit from these optimum growing conditions. When building erosion control structures, newly-graded soil surfaces may be stabilized with mulch prior to the establishment of a vegetative cover.

To establish good drainage, one or a combination of drainage and erosion control structures can be built and used depending on the site characteristics (e.g., slope, crop type, or climate). These structures include:

- *Diversions*. Diversions are vegetated channels across the slope that intercept surface runoff and redirect it along a gradient to a controlled outlet. Diversions can reduce the amount of soil/sediment and related pollutants delivered to surface waters.

- *Grassed waterways*. Grassed waterways, which are shaped or graded to specified dimensions, are used for the stable conveyance of runoff. Grassed waterways can reduce soil erosion in areas, such as gullies or ephemeral gullies, with concentrated flows.

- *Water and sediment control basins*. Water and sediment control basins are constructed to collect and store debris or sediment. They detain runoff, allowing the sediment to settle out in the basin before the water is discharged to a waterway.

- *Filter strips.* Filter strips are vegetated areas that are used to trap sediment, organic matter, and other pollutants that are carried in runoff. While filter strips require frequent maintenance and have relatively short service lives, they are generally effective in removing pollutants when a shallow sheet flow is passed through the vegetated areas.

- *Riparian buffers.* Herbaceous or forest riparian buffers are areas of grasses, shrubs, or trees placed upgrade from waterways and water bodies. These buffers prevent or minimize damage to surface waters by containing eroded sediment, chemicals, nutrients, and organics. In addition, buffers reduce the amount of these pollutants that leach into shallow groundwater.

- *Terracing and contouring.* Terracing and contouring are practices that both use sloped surfaces to reduce or control soil erosion. Terracing involves shaping an area so that it is sloped, and contouring involves moving soil in an area so that it is sloped.

- *Drainage tiles.* Surface and subsurface drainage tiles are often used to remove standing water from fields and direct them to more structured erosion control measures.

Potential Pollution Outputs and Environmental Impacts
As described above for tilling, soil erosion and its impact to surface waters is a significant environmental concern and the primary pollution from building drainage structures. Wetlands, the interface between terrestrial and aquatic systems, are particularly susceptible to impacts from runoff and soil erosion. Such impacts include damage to watershed hydrology and water quality, and the habitat for many animal and plant species.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention opportunities of drainage and erosion control structures are the minimization of soil erosion and the reduction of runoff which transports nutrients, sediments, and pesticides to the environment.

R0074297

Drainage and erosion controls can reduce the amount of sediment that is transported offsite in runoff. Any of the drainage and erosion control structures described above can be used to reduce soil erosion and transport. Additional examples of erosion control structures or activities include: field borders; grade stabilization structures; sediment retention ponds; reestablished wetlands; immediate seeding, mulch/mats, and sodding to stabilize exposed soil surfaces; wind erosion controls; and scheduled grading and shaping (e.g., construction of diversions) during dry weather.

> Preventing or controlling erosion is based on two main concepts: (1) disturb the smallest area of land possible for the shortest period of time, and (2) stabilize the disturbed soils to prevent erosion from occurring.

Adjusting the Soil pH

Adjusting the soil pH helps ensure the soil contains the proper characteristics to maximize crop production. Many crop producers add materials to soil to achieve a soil pH that maximizes crop production. Typically, alkaline materials, such as lime, lime sulfur, caustic soda, caustic potash, soda ash, magnesia, and dolomitic lime, are added to increase the pH in acidic soils.

Potential Pollution Outputs and Environmental Impacts
The adjustment of soil pH typically results in little to no pollution outputs and generally has little to no environmental impacts. However, impacts to surface waters could occur if spilled or misapplied alkaline materials are carried in runoff.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention opportunities for this activity include properly storing the materials used to adjust pH to minimize spills, and applying these materials in a manner that minimizes runoff.

III.A.2. Planting/Tending Crops

Planting involves the placement of seeds or seedlings into the soil. This activity can be conducted either by hand (in small operations) or mechanically. Tending the product involves any post-planting activities designed to maximize crop production at harvest. Tending may involve hand labor (e.g., hoeing or pruning) or machine labor.

R0074298

Potential Pollution Outputs and Environmental Impacts
Pollution outputs from planting crops include air emissions, particularly dust, and wastes such as seed bags. The planting process is often combined with other operations, such as tilling or fertilizer/pesticide application, which can pollute surface waters and groundwater from runoff and leaching, respectively. Tending activities that disturb the soil may result in soil erosion, the impacts of which are similar to those previously discussed under tilling. Tending may also produce wastes (e.g., plant branches or other parts).

Pollution Prevention/Waste Minimization Opportunities
Air emissions from planting activities can be minimized by properly maintaining farm machinery. Sections III.A.7 details how to operate and maintain farm vehicles and machinery in an environmentally responsible manner.

By buying seeds in greater bulk, farms can reduce the volume of seed bags that must be disposed of. Also, certain innovative methods of collecting and dispersing seeds are now available that eliminate the need for bags.

III.A.3. Applying Nutrients to Crops

During various phases of crop production, nutrients such as nitrogen, phosphorus, potassium, and other nutrients are applied to crops to enhance crop growth. Nutrient use has been encouraged by the adoption of high-yielding seeds that are more responsive to nutrient application. Therefore, nearly all acres planted with crops are treated with one or more sources of nutrients, such as fertilizers, manure, and/or biosolids.

Nutrients are applied directly to plants or the soil surface, incorporated or injected into the soil, or applied with irrigation water. Nutrient application methods are mechanically intensive, requiring coverage of vast areas. Fertilizers may be solids, liquids, or gasses and, depending on the state of the product, may be applied using specialized trucks, tractors pulling sprayer equipment, or pressurized tanks to apply anhydrous ammonia. Techniques used to apply fertilizer include:

- *Band placement* is used to locate the fertilizer in an optimum position relative to the seed. This increases the potential for full utilization of the fertilizer by the crop and minimizes salt injury to the developing roots.

R0074299

- *Broadcast application* refers to the practice of distributing the product uniformly over the soil surface. This method is preferred for lawns and forage and pasture crops and is the most common method used for crops. Tractors, airplanes, and helicopters are all used to broadcast fertilizers.

- *Manure injection* refers to the application of anhydrous ammonia. At normal pressure, anhydrous ammonia (NH_3) is a gas. For application as a fertilizer, it is pressurized to form a liquid. Because it is a volatile liquid, it is incorporated into the soil as a liquid under pressure to a depth of 15 to 25 cm. In the soil, NH_3 is converted to NH_4^+, which is stable. Gaseous ammonia is lost if soil pH increases much above 7, or as moisture fluctuates from field capacity. Liquid manure may be subsurface injected.

- *Addition of fertilizer to irrigation water (i.e., fertigation)* is a common practice in some areas and is usually part of a drip irrigation system that can apply water and fertilizer to a precise predetermined location.

- *Manure and biosolids* may be applied to the soil surface as a solid from a tractor-pulled box-type manure spreader as it makes passes across the field. Slurry manure and biosolids are generally applied to the soil surface by tractor-pulled or truck flail spreaders or to the subsurface by tractor or truck injection equipment. Liquid manure may be surface irrigated or subsurface injected. Manure and biosolid solids and slurries may be mechanically incorporated into the soil following application.

Potential Pollution Outputs and Environmental Impacts

There are several potential pollution outputs and environmental impacts from nutrient application and spills including runoff and leaching of nutrients which can contaminate surface water and groundwater; air emissions; and increases in the amount of soluble salts in soils. Runoff and leaching of nutrients typically occur when nutrients are applied excessively or improperly. Excessive amounts of soluble salts in the soil can prevent or delay seed germination, kill or seriously retard plant growth, and possibly render soils and groundwater unusable.

The degree of environmental impacts can depend on the application method. The surface application of fertilizer, manure, or biosolids is more likely to result in runoff than injection. Non-composted surface-applied manure will volatilize and release ammonia to the air. Spills of nutrients may also negatively impact the environment since they will be concentrated in one specific area.

Pollution Prevention/Waste Minimization Opportunities
There are several pollution prevention techniques that can be used to reduce pollution and impacts from nutrient application. These include:

✓ Application methods that prevent runoff (e.g., application by injection).

✓ Restricting application in close proximity to surface waters.

✓ Applying nutrients at agronomic (scientifically determined) rates to crops/cropland.

✓ Managing the site to eliminate erosion or reduce the runoff potential.

✓ Developing and implementing **nutrient management plans**. The primary purpose of nutrient management is to achieve the level of nutrients (e.g., nitrogen and phosphorus) required to grow the planned crop by balancing the nutrients that are already in the soil with those from other sources (e.g., manure, biosolids, commercial fertilizers) that will be applied. At a minimum, nutrient management can help prevent the application of nutrients at rates that will exceed the capacity of the soil and the planned crops to assimilate nutrients and prevent pollution.

A site-specific nutrient management plan should be developed prior to planting, reviewed annually, and updated as needed. The plan, which will direct the application of one or more nutrients to the cropland, may include:

- Soil and field maps that show setbacks and buffers, as well as wetland and groundwater maps.
- Crops and rotations.
- Soil tests.
- The calculated nutrient loading for each field.

Additional plan components may consist of manure and biosolid test results; projected manure production, storage, and treatment; commercial fertilizer needs; application rates; and the method and timing of application.

Soils, manure, and wastewater should be tested to determine nutrient content. Retesting should be completed following each significant change in the manure/biosolids source or manure waste management system.

✓ **Precision farming.** One of the more advanced technologies for improving nutrient application efficiency is known as precision farming. Typically used by larger operations, precision farming allows farmers to know their location in the field via a Global Positioning System (GPS) so that applications can be made according to a predetermined rate for that specific location. Precision farming may result in more precise applications of nutrients so there is little or no excess leached to groundwater or washed to surface waters.

III.A.4. Applying Pesticides and Pest Control

Pesticides (e.g., insecticides, herbicides, fungicides) may be applied during all phases of crop production, including during harvesting and post-harvesting activities. For crop production, pesticides prevent insects and other pests, including weeds and other unwanted plants, from harming crops. Pesticide use has been encouraged by continuous cropping, which has created favorable pest habitats in certain crops.

Pesticide application methods for crops are mechanically intensive, requiring coverage of vast areas. Pesticides are applied directly to the plant or soil surface, incorporated into the soil, or injected as a gas through fumigation. One of the most common methods of applying pesticides to crops is liquid spraying. Liquid spraying may be conducted by aircraft, tractor spray rigs, or blasters.

- Aerial methods are the most common application type with about two-thirds of all insecticides and fungicides applied in this manner.

> Citrus groves may be aerially treated 10 to 20 times per season with insecticides, fungicides, and protectant oils.

  - Helicopters are often used because the turbulence from the main rotor tends to push the pesticides down toward the crop.

R0074302

  - Fixed-wing aircraft are more commonly used in crops such as wheat and cotton.

- Tractor spray rigs are often used to apply herbicides in row crops because planting, fertilizing, and spraying can be accomplished in one pass through the field.

- Blasters are used for applying insecticides and fungicides to tree crops.

Other than the Agency's ultra-low volume exemption, concentrated pesticides must be applied according to label directions including any requirement to mix with a diluent or water. The mixing and subsequent loading into the application vehicle must be conducted in a contained area.

Biopesticides. Biopesticides (also known as biological pesticides) are certain types of pesticides derived from such natural materials as animals, plants, bacteria, and certain minerals. At the end of 1998, there were approximately 175 registered biopesticide active ingredients and 700 products. Biopesticides fall into three major classes:

- *Microbial pesticides* contain a microorganism (e.g., a bacterium, fungus, virus, or protozoan) as the active ingredient. These pesticides can kill many different kinds of pests. For example, there are fungi that control weeds, other fungi that control cockroaches, and bacteria that control plant diseases. The most widely used microbial pesticides include various types of the bacterium *Bacillus thuringiensis*, or Bt. Bt acts by producing a protein that kills the larvae of specific insect pests. One kind of Bt can control specific insects in cabbage, potatoes, and other crops, while another type of Bt kills mosquitoes. Based on available information, the bacterium appears to have no adverse effects on humans or the environment. However, additional data are needed to ensure that products containing this bacterium are safe for honey bees, wasps, fish, and aquatic invertebrates.

- *Plant pesticides* are pesticidal substances that plants produce from genetic material that has been added to the plants. For example, scientists can introduce the gene for the Bt pesticidal protein into a plant's genetic material. The plant will then manufacture the substance that destroys the pest. Both the Bt protein and its genetic material are regulated by EPA; the plant itself is not regulated.

- *Biochemical pesticides* are naturally occurring substances that control pests by nontoxic mechanisms. In contrast, conventional pesticides are synthetic materials that usually kill or inactivate the pest. Biochemical pesticides include substances, such as pheromones, that interfere with the growth or mating of a pest. Because it is sometimes difficult to determine whether a natural pesticide controls the pest by a nontoxic mode of action, EPA has established a committee to determine whether a pesticide meets the criteria of a biochemical pesticide.

Some of the advantages of using biopesticides are:

- They are inherently less harmful than conventional pesticides.
- They generally affect only the target pest and closely related organisms.
- They are often effective in very small quantities and often decompose quickly, thereby resulting in lower exposures and largely avoiding the pollution problems caused by conventional pesticides.

To use biopesticides effectively, users should have a solid understanding of how to manage pests. When used as a component of integrated pest management (IPM) programs, biopesticides can greatly decrease the use of conventional pesticides, while still allowing crop yields to remain high.

Potential Pollution Outputs and Environmental Impacts

Environmental impacts most likely result from pesticide applications that are not conducted according to label directions. Potential pollution outputs and environmental impacts from pesticide application may include:

- Runoff or leaching of pesticides to surface water or groundwater. Pesticides incorporated into soil may leach into the groundwater. Soil fumigants will include releases to groundwater through leaching. Pesticides applied through chemigation, in which the pesticide is combined and applied with irrigation water, may be released to surface water through runoff or to groundwater through leaching.
- Air emissions. The application of pesticides using spray systems is more likely to involve releases to air. Soil fumigants will include releases to air through volatilization.

- Spills to soil and surface waters. The impacts of spills may be more significant since the spilled materials will be concentrated in one specific area.

- Potential human exposure and residue levels that exceed tolerance on animals and products. Pesticides are both suspected and known for causing immediate and delayed-onset health hazards for humans. If exposed to pesticides, humans may experience adverse effects, such as nausea, respiratory distress, or more severe symptoms up to and including death. To help reduce this potential exposure, tolerance levels have been established for residues on agricultural products. Animals and birds impacted by pesticides can experience similar illnesses or develop other types of physical distress. Following label directions for application, protective gear, and disposal will help ensure such environmental impacts do not occur.

- Pesticides that are applied to water-saturated soils or highly alkaline soils may not degrade as quickly as those applied properly or with the appropriate pH additive. When pesticides do not degrade, or do not bond with the plant or soil surface, they are more likely to be released to the environment through runoff.

- If not protected with backflow prevention devices, pesticides applied through spray systems that are connected to water supplies can siphon back to the water source and potentially contaminate drinking water systems. Also, improperly cleaned and disposed pesticide containers may cause releases to the soil and/or surface waters.

- Outputs from pesticide applications can inhibit crop production through the resurgence of pests after treatment, occurrence of secondary pest outbreaks, and development of pesticide resistance in target pests. In addition, the control of insects by broad-spectrum insecticides also destroys beneficial insect populations. Populations of many previously innocuous species may then increase rapidly and cause major economic damage.

- Crop losses have occurred when pesticides were applied improperly or drifted from a treated crop to nearby susceptible crops; when excess residues prevent crops from being planted in rotation or inhibit the growth of susceptible crops; and when excessive residues of pesticides accumulate on crops, causing the harvested products to be unmarketable.

Pollution Prevention/Waste Minimization Opportunities
Environmental impacts from pesticides are minimized by following label directions for application, and preventing or minimizing their use wherever possible. Pesticide use accounts for a substantial portion of farm production costs. By reducing their use, agricultural establishments cannot only reduce production costs, but also reduce environmental impacts of their operations.

Pesticide use and impact can also be minimized by using integrated pest management approaches, new technologies, efficient application methods, controls, and basic preventive measures. Examples of these are presented below.

✓ **Integrated pest management (IPM).** IPM is an effective and environmentally sensitive approach to pest management that relies on a combination of common sense practices. IPM programs use current, comprehensive information on the life cycles of pests and their interaction with the environment. This information, in combination with available pest control methods, is used to manage pest damage by the most economical means, and with the least possible hazard to people, property, and the environment.

Crop management is a vital part of IPM because it may reduce the concentration of pests. Crop rotation can help prevent disease buildup. Rotation is particularly important when conservation tillage methods are used. For grain crops, other methods include planting of hybrid plants that are resistant to leaf blights and stalk rot, plowing under chopped corn stalks and leaves (which can kill some overwintering disease fungi, but also may promote the growth of others that live below the surface), and maintaining good drainage. An IPM plan should indicate that when a pesticide is needed, and its selection is based on persistence, toxicity, and leaching and runoff potential such that the most environmentally friendly pesticide is used.

✓ **Precision farming.** One of the more advanced technologies for improving nutrient and pesticide application efficiency is known as precision farming. Typically used by larger

R0074306

operations, precision farming allows farmers to know their location in the field via a Global Positioning System (GPS) so that applications can be made according to a predetermined rate for that specific location. Precision farming may result in more precise applications of nutrients and pesticides so there is little or no excess leached to groundwater or washed to surface waters.

✓ **Controlled droplet application (CDA).** CDA produces spray droplets that are relatively uniform in size and allows the applicator to control droplet size. In contrast, conventional spray nozzles produce droplets that vary widely from small droplets that may drift or evaporate before reaching the target, to large droplets that concentrate too much of the pesticide in one spot. CDA improves the efficiency of pesticide application, thus reducing overall pesticide use and cost. In addition, CDA may require less than one gallon of water per acre, compared with 20-30 gallons per acre with most conventional herbicide sprayers. CDA also provides time and fuel savings as well as less soil compaction. (Cornell University, Dr. Russel R. Hahn, *Controlled Droplet Application*)

✓ **Chemigation**. Another method of more efficient pesticide application is chemigation. Chemigation systems are irrigation systems that are designed for chemical application by injection with the irrigation water. The systems provide reduced water pollution by allowing prescription chemical applications to be made. If chemicals are applied frequently and only in amounts required by the irrigated crop, the presence of excessive amounts are avoided, thus preventing leaching from occurring. (University of Florida Cooperative Extension Service, 1993)

✓ **Erosion control devices.** To control pesticide losses to surface water, a farm should control erosion and reduce the volume of runoff water that leaves the field or farm. Practices such as conservation tillage, terraces, strip-cropping, and contouring reduce runoff and control erosion. Sediment basins, farm ponds, and wetlands contain or trap sediments. Keeping the chemicals in the field or trapping them in biologically active areas (e.g., ponds or wetlands) provides the opportunity for microorganisms to degrade the pesticides, eventually rendering them harmless.

✓ **Basic preventive measures**. Waste minimization strategies for pesticides include:

- Buy only the amount needed for a year or a growing season.
- Minimize the amount of product kept in storage.
- Calculate how much diluted pesticide will be needed for a job and mix only that amount.
- Apply pesticides with properly-calibrated equipment.
- Use all pesticides in accordance with label instructions.
- Purchase pesticide products packaged in such a way as to minimize disposal problems.
- Work with the state to locate a pesticide handler who can use the excess pesticide.
- Return unused product to the dealer, formulator, or manufacturer.
- Implement setbacks from wellheads for application and storage.
- Use contact pesticides that do not have to be incorporated into the soil.
- Use row banding application techniques, where appropriate, to limit the amount of pesticide applied.
- If possible, choose nonleachable pesticides labeled for the crop and pest. Nonleachable pesticides are considered those that are less likely to migrate from their target crop.

III.A.5. Irrigating Crops

Irrigation transports water to crops primarily for growth, but also to ease the shock following transplant and to keep the crops cool in arid or excessive heat conditions.

Irrigation has always been a component of crop production and provides many benefits. Over the past 150 years, the practice of irrigation has increased dramatically, increasing the number of farmable acres, producing consistent and often higher yields, and making agriculture possible in areas previously unsuitable for intensive crop production.

In addition to these recognized benefits of irrigation, other factors have contributed to the increase in its use. Investment in equipment to transport water for agricultural use has been stimulated by federal policies. Such policies have included high commodity support prices, tax incentives that include investment credits, and accelerated depreciation for equipment, water depletion allowances, and low interest rates.

In the western United States, irrigation has been encouraged by federal law, which has provided subsidized irrigation water to western growers for nearly a century. As this and other subsidy programs have declined, the number of irrigated acres has decreased. However, in the eastern states that have not received direct water subsidies in the past, the number of irrigated acres is expected to increase.

There are many different irrigation systems, all of which are designed to move water from its source to where it can be used for crop production. Irrigation water is typically obtained from pumping groundwater or surface waters from onsite sources or from offsite sources such as rivers, pipelines, canals and aqueducts that are operated by irrigation districts and private water companies. Irrigation methods may consist of flood, stationary, and traveling systems.

- Flood systems allow the water to gravity sheet flow across the cropland.

- Stationary systems include subsurface drip or trickle systems and aboveground systems, which are permanently piped and may or may not have spray heads.

- Traveling systems may be center pivot, linear-move, hard-hose, or cable-tow. Irrigation systems such as the center pivot and linear-move usually have multiple spray heads (guns). Hard-hose and cable-tow systems usually have a single spray head.

Potential Pollution Outputs and Environmental Impacts
The potential pollution outputs from irrigation include runoff and leachate contaminated with pollutants (e.g., nutrients and pesticides) and salinization. Water depletion is one of the significant environmental impacts of irrigation. Irrigation can deplete surface water supplies, not only from the removal of water from these sources to use for irrigation, but also from the reduced volume of water returning to surface water due to evaporation losses. Irrigation can also deplete groundwater supplies. Water tables have fallen, particularly in drier western states, because of large volumes of groundwater being used for irrigation. Not only has this resulted in less water for agriculture and other uses, it has also resulted in an increase in the cost of water for all users. Land subsidence of up to 10 feet has resulted in some areas because of groundwater withdrawals occurring at rates that exceeded groundwater recharge.

Irrigation contributes to the movement of nutrients and pesticides into surface waters and groundwater, particularly in sandy soils. The impacts of pollutants (e.g., nutrients, pesticides, and sediments) from irrigation-induced runoff are similar to those discussed in Section III.A.1.

Mineralization and salinization of soils are additional impacts of irrigation. Irrigation water, whether from groundwater or surface water sources, has a natural base load of dissolved mineral salts. As the water is consumed by plants or lost to the atmosphere by evaporation, the salts remain and become concentrated in the soil. This is referred to as the "concentrating effect." The total salt load carried by irrigation return flow is the sum of the salt remaining in the applied water plus any salt picked up from the irrigated land. Irrigation return flows provide the means for conveying the salts to the surface water or groundwater supplies. If the amount of salt in the return flow is low in comparison to the total stream flow, water quality may not be degraded to the extent that use is impaired. However, if the process of water diversion for irrigation and the return of salinated water is repeated many times along a surface water, water quality will be progressively degraded for downstream irrigation use as well as for other uses. In the western states, major aquifers have been depleted or destroyed through salinization, or when withdrawals exceeded recharge rates.

Pollution Prevention/Waste Minimization Opportunities
There are several pollution prevention opportunities for irrigating crops. First, minimizing the use of irrigation will reduce erosion,

runoff, groundwater depletion, and salinization. It can also save money by reducing the costs associated with irrigation. Other pollution prevention techniques include:

✓ *Using well-designed irrigation systems.* A common cause of environmental impacts from irrigation is poor system design. Poorly designed systems may apply water nonuniformly, allowing some areas to become oversaturated while others do not receive adequate water. Areas not adequately irrigated may suffer yield or quality reductions, while overirrigated areas may suffer from the leaching of chemicals.

✓ *Using efficient irrigation systems.* There are several types of efficient irrigation systems, including surge irrigation systems and drip irrigation systems.

- With surge irrigation, water is sent through the furrows between each row of crops. Rather than sending all the water at once, small amounts are sent in bursts. In this manner, erosion is reduced, more water reaches the plant, and less runoff of irrigated water occurs.

- In drip irrigation, plants are watered directly from the irrigation source. While drip irrigation conserves water, by watering only the plants' fruits and the soil immediately around them, drip irrigation can also lead to soil erosion. If drip irrigation is the sole method used, the soil between rows of crops remains dry, thus making it more susceptible to wind erosion.

The Texas Agricultural Extension Service has found irrigation efficiency for surge irrigation up to 90 percent and drip irrigation to be up to 98 percent. These systems significantly reduce the amount of irrigation water that can runoff to surface waters, thus reducing pollution. Conventional systems have a much lower efficiency rate. The efficiency of all methods can be improved by varying application volumes as water tables rise and fall.

Calculating Fuel Use Efficiency for Irrigation Pumps

The Texas Agricultural Extension Service has developed a program to determine the efficiency of various irrigation methods. The program calculates a pumping plant's fuel use efficiency performance and compares it to a given standard. The program also calculates the fuel cost per acre-inch pumped and fuel cost savings if a pumping system is brought up to the performance standard. The program can be used to evaluate the pumping performance and fuel cost for the following fuels: (1) electricity, (2) natural gas, (3) diesel, (4) gasoline, (5) propane, and (6) butane.

In addition to well-designed and efficient irrigation systems, there are many inexpensive best management practices that can be used to reduce runoff and erosion, and lower irrigation costs. These methods include the following:

- ✓ Assure all irrigation systems are in good repair, with no leaks, and that the sprinklers are adjusted to minimize misdirected spray.
- ✓ Use low-volume spray heads and stop watering if puddling and runoff is observed.
- ✓ Irrigate early in the morning or in the evening when it is generally less windy and cooler.
- ✓ Utilize efficient irrigation methods such as drip irrigation. Many existing spray systems can be changed to function as drip systems.
- ✓ Install check valves to prevent downhill sprinkler heads from draining after the system has been shut off. This keeps water in the pipes for the next sprinkling. Follow manufacturer's instructions.
- ✓ Install "rainguards" that measure rainfall and stop operation of the irrigation controller during rainfall.
- ✓ If nutrients are irrigated, calculate the discharge rate of the system and irrigate only at desired loading.
- ✓ Replace worn irrigation nozzles (increased orifice size) that may result in over application.

III.A.6. Harvesting Crops and Post-Harvesting Activities

Harvesting crops involves digging, cutting, picking, or other methods of removing the crops from the ground, stalks, vines, or trees. Small fruits and other food crops (e.g., strawberries, melons) are typically harvested by hand, though may be harvested by machine. Field crops (e.g., corn, barley, oats) are typically harvested by machine. For specific crops, such as sugar cane, pre-harvest burning may be conducted to improve access to the crop.

Post-harvesting activities include washing and processes products; packaging, loading, and transporting products; and destroying crop residue (if appropriate).

- *Washing, processing, and packaging products.* Crops may be washed at the agricultural establishment or at the processing plant. Fresh agricultural crops may be washed at the agricultural establishment and then shipped directly to distribution centers or sales outlets. Agricultural crops destined for use as processed foods (e.g., canned fruits and vegetables or snack foods), are likely to undergo extensive washing and processing at the processing plant. Unusable crops can either be picked up manually or separated out from the usable stock after the washing process.

  Following processing, crops are packaged and prepared for delivery to the appropriate customer. Crops such as tobacco require drying during the onsite curing processing. Crops may be packaged using various materials, including corrugated cardboard, paper, and plastic/fabric packaging materials.

- *Loading and transporting products.* While the loading operation will vary between establishments, individually packaged crops (e.g., berries), are commonly loaded by forklift or by hand, while bulk packaged crops (e.g., potatoes and apples) may be loaded by conveyor. Crops are then transported typically by truck or rail to their final destination.

- *Destroying crop residue.* Post-harvest crop residue destruction is a practice used for specific crops, particularly in certain areas of the United States. For example, rice and wheat stubble are often burned in the southeast and northwest respectively after harvest is complete.

R0074313

Potential Pollution Outputs and Environmental Impacts
The potential pollution outputs of harvesting and post-harvesting activities include air emissions from harvesting equipment and crop residue burning; unusable or spilled crop; wastewater potentially contaminated with organic wastes and pesticides from crop washing; wastewater and waste product from processing; and damaged or unusable packaging materials. If discharged to surface waters, wastewater from crop washing can potentially cause BOD contamination. Damaged or unusable packaging and unusable/spilled crop may be managed as solid waste. Hydraulic lifts or conveyors used in the loading process may leak oil, resulting in soil contamination.

Pollution Prevention/Waste Minimization Opportunities
There are several pollution prevention and waste minimization opportunities for harvesting and post-harvesting activities. These include:

✓ *Maintaining harvesting machinery and vehicles*. Section III.A.7. *Maintaining and Repairing Agricultural Machinery and Vehicles* discusses various methods of keeping an environmentally responsible farm vehicle.

✓ *Using unusable product as nutrients*. Unusable products can be washed to remove pesticides and then composted for future use as nutrients. This can prevent the disposal of these products as solid wastes and réduce the amount of commercial fertilizers used.

✓ *Minimizing water use for product washing*. Minimizing the amount of water used for product washing can reduce potential BOD contamination and reduce water costs. There are several types of equipment that can be used to minimize water use including control faucets and sprayers. These faucets and sprayers control the flow of water, using significantly less water than the faucets that supply a continuous flow of water. Other simple techniques to minimize water use include the following:

- Installing a time sequence sprayer that can minimize the amount of water being used.

- Using a high-pressure, low-flow nozzle during cleaning to significantly reduce water use.

- Installing sideboards or splash guards to prevent spillage.

- Shutting the water off during breaks.

✓ *Prevent contamination from oil leaks.* Place catch pans underneath hydraulic lifts or conveyors to collect oil leaks and prevent soil contamination. This oil can then be recycled.

✓ *Prevent product spills.* The use of sideboards on conveyors or other equipment designed to transport products from the ground into the vehicle can be used to prevent product spills. Additionally, catch pans or containers underneath loading areas can be used to collect any unusable products left on the ground. These products can then be composted, if appropriate.

III.A.7. Maintaining and Repairing Agricultural Machinery and Vehicles

Day-to-day maintenance and repair activities keep agricultural machinery and vehicles safe and reliable. Maintenance activities include oil and filter changes, battery replacement, and repairs, including metal machining.

Potential Pollution Outputs and Environmental Impacts

The wastes from maintenance and repair activities can include used oil, spent fluids, spent batteries, metal machining wastes, spent organic solvents, and tires. These wastes have the potential to be released to the environment if not handled properly, stored in secure areas with secondary containment, protected from exposure to weather, and properly disposed of. If released to the environment, the impact of these releases can be contamination of surface waters, groundwater, and soils, as well as toxic releases to the atmosphere. Groundwater pollution can also result from discharges of wastes to Class V wells.

> **Proper Disposal of Oil-Based Fluids.** Spent petroleum-based fluids and solids should be sent to a recycling center whenever possible. Solvents that are hazardous waste must not be mixed with used oil or, under RCRA regulations, the entire mixture may be considered hazardous waste. Non-listed hazardous wastes can be mixed with waste oil, and as long as the resulting mixture is not hazardous, can be handled as waste oil. All used drip pans and containers should be properly labeled.

R0074315

Pollution Prevention/Waste Minimization Opportunities

Preventive maintenance programs can minimize waste generation, increase equipment life, and minimize the probability of significant impacts and accidents. Where the wastes cannot be eliminated, safe handling and recycling can minimize environmental impacts. The following presents pollution prevention/waste minimization opportunities for each type of waste.

Used Oil. The impact of oil changes can be minimized by preventing releases of used oil to the environment, and recycling or reusing used oil whenever possible. Spills can be prevented by using containment around used oil containers, keeping floor drains closed when oil is being drained, and by training employees on spill prevention techniques. Oil that is contained rather than released can be recycled, thus saving the farm money, and protecting the environment.

Recycling used oil requires equipment like a drip table with a used oil collection bucket to collect oil dripping from parts. Drip pans can be placed under machinery and vehicles awaiting repairs to capture any leaking fluids. By using catch pans or buckets, rather than absorbent materials to contain leaks or spills of used oil, the used oil can be more easily recycled. To encourage recycling, the publication "How To Set Up A Local Program To Recycle Used Oil" is available at no cost from the RCRA/Superfund Hotline at 1-800-424-9346 or 1-703-412-9810.

Spent Fluids. Farm machinery and vehicles require regular changing of fluids, including oil, coolant, and others. To minimize releases to the environment, these fluids should be drained and replaced in areas where there are no connections to storm drains or municipal sewers. Minor spills should be cleaned up prior to reaching drains. Used fluid should be collected and stored in separate containers. Fluids can often be recycled. For example, brake fluid, transmission fluid, and gear oil are recyclable. Some liquids are able to be legally mixed with used motor oil which, in turn, can be reclaimed.

During the process of engine maintenance, spills of fluids are likely to occur. The "dry shop" principle encourages spills to be cleaned immediately so that spilled fluid will not evaporate to air, be transported to soil, or be discharged to waterways or sewers. The following techniques help prevent and minimize the impact of spills:

- ✓ Collect leaking or dripping fluids in designated drip pans or containers. Keep all fluids separated so they may be properly recycled.

- ✓ Keep a designated drip pan under the vehicle while unclipping hoses, unscrewing filters, or removing other parts. The drip pan prevents splattering of fluids and keeps chemicals from penetrating the shop floor or outside area where the maintenance is occurring.

- ✓ Immediately transfer used fluids to proper containers. Never leave drip pans or other open containers unattended.

Radiator fluids are often acceptable to antifreeze recyclers. This includes fluids used to flush out radiators during cleaning. Reusing the flushing fluid minimizes waste discharges. If a licensed recycler does not accept the spent flushing fluids, consider changing to another brand of fluid that can be recycled.

Batteries. Farm operators have three options for managing used batteries: recycling through a supplier, recycling directly though a battery reclamation facility, or direct disposal. Most suppliers now accept spent batteries at the time of new battery purchase. While some waste batteries must be handled as hazardous waste, lead acid batteries are not considered hazardous waste as long as they are recycled. In general, recycling batteries may reduce the amount of hazardous waste stored at a farm, and thus reduce the farm's responsibilities under RCRA.

The following best management practices are recommended to prevent used batteries from impacting the environment prior to disposal:

- ✓ Place on pallets and label by battery type (e.g., lead-acid, nickel, and cadmium).

- ✓ Protect them from the weather with a tarp, roof, or other means.

- ✓ Store them on an open rack or in a watertight secondary containment unit to prevent leaks.

- ✓ Inspect them for cracks and leaks as they come to the farm. If a battery is dropped, treat it as if it is cracked. Acid residue from cracked or leaking batteries is likely to be hazardous waste under RCRA because it is likely to demonstrate the characteristic of corrosivity, and may contain lead and other metals.

✓ Neutralize acid spills and dispose of the resulting waste as hazardous if it still exhibits a characteristic of a hazardous waste.

✓ Avoid skin contact with leaking or damaged batteries.

Machine Shop Wastes. The major hazardous wastes from metal machining are waste cutting oils, spent machine coolant, and degreasing solvents. Scrap metal can also be a component of hazardous waste produced at a machine shop. Material substitution and recycling are the two best means to reduce the volume of these wastes.

The preferred method of reducing the amount of waste cutting oils and degreasing solvents is to substitute with water-soluble cutting oils. If non-water-soluble oils must be used, recycling waste cutting oil reduces the potential environmental impact. Machine coolant can be recycled, either by an outside recycler, or through a number of in-house systems. Coolant recycling is most easily implemented when a standardized type of coolant is used throughout the shop. Reuse and recycling of solvents also is easily achieved, although it is generally done by a permitted recycler. Most shops collect scrap metals from machining operations and sell these to metal recyclers. Metal chips which have been removed from the coolant by filtration can be included in the scrap metal collection. Wastes should be carefully segregated to facilitate reuse and recycling.

III.A.8. Fuel Use and Fueling Activities

Fuel is used to operate agricultural machinery, equipment, and vehicles that are used throughout almost every step of crop production, including preparing the site/soil, planting and tending the crops, applying nutrients and pesticides, irrigating and harvesting the crops, and post-harvesting activities. Agricultural machinery and vehicles are typically fueled using an aboveground fueling dispenser that is connected to an aboveground or underground fuel tank.

Potential Pollution Outputs and Environmental Impacts
Agricultural machinery and vehicles that use fuel most likely emit pollutants to the atmosphere. The activity of fueling itself can emit air

R0074318

pollutants, and spills of fuel can cause water, soil and groundwater contamination. Underground fueling systems that are not monitored or maintained properly can leak into the surrounding soils and eventually contaminate groundwater.

Pollution Prevention/Waste Minimization Opportunities
Properly maintaining fuel tanks, lines, and fueling systems can substantially reduce the probability of accidental fuel spills or leaks. All leaking pipe joints, nozzle connections, and any damage to the fueling hose (e.g., kinks, crushing, breaks in the carcass, bulges, blistering, soft spots at the coupling, deep cracks or cuts, spots wet with fuel, or excessive wear) should be fixed immediately to reduce the amount of pollution to the environment. Spill and overflow protection devices can be installed to prevent fuel spills and secondary containment can be used to contain spills or leaks. Additional pollution prevention techniques for fueling include the following:

✓ Inspect fueling equipment daily to ensure that all components are in satisfactory condition. While refueling, check for leaks.

✓ If refueling occurs at night, make sure it is carried out in a well-lighted area.

✓ Never refuel during maintenance as it might provide a source of ignition to fuel vapors.

✓ Do not leave a fuel nozzle unattended during fueling or wedge or tie the nozzle trigger in the open position.

✓ Discourage topping off of fuel tanks.

III.A.9. Maintaining the Facility

Providing Drinking Water

As part of maintaining the physical site, an owner often is responsible for providing and maintaining a safe source of drinking water for those individuals who live or work at the site. Water provided from a surface water supply or groundwater supply may be considered a public water system and, as such, is subject to federal regulations. To be

> A public water system is a system that receives water from a well, river, reservoir, or other sources, and serves piped water to at least 15 service connections or regularly serves an average of 25 people each day for at least 60 days.

R0074319

subject to the Safe Drinking Water Act, the system must meet set criteria such that it is classified as one of the following water systems: community, non-transient non-community, or transient non-community. To ensure the drinking water source, whether surface or groundwater, is not contaminated, the regulations require the owner of the public water system to conduct periodic monitoring and analyses.

Potential Pollution Outputs and Environmental Impacts
Surface water supplies may become contaminated through runoff. Groundwater supplies may become contaminated through a variety of sources, including runoff and leaching, improperly grouted wellheads, improperly constructed or sited wellheads, or faulty onsite septic systems. Potential environmental impacts from contaminated drinking water include a wide variety of health effects for those who ingest it. Depending on the contaminant, the water may cause short-term illnesses and may also lead to long-term health effects.

Pollution Prevention/Waste Minimization Opportunities
The primary concern with drinking water is to ensure it does not become contaminated. The previous sections of this chapter discussed the pollution prevention methods associated with crop production that can help ensure that surface water or groundwater does not become contaminated, and thus result in contaminated drinking water.

Managing Equipment Containing PCBs
Facility maintenance includes managing equipment that may contain PCBs, such as generators, electrical transformers and their bushings, capacitors, reclosers, regulators, electric light ballasts, and oil switches. Facilities must ensure through activities related to the management of PCBs (e.g., inspections, proper storage) that human food or animal feed are not exposed to PCBs.

Potential Pollution Outputs and Environmental Impacts
The potential pollution outputs are spills or leaks of PCB-containing oil from this equipment and hazardous air emissions in the event of an electrical fire. These releases can result in air, water, and soil contamination. While the regulations do not establish a specific distance limit, any item containing PCBs is considered to pose an unacceptable exposure risk to food or feed if PCBs released in any form have the potential to reach/contaminate food or feed.

Pollution Prevention/Waste Minimization Opportunities
There are several techniques that can be used to prevent releases of PCBs to the environment and contamination of food or feed. These

include replacing the PCB-containing equipment; replacing the PCB-containing oil with oil that does not contain PCBs; providing secondary containment of the equipment so that spills cannot contaminate the soil or groundwater; and relocating the equipment to a location that does not present an exposure risk to food or feed. PCB-containing equipment should be inspected regularly for leaks and any deterioration that may cause an electrical fire.

Renovating and Demolishing Structures
Asbestos and lead-based paint may be present in structures that are being renovated or demolished. While EPA banned the use of many asbestos-containing materials in the 1970s, buildings built before this are likely to have asbestos-containing materials. Used as insulation and a fire retardant, asbestos and asbestos-containing materials can be found in a variety of building construction materials, including pipe and furnace insulation materials, asbestos shingles, millboard, textured paint and other coating materials, and floor tiles. It is also found in vehicle brake linings. Lead-based paint can typically be found on the interiors and exteriors of buildings constructed prior to 1978. This is because EPA banned the manufacture and use of lead-based paint and lead-based paint products in 1978.

Potential Pollution Outputs and Environmental Impacts
The renovation and demolition of structures can impact the environment as materials that may have previously been trapped within or on buildings become exposed to the environment. When encapsulated, asbestos fibers do not impact human health or the environment. However, during renovation or demolition, asbestos fibers may be released. If inhaled or ingested, asbestos fibers can cause respiratory damage.

Lead is a known carcinogen through any exposure pathway and may result in significant health effects. As with asbestos, lead-based paint that remains intact and is not chipping or otherwise deteriorating, does not present health problems. However, when it does become damaged, it should be properly removed, contained, and disposed of to prevent exposure. The activity of paint removal has the potential to impact human health and the environment as lead-containing fibers, dust, and paint chips are released. Paint chips and dust can cause indoor air contamination during renovation, and soil contamination from demolition or improper disposal. In addition, lead-based paint chips and dust, if ingested, can create severe, long-term health effects, especially for children.

Pollution Prevention/Waste Minimization Opportunities
The potential impact can be mitigated by assuring any asbestos is encapsulated within the building structure while the building is being used, and properly contained during construction and demolition.

III.B. Greenhouses and Nurseries: Operations, Impacts, and Pollution Prevention Opportunities

This section provides an overview of commonly employed operations and maintenance activities at greenhouses and nurseries. This discussion is not exhaustive; the operations and maintenance activities discussed are intended to represent the major sources pollution outputs and environmental impacts from producing greenhouse and nursery products. General pollution prevention and waste minimization opportunities are also discussed in the context of each operation.

Facilities that are engaged in greenhouse and nursery operations (e.g., horticulture), are responsible for growing and selling greenhouse and nursery products. Many of the activities related to horticulture production are quite similar to those necessary for production of crops. As a result, the material inputs, pollution outputs, and potential environmental impacts are very similar to those discussed throughout Section III.A.

While this section focuses on those activities for operations that fall under NAICS code 0114 (SIC code 018), many of these activities also take place under other parts of NAICS code 011 - Crop Production (SIC code 01). In contrast to food crops, horticultural production may include maintenance of plants and trees for two or more growing seasons. While food crops are harvested to be consumed, horticulture products are often sold live. Furthermore, horticulture production includes activities that take place both indoors and in the open air.

This section describes the following horticultural production activities:

- Preparing soil/growing media for horticulture crops
- Planting horticulture crops
- Applying nutrients to horticulture crops
- Applying pesticides and pest control for horticulture crops
- Irrigating horticulture crops
- Tending and harvesting horticulture crops
- Constructing and maintaining greenhouses
- Transporting products
- Maintaining and repairing equipment

- Fuel use and fueling equipment

Exhibit 21 presents material inputs and pollution outputs from each of these processes.

Exhibit 21. Greenhouse and Nursery Production Activities, Raw Material Inputs, and Pollution Outputs

Activity	Raw Material Input	Pollution Output
Preparing soil/growing media	– Soil, peat, or other synthetic growing media – Lime	– Air emissions (e.g., dust) – Sediment, nutrient, and pesticides runoff from soil erosion
Planting	– Seeds, seedlings	– Air emissions (e.g., dust) – Sediment, nutrient, and pesticide runoff from soil erosion – Plants, branches, leaves, etc.
Applying nutrients	– Organic nutrients – Commercial nutrients – Water	– Runoff and leaching of unused or misapplied nutrients – Chemical air emissions
Applying pesticides and pest control	– Pesticides (including insecticides, rodenticides, fungicides, and herbicides)	– Runoff and leaching of unused or misapplied nutrients – Chemical air emissions
Irrigating (not including nutrient application)	– Water – Chemicals	– Runoff contaminated with sediments, salts, pesticides, and nutrients
Tending and harvesting		– Plant and tree clippings
Constructing and maintaining greenhouses	– Construction materials – Fuel for heating and cooling – Boiler chemicals	– Construction wastes – Air emissions – Storm water runoff from increased impervious area – Spills of boiler chemicals
Packaging, loading, and transporting horticulture crops	– Plastic, burlap or paper packaging materials	– Dead plants – Waste packaging materials

Exhibit 21. Greenhouse and Nursery Production Activities, Raw Material Inputs, and Pollution Outputs

Activity	Raw Material Input	Pollution Output
Maintaining and repairing equipment	– Oil – Lubricating fluids – Fuel – Coolants – Solvents – Tires – Batteries – Equipment parts	– Used oil – Spent fluids – Spent batteries – Metal machining wastes – Spent organic solvents – Tires – Air, water, soil, and groundwater pollution resulting from spilled and/or spent fluids
Fuel use and fueling activities	– Fuel	– Air emissions from machinery – Air, water, soil, and groundwater pollution resulting from spills

III.B.1. Preparing Soil/Growing Media for Horticulture Crops

Prior to planting, the soil or growing media[3] must be prepared for growing horticulture crops. For horticulture crops grown outdoors, soil preparation generally involves tilling and the application of nutrients, primarily commercial fertilizer. Tilling aerates the soil, allows seedlings to be placed in the soil, and helps roots take hold of the soil. It also improves drainage and allows for better assimilation of nutrients (i.e., fertilizers) and pesticides into the soil. For greenhouse crops, proper soil or media preparation is key for fostering plant growth. Due to the relatively shallow depth and limited volume of greenhouse containers, soil must be amended to provide the physical and chemical properties necessary for plant growth.[4] Materials are added to the soil that promote improved aeration, drainage, and water holding capacity. These materials can include peat and peat-like materials, wood residues, rice hulls, sand, vermiculite, calcined clays, expanded polystyrene, urea formaldehydes, and bagasse (a waste byproduct of the sugar industry that is often composted to promote aeration). In addition, soil pH is often

[3] Note that many indoor growing operations use non-soil media consisting of peat moss, compost, lime, and other material, rather than soil in order to provide a more porous growth environment in a relatively small volume container.

[4] *Texas Greenhouse Management Handbook*, Dr. Don Wilkerson, Texas Agricultural Extension Service, http://aggie-horticulture.tamu.edu/greenhouse/guides/green/green.html.

adjusted by adding ground limestone, hydrated lime, or dolomitic lime to suit the plants being grown.[5]

Potential Pollution Outputs and Environmental Impacts

The major environmental impacts of soil/growing media preparation in horticulture operations is runoff that carries pollutants (e.g., soils/growing media, nutrients, pH adjusting agents, pesticides) to groundwater or surface waters.

For outdoor operations, the primary pollution output is runoff contaminated with pollutants (e.g., sediments, nutrients, and pesticides) caused by soil erosion. Soil erosion causes damage both onsite and offsite at horticulture operations. Onsite erosion can reduce the productivity of the operation and increase the need for fertilizer and other inputs. Pollutants (e.g., sediments, nutrients, and pesticides) that are transported offsite by runoff may be deposited in surface waters, leading to reduced oxygen content, increased algae growth, and overall degradation of water quality.

Indoor operations can also be sources of water pollution. Runoff that comes in contact with spills of soil/soil media, improperly managed outdoor bulk soil/media piles, or discharges of floor washdown water can transport sediments and other pollutants to surface waters. Spilled or excessively applied lime also has the potential to contaminate groundwater or surface waters.

Pollution Prevention/Waste Minimization Opportunities

When preparing soil for outdoor operations, runoff can be reduced by planting and maintaining buffer strips of grass and sod. These strips can slow runoff and trap sediment, reducing soil loss and potentially preventing water contamination. Horticulture operations that maintain grass strips between rows of plants or trees have been shown to maintain 30 percent to 50 percent more soil than those that maintain only bare soil.[6]

R0074325

Unnecessary application of materials that could potentially leach into and pollute nearby water sources can be prevented through frequent soil testing prior to application. Spills can be prevented by assuring the integrity of the containers in which the materials are kept. Containers should be routinely repaired and replaced if perforated.

III.B.2. Planting Horticulture Crops

Horticulture crops are planted after the soil/soil media is prepared. Planting involves the placement of seeds or seedlings into the soil/soil media. Planting is typically done by hand for greenhouse operations, while planting may be done either by hand or mechanically for nursery operations.

Potential Pollution Outputs and Environmental Impacts
The major inputs in planting horticulture crops are the seeds and energy used to plant them. The pollutant outputs include air emissions from any planting equipment.

Pollution Prevention/Waste Minimization Opportunities
Pollution prevention opportunities during the planting process for horticulture operations are similar to those discussed in Section III.A.2.

III.B.3. Applying Nutrients to Horticulture Crops

During all phases of the crop production process, nutrients (e.g., fertilizer, manure, biosolids) can be applied to horticulture crops. Nutrients enhance crop growth by providing essential nitrogen, phosphorus, potassium, and micro-nutrients. Nutrients can be applied directly to the plant or soil surface, incorporated into the soil, or applied with irrigation water through chemigation.

Most greenhouse operations use liquid fertilizers, supplemented by granular or slow release fertilizers which are added to the growing medium. While the frequency of fertilizer application may vary, many operations continuously fertilize through irrigation systems. For outdoor operations, nutrient application is often more mechanically intensive, requiring coverage of large areas. Nearly all acres planted are treated with one or more types of nutrients (e.g., fertilizers, manure, or biosolids). Depending on the timing of the seed planting, the application may occur simultaneously.

For outdoor operations, fertilizers may be applied in solid, liquid, or gas form. Depending on the state of the product, nutrients may be applied using specialized trucks to apply dry product, tractors to pull sprayer equipment for liquids, and pressurized tanks to apply anhydrous ammonia. Techniques used to apply fertilizer include the following:

- *Band placement* is used to locate the fertilizer in an optimum position relative to the seed. This minimizes salt injury to the developing roots.

- *Broadcast application* refers to the practice of distributing the product uniformly over the soil surface. Tractors, airplanes and helicopters are used to broadcast fertilizers.

- *Injection* refers to the application of anhydrous ammonia. At normal pressure, anhydrous ammonia (NH_3) is a gas. For application as a fertilizer, it is pressurized to form a liquid. Because it is a volatile liquid, it is incorporated into the soil as a liquid under pressure to a depth of 15 to 25 cm. In the soil, NH_3 is converted to NH_4^+, which is stable. Gaseous ammonia is lost if soil pH increases much above 7, or as moisture fluctuates from field capacity.

- *Addition of fertilizer to irrigation water* (known as fertigation), is usually part of a drip irrigation system that can apply water and fertilizer to a precise predetermined location.

- *Manure and biosolids* may be applied to the soil surface as a solid from a tractor-pulled box-type manure spreader as it makes passes across the field. Slurry manure and biosolids are generally applied to the soil surface by tractor-pulled or truck flail spreaders or subsurface by tractor or truck injection equipment. Liquid manure may be surface irrigated or subsurface injected. Manure and biosolid solids and slurries may be mechanically incorporated into the soil following application.

Potential Pollution Outputs and Environmental Impacts
There are several potential pollution outputs and environmental impacts from nutrient application and spills including runoff and leaching of improperly or excessively applied nutrients which can contaminate surface water and groundwater; air emissions; and increases in the amount of soluble salts in soils. Excessive amounts of soluble salts in the soil can prevent or delay seed germination, kill or seriously retard plant growth, and possibly render soils and groundwater unusable.

The degree of environmental impacts depends on the application method. The surface application of fertilizer, manure, or biosolids is more likely to result in runoff than injection. Non-composted surface-applied manure will volatilize and release ammonia to the air. Spills of nutrients may also negatively impact the environment since they will be concentrated in one specific area.

Pollution Prevention/Waste Minimization Opportunities
There are several pollution prevention techniques that can be used to reduce pollution and impacts from nutrient application. These include:

- ✓ Application methods that prevent runoff (e.g., application by injection).
- ✓ Restricting application in close proximity to surface waters.
- ✓ Applying nutrients at agronomic rates to crops/cropland.
- ✓ Managing the site to eliminate erosion or reduce the runoff potential.
- ✓ Developing and implementing **nutrient management plans**. The primary purpose of nutrient management is to achieve the level of nutrients (e.g., nitrogen and phosphorus) required to grow the planned crop by balancing the nutrients that are already in the soil with those from other sources (e.g., manure, biosolids, commercial fertilizers) that will be applied. At a minimum, nutrient management can help prevent the application of nutrients at rates that will exceed the capacity of the soil and the planned crops to assimilate nutrients and prevent pollution. More information on nutrient management plans is presented in Section III.A.3.

III.B.4. Applying Pesticides and Pest Control for Horticulture Crops

The pesticides commonly used in horticulture operations include insecticides, fungicides, and herbicides. For large nursery operations, pesticides are often applied through liquid spraying. As described in Section III.A.4., liquid spraying may be conducted by aircraft, tractor spray rigs, or blasters.

- Aerial methods are the most common spray applications, with about two-thirds of all insecticides and fungicides applied in this manner. Trees and shrubs may be aerially treated several times per season with insecticides, fungicides, and protectant oils. Helicopters are often used because the turbulence from the main rotor tends to push the pesticides down toward the plant.

- Tractor spray rigs provide an advantage where horticulture crops are grown in rows because planting, fertilizing and spraying can be accomplished in one pass through the field.

- Blasters can be used for applying insecticides and fungicides to trees.

Potential Pollution Outputs and Environmental Impacts
The potential environmental impacts from pesticide application are runoff or leaching to surface water or groundwater, spills to surface waters, potential human exposure, and soil contamination that could leave land unproductive. These environmental impacts may all occur if pesticides are not applied according to the label directions. Impacts from pesticide application to horticulture crops are similar to those discussed in Section III.A.4.

Pollution Prevention/Waste Minimization Opportunities
As discussed previously in Section III.A.4, the best way to prevent environmental impacts from pesticide use is follow label directions for application and prevent or minimize their use wherever possible. Pesticide use accounts for a significant portion of horticulture production costs. By reducing their use, horticulture operations cannot only reduce production costs, but also reduce environmental impacts from their operations. Pesticide use can be minimized by using integrated pest management approaches, new technologies, efficient application methods, controls, and basic preventive measures. Pollution prevention opportunities for reducing or minimizing impacts from application of pesticides are discussed in Section III.A.4.

III.B.5. Irrigating Horticulture Crops

Irrigation transports water to horticulture crops to nourish the crops, ease the shock to the plants following transplant, and keep the crops cool in arid or excessive heat conditions. There are many different irrigation systems, all of which are designed to move water from its source to where it can be used for crop production. Irrigation water is obtained from onsite groundwater and surface water sources, as well as offsite sources such as rivers, pipelines, canals and aqueducts that are operated by irrigation districts and private water companies.

All greenhouse crops are irrigated on a regular basis (since they are enclosed and do not receive water from rainfall events). Water is generally applied to the upper surface of the soil/growing media by using overhead sprinklers, drip or trickle irrigation systems, hand-held hoses, or a combination of methods. The advantage of drip or trickle systems is that they minimize water use, leaching of nutrients in the growth media, and reduce the probability of root rot in excessively moist soil. Overhead sprinklers and hand water irrigation methods are often less expensive to implement, but use more water per plant.[7]

Potential Pollution Outputs and Environmental Impacts
For indoor operations, the primary pollution outputs are wastewater and runoff that contains nutrients and pesticides. For outdoor horticulture operations, the pollution outputs from irrigation include runoff and leaching of nutrients and pesticides, salinization, and groundwater depletion. The impacts of pollutants (e.g., nutrients, pesticides, and sediments) from irrigation-induced runoff are similar to those discussed in Section III.A.5.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention opportunity for irrigation is the use of irrigation methods which efficiently apply water, thereby reducing water use and the potential for runoff. One efficient application method is drip irrigation. Drip irrigation gradually applies water directly to the soil surface over extended periods of time (i.e., 1, 2, or 5 gallons per hour), resulting in less water loss due to evaporation or runoff. If nutrients are applied using drip irrigation, the amount of fertilizer used can also be reduced if the nutrients are applied at the utilization rate of the plant. In addition to the environmental benefits, drip irrigation tends to cause roots to concentrate within the limited wetted soil area, thus creating a more concentrated root ball. More concentrated root balls make the plants easier to ship and increase their ability to survive through the sale and planting process.[8] Section III.A.5 describes other potential pollution prevention opportunities associated with irrigation.

[8] *Best Management Practices for Field Production of Nursery Stock*, North Carolina State University Biological and Agricultural Engineering Extension Service, http://www.bae.ncsu.edu/programs/extension/ag-env/nursery/.

III.B.6. Tending and Harvesting Horticulture Crops

Horticulture crops must be maintained from planting through the point of sale. Each plant may be tended for one or several growing seasons. Tending horticulture crops involves applying water, nutrients, and pesticides; transplanting crops from small to larger pots or from pots to outside areas; and pruning trees and shrubs to enhance plant health and make them more aesthetically pleasing.

Harvesting of horticulture crops involves digging, cutting, or other methods of safely removing product from the ground, stalks, vines, or trees. Harvesting must be done with care to protect the plant and assure that it remains alive through the point of sale. For flowers, small plants, and greenhouse-grown vegetables, harvesting is generally done manually. For larger trees and shrubs, harvesting may be done by hand or by machine.

Potential Pollution Outputs and Environmental Impacts
The primary pollution outputs from tending and harvesting horticulture crops are plant clippings (e.g., branches, leaves, and flowers) that have been removed during the tending/pruning activities.

Pollution Prevention/Waste Minimization Opportunities
There are several pollution prevention and waste minimization opportunities for tending and harvesting activities. These include:

- *Maintaining harvesting machinery and vehicles*. Section III.A.7. *Maintaining and Repairing Agricultural Machinery and Vehicles* discusses various methods of keeping an environmentally responsible farm vehicle.

- *Composting plant clippings*. Plant clippings can be composted, while tree clippings can be used as drying material to compost the plant clippings. Tree clippings can also be ground as mulch and reused in the fields or greenhouse. By placing wood waste under covered structures or tarps, operators can also reduce the decomposition and leaching from wood waste piles.[9]

[9] *Environmental Guidelines for Greenhouse Growers - Site Planning*, British Columbia Ministry of Agriculture and Food, 1998, http://www.agf.gov.bc.ca/resmgmt/fppa/pubs/environ/greenhse/grnhse.htm.

III.B.7. Constructing and Maintaining Greenhouses

Greenhouse construction and design can influence how effectively horticulture crops grow, as well as the operation's ability to minimize environmental impacts. Greenhouse construction includes building the structure and ensuring that it meets the operational requirements of the horticulture operation.

Greenhouse maintenance involves maintaining the structural integrity as well as the appropriate climate conditions. Activities may include operating and maintaining boilers that provide heat during cold weather; operating fans to keep crops and workers cool during warm weather; and general maintenance of the greenhouse itself.

Potential Pollution Outputs and Environmental Impacts
The potential pollutant outputs from greenhouse construction include increased potential for storm water runoff during construction; air emissions from construction equipment; and construction wastes primarily consisting of packaging materials, steel or aluminum parts, and waste concrete. Boilers used for heating greenhouse can produce air emissions and potential spills of boiler chemicals can impact the environment.

Pollution Prevention/Waste Minimization Opportunities
Many pollution prevention opportunities begin at the design and construction stage. Pollution prevention opportunities in greenhouse design include:

✓ Locating storage facilities for fuel, wood waste, fertilizer, or pesticides far away and contained from any watercourse.

✓ Locating well water sites on the highest elevation on the property and as far as possible from areas where fertilizer, pesticides, and petroleum products are stored or handled.

✓ Designing the greenhouse so that it can accommodate efficient drip irrigation systems.

✓ Planning facilities that can separate and disinfect irrigation or wash water so that the water can be reused.

✓ Installing closed systems that minimize or prevent leaching from irrigation systems.

- ✓ Constructing foundations and floors that permit recovery of leachate, such as lined soil zones and concrete floors.
- ✓ Selecting efficient watering systems.
- ✓ For outdoor areas, using well-drained gravel keeping impervious pavement to a minimum.[10]

Implementing these activities in the design and construction stage helps facilitate their implementation throughout the production process.

III.B.8. Packaging, Loading, and Transporting Products

Horticulture crops must be packaged, loaded, and transported by truck or rail to their destinations. Packaging materials may include plastic, burlap, or paper.

Potential Pollution Outputs and Environmental Impacts
The primary pollution outputs include damaged or dead plants and discarded packaging materials, all of which may be managed as solid waste. Hydraulic lifts or conveyors used in the loading process may leak oil, resulting in soil contamination.

Pollution Prevention/Waste Minimization Opportunities
Pollution prevention opportunities for packaging include reducing the volume of packaging used and recycling any waste packaging materials when possible. Pollution prevention ideas for reducing emissions from transport vehicles are similar to those discussed in Section III.A.7.

III.B.9. Maintaining and Repairing Machinery and Vehicles at Greenhouses/Nurseries

Horticulture operations operate and maintain heavy equipment that is used for preparing soil, maintaining the crops, and transporting products for sale. Day-to-day maintenance and repair activities keep machinery and vehicles safe and reliable. Maintenance activities include oil and filter changes, battery replacement, and repairs including metal machining.

[10] *Environmental Guidelines for Greenhouse Growers - Site Planning*, British Columbia Ministry of Agriculture and Food, 1998, http://www.agf.gov.bc.ca/resmgmt/fppa/pubs/environ/ gréenhse/grnhse.htm.

Potential Pollution Outputs and Environmental Impacts
The wastes from maintenance and repair activities can include used oil, spent fluids, spent batteries, metal machining wastes, spent organic solvents, and tires. These wastes have the potential to be released to the environment if not handled properly, stored in secure areas with secondary containment, protected from exposure to weather, and properly disposed of. If released to the environment, the impact of these releases can be contamination of surface waters, groundwater, and soils, as well as toxic releases to the atmosphere. Groundwater pollution can also result from discharges of wastes to Class V wells.

Pollution Prevention/Waste Minimization Opportunities
Preventive maintenance programs can minimize waste generation, increase equipment life, and minimize the probability of significant impacts and accidents. Where the wastes cannot be eliminated, safe handling and recycling can minimize environmental impacts. Pollution prevention/waste minimization opportunities for these wastes are similar to those discussed previously in Section III.A.7.

III.B.10. Fuel Use and Fueling Activities at Greenhouses/Nurseries

Fuel is used to operate agricultural machinery, equipment, and vehicles that are used for horticulture crop production, including preparing the site/soil, planting crops, applying nutrients and pesticides, irrigating, and post-harvesting activities. Agricultural machinery and vehicles are typically fueled using an aboveground fueling dispenser that is connected to an aboveground or underground fuel tank.

Potential Pollution Outputs and Environmental Impacts
Agricultural machinery and vehicles that use fuel most likely emit pollutants to the atmosphere. The activity of fueling itself can emit air pollutants, and spills of fuel can cause water, soil and groundwater contamination. Underground fueling systems that are not monitored or maintained properly can leak into the surrounding soils and eventually contaminate groundwater.

Pollution Prevention/Waste Minimization Opportunities
Properly maintaining fuel tanks, lines, and fueling systems can substantially reduce the probability of accidental fuel spills or leaks. All leaking pipe joints, nozzle connections, and any damage to the fueling hose (e.g., kinks, crushing, breaks in the carcass, bulges, blistering, soft spots at the coupling, deep cracks or cuts, spots wet with fuel, or excessive wear) should be fixed immediately to reduce

the amount of pollution to the environment. Spill and overflow protection devices can be installed to prevent fuel spills and secondary containment can be used to contain spills or leaks. Additional pollution prevention techniques to prevent fuel spills and methods to more efficiently refuel are discussed in Section III.A.8.

III.C. Forestry Production Industry: Operations, Impacts, and Pollution Prevention Opportunities

Nearly 500 million acres of forest land are managed for the production of timber in the United States. This section provides an overview of commonly employed operations and maintenance activities in the forestry industry. This discussion is not exhaustive; the operations and maintenance activities discussed are intended to represent the major sources of environmental impacts from forestry. It also presents an overview of pollution prevention and waste minimization opportunities within the industry.

Summary of General Potential Pollution Outputs and Environmental Impacts for the Forestry Production Industry

EPA's National Summary of Water Quality Conditions (1998) lists silviculture nonpoint source pollution as contributing to 7 percent of impaired river miles, 7 percent of impaired acres of lakes, and 3 percent of impaired square miles of estuaries. Forestry activities can contribute to nonpoint source pollution and water quality degradation through erosion, removal of streamside vegetation, destruction of habitat, and the use of pesticides and nutrients, primarily commercial fertilizers. Habitat destruction can impact various animals, including endangered species such as the spotted owl. Eroded forest soils potentially are carried to surface waters where sedimentation occurs and stream life is negatively impacted. The removal of streamside vegetation increases the potential for erosion and also eliminates shading of the waterbody. Turbidity from erosion and reduced shade result in higher water temperatures and lower dissolved oxygen concentration. Pesticides and fertilizers can be carried in runoff to waterbodies affecting water quality.

Summary of General Pollution Prevention/Waste Minimization Opportunities for the Forestry Production Industry

Best management practices applied to forestry operations can be classified as 1) prevention measures as part of planning, policy and management; and 2) reduction measures applied to the land as an integral part of the silvicultural activity. Prevention through management decision involves the incorporation

R0074335

of environmental protection into organizational policy and in the planning, design and scheduling of forestry activities. At this stage, location and design of logging access roads, intermediate activities, harvesting methods, and reforestation decisions should be made to prevent or minimize the aggravation of inherent pollution hazards.

The reduction measures to control erosion and sediment runoff generally utilize some physical, biological, or chemical method or technique. Reduction measures modify and reduce the unavoidable disturbances caused by an activity, for example, revegetation of cleared areas, mulching of roadcuts and fills, and removal of debris from watercourses. Reduction measures also include the construction of berms, rip-rapping, baffles, drop structures, catch basins, cross-drains, and slope stabilization on road sites. Because of the widespread nature of sediment runoff, erosion control measures must be a principal thrust of the water quality management program on each forestry management unit.

In areas where nutrients, pesticides, and other chemicals cause particular problems on surface waters or groundwater, further control measures may be necessary. These measures could relate to the application (timing methods and amount), utilization, and management of fertilizers, pesticides, and fire retardant chemicals. Particular attention should be taken to keep chemicals away from streams. Care must be exercised to ensure that thermal problems are not created in streams by excessive removal of shade canopy. Attention to proper forest management, engineering, and harvesting principles can substantially reduce pollution attributed to forestry.

The following considerations should be part of the pre-harvest planning stage: threatened and endangered species and sensitive habitats, wetland areas, streamside management area/width, cumulative effects analysis, timing of operation (i.e., to avoid moisture), and identification of landslide potential and other high risk areas.

Operations of the Forestry Production Industry

This section describes the following forestry production activities:

- Road construction and use
- Timber harvesting
- Forest Regeneration
- Site preparation
- Prescribed burning
- Application of chemicals

Exhibit 22 presents raw material inputs and pollution outputs from each of these forestry production activities.

Exhibit 22. Forestry Production Activities, Raw Material Inputs, and Pollution Outputs

Activity	Raw Material Input	Pollution Output
Road construction and use	– Fuel and oil used in construction equipment	– Sediment in runoff from soil erosion – Air emissions
Timber harvesting	– Fuel and oil used in harvesting, chipping, loading, and hauling equipment	– Sediment and organic debris in runoff from soil erosion – Thermal pollution – On-site leaks (i.e., hydraulic fluid) – Air emissions
Forest regeneration	– Fuel used in planting equipment – Commercial fertilizers	– Sediment in runoff from soil erosion – Nutrient in runoff from fertilizer application – Air emissions
Site preparation	– Fuel and oil used in mechanical equipment – Chemical herbicides	– Sediment in runoff from soil erosion – Chemicals in runoff from herbicide application – Air emissions
Prescribed burning	– Fuel to start fire	– Sediment in runoff from soil erosion – Air emissions (smoke)
Application of chemicals	– Fertilizers – Pesticides – Water – Fuel used in application equipment	– Chemical air emissions – Runoff contaminated with chemicals

III.C.1. Road Construction and Use

Building the road system to allow for harvesting involves clearing the roadway of trees, grading soil, placing culverts for stream crossings, construction, and surfacing. Following road construction, the forest becomes accessible for the

R0074337

logger to fall the trees and transport them to a landing where they will then be loaded and transported to the mill.

There are several types of roads used in timber harvesting. The cheapest and easiest road is the skid trail which is usually nothing more than a dirt path used by the skidders to get the trees to the landing area. Skid trails must be located outside of the Streamside Management Zone (SMZ) and must use a bridge or culvert of acceptable design to cross perennial or intermittent streams. The road from the landing to the main road is usually better than a skid trail because it must support the trucks that haul the wood to the mill. Some wood product companies build roads designed to last for many years. However, these type of roads are too expensive for most landowners to construct.

Rolling dips, water bars, cross-drains, water turnouts, and culverts are used to control runoff and erosion, and allow vehicles to cross intermittent or perennial streams.

Abandonment of roads, watercourse crossings, and landings must be planned and conducted in a manner that provides for permanent maintenance-free drainage to soil resources; minimizes concentration of runoff, soil erosion, and slope instability; prevents unnecessary damage to soil resources; promotes regeneration and protects the quality and beneficial uses of water.

Potential Pollution Outputs and Environmental Impacts
The primary pollution outputs during road construction and use may include air emissions from road construction equipment and machinery used for harvesting and soil erosion. Roads are considered to be the major source of erosion from forested lands, contributing up to 90 percent of the total sediment production from forestry operations. Erosion potential from roads is accelerated by increasing slope gradients on cut-and-fill slopes, intercepting subsurface water flow, and concentrating overland flow on the road surface and in channels. Roads with steep gradients, deep cut-and-fill sections, poor drainage, erodible soils, and road-stream crossings contribute to most of this sediment load, with road-stream crossings being the most frequent sources of erosion and sediment. Soil loss tends to be greatest during and immediately after road construction because of the unstabilized road bed and disturbance by passage of heavy trucks and equipment.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention methods in road construction and use are designed to reduce erosion of soil and minimize delivery of

sediment to surface waters. Proper road design and construction can prevent road fill and road backslope failure, which can result in mass movements and severe sedimentation. Proper road drainage prevents concentration of water on road surfaces, thereby preventing road saturation that can lead to rutting, road slumping, and channel washout. Proper road drainage during logging operations is especially important because that is the time when erosion is greatly accelerated by continuous road use.

Surface protection of the roadbed and cut-and-fill slopes can:

- ✓ Minimize soil losses during storms.
- ✓ Reduce frost heave erosion production.
- ✓ Restrain downslope movement of soil slumps.
- ✓ Minimize erosion from softened roadbeds.

Although there are many commonly practiced techniques to minimize erosion during the construction process, the most meaningful are related to how well the work is planned, scheduled, and controlled by the road builder and those responsible for determining that work satisfies design requirements and land management resource objectives. Most erosion from road construction occurs within a few years of disturbance. Therefore, erosion control practices that provide immediate results (such as mulching or hay bales) should be applied as soon as possible to minimize potential erosion.

Drainage of the road prism, road fills in stream channels, and road fills on steep slopes are the elements of greatest concern in road management. Roads used for active timber hauling usually require the most maintenance, and mainline roads typically require more maintenance than spur roads. Use of roads during wet or thaw periods can result in a badly rutted surface, impaired drainage, and excessive sediment leading to waterbodies. Inactive roads, not being used for timber hauling, are often overlooked and receive little maintenance.

The following pollution prevention practices can be used for road construction and use:

- ✓ Follow the design developed during preharvest planning to minimize erosion by properly timing and limiting ground disturbance operations.

- ✓ Design skid trail grades to be 15 percent or less. Do not locate and construct roads with fills on slopes greater than 60 percent.

- ✓ Avoid construction during fish egg incubation periods on streams with important spawning areas.

- ✓ Compact the road base at the proper moisture content, surfacing, and grading to give the designed road surface drainage shaping. Compact the fill to minimize erosion and ensure road stability.

- ✓ Use straw bales, straw mulch, grass-seeding, hydromulch, and other erosion control and revegetation techniques to complete the construction project. These methods are used to protect freshly disturbed soils until vegetation can be established.

- ✓ Use turnouts, wing ditches, and dips to disperse runoff and reduce road surface drainage from flowing directly into watercourses.

- ✓ Install surface drainage controls to remove storm water from the roadbed before the flow gains enough volume and velocity to erode the surface. Route discharge from drainage structures onto the forest floor so that water will disperse and infiltrate.

- ✓ Install appropriate sediment control structures to trap suspended sediment transported by runoff and prevent its discharge into the aquatic environment.

- ✓ Revegetate or stabilize disturbed areas, especially at stream crossings.

- ✓ Protect access points to the site that lead from a paved public right-of-way with stone, wood chips, corduroy logs, wooden mats, or other material to prevent soil or mud from being tracked onto the paved road.

- ✓ Construct bridges and install culverts during periods when streamflow is low. Excavation for a bridge or a large culvert should not be performed in flowing water. The water should be diverted around the work site during construction with a cofferdam or stream diversion.

✓ When soil moisture conditions are excessive, promptly suspend earthwork operations and take measures to weatherproof the partially completed work.

✓ Locate burn bays away from water and drainage courses.

✓ Maintain road surfaces by mowing, patching, or resurfacing as necessary. Clear road inlet and outlet ditches, catch basins, and culverts of obstructions. Blade and reshape the road surface to conserve existing surface material to allow normal surface runoff.

III.C.2. Timber Harvesting

Timber harvesting includes felling trees, preparing them by limbing, cutting them into desired lengths, and moving them to a central, accessible location for transport out of the forested area. The timber is removed (skidded or yarded) to a temporary storage site or landing by one of three basic methods: tractor/skidder (on skid trails), groundlead or highlead cable, or various skyline cable methods. Balloons and helicopters are also used to a limited extent in some areas.

The most common methods of harvesting in the United States are clearcutting, shelterwood, selection, and partial cutting.

- *Clearcutting* is the harvesting of all trees in an area in one cut to create a new even-aged stand. The area harvested is large enough to create an open condition. Economically, clearcutting is most efficient for the logger because all trees are removed, and the feller and skidder operator are not continually confronted with avoiding trees spared from harvest. However, because of the large volumes of material per unit area removed during clearcutting, more trips are required by the skidder, causing the greatest disturbance to the forest litter and underlying forest soil of all harvesting systems.

- *In shelterwood harvesting*, a mature stand is removed in a series of cuts. Regeneration of a new stand occurs under the cover of a partial forest canopy. The final harvest cut removes the sheltering canopy and permits the new existing stand to develop in the open as an even-aged stand.

- *Selection harvesting* involves the removal of mature or immature trees either alone or in groups at somewhat regular time intervals from a forest stand. The objective of this harvesting system is the development and maintenance of an uneven-aged stand with trees of different ages or sizes intermingled singly or in groups. Individual (single) tree selection involves the removal of individual trees, while group selection may remove several adjacent trees covering a small fraction of an acre or larger numbers of trees covering areas as large as one or two acres. Group selection is distinguished from clearcutting in that the intent of group selection is ultimately to create a balance of age or size classes in a mosaic of small contiguous groups throughout the forest stand.

Potential Pollution Outputs and Environmental Impacts

The most detrimental effects of harvesting, which include soil disturbance, soil compaction, and direct disturbance of stream channels, are related to the movement of vehicles and machinery in the forest area, and the skidding and loading of trees or logs. These effects can be enhanced or minimized depending on logging operation planning, soil and cover type, slope, and the construction and use of haul roads, skid trails, and landings for access to and movement of logs. Thus, harvesting method used directly affects the amount of erosion, including the amount of sediment and organic debris that are transported into streams from the forest floor.

Harvesting can also increase stream water temperatures (i.e., thermal pollution) due to the removal of the canopy over streams, with the greatest potential impacts occurring in small streams. Temperature is a significant aspect of water quality. In some cases, it may strongly influence dissolved oxygen concentrations and bacterial populations in streams.

As with all harvesting methods, clearcutting can cause irreversible adverse impacts to the environment and can destroy an area's ecological integrity. These impacts include:

- The removal of forest canopy, which destroys the habitat for many rainforest-dependent insects and bacteria.

- The elimination of fish and wildlife species due to soil erosion and habitat loss.

- The destruction of buffer zones which reduce the severity of flooding by absorbing and holding water.

- The removal of forest carbon sinks, leading to global warming through the increased human-induced and natural carbon dioxide build-up in the atmosphere.

- The destruction of aesthetic values and recreational opportunities.

- Increased streamflow from removal of vegetation (resulting in reduction in transpiration and evaporation functions), fish passage barriers (i.e., improperly placed culverts), and cumulative effects within the watershed.

Pollution Prevention/Waste Minimization Opportunities

The primary pollution prevention methods in timber harvesting are designed to minimize sedimentation resulting from the siting and operation of timber harvesting, and to manage petroleum products properly. Logging practices that protect water quality and soil productivity can reduce total mileage of roads and skid trails, lower equipment maintenance costs, and provide better road protection and lower road maintenance. Careful logging can disturb soil surfaces as little as 8 percent, while careless logging practices can disturb soils as much as 40 percent. Higher bulk densities and lower porosity of skid road soils due to compaction by rubber-tired skidders result in reduced soil infiltration capacity and corresponding increases in runoff and erosion.

Locating landings for both groundskidding and cable yarding harvesting systems according to preharvest planning minimizes erosion and sediment delivery to surface waters. However, final siting of landings may need to be adjusted in the field based on site characteristics.

Landings and loading decks can become very compacted and puddled and are therefore a source of runoff and erosion. Practices that prevent or disperse runoff from these areas before the runoff reaches watercourses will minimize sediment delivery to surface waters. Also, any chemicals or petroleum products spilled in harvest areas can be highly mobile, adversely affecting the water quality of nearby surface waters. Appropriate spill prevention and containment procedures are therefore necessary to prevent petroleum products from entering surface waters. Designation of appropriate areas for petroleum storage will also minimize water quality impacts due to spills or leakage.

The following pollution prevention practices can be used during timber harvesting operations.

Harvesting Practices

✓ Harvest trees so that they fall away from watercourses, whenever possible, keeping logging debris from the channel, except where debris placement is specifically prescribed for fish or wildlife habitat.

✓ Any tree accidentally dropped in a waterway should be immediately removed.

Practices for Landings

✓ Landings should be no larger than necessary to safely and efficiently store logs and load trucks.

✓ The slope of landing fills should not exceed 40 percent, and woody or organic debris should not be incorporated into fills.

✓ If landings are to be used during wet periods, protect the surface with a suitable material such as wooden matting or gravel surfacing.

✓ Install drainage structures for the landings such as water bars, culverts, and ditches to avoid sedimentation. Disperse landing drainage over sideslopes. Provide filtration or settling if water is concentrated in a ditch.

✓ Upon completion of harvest, clean up landing, regrade, and revegetate.

✓ Locate landings for cable yarding where slope profiles provide favorable deflection conditions so that the yarding equipment used does not cause yarding corridor gouge or soil plowing, which concentrates drainage or causes slope instability.

Groundskidding Practices

✓ Skid uphill to log landings whenever possible. Skid with ends of logs raised to reduce rutting and gouging.

✓ Skid perpendicular to the slope (along the contour), and avoid skidding on slopes greater than 40 percent.

✓ Avoid skid trail layouts that concentrate runoff into draws, ephemeral drainages, or watercourses.

✓ Suspend groundskidding during wet periods, when excessive rutting and churning of the soil begins, or when runoff from skid trails is turbid and no longer infiltrates within a short distance from the skid trail. Further limitation of groundskidding of logs, or use of cable yarding, may be needed on slopes where there are sensitive soils and/or during wet periods.

✓ Retire skid trails by installing water bars or other erosion control and drainage devices, removing culverts, and revegetating.

Cable Yarding Practices

✓ Use cabling systems or other systems when groundskidding would expose excess mineral soil and induce erosion and sedimentation.

✓ Avoid cable yarding in or across watercourses.

✓ Yard logs uphill rather than downhill.

Petroleum Management Practices

✓ Service equipment where spilled fuel and oil cannot reach watercourses, and drain all petroleum products and radiator water into containers. Dispose of wastes and containers in accordance with proper waste disposal procedures. Waste oil, filters, grease cartridges, and other petroleum-contaminated materials should not be left as refuse in the forest.

- ✓ Take precautions to prevent leakage and spills. Fuel trucks and pickup-mounted fuel tanks must not have leaks.

- ✓ Develop a spill contingency plan that provides for immediate spill containment and cleanup, and notification of proper authorities.

III.C.3. Site Preparation

Site preparation is a management activity designed to increase productivity of a tract by controlling competing vegetation and debris that could slow seedling growth. It includes removal or deadening of unwanted vegetation prior to planting trees. Site preparation is accomplished by conducting prescribed burning, using herbicides, or disking (or otherwise altering) the soil.

Potential Pollution Outputs and Environmental Impacts
The pollution outputs may include air emissions from the machinery used, soil erosion during and after site preparation, and chemicals in runoff. Mechanical site preparation by large tractors that shear, disk, drum-chop, or root-rake a site may result in considerable soil disturbance over large areas and has a high potential to degrade water quality. Site preparation techniques that result in the removal of vegetation and litter cover, soil compaction, exposure or disturbance of the mineral soil, and increased storm flows due to decreased infiltration and percolation, can contribute to increases in stream sediment loads. However, erosion rates decrease over time as vegetative cover grows back. Prescribed burning and herbicides are other methods used to prepare sites that may also have potential negative effects on water quality.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention methods in site preparation are designed to minimize sediment runoff caused by soil-disturbing machinery and chemicals in runoff from herbicide applications.

Leaving the forest floor litter layer intact during site preparation operations for regeneration minimizes mineral soil disturbance and detachment, thereby minimizing erosion and sedimentation. Maintenance of an unbroken litter layer prevents raindrop detachment, maintains infiltration, and slows runoff. Mechanical site preparation can potentially impact water quality in areas that have steep slopes and erodible soils, and where the prepared site is located near a waterbody. Use of mechanical site preparation treatments that expose mineral soils on steep slopes can greatly increase erosion and landslide potential. Alternative methods, such as drum chopping, herbicide application, or prescribed burning, disturb the soil surface less than mechanical practices.

The pollution prevention practices that can be used during site preparation operations include:

✓ Mechanical site preparation should not be applied on slopes greater than 30 percent.

✓ Mechanical site preparation should not be conducted in streamside management areas. Also avoid mechanical site preparation operations during periods of saturated soil conditions that may cause rutting or accelerate soil erosion.

✓ Avoid working downhill or uphill. Always work along the contour. Site preparation often involves soil disturbance and can cause extensive erosion if done in a way that increases runoff potential. Leave strips of undisturbed soil to help catch any runoff on steep slopes.

✓ When moving slash and debris into rows, avoid pulling up topsoil with the debris. Many sites are degraded by the removal of topsoil. Make sure that the dozer operator monitors the operation closely and modifies his/her approach if soil begins to build up in the rows.

✓ Use haystack piling where possible instead of windrows.

✓ Locate windrows and piles away from drainages to prevent movement of materials during high-runoff conditions.

✓ Do not place slash in natural drainages, and remove any slash that accidentally enters drainages.

✓ Provide filter strips of sufficient width to protect drainages that do not have streamside management areas from sedimentation by the 10-year storm event.

III.C.4. Forest Regeneration

Forest regeneration refers to the re-establishment of a forest cover on areas from which trees have been removed by some past occurrence, such as wildfire, timber harvesting, or temporary conversion to some other use than the growing of trees. When trees have been absent from a site for a number of years, regeneration must generally be achieved through seeding and planting. Regeneration of a harvested area includes both the natural regenerative process and man's activities in preparing the site and subsequent planting or seeding. The method of regeneration is determined largely by the silvical characteristics of the tree species involved, site limitations, economic considerations, and the land manager's desire for forest composition. In some plant communities, natural regeneration under any of the harvesting systems may also occur by regrowth from roots or stumps.

Preparation, as well as protection of an area, is sometimes needed for regrowth of a stand. Where site preparation for regrowth is needed, major activities may include (1) debris removal to reduce fire hazard and allow use of equipment for subsequent operations, (2) reduction or removal of brush or shrub cover and undesirable tree species, and (3) cultivation of the soils.

Potential Pollution Outputs and Environmental Impacts
The pollution outputs may include air emissions from machinery used for regeneration, sediment runoff caused by soil-disturbing machinery, and nutrient runoff from fertilizer applications.

When used indiscriminately for site preparation, fire, chemicals, and soil-disturbing machinery increase the potential for erosion and sedimentation and other pollution to occur. The impacts from sediment pollution as well as pollution from nutrients in runoff would be similar to those discussed in Sections III.A.1 and III.A.3, respectively. The time required before such pollution occurs is variable depending upon climatic factors, soil productivity and its influence on the rate of plant growth, the species planted or seeded, and the operational schedule. In some areas, the time span may be a single growing season, while in others, it may cover several years.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention methods in forest regeneration are designed to minimize sediment runoff caused by soil-disturbing machinery and nutrient runoff from fertilizer applications. Regeneration of harvested forest lands not only is important in terms of restocking a valuable resource, but also is important to provide

water quality protection from disturbed soils. Tree roots stabilize disturbed soils by holding the soil in place and aiding soil aggregation, decreasing slope failure potential. The presence of vegetation on disturbed soils also slows storm runoff, which in turn decreases erosion.

Mechanical planting using machines that scrape or plow the soil surface can produce erosion rills, increasing surface runoff and erosion. Natural regeneration, hand planting, and direct seeding minimize soil disturbance, especially on steep slopes with erodible soils. Fertilizers are occasionally introduced into forests to promote growth. Impacts of fertilizer application in forested areas could be significantly reduced by avoiding application techniques that could result in direct deposition into waterbodies and by maintaining a buffer area along the streambank.

The pollution prevention practices that can be used for forest regeneration operations include the following:

✓ Distribute seedlings evenly across the site.

✓ Order seedlings well in advance of planting time to ensure their availability.

✓ Hand plant highly erodible sites, steep slopes, and lands adjacent to stream channels.

✓ Operate planting machines along the contour to avoid ditch formation.

✓ Apply fertilizers during maximum plant uptake periods to minimize leaching. Base fertilizer type and application rate on soil and/or foliar analysis.

✓ For aerial spray applications of chemicals, maintain and mark a buffer area of at least 50 feet (or as specified on the label) around all watercourses and waterbodies to avoid drift or accidental application of chemicals directly to surface water.

III.C.5. Prescribed Burning

Prescribed burning is used to prepare sites for regeneration, reduce uncontrolled fire hazard due to accumulation of litter and undergrowth, control low value hardwoods and unwanted shrub species, improve wildlife habitat, provide disease control, and improve accessibility. Fire is used deliberately under conditions where the area to be burned is predetermined and the intensity of fire is controlled.

Potential Pollution Outputs and Environmental Impacts
The pollution outputs may include air emissions (smoke) from the fire and soil erosion after the prescribed burning. Prescribed burning of slash can increase erosion by eliminating protective cover and altering soil properties. The degree of erosion following a prescribed burn depends on soil erodibility, slope, precipitation timing, precipitation volume and intensity, fire severity, cover remaining on the soil, and speed of revegetation. Burning may also increase storm runoff in areas where all vegetation is killed. Such increases are partially attributable to decreased evapotranspiration rates and reduced canopy interception of precipitation. Erosion resulting from prescribed burning is generally less than that resulting from roads and skid trails and from site preparation that causes intense soil disturbance. However, significant erosion can occur during prescribed burning if the slash being burned is collected or piled, causing soil to be moved and incorporated into the slash. The impacts of erosion and sediment runoff would be similar to those discussed in Section III.A.1.

Air emissions (smoke) from prescribed burning can have adverse effects on smoke sensitive areas such as airports, resorts or recreation areas, schools, hospitals, stock barns and holding pens, etc. Smoke can cause reduced visibility or smoke irritation to livestock and humans which may cause material loss and adverse health effects.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention methods in prescribed burning are designed to minimize sediment runoff caused by removal of surface cover and smoke from fire. Prescribed burning is usually the least expensive method of obtaining several specific goals in forest management. However, it should be planned well in advance to assure success. Aerial photographs can be very helpful. Areas that will benefit most from a prescribed burn should be selected and priorities should be set. High priority will probably be protection of unmerchantable size stands. Burning stands can facilitate regeneration and reduce site preparation costs.

If recommended burning techniques and weather conditions are followed, most prescribed burning will not create smoke problems.

First, land managers should determine if any smoke sensitive areas are near the burn. These are places where reduced visibility or smoke irritation to livestock and humans could cause material loss and adverse health effects. Examples of smoke sensitive areas are: airports, heavily traveled highways, communities, resorts or recreation areas, schools, hospitals, factories, stock barns and holding pens.

Prescribed burning should not be implemented if any sensitive area is within three fourths of a mile downwind of the burn. Different wind direction should be sought in these type of situations. Also, burning should not be conducted if the area already has air pollution or a visibility problem. Burning should be carried out only when the vertical dispersion is good (from fire weather forecast).

The pollution prevention practices that can be used during prescribed burning operations include the following:

- ✓ Carefully plan burning to adhere to weather, time of year, and fuel conditions that will help achieve the desired results and minimize impacts on water quality.
- ✓ Intense prescribed fire for site preparation should not be conducted in the streamside management areas.
- ✓ Piling and burning for slash removal purposes should not be conducted in the streamside management areas.
- ✓ Avoid construction of firelines in the streamside management areas.
- ✓ In prescriptions for burns, avoid conditions requiring extensive blading of firelines by heavy equipment.
- ✓ Use natural or in-place barriers (e.g., roads, streams, lakes, wetlands) as an acceptable way to minimize the need for fireline construction in situations where artificial construction of firelines will result in excessive erosion and sedimentation.
- ✓ Construct firelines in a manner that minimizes erosion and sedimentation and prevents runoff from directly entering watercourses.
- ✓ Revegetate firelines with adapted herbaceous species.

- ✓ Execute the burn with a trained crew and avoid intense burning.

- ✓ Avoid burning on steep slopes with high erosion hazard areas or highly erodible soils.

III.C.6. Application of Chemicals

Chemicals are becoming more and more a part of forestry. Commercial fertilizers are applied to sizeable areas of forests as a means of stimulating growth of new plantations or established stands of trees. Herbicides are used widely for site preparation and stand improvement. Insecticides are used less extensively, but still comprise the major defense against damaging insects in forests.

Potential Pollution Outputs and Environmental Impacts
The potential outputs from application of forest chemicals may include runoff contaminated with chemicals associated with fertilizer and pesticide application, and chemical air emissions. Fertilizer loss may occur when fertilizers are improperly applied during the course of a silvicultural operation. Soluble forms of fertilizers may reach surface or groundwater through runoff, seepage, and/or percolation. Insoluble forms may be adsorbed on soil particles and reach surface water through erosion processes. Nutrients may also reach surface water by direct washoff of slash, debris, and recently applied fertilizer. Excessive nutrients can lead to imbalance in the natural life cycles of water bodies.

Pesticides, when applied during forest management operations, may be insoluble or soluble. Pesticides when applied aerially and in a broadcast manner may directly enter the surface waters. These chemicals then follow approximately the same pattern as nutrients. Pesticides, applied by the above methods, in a manner inconsistent with the label, may result in acute toxicity problems in water bodies.

Pollution Prevention/Waste Minimization Opportunities
The primary pollution prevention methods in operations associated with the application of chemicals are designed to minimize runoff contaminated with chemicals from fertilizer and pesticide application, and chemical air emissions. Nutrient pollution from fertilization on forest lands is controlled by using techniques which avoid direct application to surface waters. Also involved are the elimination of excessive applications, the selection of the proper fertilizer

R0074352

formulation, and the proper timing and method of application. The key factors in the selection of the type of fertilizer and the method of application which are most appropriate for pollution control are local soil nutrient deficiencies, the physical condition of the soil, the plant species requirements, cost factors, weather conditions, access, and topography.

The most common mechanism of pesticide pollution is direct transport by runoff. However, the mechanisms of leaching or subsurface flows may be important in areas of highly porous geologic materials, permeable soils, or high water tables. Practices that control erosion and runoff also reduce loss of applied pesticides. In addition to these practices, a number of other frequently used options exist. These options involve manipulation of the pesticide itself such as form, timing of application, etc. These can be used alone or in conjunction with the erosion and runoff control measures.

The pollution prevention practices that can be used during the application of forest chemicals include the following:

✓ For aerial spray applications, maintain and mark a buffer area of at least 50 feet around all watercourses and waterbodies to avoid drift or accidental application of chemicals directly to surface water. Also use nozzles and spray equipment that will reduce pesticide drift. With broadcast applications, use thickening agents, lower pressures, and larger nozzle sizes to keep the pesticide spray where it is applied.

✓ Apply pesticides and fertilizers during favorable weather conditions.

✓ Always use pesticides in accordance with label instructions, and adhere to all federal and state policies and regulations governing pesticide use. The pesticide label may specify: whether users must be trained and certified in the proper use of the pesticide; allowable use rates; safe handling, storage, and disposal requirements; and whether the pesticide can only be used under the provision of an approved Pesticide State Management Plan. Management measures and practices for pesticides should be consistent with and/or complement those in the approved Pesticide State Management Plans.

- ✓ Locate mixing and loading areas, and clean all mixing and loading equipment thoroughly after each use, in a location where pesticide residues will not enter streams or other waterbodies.
- ✓ Dispose of pesticide wastes and containers according to state and federal laws.
- ✓ Take precautions to prevent leaks and/or spills.
- ✓ Develop a spill contingency plan that provides for immediate spill containment and cleanup, and notification of proper authorities.
- ✓ Apply slow-release fertilizers, when possible.
- ✓ Apply fertilizers during maximum plant uptake periods to minimize leaching.
- ✓ Base fertilizer type and application rate on soil and/or foliar analysis.
- ✓ Consider the use of pesticides as part of an overall program to control pest problems.
- ✓ Base selection of pesticide on site factors and pesticide characteristics.
- ✓ Check all application equipment carefully, particularly for leaking hoses and connections and plugged or worn nozzles. Calibrate spray equipment periodically to achieve uniform pesticide distribution and rate.

IV. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulatory requirements.

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations (CFR) and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute. For specific agricultural information, contact The National Agricultural Compliance Assistance Center at (888) 663-2155 or visit the website at http://www.epa.gov/agriculture.

IV.A. General Description of Major Statutes

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA are classified as either "toxic" pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; or "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and "indirect" dischargers (those who discharge to publicly owned treatment works). The National Pollutant Discharge Elimination System (NPDES) permitting program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized state (EPA has authorized 43 states and 1 territory to administer the NPDES program), contain industry-specific, technology-based and water quality-based limits and establish pollutant monitoring and reporting requirements. A facility that proposes to discharge into the nation's waters must obtain a permit prior to initiating a discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

Water quality-based discharge limits are based on federal or state water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technology-based standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from state to state, and site to site, depending on the use classification of the receiving body of water. Most states follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges
In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated NPDES permitting regulations for storm water discharges. These regulations require that facilities with the following types of storm water discharges, among others, apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the state determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR §122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; SIC 311-leather tanning and finishing; SIC 32 (except 323)-stone, clay, glass, and concrete; SIC 33-primary metals; SIC 3441-fabricated structural metal; and SIC 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products;

R0074357

SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly owned treatment works (POTW). The national pretreatment program (CWA § 307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a state is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than federal standards.

Wetlands

Wetlands, commonly called swamps, marshes, fens, bogs, vernal pools, playas, and prairie potholes, are a subset of "waters of the United States," as defined in Section 404 of the CWA. The placement of dredge and fill material into wetlands and other water bodies (i.e., waters of the United States) is regulated by the U.S. Army Corps of Engineers (Corps) under 33 CFR Part 328. The Corps regulates wetlands by administering the CWA Section 404 permit program for activities that impact wetlands. EPA's authority under Section 404 includes veto power of Corps permits, authority to interpret statutory exemptions and jurisdiction, enforcement actions, and delegating the Section 404 program to the states.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed *through the Ground Water and Drinking Water resource center, at (202) 260-7786.*

Oil Pollution Prevention Regulation
Section 311(b) of the CWA prohibits the discharge of oil, in such quantities as may be harmful, into the navigable waters of the United States and adjoining shorelines. The EPA Discharge of Oil regulation, 40 CFR Part 110, provides information regarding these discharges. The Oil Pollution Prevention regulation, 40 CFR Part 112, under the authority of Section 311(j) of the CWA, requires regulated facilities to prepare and implement Spill Prevention Control and Countermeasure (SPCC) plans. The intent of a SPCC plan is to prevent the discharge of oil from onshore and offshore non-transportation-related facilities. In 1990 Congress passed the Oil Pollution Act which amended Section 311(j) of the CWA to require facilities that because of their location could reasonably be expected to cause "substantial harm" to the environment by a discharge of oil to develop and implement Facility Response Plans (FRP). The intent of a FRP is to provide for planned responses to discharges of oil.

A facility is SPCC-regulated if the facility, due to its location, could reasonably be expected to discharge oil into or upon the navigable waters of the United States or adjoining shorelines, and the facility meets one of the following criteria regarding oil storage: (1) the capacity of any aboveground storage tank exceeds 660 gallons, or (2) the total aboveground storage capacity exceeds 1,320 gallons, or (3) the underground storage capacity exceeds 42,000 gallons. 40 CFR § 112.7 contains the format and content requirements for a SPCC plan. In New Jersey, SPCC plans can be combined with DPCC plans, required by the state, provided there is an appropriate cross-reference index to the requirements of both regulations at the front of the plan.

According to the FRP regulation, a facility can cause "substantial harm" if it meets one of the following criteria: (1) the facility has a total oil storage capacity greater than or equal to 42,000 gallons and transfers oil over water to or from vessels; or (2) the facility has a total oil storage capacity greater than or equal to 1 million gallons and meets any one of the following conditions: (i) does not have adequate secondary containment, (ii) a discharge could cause "injury" to fish and wildlife and sensitive environments, (iii) shut down a public drinking water intake, or (iv) has had a reportable oil spill greater than or equal to 10,000 gallons in the past 5 years. Appendix F of 40 CFR Part 112 contains the format and content requirements for a FRP. FRPs that meet EPA's requirements can be combined with U.S. Coast Guard FRPs or other contingency plans, provided there is an appropriate cross-reference index to the requirements of all applicable regulations at the front of the plan.

For additional information regarding SPCC plans, contact EPA's RCRA. Superfund, and EPCRA Hotline, at (800) 424-9346. Additional documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Coastal Zone Management Act

The Coastal Zone Management Act (CZMA) encourages states/tribes to preserve, protect, develop, and where possible, restore or enhance valuable natural coastal resources such as wetlands, floodplains, estuaries, beaches, dunes, barrier islands, and coral reefs, as well as the fish and wildlife using those habitats. It includes areas bordering the Atlantic, Pacific, and Arctic Oceans, Gulf of Mexico, Long Island Sound, and Great Lakes. A unique feature of this law is that participation by states/tribes is voluntary.

In the Coastal Zone Management Act Reauthorization Amendments (CZARA) of 1990, Congress identified nonpoint source pollution as a major factor in the continuing degradation of coastal waters. Congress also recognized that effective solutions to nonpoint source pollution could be implemented at the state/tribe and local levels. In CZARA, Congress added Section 6217 (16 U.S.C. § 1455b), which calls upon states/tribes with federally-approved coastal zone management programs to develop and implement coastal nonpoint pollution control programs. The Section 6217 program is administered at the federal level jointly by EPA and the National Oceanic and Atmospheric Administration (NOAA).

Section 6217(g) called for EPA, in consultation with other agencies, to develop guidance on "management measures" for sources of nonpoint source pollution in coastal waters. Under Section 6217, EPA is responsible for developing technical guidance to assist states/tribes in designing coastal nonpoint pollution control programs. On January 19, 1993, EPA issued its *Guidance Specifying Management Measures For Sources of Nonpoint Pollution in Coastal Waters*, which addresses five major source categories of nonpoint pollution: (1) urban runoff, (2) agriculture runoff, (3) forestry runoff, (4) marinas and recreational boating, and (5) hydromodification.

Additional information on coastal zone management may be obtained from EPA's Office of Wetlands, Oceans, and Watersheds at http://www.epa.gov/owow or from the Watershed Information Network at http://www.epa.gov/win. The NOAA website at http://www.nos.noaa.gov/ocrm/czm/ also contains additional information on coastal zone management.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint federal-state system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of fluid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized states enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set generally as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is often state/tribe-enforced, since EPA has authorized many states/tribes to administer the program. Currently, EPA shares the UIC permit program responsibility in seven states and completely runs the program in 10 states and on all tribal lands.

The SDWA also provides for a federally-implemented Sole Source Aquifer program, which prohibits federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a state-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

The SDWA Amendments of 1996 require states to develop and implement source water assessment programs (SWAPs) to analyze existing and potential threats to the quality of the public drinking water throughout the state. Every state is required to submit a program to EPA and to complete all assessments within 3 ½ years of EPA approval of the program. SWAPs include: (1) delineating the source water protection area, (2) conducting a contaminant source inventory, (3) determining the susceptibility of the public water supply to contamination from the inventories sources, and (4) releasing the results of the assessments to the public.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding federal holidays. Visit the website at http://www.epa.gov/ogwdw for additional material.

Resource Conservation and Recovery Act

The Solid Waste Disposal Act (SWDA), as amended by the Resource Conservation and Recovery Act (RCRA) of 1976, addresses solid and hazardous waste management activities. The Act is commonly referred to as RCRA. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (discarded commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. A hazardous waste facility may accumulate hazardous waste for up to 90 days (or 180 days depending on the amount generated per month) without a permit or interim status. Generators may also treat hazardous waste in accumulation tanks or containers (in accordance with the requirements of 40 CFR 262.34) without a permit or interim status.

Facilities that treat, store, or dispose of hazardous waste are generally required to obtain a RCRA permit. Subtitle C permits for treatment, storage, or disposal facilities contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Subparts I and S) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA treatment, storage, or disposal facilities.

Although RCRA is a federal statute, many states implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 states and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Criteria for Classification of Solid Waste Disposal Facilities and Practices** (40 CFR Part 257) establishes the criteria for determining which solid waste disposal facilities and practices pose a reasonable probability of adverse effects on health or the environment. The criteria were adopted to ensure non-municipal, non-hazardous waste disposal units that receive conditionally exempt small quantity generator waste do not present risks to human health and environment.

- **Criteria for Municipal Solid Waste Landfills** (40 CFR Part 258) establishes minimum national criteria for all municipal solid waste landfill units, including those that are used to dispose of sewage sludge.

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) establishes the standard to determine whether the material in question is considered a solid waste and, if so, whether it is a hazardous waste or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste on-site for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including large quantity generators accumulating waste prior to shipment offsite.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that were to be met by December 22, 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and, in some cases, restrict the type of waste that may be burned.

EPA's RCRA, Superfund, and EPCRA Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. Additional documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response or remediation costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more federal or state emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for cleanups. The National Priorities List (NPL) currently includes approximately 1,300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct cleanups and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. Documents and resources can be obtained from the hotline's homepage at http://www.epa.gov/epaoswer/hotline. The Superfund Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by state and local governments. Under EPCRA, states establish State Emergency Response Commissions (SERCs), responsible for coordinating certain emergency

response activities and for appointing Local Emergency Planning Committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA § 302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance at the facility in an amount in excess of the established threshold planning quantity. The list of extremely hazardous substances and their threshold planning quantities is found at 40 CFR Part 355, Appendices A and B.

- **EPCRA § 303** requires that each LEPC develop an emergency plan. The plan must contain (but is not limited to) the identification of facilities within the planning district, likely routes for transporting extremely hazardous substances, a description of the methods and procedures to be followed by facility owners and operators, and the designation of community and facility emergency response coordinators.

- **EPCRA § 304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance (defined at 40 CFR 302) or an EPCRA extremely hazardous substance.

- **EPCRA § 311 and § 312** requires a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA § 313** requires certain covered facilities, including SIC codes 20 through 39 and others, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media. EPA maintains the data reported in a publically accessible database known as the Toxics Release Inventory (TRI).

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. Documents and resources can be obtained from the hotline's homepage at http://www.epa.gov/epaoswer/hotline. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the states to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAA, many facilities are required to obtain operating permits that consolidate their air emission requirements. State and local governments oversee, manage, and enforce many of the requirements of the CAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are designated as attainment areas; those that do not meet NAAQSs are designated as non-attainment areas. Under §110 and other provisions of the CAA, each state must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and will become effective in 2001.

Title I also authorizes EPA to establish New Source Performance Standards (NSPS), which are nationally uniform emission standards for new and modified stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source (*see* 40 CFR Part 60).

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented toward controlling specific hazardous air pollutants (HAPs). Section 112(c) of the CAA further directs EPA to develop a list of sources that emit any of

188 HAPs, and to develop regulations for these categories of sources. To date, EPA has listed 185 source categories and developed a schedule for the establishment of emission standards. The emission standards are being developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV-A establishes a sulfur dioxide and nitrogen oxides emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances that are set below previous levels of sulfur dioxide releases.

Title V of the CAA establishes an operating permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States have developed the permit programs in accordance with guidance and regulations from EPA. Once a state program is approved by EPA, permits are issued and monitored by that state.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restricting their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), were phased out (except for essential uses) in 1996. Methyl bromide, a common pesticide, has been identified as a significant stratospheric ozone depleting chemical. The production and importation of methyl bromide, therefore, is currently being phased out in the United States and internationally. As specified in the Federal Register of June 1, 1999 (Volume 64, Number 104) and in 40 CFR Part 82, methyl bromide production and importation will be reduced from 1991 levels by 25% in 1999, by 50% in 2001, by 70% in 2003, and completely phased out by 2005. Some uses of methyl bromide, such as the production, importation, and consumption of methyl bromide to fumigate commodities entering or leaving the United States or any state (or political subdivision thereof) for purposes of compliance with Animal and Plant Health Inspection Service requirements or with any international, federal, state, or local sanitation or food protection standard, will be exempt from this rule. After 2005, exceptions may also be made for critical agricultural uses. The United States EPA and the United

Nations Environmental Programme have identified alternatives to using methyl bromide in agriculture. Information on methyl bromide phase-out, including alternatives can be found at the EPA Methyl Bromide Phase-Out Web Site: (http://www.epa.gov/docs/ozone/mbr/mbrqa.html).

EPA's Clean Air Technology Center, at (919) 541-0800 and at the Center's homepage at www.epa.gov/ttn/catc, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996 and at http://www.epa.gov/ozone, provides general information about regulations promulgated under Title VI of the CAA; EPA's EPCRA Hotline, at (800) 535-0202 and at http://www.epa.gov/epaoswer/hotline, answers questions about accidental release prevention under CAA §112(r); and information on air toxics can be accessed through the Unified Air Toxics website at http://www.epa.gov/ttn/uatw. In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

Federal Insecticide, Fungicide, and Rodenticide Act

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) was first passed in 1947, and amended numerous times, most recently by the Food Quality Protection Act (FQPA) of 1996. FIFRA provides EPA with the authority to oversee, among other things, the registration, distribution, sale and use of pesticides. The Act applies to all types of pesticides, including insecticides, herbicides, fungicides, rodenticides and antimicrobials. FIFRA covers both intrastate and interstate commerce.

Establishment Registration
Section 7 of FIFRA requires that establishments producing pesticides, or active ingredients used in producing a pesticide subject to FIFRA, register with EPA. Registered establishments must report the types and amounts of pesticides and active ingredients they produce. The Act also provides EPA inspection authority and enforcement authority for facilities/persons that are not in compliance with FIFRA.

Product Registration
Under §3 of FIFRA, all pesticides (with few exceptions) sold or distributed in the United States must be registered by EPA. Pesticide registration is very specific and generally allows use of the product only as specified on the label. Each registration specifies the use site, i.e., where the product may be used, and the amount that may be applied. The person who seeks to register the pesticide must file an application for registration. The application process

often requires either the citation or submission of extensive environmental, health and safety data.

To register a pesticide, the EPA Administrator must make a number of findings, one of which is that the pesticide, when used in accordance with widespread and commonly recognized practice, will not generally cause unreasonable adverse effects on the environment.

FIFRA defines "unreasonable adverse effects on the environment" as "(1) any unreasonable risk to man or the environment, taking into account the economic, social, and environmental costs and benefits of the use of the pesticide, or (2) a human dietary risk from residues that result from a use of a pesticide in or on any food inconsistent with the standard under §408 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 346a)."

Under FIFRA § 6(a)(2), after a pesticide is registered, the registrant must also notify EPA of any additional facts and information concerning unreasonable adverse environmental effects of the pesticide. Also, if EPA determines that additional data are needed to support a registered pesticide, registrants may be requested to provide additional data. If EPA determines that the registrant(s) did not comply with their request for more information, the registration can be suspended under FIFRA § 3(c)(2)(B) and § 4.

Use Restrictions
As a part of the pesticide registration, EPA must classify the product for general use, restricted use, or general for some uses and restricted for others (Miller, 1993). For pesticides that may cause unreasonable adverse effects on the environment, including injury to the applicator, EPA may require that the pesticide be applied either by or under the direct supervision of a certified applicator.

Reregistration
Due to concerns that much of the safety data underlying pesticide registrations becomes outdated and inadequate, in addition to providing that registrations be reviewed every 15 years, FIFRA requires EPA to reregister all pesticides that were registered prior to 1984 (§ 4). After reviewing existing data, EPA may approve the reregistration, request additional data to support the registration, cancel, or suspend the pesticide.

Tolerances and Exemptions
A tolerance is the maximum amount of pesticide residue that can be on a raw product and still be considered safe. Before EPA can register a pesticide that is used on raw agricultural products, it must grant a tolerance or exemption from a tolerance (40 CFR.163.10 through 163.12). Under the Federal Food,

Drug, and Cosmetic Act (FFDCA), a raw agricultural product is deemed unsafe if it contains a pesticide residue, unless the residue is within the limits of a tolerance established by EPA or is exempt from the requirement.

Cancellation and Suspension
EPA can cancel a registration if it is determined that the pesticide or its labeling does not comply with the requirements of FIFRA or causes unreasonable adverse effects on the environment (Haugrud, 1993).

In cases where EPA believes that an "imminent hazard" would exist if a pesticide were to continue to be used through the cancellation proceedings, EPA may suspend the pesticide registration through an order and thereby halt the sale, distribution, and usage of the pesticide. An "imminent hazard" is defined as an unreasonable adverse effect on the environment or an unreasonable hazard to the survival of a threatened or endangered species that would be the likely result of allowing continued use of a pesticide during a cancellation process.

When EPA believes an emergency exists that does not permit a hearing to be held prior to suspending, EPA can issue an emergency order that makes the suspension immediately effective.

Imports and Exports
Under FIFRA § 17(a), pesticides not registered in the United States and intended solely for export are not required to be registered provided that the exporter obtains and submits to EPA, prior to export, a statement from the foreign purchaser acknowledging that the purchaser is aware that the product is not registered in the United States and cannot be sold for use there. EPA sends these statements to the government of the importing country. FIFRA sets forth additional requirements that must be met by pesticides intended solely for export. The enforcement policy for exports is codified in 40 CFR § 168.65, 168.75, and 168.85.

Under FIFRA §17(c), imported pesticides and devices must comply with United States pesticide law. Except where exempted by regulation or statute, imported pesticides must be registered. FIFRA §17(c) requires that EPA be notified of the arrival of imported pesticides and devices. This is accomplished through the Notice of Arrival (NOA) (EPA Form 3540-1), which is filled out by the importer prior to importation and submitted to the EPA regional office applicable to the intended port of entry. United States Customs regulations prohibit the importation of pesticides without a completed NOA. The EPA-reviewed and signed form is returned to the importer for presentation to United States Customs when the shipment arrives in the United States. NOA forms can be obtained from contacts in the EPA Regional Offices or www.epa.gov/oppfead1/international/noalist.htm.

Additional information on FIFRA and the regulation of pesticides can be obtained from a variety of sources, including EPA's Office of Pesticide Programs' homepage at www.epa.gov/pesticides, EPA's Office of Compliance, Agriculture Division at http://es.epa.gov/oeca/main/offices/division/ag.html, or The National Agriculture Compliance Assistance Center toll-free at (888) 663-2155 or http://www.epa.gov/agriculture. Other sources include the National Pesticide Telecommunications Network toll-free at (800) 858-7378 and the National Antimicrobial Information Network toll-free at (800) 447-6349.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk. It is important to note that pesticides as defined in FIFRA are not included in the definition of a "chemical substance" when manufactured, processed, or distributed in commerce for use as a pesticide.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA § 6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under § 6 authority are asbestos, chlorofluorocarbons (CFCs), lead, and polychlorinated biphenyls (PCBs).

Under TSCA § 8(e), EPA requires the producers and importers (and others) of chemicals to report information on a chemicals' production, use, exposure, and risks. Companies producing and importing chemicals can be required to report unpublished health and safety studies on listed chemicals and to collect and record any allegations of adverse reactions or any information indicating that a substance may pose a substantial risk to humans or the environment.

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding federal holidays.

IV.B. Industry-Specific Requirements for Agricultural Production Industries: Crops, Greenhouses/Nurseries, and Forestry

The agricultural production industries discussed in this notebook are regulated by several different federal, state, and local agencies. EPA has traditionally relied on delegation to states to meet environmental standards, in many cases without regard to the methods used to achieve certain performance standards. This has resulted in some states with more stringent air, water, and hazardous waste requirements than the federal minimum requirements. This document does not attempt to discuss state standards, but rather highlights relevant federal laws and proposals that affect the agricultural production industries of crops, greenhouses/nurseries, and forestry.

Clean Water Act

Under the CWA, there are five program areas that potentially affect agricultural establishments and businesses. These include: point source discharges, storm water discharges, nonpoint source pollution, wetland regulation, and sludge management. Key provisions addressing each of these areas are summarized below:

- **Point Source Discharges**: The CWA establishes a permitting program known as the NPDES program for "point sources" of pollution. The term "point source" includes facilities from which pollutants are or may be discharged to waters of the United States and is further defined at 40 CFR Part 122. If granted, the permit will place limits and conditions on the proposed discharges based on the performance of available control technologies and on any applicable (more stringent) water quality considerations. Usually the permit also will require specific compliance measures, establish schedules, and specify monitoring and reporting requirements.
  - **Concentrated Animal Feeding Operations (CAFOs):** The CWA defines CAFOs as point sources. Therefore, CAFOs are subject to the NPDES permitting program. See 40 CFR Part

R0074373

122.23 and 40 CFR 122 Appendix B. A CAFO is prohibited from discharging pollutants to waters of the U.S. unless it has obtained an NPDES permit for the discharge.

- Definition of an AFO – An AFO is defined in EPA regulations as a lot or facility where (1) animals have been, are, or will be stabled or confined and fed or maintained for a total of 45 days or more in any 12-month period, and (2) crops, vegetation, forage growth, or post-harvest residues are not sustained in the normal growing season over any portion of the lot or facility.
- Definition of a CAFO – CAFOs are a subset of all AFOs. Whether an AFO is a CAFO under the regulations depends on the number of animals confined at the facility. A CAFO is defined as follows:

(1) More than 1,000 AUs are confined at the facility [40 CFR 122, Appendix B (a)]; **OR**

(2) ***From 301 to 1,000 AUs*** are confined at the facility ***and***:

- Pollutants are discharged into waters of the U.S. through a man-made ditch, flushing system, or other similar man-made device; or
- Pollutants are discharged directly into waters of the U.S. that originate outside of and pass over, across, or through the facility or come into direct contact with the confined animals. [40 CFR 122, Appendix B (b)] ***OR***

(3) The facility has been **designated as a CAFO** by the permitting authority on a ***case-by-case basis*** [40 CFR 122.23(c)], based on the permitting authority's determination that the operation is a "significant contributor of pollution." In making this determination, the permitting authority considers the following factors:

- Size of the operation;
- Amount of waste reaching waters of the United States;

R0074374

- Location of the operation relative to waters of the U.S.;
- The means of conveyance of animal wastes and process wastewater into waters of the United States;
- The slope, vegetation, rainfall, and other factors affecting the likelihood or frequency of discharge of animal wastes and process wastewater into waters of the U.S.; and
- Other relevant factors (e.g.,waste handling and storage, land application timing, methods, rates and areas, etc.).

A permit application shall not be required from a concentrated animal feeding designated under the case-by-case authority until after the Director has conducted an on-site inspection and determined that the operation should and could be regulated under the NPDES permit program.

No animal feeding operation with less than the number of animals set forth in 40 CFR 122, Appendix B shall be designated as a concentrated animal feeding operation unless either (1) pollutants are discharged into waters of the U.S. through a manmade ditch, flushing system, or other similar means, or (2) pollutants are discharged directly into waters of the U.S. which originate outside of the facility and pass over, across, or through the facility, or otherwise come into direct contact with the animals confined in the operation.

The NPDES permit regulations [40 CFR 122, Appendix B] contain an exemption for any AFO from being defined as a CAFO if it discharges

> A 25-year, 24-hour rainfall event means the maximum precipitation event with a probable occurrence of once in 25 years, as defined by the National Weather Service in Technical Paper Number 40, "Rainfall Frequency Atlas of the United States," May 1961, and subsequent amendments, or equivalent regional or state rainfall probability information developed therefrom [40 CFR Part 412.11(e)]

only in the event of a 25 year, 24-hour, or larger, storm event. To be eligible for an exemption, the facility must demonstrate to the permitting authority that it has not had a discharge. It must also demonstrate that the entire facility is designed, constructed, and operated to contain a storm event of this magnitude in addition to process wastewater. An operation that qualifies for this exemption from being defined as a CAFO may still be designated as a CAFO by the permitting authority on a case-by-case basis.

- **Storm Water Discharges:** Under 40 CFR §122.2, the definition of "point source" excludes agricultural storm water runoff. Thus, such runoff is not subject to the storm water permit application regulations at 40 CFR §122.26. Non-agricultural storm water discharges, however, are regulated if the discharge results from construction over 5 acres or certain other types of industrial activity such as landfills, automobile junk yards, vehicle maintenance facilities, etc.

  – **Concentrated Aquatic Animal Production Facilities:** Under 40 CFR Part 122.24, a *concentrated aquatic animal production facility* is defined and designated as a point source subject to the NPDES permit program.

    ▸ Definition of concentrated aquatic animal production facility (40 CFR Part 122 Appendix C) -- A *concentrated aquatic animal production facility* is a hatchery, fish farm, or other facility that meets one of the following criteria:

    (1) A facility that contains, grows, or holds cold water fish species or other cold water aquatic animals in ponds, raceways, or similar structures which discharge at least 30 days per year. The term does not include (a) facilities which produce less than 9,090 harvest weight kilograms (approximately 20,000 pounds) of aquatic animals per year, and (b) facilities which feed less than 2,272 kilograms (approximately 5,000 pounds) of food during the calendar month of maximum feeding. Cold water aquatic animals include, but are not limited to, the *salmonidae* family (e.g., trout and salmon).

    (2) A facility that contains, grows, or holds warm water fish species or other warm water aquatic animals in

R0074376

ponds, raceways, or similar structures which discharge at least 30 days per year. The term does not include (a) facilities which produce 45,454 harvest weight kilograms (approximately 100,000 pounds) of aquatic animals per year or (b) closed ponds which discharge only during periods of excess runoff. Warm water aquatic animals include, but are not limited to, the *Ameiuridae*, *Centrarchidae*, and *Cyprinidae* families of fish (e.g., respectively catfish, sunfish, and minnows).

Designated facility -- A facility that does not otherwise meet the criteria in 40 CFR Part 122 Appendix C (described above) may be *designated* as a concentrated aquatic animal production facility if EPA or an authorized state determines the production facility is a significant contributor of pollution to waters of the U.S. No permit is required for such a designated facility until the EPA or state officials have conducted an onsite inspection and determined that the facility should be regulated under the NPDES permit program.

- **Aquaculture Projects**: Under 40 CFR Part 122.25(b), *aquaculture* means a defined, managed water area that uses discharges of pollutants to maintain or produce harvestable freshwater, estuarine, or marine plants or animals. Discharges into approved aquaculture projects are not required to meet effluent limitations that might otherwise apply. The entire aquaculture project (discharges into and out of the project) is addressed in an NPDES permit.

- **Exemption for Irrigation Return Flows:** Under 40 CFR Part 122.3(f), return flows from irrigated agriculture do not require NPDES permits.

- **Wastewater Guidelines for Point Source Silviculture Activities:** Under 40 CFR §122.27, silvicultural point sources are subject to the NPDES permit program. Such silviculture point sources include discrete conveyances related to rock crushing, gravel washing, log sorting or log storage facilities operated in connection with silvicultural activities and from which pollutants are discharged into waters of the U.S. The term does not include nonpoint source silviculture activities such as nursery operations, site preparation, reforestation, thinning, prescribed burning, pest and fire control, harvesting operations, surface drainage, or road construction and maintenance from which there is natural runoff.

- **Nonpoint Source Pollution:** Under the CWA §319 Nonpoint Source (NPS) Management Program and 40 CFR §130.6, states (tribes, and territories) establish programs to manage NPS pollution, including runoff and leaching of fertilizers and pesticides, and irrigation return flows. These NPS management programs must identify: (a) best management practices (BMPs) to be used in reducing NPS pollution loadings; (b) programs to be used to assure implementation of BMPs; (c) a schedule for program implementation with specific milestones; and (d) sources of federal or other funding that will be used each year for the support of the state's NPS pollution management program. Congress provides grant funds to the states annually for the administration of these management programs.

- **Discharges to Publicly Owned Treatment Works (POTWs):** Under 40 CFR Part 403, facilities, including agricultural establishments, may discharge certain substances to a POTW if the facility has received prior written permission from the POTW and has completed any required pretreatment. Facilities must check with their POTWs for information about permitted discharges and for conditions and limitations.

- **Discharges of Designated Hazardous Substances.** Under 40 CFR Parts 116-117, facilities, including agricultural establishments, must immediately notify the National Response Center (1-800-424-8802) and their state agency of any unauthorized discharge of a designated hazardous substance into (1) navigable waters, (2) the shorelines of navigable waters, or (3) contiguous zones, IF the quantity discharged in any 24-hour period equals or exceeds the reportable quantity. A *designated hazardous substance* is any chemical listed in Section 311 of the Clean Water Act. The *reportable quantity* is the amount of the hazardous substance that EPA has determined might cause harm. The list of hazardous substances along with each chemical's reportable quantity is found in 40 CFR Parts 116 and 117. Ammonia and several pesticides are on the list.

- **Discharges of Oil.** Under 40 CFR Part 110, facilities must immediately notify EPA's National Response Center (1-800-424-8802) of any unauthorized discharge of a *harmful quantity of oil* (including petroleum, fuel oil, sludge, oil refuse, or oil mixed with other wastes) into (1) navigable waters, (2) the shorelines of navigable waters, or (3) contiguous zones and beyond. A discharge of oil is considered harmful if it violates applicable water quality standards, causes a sludge or emulsion to be deposited under the surface of the water or on adjoining shorelines, or causes a film or sheen on, or discoloration of, the water or adjoining shorelines. In practice, any quantity of oil or a petroleum product is a harmful quantity, since even small amounts will cause a film or sheen on surface water.

– **Oil Spill Prevention Control and Countermeasure (SPCC) Program**: Under 40 CFR Part 112, facilities, including agricultural establishments, must comply with EPA's SPCC program when they store oil at their facility. SPCC requirements apply to non-transportation related onshore and offshore facilities of specified size engaged in storing, processing, refining, transferring or consuming oil products, which due to their location, could potentially discharge oil into waters of the U.S. or adjoining shorelines.

  Facilities must comply with the SPCC program: (1) if they have a single aboveground container with an oil storage capacity of more than 660 gallons, multiple aboveground containers with a combined oil storage capacity of more than 1,320 gallons, or a total underground oil storage capacity of more than 42,000 gallons *and* (2) if there is a reasonable expectation that a discharge (spill, leak, or overfill) from the tank will release harmful quantities of oil into navigable waters or adjoining shorelines. The requirements are triggered by tank capacity, regardless of whether tanks are completely filled.

  Facilities subject to the SPCC requirements must prepare an SPCC plan. This plan must include: (1) *prevention* measures that keep oil releases from occurring, (2) *control* measures installed to prevent oil releases from reaching navigable waters, and (3) *countermeasures* to contain, clean up, and mitigate the effects of any oil release that reaches navigable waters. Each plan must be unique to the facility and must be signed by a registered professional engineer.

- **Wetlands on Agricultural Lands**: Swamps, marshes, fens, bogs, vernal pools, playas, and prairie potholes are common names for wetlands. Wetlands provide a habitat for threatened and endangered species as well as a diversity of other plant, wildlife, and fish species. In addition to providing habitat, wetlands serve other functions, including stabilizing shorelines; storing flood waters; filtering sediments, nutrients, and toxic chemicals from water; and providing an area for the recharge and discharge of groundwater. It is important to note that not all wetlands will be obvious to the untrained observer. For example, an area can appear dry during much of the year and still be classified as a wetland. Your local Natural Resources Conservation Service (NRCS) office can help to identify and delineate wetlands on your property.

NRCS, formerly the Soil Conservation Service, is the lead agency for identifying wetlands on *agricultural lands*. According to NRCS, agricultural lands means those lands intensively used and managed for the production of food or fiber to the extent that the natural vegetation has been removed and therefore does not provide reliable indicators of wetland vegetation. Areas that meet this definition may include intensively used and managed cropland, hayland, pastureland, orchards, vineyards, and areas that support wetland crops (e.g., cranberries, taro, watercress, rice). Lands not included in the definition of *agricultural lands* include rangelands, forest lands, woodlots, and tree farms.

- ***Exemption to Section 404 Permit Requirements***. The placement of dredge and fill material into wetlands and other water bodies (i.e., waters of the United States) is regulated by the U.S. Army Corps of Engineers (Corps) under 33 CFR Part 328. The Corps regulates wetlands by administering the CWA Section 404 permit program for activities that impact wetlands. The 404 permit program requires a permit for point source discharges of dredged and fill material into waters of the United States. However, many normal established farming activities (e.g., plowing, cultivating, minor drainage, and harvesting), silviculture, and ranching activities that involve discharges of dredged or fill materials into U.S. waters are **exempt from Section 404 permits** and do **NOT** require a permit (33 CFR §323.4). In order to be exempt, the activity must be part of an ongoing operation and cannot be associated with bringing a wetland into agricultural production or converting an agricultural wetland to a non-wetland area.

  If not covered by the above exemption, a permit is required before discharging dredged or fill material into U.S. waters, including most wetlands (33 CFR Part 323). The Army Corps of Engineers (Corps) reviews Section 404 permit applications to determine if a project is the least environmentally damaging and practicable alternative.

- **POTW Sludge Management - Land Application of Biosolids**. Land application is the application of biosolids to land to either condition the soil or fertilize crops or other vegetation grown in the soil. Biosolids are a primarily organic solid product produced by wastewater treatment processes that can be beneficially recycled.

  EPA regulates the land application of biosolids under 40 CFR Part 503. As described in *A Plain English Guide to the EPA Part 503 Biosolids Rule* (EPA/832/R-93-003, September 1994), the Part 503 rule includes general provisions, and requirements for land application, surface disposal, pathogen and vector attraction reduction, and incineration. For each regulated use or disposal practice, a Part 503 standard includes general requirements, pollutant limits, management practices, operational standards, and requirements for the frequency of monitoring, recordkeeping, and reporting. For the most part, the requirements of the Part 503 rule are ***self-implementing*** and must be followed even without the issuance of a permit covering biosolids use or disposal requirements.

- **Total Maximum Daily Load (TMDL) program**. There are still waters in the nation that do not meet the CWA national goal of "fishable, swimmable" despite the fact that nationally required levels of pollution control technology have been implemented by many pollution sources. The TMDL program, established under Section 303(d) of the Clean Water Act, focuses on identifying and allocating pollutant loads to these waterbodies. The goal of a TMDL is the attainment of water quality standards.

  A TMDL identifies the amount a pollutant needs to be reduced to meet water quality standards, allocates pollutant load reductions among pollutant sources in a watershed, and provides the basis for taking actions needed to restore a waterbody. It can identify the need for point source and nonpoint source controls.

  Under this provision, States are required to (1) identify and list waterbodies where State water quality standards are not being met following the application of technology-based point source pollution controls; and (2) establish TMDLs for these waters. EPA must review and approve (or disapprove) State lists and TMDLs. If state actions are not adequate, EPA must prepare lists and TMDLs. TMDLs are to be implemented using existing federal, state, and local authorities and voluntary programs.

TMDLs should address all significant pollutants which cause or threaten to cause waterbody use impairment, including:

- Point sources (e.g., sewage treatment plant discharges)
- Nonpoint sources (e.g., runoff from fields, streets, range, or forest land)
- Naturally occurring sources (e.g., runoff from undisturbed lands)

A TMDL is the sum of the individual wasteload allocations for point sources, load allocations for nonpoint sources and natural background pollutants, and an appropriate margin of safety. TMDLs may address individual pollutants or groups of pollutants, as long as they clearly identify the links between: (1) the waterbody use impairment or threat of concern, (2) the causes of the impairment or threat, and (3) the load reductions or actions needed to remedy or prevent the impairment.

TMDLs may be based on readily available information and studies. In some cases, complex studies or models are needed to understand how pollutants are causing waterbody impairment. In many cases, simple analytical efforts provide an adequate basis for pollutant assessment and implementation planning.

Where inadequate information is available to draw precise links between these factors, TMDLs may be developed through a phased approach. The phased approach enables states to use available information to establish interim targets, begin to implement needed controls and restoration actions, monitor waterbody response to these actions, and plan for TMDL review and revision in the future. Phased approach TMDLs are particularly appropriate to address nonpoint source issues.

Numerous TMDLs are under development in many states and TMDLs are likely to impact agricultural activities by prompting states and stakeholders to mitigate water pollution caused by agricultural sources (assuming agriculture-related industries are identified as significant contributors to water quality impairment).

Coastal Zone Act Reauthorization Amendments of 1990

The Coastal Nonpoint Pollution Control Program, which is implemented under the authority of Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990, is administered at the federal level jointly by EPA and the National Oceanic and Atmospheric Administration (NOAA).

The Section 6217 program requires the 29 states and territories with NOAA-approved coastal zone management programs to develop and implement coastal nonpoint pollution control programs. These programs are intended to serve as an update and expansion of existing state programs focused on nonpoint source pollution affecting coastal areas. These submitted programs must include: (1) management measures that are in conformity with applicable federal guidance and (2) state-developed management measures as necessary to achieve and maintain applicable water quality standards.

On January 19, 1993, EPA issued its *Guidance Specifying Management Measures For Sources of Nonpoint Pollution in Coastal Waters*. The federal guidance specifies management measures for the following agricultural sources: (1) erosion from cropland, (2) confined animal facilities, (3) the application of nutrients to croplands, (4) the application of pesticides to cropland, (5) grazing management, and (6) irrigation of cropland.

Once approved, the programs are implemented through state nonpoint source programs (under CWA §319) and state coastal zone management programs (authorized under §306 of the Coastal Zone Management Act). Agricultural establishments located in coastal states should determine whether their land is included in the state's coastal management area. If so, they must comply with their state's applicable coastal nonpoint programs. Currently, all state coastal nonpoint management programs have been conditionally approved and have begun to be implemented.

Coastal Zone Management Act

The 1996 amendments to the Coastal Zone Management Act that may affect agriculture-related industries include those that relate to aquaculture in the coastal zone. Eligible states may now receive grants for developing a coordinated process among state agencies to regulate and issue permits for aquaculture facilities in the coastal zone. States may also receive grants for adopting procedures and policies to evaluate facilities in the coastal zone that will enable the states to formulate, administer, and implement strategic plans for marine aquaculture. Each state that receives such grants will make its own determination as part of its coastal management plan on how to specifically use the funds. Therefore, persons engaged in aquaculture productivity in the coastal zone may be eligible for technical or financial assistance under their state's plan.

Safe Drinking Water Act

The SDWA, which has been amended twice since 1974, protects the water supply through water quality regulations and source protection, such as

R0074383

underground injection control (UIC) regulations. SDWA requirements apply to all public water systems (PWSs). Currently, 54 of 56 states and territories have been delegated primacy to run the drinking water program.

- **Public Water Systems**. Under 40 CFR Parts 141-143, facilities that operate a PWS or receive water from a PWS and provide treatment to it are subject to SDWA regulations. Prior to 1996, SDWA defined a PWS as "a system for the provision to the public of piped water *for human consumption* if such system has at least 15 service connections or regularly serves at least 25 individuals." The 1996 Amendments expanded the means of delivering water to include not only pipes, but also other constructed conveyances such as ditches and waterways.

  While there are three categories of PWSs, an agricultural establishment will most likely operate a non-transient, non-community system. This type of system serves at least 25 people for over 6 months of the year, but the people generally do not live at the facility. All PWSs must comply with the national primary drinking water regulations (40 CFR 141). Under 40 CFR Part 141 Subpart G, EPA has established drinking water standards for numerous pesticides.

  Establishments that operate a non-transient, non-community system, in general, will need to: (1) monitor for the contaminants the state has established for that type of system, (2) keep records of the monitoring results, (3) report results from all tests and analyses to the state/tribe on a set schedule, (4) take immediate action to correct any violations in the allowable contaminant levels, (5) make a public announcement of any violations to warn people about potential adverse effects and to describe the steps taken to remedy the problem, and (6) keep records of actions taken to correct violations.

- **Comprehensive State Ground Water Protection Program**. Under the SDWA §1429, states/tribes are allowed to establish a Comprehensive State Ground Water Protection Program to protect underground sources of drinking water. Under this program, a state/tribe can require facilities, including agricultural establishments, to use designated best management practices (BMPs) to help prevent contamination of groundwater by nitrates, phosphates, pesticides, microorganisms, or petroleum products. These requirements generally apply only to facilities that are subject to the public water system supervision program. Persons applying pesticides or fertilizers must know the location of all the public water supply source areas in the vicinity that are protected by state/tribal (and sometimes local) requirements.

- **Source Water Protection Program**. Under the SDWA, states are required to develop comprehensive Source Water Assessment Programs (SWAP). The statutorily defined goals for SWAPs are to provide for the protection and benefit of public water systems and for the support of monitoring flexibility. These programs plan to identify the areas that supply public tap water, inventory contaminants and assess water system susceptibility to contamination, and inform the public of the result.

- **Wellhead Protection Program**. Under the SDWA §1428, if a facility, has an onsite water source (e.g., well) that qualifies as a PWS, it must take the steps required by the state/tribe to protect the wellhead from contaminants. A wellhead protection area is the surface and subsurface area surrounding a water well or wellfield supplying a PWS through which contaminants are reasonably likely to move toward and reach such water well or wellfield.

  Since drinking water standards (40 CFR Part 141 Subpart G) exist for numerous pesticides, which may be used in various agriculture-related activities, some state/tribe and local wellhead and source water protection programs restrict the use of agricultural chemicals in designated wellhead protection areas. In addition, persons applying pesticides or fertilizers must know the location of all the public water supply source areas in the vicinity that are protected by state/tribal (and sometimes local) requirements, and the requirements for mixing, loading, and applying agricultural chemicals within any designated wellhead or source water protection areas.

- **Sole Source Aquifer Protection Program**. Under the SDWA §1424 and 40 CFR Part 149 Subpart B, EPA can establish requirements for protecting sole source aquifers. EPA designates an aquifer as a ***sole source aquifer*** if it supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer and no alternative drinking water sources are feasible. The Sole Source Aquifer program prohibits federal financial assistance (any grant, contract, loan guarantee, or otherwise) for any project, including agricultural projects, that may result in contamination to the aquifer and create a hazard to public heath. Currently, only a few aquifers have been designated as protected sole source aquifers.

- **Underground Injection Control (UIC) Program**. The UIC program (40 CFR Parts 144 and 146-148) is a permit program that protects underground sources of drinking water by regulating five classes of injection wells (I - V). *Underground injection* means depositing fluids beneath the surface of the ground by injecting them into a hole (any hole that is deeper than it is wide). *Fluids* means any material or substance which flows or moves whether in a semisolid, liquid, sludge, gas, or any other form or state.

If a facility disposes of (or formerly disposed of) waste fluids onsite in an injection well, it triggers the UIC requirements. In general, a facility may not inject contaminants into any well if the contaminant could cause a violation of any primary drinking water regulation or endanger an underground source of water if the activity would adversely affect the public health. Most deep well underground injections are prohibited without a UIC permit. No Class I, II, or III injection well may be constructed or opened before a permit has been issued. UIC permits include design, operating, inspection, and monitoring requirements. In many states/tribes, EPA has authorized the state/tribal agency to administer the program.

Class V Wells. Owners/operators of Class V wells (shallow wells that inject fluids above an underground source of water) must not construct, operate, maintain, convert, plug, abandon, or conduct any other injection activity in a manner that allows the movement of fluid containing any contaminant into underground sources of drinking water, if the presence of that contaminant may cause a violation of any primary drinking water regulation (40 CFR Part 142) or may otherwise adversely affect the health of persons. Examples of Class V wells potentially applicable to agricultural establishments include, but are not limited to:

- Drainage wells, such as agricultural drainage wells, primarily used for storm runoff.

- Cesspools with open bottoms (and sometimes perforated sides) and septic system wells used to inject waste or effluent from multiple dwellings or businesses (the UIC requirements do not apply to single family residential septic system or cesspool wells or to non-residential septic system or cesspool wells that are used solely for the disposal of sanitary wastes and have the capacity to serve fewer than 20 persons per day).

- Dry wells used for waste injection.

- Recharge wells used to replenish aquifers.

- Injection wells associated with the recovery of geothermal energy for heating, aquaculture, and production of electric power.
- Floor drains in maintenance shops/work areas.

> ***Agricultural drainage wells*** typically drain water from low-lying farm land, but some serve to recharge aquifers from which irrigation water is withdrawn. These wells are usually constructed in areas with poor soil drainage, but where underlying geologic formations allow rapid infiltration of water. Sometimes abandoned water supply wells are adapted for use in agricultural drainage. Agricultural drainage wells typically receive field drainage from saturated topsoil and subsoil, and from precipitation, snowmelt, floodwaters, irrigation return flow, and animal feedlots. The types of pollutants injected into these wells include (1) pesticide runoff, (2) nitrate, nitrite, and salts, such as those of calcium, magnesium, sodium, potassium, chloride, sulfate, and carbonate from fertilizer runoff, (3) salts and metals (i.e., iron, lead, cadmium, and mercury) from biosolid sludges and compost, (4) microbes (i.e., bacteria and viruses) from animal waste runoff, and (5) petroleum contaminants, such as fuel and oil, from runoff from roads or equipment maintenance areas.

If a facility has a Class V well, it must furnish inventory information about the well to the appropriate state/tribal agency. If at any time EPA or the state/tribal agency learns that a Class V well may cause a violation of primary drinking water regulations (40 CFR Part 142) or may be otherwise adversely affecting the health of persons, it may require the injector to obtain an individual UIC permit, or order the injector to take such actions (including, where required, closure of the injection well) as may be necessary to prevent the violation.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) was enacted to address problems related to hazardous and solid waste management. RCRA gives EPA the authority to establish a list of solid and hazardous wastes and to establish standards and regulations for the treatment, storage, and disposal of these wastes. Regulations in Subtitle C of RCRA address the identification, generation, transportation, treatment, storage, and disposal of hazardous wastes. These regulations are found in 40 CFR Part 124 and 40 CFR Parts 260-279. Under RCRA, persons who generate waste must determine whether the waste is defined as solid waste or hazardous waste. Solid wastes are considered hazardous wastes if they are listed by EPA as hazardous or if they exhibit characteristics of a hazardous waste: toxicity, ignitability, corrosivity, or reactivity.

Most agriculture-related activities do not generate significant amounts of hazardous waste. Generally, the activities potentially subject to RCRA involve the use of pesticides and fertilizers, and the use and maintenance of different types of machinery.

Hazardous Waste Generator Categories. Facilities that generate hazardous waste can be classified into one of three hazardous waste generator categories as defined in 40 CFR Part 262:

- ***Conditionally exempt small quantity generator (CESQG).*** A facility is classified as a CESQG if it generates no more than 220 lbs (100 kg) of hazardous waste in a calendar month. There is no time limit for accumulating ≤2,200 lbs of hazardous waste onsite. However, CESQGs cannot store more than 2,200 lbs (1,000 kg) of hazardous waste onsite at any time. In addition, CESQGs cannot accumulate onsite more than 2.2 lbs (1 kg) of acutely hazardous waste or more than 220 lbs spill residue from acutely hazardous waste for any period of time.

- ***Small quantity generator (SQG).*** A facility is classified as a SQG if it generates >220 lbs (100 kg) and <2,200 lbs (1,000 kg) of hazardous waste in a calendar month. SQGs can accumulate onsite no more than 13,200 lbs (6,000 kg) of hazardous waste. SQGs can store hazardous waste onsite for up to 180 days (or up to 270 days if the waste treatment/disposal facility is more than 200 miles away).

- ***Large quantity generator (LQG).*** A facility is classified as a LQG if it generates > 2,200 lbs (1,000 kg) of hazardous waste in a calendar month. While there is no limit on the amount of hazardous waste that LQGs can accumulate onsite, they can only store it onsite for up to 90 days.

If a facility is a CESQG and generates ≤2.2 lbs (1 kg) of acutely hazardous waste; or ≤220 lbs (100 kg) of acutely hazardous waste spill residues in a calendar month, and never stores more than that amount for any period of time, it may manage the acutely hazardous waste according to CESQG requirements. If it generates more than 2.2 lbs (1 kg) of acutely hazardous waste or >220 lbs (100 kg) of acutely hazardous waste spill residues in a calendar month, the facility must manage it according to LQG requirements.

The hazardous wastes that must be measured are those: (1) accumulated at the facility for any period of time before disposal or recycling, (2) packaged and transported away from the facility, (3) placed directly into a treatment or disposal unit at the facility, or (4) generated as still bottoms or sludges *and* removed from product storage tanks.

Requirements for CESQGs. Based on the quantity of hazardous waste generated per month, most agricultural establishments will qualify as CESQGs. As CESQGs, facilities must comply with three basic waste management requirements:

(1) Identify all hazardous waste generated.

(2) Do not generate per month more than 220 lbs (100 kg) of hazardous waste; more than 2.2 lbs (1 kg) of acutely hazardous waste; or more than 220 lbs (100 kg) of acutely hazardous waste spill residues; and never store onsite more than 2,200 lbs (1,000 kg) of hazardous waste; 2.2 lbs of acutely hazardous waste; or 220 lbs of acutely hazardous waste spill residues for any period of time.

(3) Ensure proper treatment and disposal of the waste. This means ensuring that the disposal facility is one of the following:

- A state or federally regulated hazardous waste management treatment, storage, or disposal facility.
- A facility permitted, licensed, or registered by a state to manage municipal or industrial solid waste.
- A facility that uses, reuses, or legitimately recycles the waste (or treats the waste before use, reuse, or recycling).
- A universal waste handler or destination facility subject to the requirements for universal wastes.

CESQGs are allowed to transport their own wastes to the treatment or storage facility, unlike SQGs and LQGs who are required to use a licensed, certified transporter. While there are no specific RCRA requirements for CESQGs who transport their own wastes, the U.S. Department of Transportation (DOT) requires all transporters of hazardous waste to comply with all applicable DOT regulations. Specifically, DOT regulations require all transporters, including CESQGs, transporting hazardous waste that qualifies as a DOT hazardous material to comply with EPA hazardous waste transporter requirements found in 40 CFR Part 263. CESQGs are not required by federal hazardous waste laws to train their employees on waste handling or emergency preparedness.

Requirements for SQGs and LQGs. Facilities determined to be SQGs or LQGs must meet many requirements under the RCRA regulations. These requirements, found in 40 CFR 260-279, include identifying hazardous waste; obtaining an EPA identification numbers; meeting requirements for waste accumulation and storage limits; container management; conducting personnel training; preparing a manifest; ensuring proper hazardous waste packaging, labeling, and placarding; reporting and recordkeeping; and contingency planning, emergency procedures, and accident prevention.

Notes: Facilities that fall into different generator categories during different months may choose to simplify compliance by satisfying the more stringent requirements all the time.

Specific Provisions. RCRA regulations include several specific provisions addressing agriculture-related materials and activities. Key provisions are briefly summarized below:

- ***Exemption for Certain Solid Wastes Used as Fertilizers.*** Under 40 CFR §261.4(b), solid wastes generated by (1) growing and harvesting of agricultural crops, or (2) raising animals (including animal manure), and that are returned to the soils as fertilizers are excluded from regulation as hazardous waste.

- ***Exemption for Certain Hazardous Waste Pesticides.*** Under 40 CFR §262.70, farmers who generate any amount of hazardous waste pesticides from their own use are excluded from the generator, treatment/storage/disposal facility, land disposal, and permit requirements under RCRA Subtitle C, provided that the farmer: (1) disposes of the waste pesticide in a manner consistent with the label on the pesticide container; (2) triple rinses each empty container in accordance with requirements at 40 CFR §261.7(b)(3); and (3) disposes of the rinsate on his own farm in accordance with the instructions on the label. If the label does not include disposal instruction, or no instructions are available from the pesticide manufacturer, the waste pesticide and rinsate must be disposed of in accordance with Subtitle C hazardous waste requirements. (Also see 40 CFR Part 165 - FIFRA).

- ***Exemption for Commercial Fertilizers.*** Under 40 CFR §266.20, commercial fertilizers produced for general public (including agricultural) use that contain recyclable materials are not presently subject to regulation provided they meet the applicable land disposal restriction (LDR) standards for each recyclable material they contain. For example, zinc-containing fertilizers containing K061 (emission control dust from the primary production of steel in electric furnaces) are not subject to regulation.

- ***Fertilizers Made from Hazardous Wastes***. Under 40 CFR Parts 266 and 268, EPA regulates fertilizers containing hazardous wastes as ingredients. Hazardous wastes may be used as ingredients in fertilizers under certain conditions, since such wastes can be a beneficial component of legitimate fertilizers. EPA has established standards that specify limits on the levels of heavy metals and other contents used as fertilizer ingredients. These standards are based on treatment, by the best technology currently available, to reduce the toxicity and mobility of all the contents of the hazardous waste components. These standards are based on waste management considerations and do not include consideration of the potential agronomic or dietary risk.

- ***Food Chain Crops Grown on Hazardous Waste Land Treatment Units***. Under 40 CFR Part 264.276, food chain crops (including feed for animals consumed by humans) may be grown in or on hazardous waste land treatment units under certain conditions and only with a permit. The permit for a facility will list the specific food-chain crops that may be grown. To obtain a permit, the owner/operator of the facility wishing to grow the food-chain crops must demonstrate -- prior to the planting of such crops -- that there is no substantial risk to human health caused by the growth of such crops in or on the treatment zone.

- ***Solid Waste Disposal Criteria***. Under RCRA Subtitle D, 40 CFR 257.3 establishes solid waste disposal criteria addressing floodplains, endangered species, groundwater protection, application to land used for food chain crops, disease vectors, air pollution, and safety. These criteria are largely guidelines used by states in developing solid waste regulations, which control the disposal of waste on a farmer's property.

- ***Land Application of Fertilizers Derived from Drinking Water Sludge***. Under 40 CFR Part 257, EPA regulates the land application of solid wastes, including drinking water sludge applied as fertilizer. These requirements include: (1) cadmium limits on land used for the production of food-chain crops (tobacco, human food, and animal feed) or alternative less stringent cadmium limits on land used solely for production of animal feed; (2) polychlorinated biphenyls (PCBs) limits on land used for producing animal feed, including pasture crops for animals raised for milk; and (3) minimization of disease vectors, such as rodents, flies, and mosquitoes, at the site of application through incorporation of the fertilizer into soil so as to impede the vectors' access to the sludge.

- ***Pesticides That Are Universal Wastes.*** Under 40 CFR Part 273, EPA has established a separate set of requirements for three types of wastes called *universal wastes.* Universal wastes include certain batteries, certain pesticides, and mercury thermostats. Pesticides designated as universal wastes include (1) recalled pesticides that are stocks of a suspended or canceled pesticide and part of a voluntary or mandatory recall under FIFRA §19(b); (2) recalled pesticides that are stocks of a suspended or canceled pesticide, or a pesticide that is not in compliance with FIFRA, that are part of a voluntary recall [see FIFRA §19(b)(2)] by the registrant; and (3) stocks of other unused pesticide products that are collected and managed as part of a waste pesticide collection program.

  The Universal Waste rule is *optional* for states/tribe to adopt. In those states/tribes that have not adopted the Universal Waste rule, these wastes must be disposed of in accordance with the hazardous (or acutely hazardous) waste requirements (see 40 CFR Part 262).

- ***Exemption for Small Quantities of Used Oil.*** Under 40 CFR §279.20, agricultural establishments that generate an average of 25 gallons or less of used oil per month over a calendar year from vehicles or machinery used on the establishment are not subject to the requirements of 40 CFR Part 279.

- ***Exemption for "Farm Tanks" and Tanks of 110 Gallons or Less.*** Under the underground storage tank (UST) regulations (RCRA Subtitle I, 40 CFR §280.12), "farm tanks" of 1,100 gallons or less capacity used for storing motor fuel for non-commercial purposes are not regulated as underground storage tanks. *"Farm tanks"* include tanks located on a tract of land devoted to the production of crops or raising animals (including fish) and associated residences and improvements. Also under 40 CFR §280.10, the UST program does not apply to UST systems of 110 gallons or less capacity, or that contain a *de minimis* concentration of a regulated substance.

  Even with the above exemptions, keep in mind that many agricultural establishments may be subject to the UST program (40 CFR Part 280). The UST regulations apply to facilities that store either petroleum products or hazardous substances (except hazardous wastes) identified under CERCLA. UST regulations address design standards, leak detection, operating practices, response to releases, financial responsibility for releases, and closure standards.

Comprehensive Environmental Response, Compensation, and Liability Act

Under CERCLA, there are a limited number of statutory and regulatory requirements that potentially affect agricultural businesses. The key provisions are summarized below:

- **Emergency Release Notification Requirements**. Under CERCLA §103(a), facilities are required to notify the National Response Center about any release of a CERCLA hazardous substance in quantities equal to or greater than its reportable quantity (RQ). Releases include discharges into the air, soil, surface water, or groundwater. Any release at or above the RQ must be reported regardless of whether there is a potential for offsite exposure.
  - ***Hazardous Substances.*** The term "hazardous substance" is defined in CERCLA §101(14) and these substances (more than 700) are listed at 40 CFR Part 302, Table 302.4. Several agricultural chemicals are on the CERCLA hazardous substance list, including many pesticides, anhydrous ammonia, and ethylene glycol.
  - ***Reportable Quantities***. For each hazardous substance, EPA has designated a RQ of 1, 10, 100, 1,000, or 5,000 pounds. RQs are listed in 40 CFR Part 355, Appendices A and B and 40 CFR Part 302, Table 302.4.
  - ***When No Notification is Required***. There are several types of releases that are excluded from the requirements of CERCLA release notification. Two of these releases, excluded under CERCLA §§101(22) and 103(e), include the normal application of fertilizer and the application of pesticide products registered under FIFRA. *Keep in mind that spills, leaks, or other accidental or unintended releases of fertilizers and pesticides are subject to the reporting requirements.*

- **Facility Notification and Recordkeeping Requirements - Exemption for Agricultural Producers**. Under CERCLA §§103(c) and (d), certain facilities must notify EPA of their existence and the owners/operators must keep records. However, CERCLA §103(e) exempts agricultural producers who store and handle FIFRA-registered pesticides from the facility notification and recordkeeping

R0074393

requirements. CERCLA does not define the term *agricultural producer*.

- **Liability for Damages**. Under CERCLA §107(a), an owner/operator of a facility that has CERCLA hazardous substances onsite may be liable for cleanup costs, response costs, and natural resource damages associated with a release or threatened release of hazardous substances. Agricultural establishments are potentially liable under this section, and that liability extends to past practices.

Emergency Planning and Community Right-to-Know Act

A summary of the potential applicability of specific sections of EPCRA on the agricultural sector follows below.

- **Emergency Planning and Notification**. Under EPCRA §302, owners or operators of any facility, including agricultural establishments, that have *extremely hazardous substances* (40 CFR Part 355 Appendices A and B) present in excess of the *threshold planning quantity* must notify in writing their state emergency response commission (SERC) and their local emergency planning committee (LEPC) that they are subject to EPCRA planning requirements. Under EPCRA §303, they must also notify the LEPC of the name of a person at their facility whom the LEPC may contact in regard to planning issues related to these extremely hazardous substances. They must also inform the LEPC promptly of any relevant changes, and when requested, must provide information to the LEPC necessary for emergency planning.

  Ammonia, several agricultural pesticides, and certain fuels are included on the list of extremely hazardous substances found in 40 CFR Part 355 Appendices A and B. If a listed substance is a solid, two different planning quantities are listed (e.g., 500 lbs/10,000 lbs). The smaller amount (e.g., 500 lbs.) applies if the substance is in powder form, such as a soluble or wettable powder, or if it is in solution or molten form. The larger quantity (10,000 lbs.) applies for most other forms of the substance. If the extremely hazardous substance is part of a mixture or solution, then the amount is calculated by multiplying its percent by weight times the total weight of the mixture or solution. If the percent by weight is less than one percent, the calculation is not required (40 CFR Part 355.30).

  ✓ Ammonia -- The quantity of anhydrous ammonia that triggers the planning requirement is 500 pounds.

- ✓ Pesticides -- Examples of pesticides on the list with the quantity in pounds that triggers the planning requirement include: ethion (1,000), nicotine (100), dichlorvos (1,000), parathion (100), chlordane (1,000), methyl bromide (1,000), ethylene oxide (1,000), fenitrothion (500), phorate (10), zinc phosphide (500), aluminum phosphide (500), terbufos (100), phosphamidon (100), demeton (500), ethoprop (1,000), and disulfoton (500).

- ✓ Solid Pesticides -- Examples of pesticides with dual quantities that trigger the planning requirements include: coumaphos (100/10,000), strychnine (100/10,000), dimethoate (500/10,000), warfarin (500/10,000), azinphos-methyl (10/10,000), methyl parathion (100/10,000), phosmet (10/10,000), methidathion (500/10,000), carbofuran (10/10,000), paraquat (10/10,000), methiocarb (500/10,000), methamidophos (100/10,000), methomyl (500/10,000), fenamiphos (10/10,000), and oxamyl (100/10,000).

- **§304 Emergency Release Notification**. Under 40 CFR 355, facilities must *immediately* notify the SERC and LEPC of releases of EPCRA extremely hazardous substances and CERCLA hazardous substances when the release equals or exceeds the reportable quantity within a 24-hour period and has the *potential* for offsite exposure. There are two notifications required: the initial notification and the written followup notification.

  Exemption for Substances Used in Agricultural Operations. Only facilities that produce, use or store *hazardous chemicals* are subject to EPCRA release reporting. EPCRA §311(e) excludes from the definition of *hazardous chemicals* those substances used in routine agricultural operations. The exemption covers fertilizers and pesticides used in routine agricultural operations and fuels for operating farm equipment (including to transport crops to market). If all the hazardous chemicals present at the facility do not fall within this exemption, the facility must report all releases of any EPCRA extremely hazardous substance or CERCLA hazardous substance. Additionally, spills, leaks, or other accidental or unintended releases of fertilizers and pesticides are subject to the EPCRA release reporting requirements.

- **§311 and §312 Hazardous Chemical Inventory and Reporting**. Under EPCRA §311 and §312, facilities must inventory the hazardous chemicals present onsite in amounts equal to or in excess of the threshold planning quantities, and meet two reporting requirements:

- A one-time notification of the presence of hazardous chemicals onsite in excess of threshold levels (EPCRA §311) to the SERC, LEPC, and the local fire department; and

- An annual notification (Tier I or Tier II report) to the SERC, LEPC, and the local fire department detailing the locations and hazards associated with the hazardous chemicals found on facility grounds (EPCRA §312).

Exemption for Substances Used in Agricultural Operations. As mentioned above, the term "hazardous chemical," as defined in EPCRA §311(e), *excludes* substances used in routine agricultural operations.

Clean Air Act

Agriculture-related industries generally do not include those industry sectors considered to be major sources of air pollution. Nevertheless, some agriculture-related activities are potentially subject to regulation under the CAA. The provisions identified below summarize the CAA requirements applicable to certain agriculture-related activities:

- **Risk Management Program.** Under §112(r) of the Clean Air Act, EPA has promulgated the Risk Management Program Rule. The rule's main goals are to prevent accidental releases of regulated substances and to reduce the severity of those releases that do occur by requiring facilities to develop risk management programs. A facility's risk management program must incorporate three elements: a hazard assessment, a prevention program, and an emergency response program. These programs are to be summarized in a risk management plan (RMP) that will be made available to state and local government agencies and the public.

  Under 40 CFR Part 68, facilities that have more than the threshold quantity of any of the listed regulated substances in a single process are required to comply with the regulation. *Process* means any regulated activity involving a regulated substance, including manufacturing, storing, distributing, or handling a regulated substance or using it in any other way. Any group of interconnected vessels (including piping), or separate vessels located close enough together to be involved in a single accident, are considered a single process. Transportation is not included.

Listed regulated substances are acutely toxic substances, flammable gases, volatile liquids, and highly explosive substances listed by EPA in the Risk Management Program rule. The *threshold quantity* is the amount of a regulated substance that triggers the development of a RMP. The list of regulated substances and their corresponding threshold quantities are found at 40 CFR Part 68. Examples of threshold quantities of listed regulated substances include: formaldehyde -- 15,000 pounds; ethylene oxide -- 10,000 pounds; methyl isocyanate -- 10,000 pounds; anhydrous ammonia -- 10,000 pounds; and mixtures containing ammonia in a concentration of 20 percent or greater -- 20,000 pounds.

Exception: Ammonia that farmers are holding for use as fertilizer is not a regulated substance under the risk management program. Farmers are not responsible for preparing a risk management plan if ammonia held for use as a fertilizer is the only listed regulated substance that they have in more than threshold quantities. However, ammonia that is on a farm for any other use, such as for distribution or as a coolant/refrigerant, is not exempt.

Three program levels. The risk management planning regulation (40 CFR Part 68) defines the activities facilities must undertake to address the risks posed by regulated substances in covered processes. To ensure that individual processes are subject to appropriate requirements that match their size and the risks they may pose, EPA has classified them into 3 categories ("programs"):

- **Program 1** requirements apply to processes for which a worst-case release, as evaluated in the hazard assessment, would not affect the public. These are processes that have **not** had an accidental release that caused serious offsite consequences.

- **Program 2** requirements apply to less complex operations that do **not** involve chemical processing.

- **Program 3** requirements apply to higher risk, complex chemical processing operations and to processes already subject to the **OSHA Process Safety Management Standard (29 CFR 1910.119)**.

Risk Management Planning. Facilities with more than a threshold quantity of any of the 140 regulated substances in a single process are required to develop a risk management program and to summarize their program in a risk management plan (RMP). A facility subject to the requirements were required to submit a registration and RMP by June 21, 1999, or whenever it first exceeds the threshold for a listed regulated substance after that date.

All facilities with processes in Program 1 must carry out the following elements of risk management planning:

- An offsite consequence analysis that evaluates specific potential release scenarios, including worst-case and alternative scenarios.
- A five-year history of certain accidental releases of regulated substances from covered processes.
- A risk management plan, revised at least once every five years, that describes and documents these activities for all covered processes.

Facilities with processes in Programs 2 and 3 must also address each of the following elements:

- An integrated prevention program to manage risk. The prevention program will include identification of hazards, written operating procedures, training, maintenance, and accident investigation.
- An emergency response program.
- An overall management system to put these program elements into effect.

- **National Ambient Air Quality Standards (NAAQS)/SIPS**. Under the CAA §10, each state must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet federal air quality standards. If the applicable SIP imposes requirements on an agricultural establishment, that facility must comply with the SIP. The most likely pollutant of concern with respect to agriculture-related businesses is particulate matter.

Federal Insecticide, Fungicide, and Rodenticide Act

For agricultural producers, FIFRA is the environmental statute that most significantly impacts day-to-day operations of pesticide use. It also imposes administrative requirements on pesticide users, including agricultural producers. A summary of major provisions applicable to agricultural producers is provided below.

- **Use restrictions:** The pesticide product label is information printed on or attached to the pesticide container. Users are legally required to follow the label. Labeling is the pesticide product label and other accompanying materials which contain directions that pesticide users are legally required to follow. Under FIFRA §12, each pesticide must be used only in a way that is consistent with its labeling.

  - As a part of the pesticide registration, EPA must classify the product for general use, restricted use, or general for some uses and restricted for others (Miller, 1993). For pesticides that may cause unreasonable adverse effects on the environment, including injury to the applicator, EPA may require that the pesticide be applied either by or under the direct supervision of a certified applicator.

  - It is against the law (Endangered Species Act) to harm an endangered species. Harm includes not only acts that directly injure or kill the protected species, but also significant habitat modification or degradation that disrupts breeding, feeding, or sheltering. Pesticide users must comply with any pesticide labeling restrictions or requirements that concern the protection of endangered species or their habitats.

- **Tolerances and Exemptions** A tolerance is the maximum amount of pesticide residue that can be on a raw product and still be considered safe. Before EPA can register a pesticide that is used on raw agricultural products, it must grant a tolerance or exemption from a tolerance (40 CFR.163.10 through 163.12). Under the Federal Food, Drug, and Cosmetic Act (FFDCA), a raw agricultural product is deemed unsafe if it contains a pesticide residue, unless the residue is within the limits of a tolerance established by EPA or is exempt from the requirement.

  To avoid being responsible for products being over tolerance, users must be particularly careful to comply with the label instructions concerning application rate and minimum days between pesticide application and harvest (i.e., preharvest interval), slaughter, freshening, or grazing.

- **Worker Protection Standard (WPS) Requirements for Users**. The WPS for Agricultural Pesticides (40 CFR Parts 156 and 170) covers pesticides that are used in the commercial production of agricultural plants on farms, forests, nurseries, and greenhouses. The WPS requires pesticide users to take steps to reduce the risk of pesticide-related illness and injury if they or their employees may be exposed to pesticides used in the commercial production of agricultural plants.

- **Cancellation and Suspension** EPA can cancel a registration if it is determined that the pesticide or its labeling does not comply with the requirements of FIFRA or causes unreasonable adverse effects on the environment (Haugrud, 1993).

  In cases where EPA believes that an "imminent hazard" would exist if a pesticide were to continue to be used through the cancellation proceedings, EPA may suspend the pesticide registration through an order and thereby halt the sale, distribution, and usage of the pesticide. An "imminent hazard" is defined as an unreasonable adverse effect on the environment or an unreasonable hazard to the survival of a threatened or endangered species that would be the likely result of allowing continued use of a pesticide during a cancellation process.

  When EPA believes and emergency exists that does not permit a hearing to be held prior to suspending, EPA can issue an emergency order that makes the suspension immediately effective.

Toxic Substances Control Act

TSCA has a limited impact on the agricultural sector. TSCA §3, Definitions, specifies that the term chemical substance means any organic or inorganic substance of a particular molecular identity. The definition also states, as declared at subsection (2)(B)(ii), that such term does not include any pesticide (as defined in FIFRA) when manufactured, processed, or distributed in commerce for use as a pesticide. Since the majority of potentially hazardous substances used by agricultural producers are pesticides, they are regulated under FIFRA. Regulation of hazardous substances under other authorities is part of TSCA's overall scheme which allows EPA to decline to regulate a chemical under TSCA if other federal regulatory authorities (e.g., FIFRA) are sufficiently addressing the risks posed from those substances.

- **Asbestos and Asbestos-Containing Material**. Under TSCA §6 and 40 CFR Part 61, Subpart M, EPA regulates the renovation/demolition activities, notification, work practices and removal, and disposal of asbestos-containing material (ACM). ACM should be carefully monitored; however, the mere presence of asbestos in a building is not considered hazardous. ACM that becomes damaged, however, may pose a health risk since it may release asbestos fibers over time. If a material is suspected of containing asbestos and it is more than slightly damaged, or if changes need to be made to a building that might disturb it, repair or removal of the ACM by a professional is needed.

- **Asbestos Brake Pads**. Facilities that repair their own brakes should be aware of asbestos requirements. Asbestos brake pads must be removed using appropriate control measures so that no visible emissions of asbestos will be discharged to the outside air. These measures can include one of the following: (1) wetting that is generally done through the use of a brake washing solvent bath, such as those provided by a service; (2) vacuuming that is usually performed with a commercial brake vacuum specifically designed for use during brake pad changing or pad re-lining operations; or (3) combination of wetting and vacuuming.

  Asbestos brake pads and wastes must be managed by: (1) labeling equipment, (2) properly disposing of spent solvent, (3) properly disposing of used vacuum filters, and (4) sealing used brake pads. The containers or wrapped packages must be labeled using warning labels as specified by OSHA [29 CFR 1910.001 (j) (2) or 1926.58 (k)(2)(iii)].

  Asbestos waste must be disposed of as soon as practical at an EPA-approved disposal site. The asbestos containers must be labeled with the name and location of the waste generator. Vehicles used to transport the asbestos must be clearly labeled during loading and unloading. The waste shipment records must be maintained (40 CFR 61.150) so that the asbestos shipment can be tracked and substantiated.

- **Polychlorinated Biphenyls (PCBs)**. PCBs were widely used in electrical equipment manufactured from 1932 to 1978. Types of equipment potentially containing PCBs include transformers and their bushings, capacitors, reclosers, regulators, electric light ballasts, and oil switches. Any equipment containing PCBs in their dielectric fluid at concentrations of greater than 50 ppm are subject to the PCB requirements.

  Under TSCA §6 and 40 CFR Part 761, facilities must ensure through activities related to the management of PCBs (e.g., inspections for leaks, proper storage) that human food or animal feed are not exposed to PCBs. While the regulations do not establish a specific distance limit, any item containing PCBs is considered to pose an unacceptable

R0074401

exposure risk to food or feed if PCBs released in any form have the potential to reach/contaminate food or feed.

- **Lead**. Approximately 1.7 million children have blood-lead levels high enough to raise health concerns. Studies suggest that lead exposure from deteriorated residential lead-based paint, contaminated soil, and lead in dust are among the major existing sources of lead exposure among children in the U.S.

  Section 1018 of the Residential Lead-Based Paint Hazard Reduction Act of 1992 directs EPA and the Department of Housing and Urban Development (HUD) to jointly issue regulations requiring disclosure of known lead-based paint and/or lead-based paint hazards by persons selling or leasing housing constructed before the phaseout of residential lead-based paint use in 1978. Under that authority, EPA and HUD jointly issued on March 6, 1996, regulations titled *Lead; Requirements for Disclosure of Known Lead-Based Paint and/or Lead-Based Paint Hazards in Housing* (40 CFR Part 35 and 40 CFR Part 745). In these regulations, EPA and HUD established requirements for sellers/lessors of residential housing built before 1978.

  Pre-Renovation Lead Information Rule. If conducted improperly, renovations in housing with lead-based paint can create serious health hazards to workers and occupants by releasing large amounts of lead dust and debris. Under TSCA §406 and through a rule published on June 1, 1998 entitled *Lead; Requirements for Hazard Education Before Renovation of Target Housing* (40 CFR Part 745), EPA required the distribution of lead hazard information (i.e., EPA-developed pamphlet) prior to professional renovations on residential housing built before 1978.

IV.C. Proposed and Pending Regulations

Coastal Zone Act Reauthorization Amendments of 1990

Implementation of Management Measures. Under Section 6217, states/tribes must fully implement the management measures in their Coastal Nonpoint Pollution Control Programs by January 2004. States/tribes are required to perform effectiveness monitoring between 2004 and 2006 and implement other measures between 2006 and 2009.

Safe Drinking Water Act

Management of Class V Wells. EPA plans to propose additional requirements addressing the environmental risks posed by the highest risk Class V wells. This rulemaking potentially affects agricultural operations that use industrial and commercial disposal wells and large capacity cesspools.

Federal Insecticide, Fungicide, and Rodenticide Act

Pesticide Management and Disposal: Proposed Rule - issued on May 5, 1993 (FR26857). The regulations for this rule will be found in the Code of Federal Regulations (CFR) at 40 CFR Part 165 - Regulations for the Acceptance of Certain Pesticides and Recommended Procedures for the Disposal and Storage of Pesticides and Pesticides Containers. This final rule will:

- Describe procedures for voluntary and mandatory recall actions.
- Establish criteria for acceptable storage and disposal plans which registrants may submit to EPA to become eligible for reimbursement of storage costs.
- Establish procedures for the indemnification of owners of suspended and canceled pesticides.
- Amend the Agency's responsibility for accepting for disposal suspended and canceled pesticides.

THIS PAGE LEFT INTENTIONALLY BLANK

V. COMPLIANCE AND ENFORCEMENT HISTORY

V.A. Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match air, water, waste, toxics/pesticides, EPCRA, Toxics Release Inventory (TRI), and enforcement docket records for a given facility and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, EPA is developing sector-specific measures of success for compliance assistance efforts.

V.B. Compliance and Enforcement Profile Description

This section uses inspection, violation, and enforcement data from the IDEA system to provide information about the historical compliance and enforcement activity of this sector. While other sector notebooks have used Standard Industrial Classification (SIC) data from the Toxics Release Inventory System (TRIS) to define their data sampling universes, none of the SIC codes associated with the crop production sectors identifies facilities that report to the TRI program. As such, sector-defining data have been provided from EPA data systems linked to EPA's Facility Indexing System (FINDS), which

> *Note: Many of the previously published sector notebooks contained a chapter titled "Chemical Release and Transfer Profile." The information and data for that chapter were taken primarily from EPA's Toxic Release Inventory (TRI). Because the industries discussed in this notebook do not, in general, directly report to TRI, that chapter has not been included in this sector notebook.*

tracks facilities in all media databases. This section does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census. With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Before presenting the data, the next section defines general terms and the column heads used in the data tables. The data represent a retrospective summary of inspections and enforcement actions and solely reflect EPA, state, and local compliance assurance activities that have been entered into EPA databases. To identify trends, EPA ran two data queries, one for five calendar years (March 7, 1992 to March 6, 1997) and the other for a twelve-month period (March 7, 1996 to March 6, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and state's efforts within each media program. The presented data illustrate the variations across EPA regions for certain sectors.[1] This variation may be attributable to state/local data entry variation, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

---

1 EPA Regions are as follows: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) - assigns a common facility number to EPA single-media permit records, establishing a linkage capability to the permit data. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) - is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, this creating a "master list" of records for that facility. Some of the data systems accessible through IDEA are AFS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS. IDEA also contains information from outside sources, such as Dun and Bradstreet (DUN) and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in this section were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search - based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, or industries in which only a very small fraction of facilities report to TRI, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected - indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections - measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections - provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities With One or More Enforcement Actions - expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal state actions. A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions - describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (i.e., a facility with 3 enforcement actions counts as 3).

State Lead Actions - shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions - shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from state agencies. Many of these actions result from coordinated or joint federal/state efforts.

Enforcement to Inspection Rate - is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. The ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified - expresses the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections - four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

V.C. Compliance History for the Agricultural Production Industries: Crops, Greenhouses/Nurseries, and Forestry

Exhibit 23 provides an overview of the reported compliance and enforcement data for the agricultural production industries over the past 5 years (March 1992 to March 1997). These data are also broken out by EPA regions thereby permitting geographical comparisons.

> **Note:** It should be noted that the data presented in this section represent federal enforcement activity only. Enforcement activity conducted at the state level is not included in this analysis.

A few points evident from the data are listed below. It should also be noted that agriculture crop production (SIC code 01) and forestry (SIC code 08) are presented separately in the exhibits.

- As shown, of the 6,688 facilities identified through IDEA with crop production NAICS codes, nearly half (3,046) were inspected over the 5-year period. The total number of inspections over the same 5 years was 10,453, which means that, on average, each facility was subjected to nearly 3.5 inspections over the 5 years.

- Region 7 has the most crop production facilities with 2,391 and has conducted the most inspections (3,180). Similarly, Region 5 has the second most facilities and has conducted the second most inspections. Inspections in these regions comprise more than half (57%) of all inspections conducted.

- The 10,453 inspections conducted nationwide have resulted in 262 enforcement actions, which results in an enforcement-to-inspection rate of 0.03. This means that for every 100 inspections conducted, there are approximately 3 resulting enforcement actions.

- The average enforcement-to-inspection rate across the regions ranged from 0.01 in Region 5 to 0.08 in Regions 1 and 2.

Exhibit 24 provides an overview of the reported compliance and enforcement data for forestry SIC codes over the 5-year period by EPA region.

- Of the 97 facilities identified, approximately 25 percent (24 facilities) were inspected in the 5-year period.
- The 68 inspections conducted nationwide have resulted in 10 enforcement actions, which results in an enforcement-to-inspection rate of 0.15.

Comparison of Enforcement Activity Between Selected Industries

Exhibits 25 and 26 provide both the 5-year and 1-year enforcement and compliance data for most of the industries covered by the sector notebooks. These data allow the reader to compare the enforcement and compliance history of the sectors and identify trends across sectors and over the 5-year period.

- Of the industries presented, the crop production sector has the second most identified facilities with 6,688; it also has the second highest number of facilities inspected (3,046) over the 5-year period. The enforcement-to-inspection rate of 0.03 was the second lowest among all sectors.

- Forestry has the second fewest number of facilities (97) among all sectors and the fewest number of facilities inspected (24). Its enforcement-to-inspection rate of 0.15 is the second highest, next to petroleum refining (0.25).

In Exhibit 26, when compared to all sectors over the last year, the crop production sector had the fifth most facilities inspected (1,012) and the fourth most inspections conducted (1,459). The enforcement-to-inspection rate of 0.02 for the crop production sector was among the lowest rates across all sectors. From March 1996 - March 1997, forestry had the fewest number of facilities inspected and the lowest number of inspections conducted.

Exhibits 27 and 28 provide a more in-depth comparison between the crop production and forestry sectors and others by organizing inspection and enforcement data by environmental statute. Exhibit 27 provides inspection and enforcement data over the 5-year period, while Exhibit 28 provides data for the March 1996 - March 1997 only.

As shown in Exhibit 27, over the 5-year period, nearly three-quarters of all inspections conducted at crop production facilities were under the Clean Air Act. However, the CAA accounts for only 35 percent of all enforcement actions. The enforcement actions are spread out across the CAA (35%), CWA (23%), and RCRA (25%) with FIFRA/TSCA/EPCRA/Other having the lowest percentage of enforcement actions (17%). For forestry, more than half of all inspections and exactly half of all enforcement actions have come under RCRA.

For March 1996 - March 1997 (see Exhibit 28), again CAA inspections account for nearly three-quarters of all inspections for the crop production sectors. And, similarly to the 5-year history, enforcement actions are fairly evenly disbursed among the CAA (31%), CWA (34%), and RCRA (28%). It should be noted that 7 percent of all enforcement actions were taken under the FIFRA/TSCA/EPCRA/Other category although no inspections were conducted within that category. This number is possible because in many EPA regions, media inspectors are being trained to examine the facility from a multimedia viewpoint. As a result, these actions may originate from the media inspections. Regarding the forestry industry, 83 percent of all inspections were conducted under the RCRA program. However, no enforcement actions were taken based on those inspections. Two-thirds of all enforcement actions were taken under the FIFRA/TSCA/EPCRA/Other category, although no inspections were conducted under those programs (see above note).

R0074418

VI. Review of Major Legal Actions

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

Review of Major Cases

The following cases are examples of EPA's enforcement against the agricultural production industries of crops, greenhouses/nurseries, and forestry.

Cumberland Farms, Inc. In September 1996, a District Court entered a consent decree between the U.S. and Cumberland Farms, Inc., which resolves a long standing wetlands enforcement action against Cumberland Farms, Inc., for its unpermitted filling of 180 acres of wetlands in violation of the Clean Water Act between 1977 and 1990 in Halifax and Hanson, Massachusetts. Under the consent decree, Cumberland is required to deed two undeveloped tracts of land, totaling 225 acres, to the Massachusetts Division of Fisheries and Wildlife for permanent conservation. In addition, the company will establish a 30-acre wildlife and wetlands corridor on the most seriously damaged site and pay a civil $50,000 penalty. This settlement, along with others, will preserve a total of 490 acres of undeveloped habitat in the same watershed as the violations. This represents the largest permanent preservation of habitat arising from a federal enforcement in New England.

U.S. v. Tropical Fruit. Tropical Fruit, S.E., in Guayanilla, Puerto Rico, operates a plantation where it grows mangoes, bananas, and other fruits. On December 20, 1996, Region 2 issued an administrative order under CERCLA 106(a) to Tropical Fruit, S.E., and its three individual partners of that company (Avshalom Lubin, Cesar Otero Acevedo, and Pedro Toledo Gonzalez) for application of pesticides using a high pressure applicator that produced a cloud which sometimes would drift into the adjacent residential community, which is composed of minority and low income residents. The CERCLA order requires that the respondents immediately cease and desist from spraying pesticides, fungicides, and any other materials that contain hazardous substances in such a manner that these substances might drift or otherwise migrate beyond the boundaries of the farm.

Region 2 also issued an administrative complaint for violations of the Worker Protection Standard for agricultural workers under FIFRA. The complaint cited Tropical Fruit's failure to post warning signs during and after application, as well as its failure to maintain a decontamination area and a central bulletin board with pesticide safety information.

On March 26, 1997, DOJ (acting on EPA's behalf) filed a complaint against Tropical Fruit seeking an injunction requiring the firm and its partners to comply with EPA's CERCLA order and all applicable FIFRA requirements. Three of the pesticides routinely used by Tropical Fruits on its mango trees are not registered for use on mangoes; their use in this manner is in violation of FIFRA. The judicial complaint also sought penalties for violations of the CERCLA order since its issuance. Also on March 26, 1997, the court signed an interim consent order requiring Tropical Fruit to modify its pesticide application procedures to prevent these substances from drifting into the adjacent residential community. The order also requires Tropical Fruit to better protect its workers by providing extensive training, protective clothing, respirators, and decontamination equipment. Subsequently on May 21, 1997, EPA documented further violations of the CERCLA administrative order and the judicial interim consent order. On August 22, 1997, Tropical Fruit paid $10,000 in stipulated penalties for those violations.

Region 2 also has documented additional FIFRA violations by Tropical Fruit, which included the illegal importation of Cultar, an unregistered pesticide from the Middle East. In addition, the region has documented violations of RCRA UST regulations, as well as violations of CWA §404 and the associated regulations regarding discharge of dredged or fill materials into wetlands. EPA anticipates that all of these violations will be subject to further enforcement action.

Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility. Information on SEPs can be accessed via the internet at http://www.epa.gov/oeca/sep.

There was one SEP at an agricultural crop producing facility. This SEP was negotiated with Franklin Mushroom Farms, Incorporated (Franklin Farms) of Southington, CT. The complaint alleged that Franklin Farms illegally discharged pollutants to a nearby river in violation of their NPDES Permit. As part of a settlement, Franklin Farms agreed to a SEP in which they would institute water recycling/conservation methods to reduce overall pollutant loading to the river. The cost of instituting these methods was $89,900 at the time of the settlement. Franklin Farms also was required to pay a penalty of $75,000. Details on this SEP can be found by accessing http://es.epa.gov/oeca/sep/searchsep.html, selecting '01 Agriculture - Crop Production' in the *Industrial Sector of Violation* field, and choosing the *Submit Search* button.

VII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VII.A. Sector-Related Environmental Programs and Activities

There are several federal programs available to the agricultural community to assist agricultural producers in complying with environmental regulations and reducing pollution. The following examples represent some industry initiatives that promote compliance or assess methods to reduce environmental contamination.

National Agriculture Compliance Assistance Center

The U.S. Environmental Protection Agency (EPA), with the support of the Department of Agriculture (USDA), has developed a national Agriculture Compliance Assistance Center (Ag Center) to provide a base for "first-stop shopping" for the agricultural community -- one place for the development of comprehensive, easy-to-understand information about approaches to compliance that are both environmentally protective and agriculturally sound. The Ag Center, a program offered by EPA's Office of Compliance, seeks to increase compliance by helping the agricultural community identify flexible, common sense ways to comply with the many environmental requirements that affect their business. Initial efforts will focus on providing information about EPA's requirements. The Ag Center will rely heavily on existing sources of agricultural information and established distribution mechanisms. The Ag Center is designed so growers, livestock producers, other agribusinesses, and agricultural information/education providers can access its resources easily -- through telephone, fax, mail, and Internet. The Ag Center website can be accessed at http://www.epa.gov/agriculture.

Unified National Strategy for Animal Feeding Operations

As part of President Clinton's Clean Water Action Plan (CWAP), a USDA-EPA unified national strategy has been developed to minimize the water quality and public health impacts (e.g., nutrient loading, fish kills, odors) of animal feeding operations (AFOs). USDA and EPA's goal is for AFO owners and operators to take actions to minimize water pollution from confinement facilities and land application of manure. To accomplish this goal, this Strategy is based on a national performance expectation that all AFOs should

R0074421

develop and implement technically sound, economically feasible, and site-specific Comprehensive Nutrient Management Plans (CNMPs) to minimize impacts on water quality and public health.

CNMPs identify actions or priorities that will be followed to meet clearly defined nutrient management goals at an agricultural operation. They should address, as necessary, feed management, manure handling and storage, land application of manure, land management, recordkeeping, and other utilization options. While nutrients are often the major pollutants of concern, the plan should address risks from other pollutants, such as pathogens, to minimize water quality and public health impacts from AFOs. CNMPs should be site-specific and be developed and implemented to address the goals and needs of the individual owner/operator, as well as the conditions on the farm. USDA and EPA issued the final draft of this Strategy in March 1999. For more information, the complete unified national strategy can be accessed at http://www.epa.gov/owm/finafost.htm.

VII.B. EPA Programs and Activities

Section 319 Nonpoint Source Management Program
In 1987, Congress amended the Clean Water Act (CWA) to establish the §319 Nonpoint Source Management Program in recognition of the need for greater federal leadership to help focus state and local nonpoint source efforts. Under §319, states, territories, and Indian tribes receive grant money to support a wide variety of activities, including technical assistance, financial assistance, education, training, technology transfer, demonstration projects, and monitoring to assess the success of specific nonpoint source implementation projects. For more information about the Clean Water Act §319 Program, refer to EPA's Office of Water website at http://www.epa.gov/OWOW/NPS/sec319.html.

Clean Lakes Program
EPA's Clean Lakes Program supports a variety of lake management activities including classification, assessment, study, and restoration of lakes. The program, authorized in §314 of the Clean Water Act, was established to provide technical and financial assistance to states/tribes for restoring the quality of publicly owned lakes. The Clean Lakes Program has funded approximately $145 million for grant activities since 1976 to address lake problems, but there have been no appropriations for the program since 1994. EPA has not requested funds for the Clean Lakes Program in recent years, but has encouraged states to use §319 funds to fund "eligible activities that might have been funded in previous years under Section 314." Information on the Clean Lakes Program is available at the following Internet site: http://www.epa.gov/owow/lakes/cllkspgm.html.

National Estuary Program
EPA's National Estuary Program is a national demonstration program, authorized in §320 of the Clean Water Act, that uses a comprehensive watershed management approach to address water quality and habitat problems in 17 estuaries. Nonpoint source pollution is a major contributor of contaminants in the estuary and coastal waters around the country. In this program, EPA and states/tribes develop conservation and management plans that recommend priority corrective actions to restore estuarine water quality, fish populations, and other designated uses of the waters. Information on the National Estuary Program is available at the following Internet site: http://www.epa.gov/owowwtr1/estuaries/nep.html or by contacting the National Estuary Program Office at (202) 260-1952.

Chesapeake Bay Program and The Great Lakes National Program
EPA's Chesapeake Bay Program and the Great Lakes National Program focus substantial resources on understanding the extent of nonpoint source pollution problems in their respective watersheds and supporting State implementation of nonpoint source pollution controls. Since 1984, the Chesapeake Bay Program, in particular, has supported the implementation of a substantial amount of animal waste management practices through State cost share programs funded jointly by the Bay States and EPA. Information on the Chesapeake Bay Program is available at http://www.epa.gov/owowwtr1/ecoplaces/part1/site2.html. Information on The Great Lakes National Program is available at http://www.epa.gov/glnpo/.

AgSTAR Program
The AgSTAR program is a voluntary program that promotes the use of profitable manure management systems that reduce pollution. The program, a component of President Clinton's Climate Action Plan, is based on a computer model that shows the economic value of capturing the methane naturally produced by manure.

AgSTAR, a joint program of EPA, USDA, and the Department of Energy, helps agricultural producers determine which methane recovery and use technologies will work best for them, and develops financing sources to help with start-up costs. By investing in these technologies, AgSTAR participants realize substantial returns through reduced electrical, gas, and oil bills, revenues from high quality manure by-products, and savings on manure management operational costs. Partners also reduce pollution associated with water resources, odors, and global warming. Information on AgSTAR is available at the following Internet site: http://yosemite.epa.gov/methane/home.nsf/pages/agstar.

Pesticide Environmental Stewardship Program

EPA's Pesticide Environmental Stewardship Program (PESP) is a voluntary program dedicated to protecting human health and preserving the environment by reducing the risks associated with pesticide use. The partnership is a key element of the program, which is sponsored by EPA, USDA, and FDA. Current partners include agricultural producers as well as non-agricultural interests. Partners in PESP volunteer to develop and implement a well designed pesticide management plan that will produce the safest and most effective way to use pesticides. In turn, EPA provides a liaison to assist the partner in developing comprehensive, achievable goals. Liaisons act as "customer service representatives" for EPA, providing the partner with access to information and personnel. EPA also promises to integrate the partners' stewardship plans into its agricultural policies and programs.

So far, agricultural producers have committed to a number of projects, including conducting more research into IPM techniques, developing computer prediction models for more precise pesticide applications, educating their members and the public regarding pesticide use, and working with equipment manufacturers to refine application techniques. Information on PESP is available at the following Internet site: http://www.pesp.org, or contact the PESP hotline at (800) 972-7717.

Endangered Species Protection Program

The Endangered Species Protection Program (ESPP) began in 1988. This program is largely voluntary at the present time and relies on cooperation between the U.S. Fish and Wildlife Service (FWS), EPA Regions, States, and pesticide users. EPA's Endangered Species Protection Program is designed to protect Federally-listed endangered and threatened species from exposure to pesticides. The program is intended to provide information concerning and regulation for the use of pesticides that may adversely affect the survival, reproduction and/or food supply of listed species. Due to labeling requirements, potential users will be informed prior to making a purchase that there may be local limitations on product use due to endangered species concerns. Information on the Endangered Species Protection Program is available at the following Internet site: http://www.epa.gov/oppfead1/endanger/index.htm.

Energy Star® Buildings and Green Lights® Partnership

In 1991, EPA introduced Green Lights®, a program designed for businesses and organizations to proactively combat pollution by installing energy-efficient lighting technologies in their commercial and industrial buildings. In April 1995, Green Lights® expanded into Energy Star® Buildings— a strategy that optimizes whole-building energy-efficiency opportunities. The energy needed to run commercial and industrial buildings in the United States produces 19 percent of U.S. carbon dioxide emissions, 12 percent of nitrogen oxides, and 25 percent of sulfur dioxide, at a cost of $110 billion a year. If implemented in every U.S. commercial and industrial building, the Energy Star® Buildings upgrade approach could prevent up to 35 percent of the emissions associated with these buildings and cut the nation's energy bill by up to $25 billion annually.

The more than 2,900 participants include corporations, small businesses, universities, health care facilities, nonprofit organizations, school districts, and federal and local governments. As of March 31, 1999, Energy Star®Buildings and Green Lights® Program participants are saving $775 million in energy bills with an annual savings of 31.75 kilowatt per square foot and annual cost savings of $0.47 per square foot. By joining, participants agree to upgrade 90 percent of their owned facilities with energy-efficient lighting and 50 percent of their owned facilities with whole-building upgrades, where profitable, over a seven-year period. Energy Star® participants first reduce their energy loads with the Green Lights® approach to building tune-ups, then focus on "right sizing" their heating and cooling equipment to match their new energy needs. EPA's Office of Air and Radiation is responsible for operating the Energy Star® Buildings and Green Lights® Program. (Contact: Energy Star Hotline, 1-888-STAR-YES (1-888-782-7937) or Maria Tikoff Vargas, Co-Director at (202) 564-9178 or visit the website at http://www.epa.gov/buildings.)

WasteWi$e Program

The WasteWiSe Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection, and the manufacturing and purchase of recycled products. As of 1998, the program had about 700 business, government, and institutional partners. Partners agree to identify and implement actions to reduce their solid wastes by setting waste reduction goals and providing EPA with yearly progress reports for a three-year period. EPA, in turn, provides partners with technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at (800) 372-9473 or Joanne Oxley, EPA Program Manager, (703) 308-0199.)

Climate Wise Program

In October 1993, President Clinton unveiled the Climate Change Action Plan (CCAP) in honor of the United States' commitment to reducing its greenhouse gas emissions to 1990 levels by the year 2000. Climate Wise, a project jointly sponsored by the U.S. Department of Energy and EPA, is one of the projects initiated under CCAP.

R0074425

Climate Wise is a partnership between government and industry that offers companies a nonregulatory approach to reducing greenhouse gas emissions. Climate Wise state and local government "allies" work with U.S. industries to develop flexible, comprehensive strategies for achieving energy efficiency and pollution prevention. They help local business identify and implement projects that often require little capital investment, but promise a high rate of return. Companies that become Climate Wise partners receive technical assistance and financing information to help them develop and implement cost-effective changes. (Contact: Climate Wise Clearinghouse at (301) 230-4736 or visit the Climate Wise website at http://www.epa.gov/climatewise/allies.htm or http://www.epa.gov/climatewise/index.htm.)

VII.C. USDA Programs and Activities

Environmental Quality Incentives Program
The Environmental Quality Incentives Program (EQIP) is a USDA funded program (led by Natural Resources Conservation Service) that was established in the 1996 Farm Bill to provide a voluntary conservation program for farmers and ranchers who face serious threats to soil, water, and related natural resources. EQIP embodies four of USDA's former conservation programs, including the Agricultural Conservation Program, the Water Quality Incentives Program, the Great Plains Conservation Program, and the Colorado River Basin Salinity Control Program.

EQIP offers 5 to 10 year contracts that provide *incentive payments* and *cost-sharing* for conservation practices called for in a site-specific conservation plan that is required for all EQIP activities. *Cost-sharing* may include up to 75 percent of the costs of certain conservation practices, such as grassed waterways, filter strips, manure management facilities, capping abandoned wells, and other practices. *Incentive payments* may be made to encourage land management practices such as nutrient management, manure management, integrated pest management, irrigation water management, and wildlife habitat management. These payments may be provided for up to three years to encourage producers to carry out management practices they may not otherwise use without the program incentive.

EQIP has an authorized budget of $1.3 billion through the year 2002. It was funded for $174 million in 1999. Total cost-share and incentive payments are limited to $10,000 per person per year and $50,000 for the length of the contract. Eligibility is limited to persons who are engaged in livestock or agricultural production. Fifty percent of the funds must be spent on livestock production. The 1996 Farm Bill prohibits owners of large confined livestock operations from being eligible for cost-share assistance for animal waste storage or treatment facilities. However, technical, educational, and financial assistance may be provided for other conservation practices on such operations. Further information relating to EQIP may be found on NRCS's website located at http://www.nhq.nrcs.usda.gov/OPA/FB96OPA/eqipfact.html.

Conservation Reserve Program

The Conservation Reserve Program (CRP) is a highly successful conservation program administered by USDA. Since 1986, CRP has provided financial incentives to farmers and ranchers to take land out of agricultural production and plant trees, grass and other types of vegetation. The result has been reduced soil erosion, improved air and water quality, and establishment of millions of acres of wildlife habitat.

With the New Conservation Reserve Program, launched with the final rule published in the Federal Register on February 19, 1997, the Farm Service Agency (FSA) begins a renewed effort to achieve the full potential of government-farmer conservation partnerships. Only the most environmentally-sensitive land, yielding the greatest environmental benefits, will be accepted into the program.

The 36.4-million-acre congressionally mandated cap on enrollments is carried over from the previous program, meaning that the new CRP has authority to enroll only about 15 percent of the eligible cropland. To make the most of the program's potential, a new Environmental Benefits Index (EBI) was developed. The new EBI will be used to select areas and acreages offering the greatest environmental benefits.

Conservation priority areas (CPAs) are regions targeted for CRP enrollment. The four national CPAs are the Long Island Sound region, the Chesapeake Bay and surrounding areas, an area adjacent to the Great Lakes, and the Prairie Pothole region. FSA State Committees may also designate up to 10 percent of a State's remaining cropland as a State Conservation Priority Area. The NRCS is responsible for determining the relative environmental benefits of each acre offered for participation.

Continuous Sign-Up. For certain high-priority conservation practices yielding highly desirable environmental benefits, producers may sign up at any time, without waiting for an announced sign-up period. Continuous sign-up allows farmers and ranchers management flexibility in implementing certain conservation practices on their cropland. These practices are specially designed to achieve significant environmental benefits, giving participants a chance to help protect and enhance wildlife habitat, improve air quality, and improve the condition of America's waterways. Unlike the general CRP program, sign-up for these special practices is open continuously. Provided certain eligibility requirements are met, acreage is automatically accepted into the program at a per-acre rental rate not to exceed the Commodity Credit Corporation's maximum payment amount, based on site-specific soil productivity and local prevailing cash-equivalent rental rates. For more information on the CRP, see USDA's website at http://www.fsa.usda.gov/dafp/cepd/crpinfo.htm.

Conservation Reserve Enhancement Program
The Conservation Reserve Enhancement Program (CREP), a refinement of the CRP, is a state-federal conservation partnership program targeted to address *specific* state and nationally significant water quality, soil erosion and wildlife habitat issues related to agricultural use. The program uses financial incentives to encourage farmers and ranchers to voluntarily enroll in contracts of 10 to 15 years in duration to remove lands from agricultural production. This community-based conservation program provides a flexible design of conservation practices and financial incentives to address environmental issues. For more information about CREP, refer to USDA's website at http://www.fsa.usda.gov/dafp/cepd/crep/crephome.htm.

Wetlands Reserve Program
Congress authorized the Wetlands Reserve Program (WRP) under the Food Security Act of 1985, as amended by the 1990 and 1996 Farm Bills. USDA's Natural Resources Conservation Service (NRCS) administers the program in consultation with the Farm Service Agency and other Federal agencies. WRP is a voluntary program to restore wetlands. Landowners who choose to participate in WRP may sell a conservation easement or enter into a cost-share restoration agreement with USDA to restore and protect wetlands. The landowner voluntarily limits future use of the land, yet retains private ownership.

WRP offers landowners three options: *permanent easements*, *30-year easements*, and *restoration cost-share agreements* of a minimum 10-year duration. In exchange for establishing a *permanent easement*, the landowner receives payment up to the agricultural value of the land and 100 percent of the restoration costs for restoring the wetland. In exchange for the *30-year easement*, the landowner receives a payment of 75 percent of what would be provided for a permanent easement on the same site and 75 percent of the restoration cost. The *restoration cost-share agreement* is an agreement (generally for a minimum of 10 years) to re-establish degraded or lost wetland habitat, in which USDA pays the landowner 75 percent of the cost of the restoration activity. Restoration cost-share agreements establish wetland protection and restoration as the primary land use for the duration of the agreement. In all instances, landowners continue to control access to their land. For more information about WRP, see NRCS's website at:

http://wl.fb-net.org/.

Conservation Farm Option
The Conservation Farm Option (CFO) is a voluntary pilot program for producers of wheat, feed grains, cotton, and rice. The program purposes include conservation of soil, water, and related resources, water quality protection and improvement, wetland restoration, protection and creation, wildlife habitat development and protection, or other similar conservation activities. Eligibility is limited to owners and producers who have contract acreage enrolled in the Agricultural Market Transition program. Participants are required to develop and implement a conservation farm plan. The plan becomes part of the CFO contract which covers a ten year period. CFO is not restricted as to what measures may be included in the conservation plan, so long as they provide environmental benefits. During the contract period the owner or producer (1) receives annual payments for implementing the CFO contract, and (2) agrees to forgo payments under the Conservation Reserve Program, the Wetlands Reserve Program, and the Environmental Quality Incentives Program in exchange for one consolidated program.

Wildlife Habitat Incentives Program
The Wildlife Habitat Incentives Program (WHIP) is a voluntary program (administered by NRCS) for people who want to develop and improve wildlife habitat primarily on private lands. It provides both technical assistance and cost-share payments to help establish and improve fish and wildlife habitat.

Under this program, NRCS helps participants prepare a wildlife habitat development plan in consultation with the local conservation district. The plan describes the landowner's goals for improving wildlife habitat, includes a list of practices and a schedule for installing them, and details the steps necessary to maintain the habitat for the life of the agreement. This plan may or may not be part of a larger conservation plan that addresses other resource needs such as water quality and soil erosion.

USDA and the participant enter into a cost-share agreement that generally lasts between 5 to 10 years from the date the agreement is signed. Under the agreement: the landowner agrees to install and maintain WHIP practices and allow NRCS or its agent access to monitor the effectiveness of the practices; and USDA agrees to provide technical assistance and pay up to 75 percent of the cost of installing the wildlife habitat practices.

WHIP is currently budgeted for $50 million total through the year 2002. WHIP funds are distributed to States based on State wildlife habitat priorities, which may include wildlife habitat areas, targeted species and their habitats and specific practices. WHIP may be implemented in cooperation with other

Federal, State, or local agencies; conservation districts; or private conservation groups. For more information, see NRCS's website at http://www.nrcs.usda.gov.

Conservation of Private Grazing Land Initiative
The Conservation of Private Grazing Land initiative will ensure that technical, educational, and related assistance is provided to those who own private grazing lands. It is not a cost share program. This technical assistance will offer opportunities for better grazing and land management; protecting soil from erosive wind and water; using more energy-efficient ways to produce food and fiber; conserving water; providing habitat for wildlife; sustaining forage and grazing plants; using plants to sequester greenhouse gases and increase soil organic matter; and using grazing lands as a source of biomass energy and raw materials for industrial products.

The Wetland Conservation Provision (Swampbuster)
This provision, part of the 1985, 1990, and 1996 farm bills, requires all agriculture producers to protect wetlands on the farms they own or operate if they want to be eligible for USDA farm program benefits. The Swampbuster program generally allows the continuation of most ongoing farming practices as long as wetlands are not converted or wetland drainage increased. The program discourages farmers from altering wetlands by withholding Federal farm program benefits from any person who does the following:

- Plants an agricultural commodity on a converted wetland that was converted by drainage, dredging, leveling or any other means after December 23, 1985.
- Converts a wetland for the purpose of or to make agricultural commodity production after November 28, 1990.

In order to ensure farm program benefits under the Swampbuster provisions, the local NRCS office should be contacted before clearing, draining, or manipulating any wet areas on any farmland.

VII.D. Other Voluntary Initiatives

NICE^3
The U.S. Department of Energy sponsors a grant program called National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). The NICE^3 program provides funding to state and industry partnerships (large and small businesses) for projects demonstrating advances in energy efficiency and clean production technologies. The goal of the NICE^3 program is to demonstrate the performance and economics of innovative technologies in the U.S., leading to the commercialization of improved

industrial manufacturing processes. These processes should conserve energy, reduce waste, and improve industrial cost-competitiveness. Industry applicants must submit project proposals through a state energy, pollution prevention, or business development office. Awardees receive a one-time, three-year grant of up to $400,000, representing up to 50 percent of a project's total cost. In addition, up to $25,000 is available to support the state applicant's cost share. (Contact: View the website at http//www.oit.doe.gov/Access/nice3; Steve Blazek, DOE, (303) 275-4723; or Eric Hass, DOE, (303) 275-4728.)

ISO 14000

ISO 14000 is a series of internationally-accepted standards for environmental management. The series includes standards for environmental management systems (EMS), guidelines on conducting EMS audits, standards for auditor qualifications, and standards and guidance for conducting product lifecycle analysis. Standards for auditing and EMS were adopted in September 1996, while other elements of the ISO 14000 series are currently in draft form. While regulations and levels of environmental control vary from country to country, ISO 14000 attempts to provide a common standard for environmental management. The governing body for ISO 14000 is the International Organization for Standardization (ISO), a worldwide federation of over 110 country members based in Geneva, Switzerland. The American National Standards Institute (ANSI) is the United States representative to ISO. Information on ISO is available at the following Internet site: http://www.iso.ch/welcome.html.

American Forest and Paper Association Sustainable Forest Initiative (SFI)

The Sustainable Forestry Initiative (SFI) program is a comprehensive system of principles, objectives and performance measures that integrates the perpetual growing and harvesting of trees with the protection of wildlife, plants, soil and water quality. AFPA members are committed to following the substance and spirit of best management practices (BMPs) on their own land and in operations they are involved in with other landowners and loggers.

VII.E. Summary of Trade Associations

There are more than 200 trade associations that deal with agricultural issues. Many of these are at the national level, while others deal specifically with regions of the country or individual states. The following identify some of the major associations addressing agricultural production.

Agricultural Retailers Association (ARA)
11701 Borman Drive, Suite 110
St. Louis, MO 63146
314-567-6655

American Farm Bureau Federation
Headquarters Office
225 Touhy Ave.
Park Ridge, IL 60068
847-685-8600

American Farm Bureau Federation
Washington DC Office
Suite 800
600 Maryland Ave. S.W.
Washington, DC 20024
202-484-3600

American Feed Industry Association
1501 Wilson Blvd., Suite 1100
Arlington, VA 22209
703-524-0810

American Oat Association
415 Shelard Parkway, Suite 101
Minneapolis, MN 55426
612-542-9817

American Society of Agronomy
677 S. Segoe Rd.
Madison, WI 53711
608-273-8080 ext.3030

American Sugarbeet Growers Association
156 15th Street, NW, Suite 1101
Washington, DC 20005
202-833-2398

American Crop Protection Association
1156 15th Street, NW, Suite 400
Washington, DC 20005
202-296-1595

American Forest & Paper Association (AF&PA)
1111 19th St., NW, Suite 800
Washington, DC 20036
202-463-2700
E-mail: INFO@afandpa.org

American Nursery & Landscape Association
1250 I Street, NW
Suite 500
Washington, DC 20005
202-789-2933

American Pulpwood Association, Inc.
600 Jefferson Plaza, Suite 350
Rockville, Maryland 20852
301-838-9385

American Soybean Association
540 Maryville Centre Drive
P.O. Box 419200
St. Louis, MO 63141
314-576-1770

Association of American Pesticide Control Officials
P.O. Box 1249
Hardwick, VT 05843
802-472-6956

R0074432

Association of American Plant Food Control Officials (AAPFCO)
Food & Drug Protection Division
North Carolina Department of Agriculture
4000 Reedy Creek Rd.
Raleigh, NC 27607
919-733-7366

Clean Water Network
1200 New York Ave, NW
Washington, DC 20005
202-287-2395

Eastern Dark-fired Tobacco Growers Association
1109 S. Main Street
PO Box 517
Springfield, TN 37172
615-384-4543

Farmworker Justice Fund
1111 19th Street, NW Suite 1000
Washington, DC 20036
202-776-1757

Garden Centers of America
1250 I Street, NW, Suite 500
Washington, DC 20005
202-789-2900

National Association of State Departments of Agriculture (NASDA)
1156 15th St., NW, Suite 1020
Washington, DC 20005
202-296-9680

National Coalition Against the Misuse of Pesticides
701 E Street, SE, Suite 200
Washington, DC 20003
202-543-5450

Burley Tobacco Growers Cooperative Association
PO Box 860
Lexington, KY 40587
606-252-3561

California Fertilizers Association
1700 I St., Suite 130
Sacramento, CA 95814
916-441-1584

Conservation Technology Information Center (CTIC)
1220 Potter Drive, Room 170
West Lafayette, IN 47906-1383
765-494-9555

Environmental Working Group
1101 Wilson Blvd.
Arlington, VA 22209
703-243-3002

Forest Landowners Association
P.O. Box 95385
Atlanta, Georgia 30347
800-325-2954

Institute for Agriculture and Trade Policy
2105 1st Avenue South
Minneapolis, MN 55404
612-870-0453

National Association of Wheat Growers
415 2nd Street, NE, Suite 300
Washington, DC 20002
202-547-7800

National Corn Growers Association
1000 Executive Parkway, Suite 105
St. Louis, MO 63141
314-275-9915

National Cotton Council
1521 New Hampshire Avenue, NW
Washington, DC 20036
202-745-7805

National Council of Farmer Coops. (NCFC)
50 F Street, NW, Suite 900
Washington, DC 20001

National Hay Association
102 Treasure Island Causeway
Suite 201
St. Petersburg, FL 33706
813-367-9702

National Sunflower Association
4023 State Street
Bismark, ND 58501
701-328-5100

Society of American Foresters
5400 Grosvenor Lane
Bethesda, MD 20814
301-897-8720
E-mail: safweb@safnet.org

United Farm Workers of America
1188 Franklin Street, Suite 203
San Francisco, CA 94109
415-674-1884

USDA's Forest Service
Auditors Building
201 14th Street, S.W.
Washington, DC 20024
202-205-1661

National Council of Agricultural Employers
1112 6th Street, NW, Suite 920
Washington, DC 20036
202-728-0300

National Grain and Feed Association
1201 New York Avenue, NW
Suite 830
Washington, DC 20005
202-289-0873

National Pest Control Association
8100 Oak Street (NPCA)
Dunn Loring, VA 22027
703-573-8330

Potato Association of America
University of Idaho
1776 Science Center Drive
Idaho Falls, ID 83402
208-529-8376

The Fertilizer Institute (TFI)
501 Second Street, NE
Washington, DC 20002

USA Rice Council
P.O. Box 740123
Houston, TX 77274
713-270-6699

VIII. CONTACTS/RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the agricultural crop production industries, a list of contacts and publications are provided below.

Contacts[2]

Name	Organization	Telephone	Subject
Ginah Mortensen	EPA, Office of Enforcement and Compliance Assurance (OECA), Agriculture Division, Agriculture Branch	913-551-5211	Notebook Contact
Arty Williams	EPA, Office of Prevention, Pesticides and Toxic Substances (OPPT)	703-305-5239	Ground Water Pesticide Management Plan Rule
Jean Frane	EPA, OPPT	703-305-5944	Food Quality Protection Act
David Stangel	EPA, OECA	202-564-4162	Stored or Suspended Pesticides: Good Laboratory Practice Standards; Pesticide Management and Disposal
Joseph Hogue	EPA, OPPT	703-308-9072	FIFRA Restricted Use Classifications

GENERAL INFORMATION

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by GeoLogics Corporation (Alexandria, VA), Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). A listing of available Sector Notebooks is included on the following page.

Obtaining copies:

Electronic versions of all sector notebooks are available via Internet on the Enviro**ene** World Wide Web at **www.epa.gov/oeca/sector**. Enviroene is a free, public, environmental exchange system operated by EPA's Office of Enforcement and Compliance Assurance and Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization. Direct technical questions to the "Feedback" button on the bottom of the web page.

Purchase printed bound copies from the **Government Printing Office (GPO)** by consulting the order form at the back of this document or order via the Internet by visiting the on-line GPO Sales Product Catalog at **http://orders.access.gpo.gov/su_docs/sale/prf/prf.html**. Search using the exact title of the document "Profile of the XXXX Industry" or simply "Sector Notebook." When ordering, use the GPO document number found on the order form at the back of this document.

Complimentary volumes are available to certain groups or subscribers, including public and academic libraries; federal, state, tribal, and local governments; and the media from EPA's National Service Center for Environmental Publications at **(800) 490-9198.** When ordering, use the EPA publication number found on the following page.

The Sector Notebooks were developed by the EPA's Office of Compliance. Direct general questions about the Sector Notebook Project to:

Seth Heminway, Coordinator, Sector Notebook Project
US EPA Office of Compliance
Ariel Rios Building
1200 Pennsylvania Avenue, NW
Washington, DC 20460
(202) 564-7017

For further information, and for answers to questions pertaining to these documents, please refer to the contact names listed on the following page.

R0074443

SECTOR NOTEBOOK CONTACTS

Questions and comments regarding the individual documents should be directed to the specialists listed below. **See the Notebook web page at: *www.epa.gov/oeca/sector* for the most recent titles and staff contacts.**

WRP	Wetlands Reserve Program

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution (such as economic sector, and community-based approaches) are becoming an important supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these interrelationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies addressing all media for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition by the EPA Office of Compliance of the need to develop the industrial "sector-based" approach led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several interrelated topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above alone could be the subject of a lengthy volume. However, to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be explored further based upon the references listed at the end of this profile. As a check on the information included, each notebook went through an external document review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be sent via the web page.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the relative national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers also may want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting the development of new notebooks, please contact the Office of Compliance at 202-564-2310.

II. Introduction to the Agricultural Livestock Production Industry

This section provides background information on the agricultural livestock production industry. It presents the types of facilities described within this document and defines them in terms of their North American Industrial Classification System (NAICS) codes.

Establishments that produce livestock are classified in ***NAICS code 112 (Animal Production)***. Data for the notebook, specifically in this chapter, were obtained from the U.S. Department of Agriculture (USDA) and the 1997 Agriculture Census (Ag Census). All data are the most recent publicly available data for the source cited.

> The Office of Management and Budget (OMB) has replaced the Standard Industrial Classification (SIC) system, which was used to track the flow of goods and services within the economy, with the NAICS. The NAICS, which is based on similar production processes to the SIC system, is being implemented by OMB.

It should be noted that the data on the number of livestock establishments presented in the following sections do not represent the number of animal feeding operations (AFOs) or concentrated animal feeding operations (CAFOs) in the U.S. The data simply represent numbers of livestock establishments only. Additional information on AFOs and CAFOs is presented in Section II.C.

Establishments primarily engaged in livestock production are classified in subgroups up to six digits in length, based on the total value of sales of agricultural products. An establishment would be placed in the group that represents 50 percent or more of its total sales. For example, if 51 percent of the total sales of an establishment are from sales of beef cattle, that establishment would first be classified under NAICS code 1121 (Cattle Ranching and Farming), then 11211 (Beef cattle ranching and farming, including feedlots), and finally under 112111 (Beef cattle ranching and farming).

II.A. General Overview of Agricultural Establishments

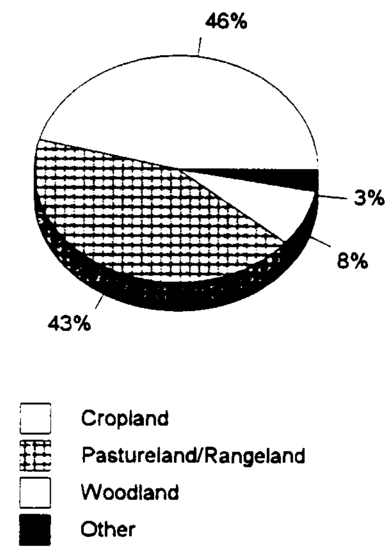
This section presents a general overview of all agricultural establishments to provide the reader with background information regarding the number and organization of such establishments and production data. The USDA's National Agricultural Statistics Service (NASS) defines an *agricultural establishment* (farm) based on production. It defines an agricultural establishment as a place which produced or sold, or normally would have

R0074453

produced or sold, $1,000 or more of agricultural products during the year. Agricultural products include all products grown by establishments under NAICS codes 111 - Crop Production and 112 - Animal Production.

According to the 1997 Ag Census, there were more than 1.9 million farms (i.e., agricultural establishments) in the United States. Of these, approximately 53 percent (1,009,487 farms) were classified as NAICS code 112 - Animal Production. The other 47 percent (902,372 farms) were classified as NAICS code 111 - Crop Production. These 1.9 million agricultural establishments represent nearly 932 million acres of land, with the average agricultural establishment consisting of 487 acres. (Note: 1 acre is approximately the size of a football field.) Both of these numbers--932 million acres and 487 acres--are smaller than those for 1992, which were 946 million acres and 491 acres, respectively.

Exhibit 1. Agricultural Land Use in the U.S. (1997 Ag Census)

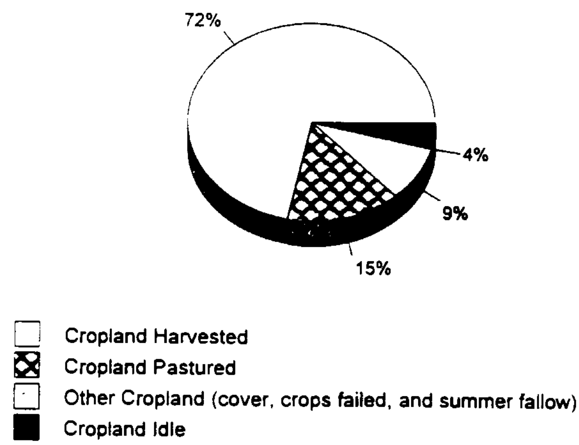


As shown in Exhibit 1, of the 932 million acres of agricultural land, the overwhelming majority (89%) consists of cropland and pastureland/rangeland.

R0074454

As presented in Exhibit 2, the 1997 Ag Census describes cropland as:

Exhibit 2. Types of Cropland
(1997 Ag Census)



- *Harvested cropland* -- Includes all acreage from which crops are harvested, such as: (1) corn, wheat, barley, oats, sorghum, soybeans, cotton, and tobacco; (2) wild or tame harvested hay, silage, and green chop; and (3) vegetables. It also includes land in orchards and vineyards; all acres in greenhouses, nurseries, Christmas trees, and sod; and any other acreage from which a crop is harvested even if the crop is considered a partial failure and the yield is very low.

- *Cropland used only for pasture or grazing* -- Includes land pastured or grazed which could be used for crops without any additional improvement, and land in planted crops that is pastured or grazed before reaching maturity.

- *Cropland used for cover crops* -- Includes land used only to grow cover crops for controlling erosion or to be plowed under for improving the soil.

- *Cropland on which all crops failed* -- Includes: (1) all land from which a crop failed (except fruit or nuts in an orchard, grove, or vineyard being maintained for production) and no other crop is harvested and which is not pastured or grazed, and (2) acreage not harvested due to low prices or labor shortages.

- *Cultivated summer fallow* -- Includes cropland left unseeded for harvest, and cultivated or treated with herbicides to control weeds and conserve moisture.

- *Idle cropland* -- Includes any other acreage which could be used for crops without any additional improvement and which is not included in one of the above categories of cropland.

The 1997 Ag Census describes pastureland and rangeland as land, other than cropland or woodland pasture, that is normally used for pasture or grazing. This land, sometimes called "meadow" or "prairie," may be composed of bunchgrass, shortgrass, buffalo grass, bluestem, bluegrass, switchgrass, desert shrubs, sagebrush, mesquite, greasewood, mountain browse, salt brush, cactus, juniper, and pinion. It also can be predominantly covered with brush or browse.

As presented in Exhibit 3, approximately 82 percent of agricultural establishments in 1997 consisted of fewer than 500 acres; only 4 percent consisted of 2,000 or more acres.

According to the 1997 Ag Census, all agricultural establishments combined to produce approximately $197 billion worth of agricultural products.

Exhibit 3. Acreage of Agricultural Establishments in the U.S. (1997 Ag Census)

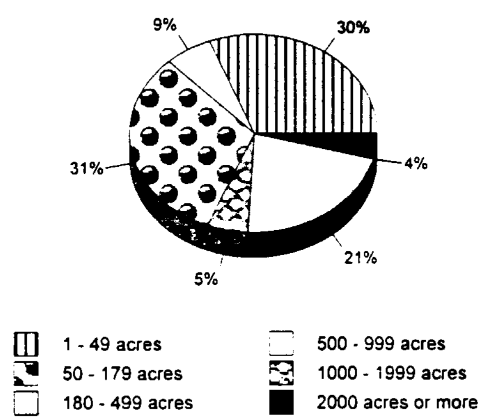


Exhibit 4. Agricultural Establishments by Value of Sales (1997 Ag Census)

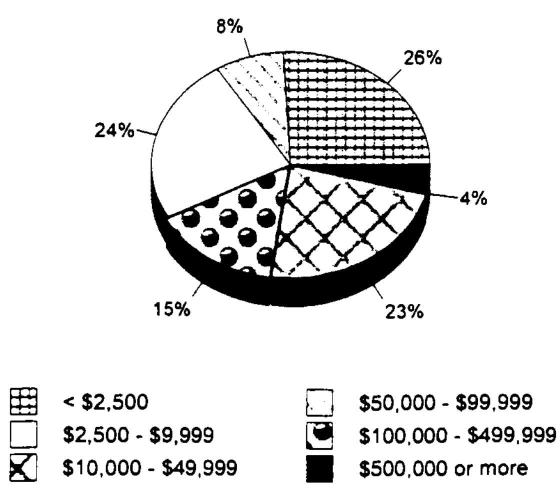


The market value of the agricultural products sold was split almost evenly between crop production, including nursery and greenhouse crops (49.6%) and livestock production (50.4%).

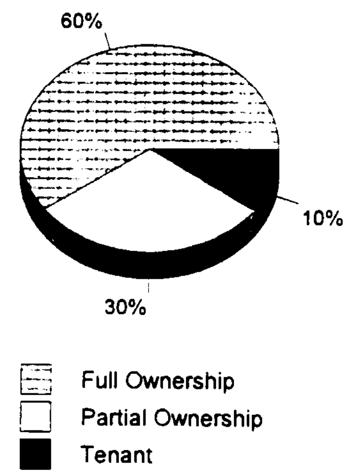
As shown in Exhibit 4, approximately 73 percent of all agricultural establishments produced less than $50,000 worth of agricultural products.

R0074456

In addition to tracking the number of agricultural establishments and the value of products sold, the Ag Census tracks and identifies other characteristics of agricultural establishments, such as ownership and organization. Exhibit 5 presents a breakdown of the ownership status of agricultural establishments in the U.S. The Ag Census basically identifies the ownership status of agricultural establishments by one of three categories:

- Full ownership, in which full owners operate only the land they own.
- Partial ownership, in which partial owners operate land they own and also land they rent from others.
- Tenant/rental arrangement, in which tenants operate only land they rent from others or work on shares for others.

Exhibit 5. Ownership Status of Agricultural Establishments in the U.S. (1997 Ag Census)



The Census further classifies agricultural establishment ownership by the person or entity who owns the establishment. There are four distinct types of organization: (1) individual or family (sole proprietorship), (2) partnership, including family partnership, (3) corporation, including family corporation, and (4) other, including cooperatives, estate or trust, and institutional. Approximately 86 percent of all establishments are owned and operated by individuals or families. Partnerships account for another 9 percent of the establishments and corporations own just more than 4 percent of the establishments. Fewer than 1 percent of all farms are owned by other organizations (1997 Ag Census).

II.B. Characterization of the Livestock Production Industry

This section provides data and information on the livestock production industry. For the purposes of this profile, livestock production includes the six categories of livestock presented in Exhibit 6. It should be noted that this profile does not include the processing of agricultural livestock products (e.g., meat processing plants, milk processing, etc.), and only discusses livestock

R0074457

production to the point of sending the livestock to the processing point (e.g., beyond the feedlot). This notebook follows the structure provided by the 1997 Ag Census, which classifies all of these livestock production operations within NAICS code 112.

Exhibit 6. 1997 NAICS Descriptions for Animal Production (NAICS 112)

Type of Establishment	NAICS Code	SIC Code	Description
Cattle ranching and farming, dairy farming	1121	0211, 0212, 0241	Establishments primarily engaged in raising cattle, milking dairy cattle, or feeding cattle for fattening.
Hog and pig farming	1122	0213	Establishments primarily engaged in raising hogs and pigs. These establishments may include farming activities, such as breeding, farrowing, and the raising of weaning pigs, feeder pigs, or market size hogs.
Poultry and egg production	1123	0251, 0252, 0253, 0254, 0259	Establishments primarily engaged in breeding, hatching, and raising poultry for meat or egg production.
Sheep and goat farming	1124	0214	Establishments primarily engaged in raising sheep, lambs, and goats, or feeding lambs for fattening.
Animal aquaculture	1125	0273, 0279, 0919, 0921	Establishments primarily engaged in the farm raising of finfish, shellfish, or any other kind of animal aquaculture. These establishments use some form of intervention in the rearing process to enhance production, such as holding in captivity, regular stocking, feeding, and protecting from predators.
Other animal production	1129	0271, 0272, 0279	Establishments primarily engaged in raising animals and insects for sale or product production (except those listed above), including bees, horses and other equines, rabbits and other fur-bearing animals and associated products (e.g., honey). Also includes those establishments for which no one animal or animal family represents one-half of production.

According to the 1997 Ag Census, there were 1,009,487 establishments producing the six categories of livestock referenced above (see Exhibit 7). Of the 1,009,487 livestock producing establishments, approximately 78 percent were classified as cattle ranching and farming.

All livestock producing establishments combined covered nearly 530 million acres of land. Based on the number of establishments and total acreage for each NAICS code, Exhibit 8 presents the average size of each type of establishment.

Exhibit 7. Number of Livestock-Producing Establishments by NAICS Code (1997 Ag Census)

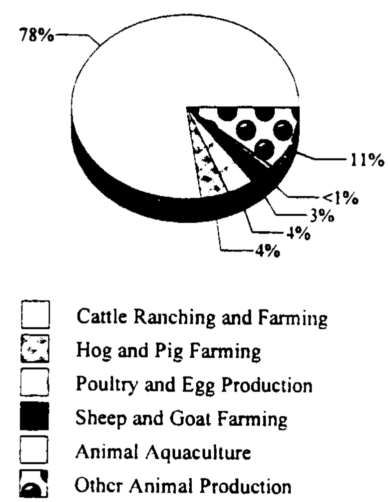


Exhibit 8. Average Establishment Size (1997 Ag Census)

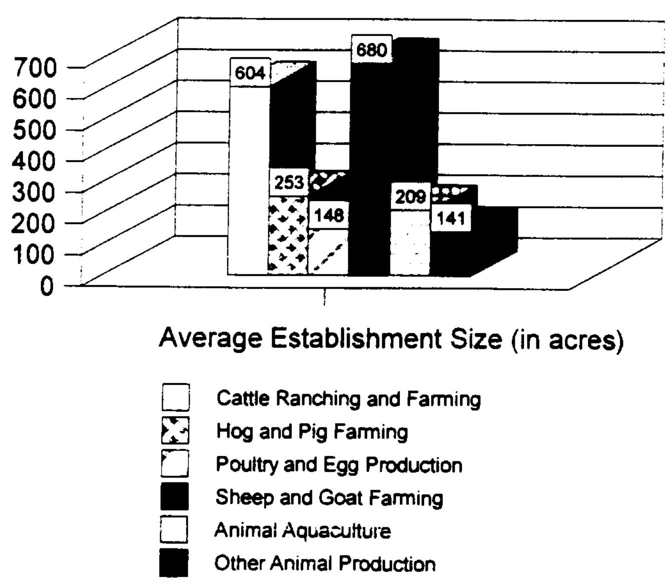


R0074459

The six types of livestock producing establishments defined above accounted for approximately $99 billion worth of products sold in 1997. Exhibit 9 presents the distribution of total sales among the six types of establishments compared to the total number of establishments. EPA's *Preliminary Data Summary Feedlots Point Source Category Study* released in January 1999 contains additional detailed information for beef cattle, dairy, pork, sheep, and poultry operations.

Exhibit 9. Percentage of Establishments & Sales by Type (1997 Ag Census)

Type of Livestock Establishment	Percent of Establishments	Percent of Sales
Cattle Ranching and Farming	78	60
Hog and Pig Farming	4	14
Poultry and Egg Production	4	23
Sheep and Goat Farming	3	<1
Animal Aquaculture	<1	<1
Other Animal Production	11	2

II.B.1. Cattle Ranching and Farming

Cattle ranching and farming establishments (NAICS code 1121) comprise the overwhelming majority of all establishments categorized under NAICS code 112 by accounting for 77.9 percent of all livestock establishments. In the U.S. in 1997, there were 785,672 cattle ranching and farming establishments. Of these, approximately 89 percent (699,650 establishments) were categorized as beef cattle establishments, including feedlots. The remaining 11 percent (86,022 establishments) were categorized as dairy cattle and milk production facilities. In 1997, the average beef cattle establishment was nearly 635 acres in size. Establishments raising dairy cattle and producing milk averaged approximately 356 acres.

Cattle ranching and farming establishments accounted for approximately $60 billion of sales in 1997. Of that $60 billion, beef cattle establishments had sales of approximately $38 billion (approximately 65 percent of sales), while dairy cattle and milk production accounted for the remaining $21 billion. Exhibit 10 compares the percentage sales of each subcategory to the percentage of establishments.

Exhibit 10. Percentage of Establishments & Sales in the Cattle Ranching and Farming Industry (1997 Ag Census)

Type of Establishment	Percent of Establishments	Percent of Sales
Beef cattle ranch and farming, including feedlots	89	65
Dairy cattle and milk production	11	35

II.B.2. Hog and Pig Farming

Hog and pig farming (NAICS code 1122) comprised approximately 4.6 percent (46,353 establishments) of all the livestock producing establishments in the U.S. in 1997. These establishments accounted for nearly $14 billion in total sales, or approximately 14 percent of total livestock producing establishment sales in 1997.

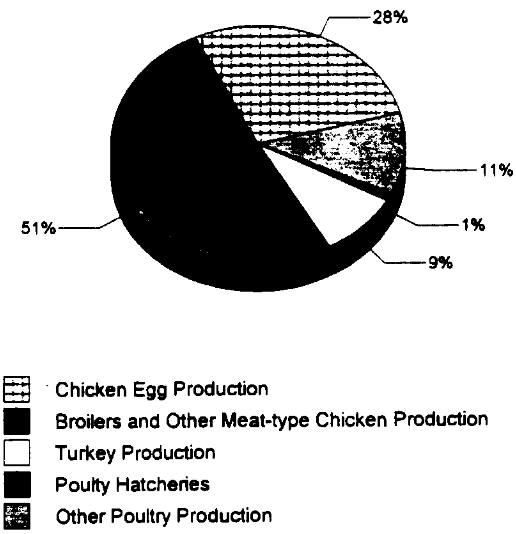
II.B.3. Poultry and Egg Production

Poultry and egg production is classified in NAICS code 1123. In 1997, this category included 36,944 establishments, or approximately 4 percent of all livestock producing establishments in the U.S. Poultry and egg production is divided into 5 subclassifications:

- Chicken egg production (NAICS code 11231)
- Broilers and other meat-type chicken production (NAICS code 11232)
- Turkey production (NAICS code 11233)
- Poultry hatcheries (NAICS code 11234)
- Other poultry production, including ducks, emus, geese, ostrich, pheasant, quail, and ratite (NAICS code 11239)

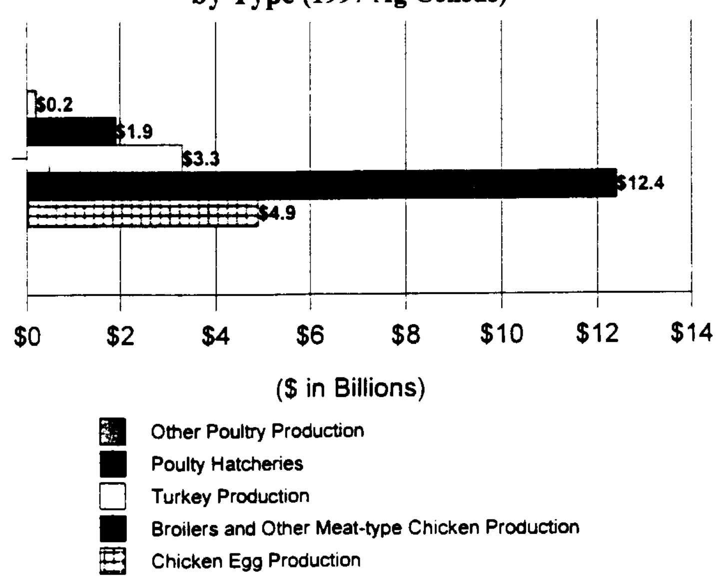
Exhibit 11 provides a breakdown of the 5 subclassifications by number of establishments. Each of these establishments averages approximately 150 acres in size.

Exhibit 11. Percent of Poultry and Egg Production Establishments by Type (1997 Ag Census)



In 1997, the poultry and egg production industry combined for nearly $23 billion in sales, which accounted for 23 percent of total livestock sales in the U.S. Sales of broilers and other meat-type chicken accounted for 54 percent of those sales (approximately $12.4 billion). Exhibit 12 presents the total sales of each of the subclassifications of the poultry and egg production industry.

Exhibit 12. Total Sales of Poultry and Egg Production Establishments by Type (1997 Ag Census)



R0074462

The poultry industry has increased its use of contractual agreements because of the high number of producers relative to the number of available buyers willing to handle raw farm products. The use of contracts has been noted to affect the organizational structure of the poultry industry raising questions about ownership responsibility as well as environmental concerns. This is particularly true when animals are produced under contracts where the contractor (processor or integrator) dictates the terms of the contract and controls the amount produced and the production practices used, but the contractee (grower) retains responsibility for increased animal waste management and disease control often without adequate compensation to meet these additional costs. In a 1993 study, USDA showed that almost 90 percent of the value of all poultry production is produced under contract, which has played a key role in the influence of integrators on the poultry sector.

II.B.4. Sheep and Goat Farming

Sheep and goat farming (NAICS code 1124) comprised 3 percent of all livestock establishments in the U.S. in 1997 and accounted for nearly 4 percent of the total acreage of livestock establishments. Of the 29,938 sheep and goat establishments, 21,084 (approximately 70 percent) are sheep farms; the remaining 8,854 are goat farms. The average sheep farm is approximately 830 acres in size. Goat farms average approximately 320 acres.

In 1997, sheep and goat farms combined for $625 million in total sales, which is less than 1 percent of total livestock producing establishment sales and the least amount of the six primary NAICS codes. Sheep accounted for $568 million in sales (approximately 91 percent) and goat sales accounted for the remaining $57 million.

II.B.5. Animal Aquaculture

Animal aquaculture (NAICS code 1125) is the smallest of the livestock producing establishments in terms of number of establishments, with only 3,079 active establishments in 1997. This accounted for fewer than 1 percent of all livestock producing establishments in the U.S. It also accounted for less than 1 percent ($800 million) of the 1997 total sales of livestock producing establishments. NAICS subdivides animal aquaculture establishments as follows:

- Finfish farming and fish hatcheries (NAICS code 112511), which is raising finfish (e.g., catfish, trout, goldfish, tropical fish, salmon, and minnows) and/or hatching fish of any kind.
- Shellfish farming (NAICS code 112512), which is raising crayfish, shrimp, oysters, clams, and/or mollusks.

- Other animal aquaculture (NAICS code 112519), which is raising animals other than finfish and shellfish, including alligators, frogs, and/or turtles.

While data for each of the specific NAICS subclassifications were not available through the 1997 Ag Census, USDA's NASS has identified at least 955 catfish producing operations. These operations are located primarily in four states--Alabama, Arkansas, Louisiana, and Mississippi. Similarly, the USDA has identified 451 trout operations located in 16 states, but primarily in North Carolina, Wisconsin, and Michigan. These trout operations had total sales in 1998 of $78.9 million. Both the number of operations and the value of total sales are down from the 1997 totals of 465 and $79.8 million, respectively.

II.B.6. Other Animal Production

Production of other animals (NAICS code 1129) occurred at 107,051 establishments in 1997, which is approximately 11 percent of all livestock producing establishments in the U.S. These establishments produce a variety of other animals including:

- Apiculture [bee farming (i.e., raising bees)] (NAICS code 11291)
- Horse and other equine production, including burros, donkeys, mules, and ponies (NAICS code 11292)
- Fur-bearing animal and rabbit production, including chinchillas, foxes, and mink (NAICS code 11293)
- All other animal production, including aviaries, bison/buffalo, cats/dogs, llamas, snakes, and worms (NAICS code 11299)

These four subclassifications accounted for just more than 2 percent of the total sales of livestock producing establishments in 1997. Exhibit 13 provides a breakdown of the 4 subclassifications by percent of establishments, as well as by percent of sales.

Exhibit 13. Percent of Establishments & Sales for the Other Animal Production Industry (1997 Ag Census)

Establishment Type	Percent of Establishments	Percent of Sales
Apiculture	4	5.9
Horse and Other Equine Production	86	42.9
Fur-bearing Animal and Rabbit Production	1	4.7
All Other Animal Production	9	46.5

II.C. Animal Feeding Operations

Many livestock establishments within NAICS code 112 are defined by EPA as either animal feeding operations (AFOs) or concentrated animal feeding operations (CAFOs). The primary factor classifying a livestock operation as an AFO or CAFO is the confinement of animals in a relatively small area devoid of sustaining vegetation. According to the USDA/EPA Unified National Strategy for AFOs, "AFOs congregate animals, feed, manure and urine, dead animals, and production operations on a small area of land." This factor separates AFOs (and CAFOs) from the pasture and range operations. The number of animals, among other factors, separates the AFOs from the CAFOs.

EPA is currently collecting and analyzing data on livestock production facilities to determine the number of facilities which meet the definition of AFO or CAFO. This will allow the Agency to better understand the universe of the regulated community, assist compliance, and as necessary, take enforcement action. EPA is currently developing AFO guidance documents and revised regulations that address permitting, performance standards, and other issues. The following sections provide information on the regulatory definitions of both AFOs and CAFOs.

Animal Feeding Operations

What is an AFO?
The term animal feeding operation or AFO is defined in EPA regulations [40 CFR 122.23(b)(1)] as:

- A lot or facility where animals have been, are, or will be stabled or confined and fed or maintained for a total of 45 days or more in any 12-month period; AND

- Where crops, vegetation, forage growth, or post-harvest residues are not sustained over any portion of the lot or facility in the normal growing season.

According to EPA[1], the first part of this regulatory definition of an AFO states that animals must be kept on the lot or facility for a minimum of 45 days. If an animal is at a facility for any portion of a day, it is considered to be at the facility for a full day. However, this does not mean that the same animals must remain on the lot for 45 days; only that some animals are fed or maintained on the lot or facility 45 days out of any 12-month period. The 45 days do not have to be consecutive, and the 12-month period does not have to correspond to the calendar year. For example, June 1 to the following May 31 would constitute a 12-month period.

The second part of the regulatory definition of an AFO is meant to distinguish facilities that have feedlots (concentrated confinement areas) from those which have pasture and grazing land, which are generally not AFOs. Facilities that have feedlots with constructed floors, such as solid concrete or metal slots, satisfy this part of the definition. If a facility maintains animals in an area without vegetation, including dirt lots, the facility meets this part of the definition. Dirt lots with nominal vegetative growth along the edges while animals are present or during months when animals are kept elsewhere are also considered by EPA to meet the second part of the definition.

The NPDES permit regulations [40 CFR Part 122.23(b)(1)] give the permitting authority (EPA or NPDES-authorized States) considerable discretion in applying the AFO definition. EPA defines the AFO to include the confinement area and the storage and handling areas necessary to support the operation (e.g., waste storage areas). Grazing and winter feeding of animals in a confined area on pasture or range land are not normally considered to meet the AFO definition.

As indicated in the USDA/EPA Unified National Strategy for AFOs, discharges from areas where manure and wastewater are applied to the land can have a significant impact on water quality. These land application areas are outside the area of confined animals but can be implicated by their direct relationship to AFO waste. Discharges of CAFO wastes from land application

[1] *Guidance Manual and Example NPDES Permit for Concentrated Animal Feeding Operations (Draft)*, U.S. Environmental Protection Agency, August 6, 1999.

areas can qualify as point source discharges in certain circumstances. Accordingly, NPDES permits for CAFOs should address land application of wastes from CAFOs.

How Do You Determine the Size of an AFO?
Once the facility meets the AFO definition, its size, based upon the total numbers of animals confined, is a fundamental factor in determining whether it is a CAFO. The animal livestock industry is diverse and includes a number of different types of animals that are kept and raised in confined situations. In order to define these various livestock sectors in relative terms, the concept of an "animal unit"[2] was established in the EPA regulations [40 CFR Part 122 Appendix B]. An animal unit (AU) varies according to animal type; one animal is not necessarily equal to one AU. Each livestock type, except poultry, is assigned a multiplication factor to facilitate determining the total number of AUs at a given facility. Multiplication factors are defined in Exhibit 14.

Exhibit 14. Multiplication Factors to Calculate Animal Units

Animal Type	Multiplication Factor
Beef Cattle (slaughter and feeder)	1.0
Mature Dairy Cattle	1.4
Swine (weighing more than 55 lbs.)	0.4
Sheep	0.1
Horses	2.0
Poultry	There are currently no animal unit conversions for poultry operations. However the regulations [40 CFR 122, Appendix B] define the total number of animals (subject to waste handling technology restrictions) for specific poultry types that make these operations subject to the regulation.

These factors also are used when determining the total number of animal units at a facility with multiple animal types. Multiplication factors are applied to the total for each type of animal to determine the AU for that animal type. The AUs for each are then totaled for the facility total. A hypothetical AFO with

[2] EPA and USDA both use the concept of "animal unit," however it is important to recognize that with respect to swine and poultry, there are Agency differences in the application of this concept.

multiple animal types and the calculation to determine the total number of animals confined at the facility is presented below (see box).

Example: Animal Unit Determination for an AFO with Multiple Animal Types

Situation: An AFO is being evaluated to determine if it meets the animal unit criteria for being defined as a CAFO and subject to NPDES permitting. The facility confines 200 horses, 300 sheep, and 500 beef cattle.

Animal Unit Calculation:		
	200 Horses x 2.0 =	400 AUs
	300 Sheep x 0.1=	30 AUs
	500 Beef Cattle x 1.0 =	500 AUs
	Total	930 AUs

Under the regulations, two or more AFOs under common ownership are considered one operation if they adjoin each other or use a common waste disposal system [40 CFR 122.23(b)(2)]. For example, facilities have a common waste disposal system if the wastes are commingled (e.g., stored in the same pond or lagoon or land applied on commonly owned fields) prior to use or disposal. The collective number of animal units of the adjoining facilities is used in determining the size of the AFO. Many poultry feeding operations adjoin each other and often meet the definition of one facility.

Concentrated Animal Feeding Operations

AFOs are CAFOs if they meet the regulatory definition [40 CFR 122, Appendix B] or have been designated on a case-by-case basis [40 CFR 122.23 (c)] by the NPDES-authorized permitting authority.

AFOs <u>Defined</u> as CAFOs
According to the NPDES regulations, a specific definition must be used when determining whether an AFO is a CAFO. The definition is broken down according to the number of animals confined at the facility (see box). AFOs

AFOs are Defined as CAFOs if:

- More than 1,000 AUs are confined at the facility [40 CFR 122, Appendix B (a)]; ***or***
- From 301 to 1,000 AUs are confined at the facility and:
  - Pollutants are discharged into waters of the U.S. through a man-made ditch, flushing system, or other similar man-made device; or
  - Pollutants are discharged directly into waters of the U.S. that originate outside of and pass over, across, or through the facility or come into direct contact with the confined animals.

R0074468

with more than 1,000 AUs are CAFOs. AFOs with 301 to 1,000 AUs are defined as CAFOs only if, in addition to the number of animals confined, they also meet one of the specific criteria addressing the method of discharge (see text box).

AFOs with fewer than 300 AUs are not defined as CAFOs under the current regulations but may be designated as a CAFO.

- ***AFOs With More Than 1,000 AUs are CAFOs.*** Under existing regulations, virtually all AFOs with more than 1,000 AUs are CAFOs and should apply for an NPDES permit. For individual animal types, the regulations state the number of animals required for the facility to be defined as a CAFO. These numbers are presented in Exhibit 15. If the number of AUs for any one animal type at a facility exceeds the corresponding number, or if the cumulative number of animal types exceeds 1,000 AUs, the facility is defined as a CAFO.

Exhibit 15. Threshold Number of Animals (by Animal Type) to Meet the Definition of a CAFO with More Than 1,000 AUs

Animal Type	Number of Animals Units
Beef cattle	1,000 slaughter or feeder cattle
Dairy cattle	700 mature dairy cattle (whether milked or dry)
Swine	2,500 swine (over 25 kilos - approximately 55 lbs.)
Sheep	10,000 sheep or lambs
Horses	500 horses
Chickens	100,000 laying hens or broilers (if continuous flow watering system); 30,000 laying hens or broilers (if liquid manure system)
Turkeys	55,000 turkeys
Ducks	5,000 ducks

Source: 40 CFR Part 122, Appendix B (a)

- **AFOs With 301 to 1,000 AUs *May Be* CAFOs.** AFOs with 301 to 1,000 AUs are defined as CAFOs only if, in addition to the number of animals confined, they also meet one of the specific criteria governing "method of discharge." If the number of AUs for any one animal type exceeds the specified number [40 CFR Part 122, Appendix B(b)], or if the *cumulative* number of animal types exceeds 300 AUs, **and** only one of the "method of discharge" criteria are met, the facility is defined as a CAFO.

- **AFOs with up to 300 AUs.** An AFO with up to 300 AUs may be considered a CAFO only if designated as such by the permitting authority and if it meets the discharge criteria (see below).

AFOs Designated as CAFOs
According to the NPDES permit regulations [40 CFR 122.23 (c)], the NPDES-authorized permitting authority can, on a case-by-case basis, designate any AFO as a CAFO after determining that it is a significant contributor of pollution to waters of the United States. No AFO with fewer than 300 AUs shall be designated a CAFO unless it also meets the discharge criteria outlined in 40 CFR 122.23(c).

An AFO *cannot* be designated a CAFO on a case-by-case basis until the inspector has conducted an on-site inspection of the facility and determined that the facility is a significant contributor of pollution. The designation is based on the factors listed in 40 CFR 122.23 (c) and shown below. This determination may be based on visual observations as well as water quality monitoring. Exhibit 16 shows example case-by-case designation factors and the inspection focus related to each factor.

Exhibit 16. Example Factors for Case-by-Case CAFO Designation

Designation Factor	Inspection Focus
Size of the operation and amount of waste reaching waters of the United States	• Number of animals • Type of feedlot surface • Feedlot design capacity • Waste handling/storage system design capacity
Location of the operation relative to waters of the United States	• Location of water bodies • Location of flood plain • Proximity to surface waters • Depth to groundwater, direct hydrologic connection to surface water
Means of conveyance of animal waste and process waste waters into waters of the United States	• Identify existing or potential man-made (includes natural and artificial materials) structures that may convey waste • Direct contact between animals and surface water
Slope, vegetation, rainfall and other factors affecting the likelihood or frequency of discharge	• Slope of feedlot and surrounding land • Type of feedlot (concrete, soil, etc.) • Climate (e.g., arid or wet) • Type and condition of soils • Depth to groundwater • Drainage controls • Storage structures • Amount of rainfall • Volume and quantity of runoff • Buffers
Other Relevant Factors	• Waste handling and storage • Land application timing, methods, rates and areas

Following the on-site inspection, the NPDES permitting authority will prepare a brief report that: (1) identifies findings and any follow-up actions; (2) determines whether or not the facility should be designated as a CAFO; and (3) documents the reasons for that determination. Regardless of the outcome, a letter would be prepared and sent to the facility. The letter should inform the facility that it has been either: (1) designated a CAFO and required to apply for an NPDES permit; or (2) has not been designated as a CAFO at this time. In those cases where a facility has not been designated as a CAFO but the NPDES authority has identified areas of concern, these would be noted in the letter.

II.D. Geographic Distribution and Economic Trends

As described in the executive summary of the *Preliminary Data Summary: Feedlots Point Source Category Study* (December 1998), livestock production operations in the U.S. vary widely in both the mode and scale of production, with individual farms spanning small scale production facilities with few animals to large, intensive production facilities. The following are summaries of the principal producing States in 1992 by animal commodity for beef cattle, swine, dairy cattle, and poultry.

- Ranked by the number of cattle and calves sold, the top ten producing states controlled 65 percent of U.S. beef production in 1992. Texas was the largest beef producing state accounting for 16 percent of 1992 sales. Other major states included Kansas, Nebraska, Oklahoma, Colorado, Iowa, California, South Dakota, Missouri, Wisconsin, and Montana.

- The hog farming sector is concentrated among the top five producing states that together supply about 60 percent of U.S. pork production. Iowa accounted for 24 percent of 1992 hog sales. Other major hog producing states included North Carolina, Illinois, Minnesota, Indiana, and Nebraska.

- The top five dairy cattle states controlled more than 50 percent of all U.S. milk production in 1992. Wisconsin was the largest dairy producing state with 16 percent of volume milk sales. Other major milk producing states included California, New York, Pennsylvania, and Minnesota.

- Broiler and chicken meat production is controlled by 10 producing states, which supply about 80 percent of all broilers sold. Arkansas was the largest broiler producer in 1992, with 16 percent of sales. Other major states included Georgia, Alabama, North Carolina, Mississippi, Texas, Maryland, California, Delaware, and Virginia.

- The top ten producing states accounted for about 80 percent of turkey production. North Carolina was the largest turkey producing state in 1992, with about 20 percent of sales. Other top producing states included Minnesota, California, Arkansas, Virginia, Missouri, Indiana, Texas, Iowa, and Pennsylvania.

- Egg production is dominated by 10 producing states that supply almost two-thirds of the eggs sold. California was the largest egg producing state in 1992 with about 12 percent of all eggs sales. Other major producers included Indiana, Pennsylvania, Georgia, Ohio, Arkansas, Texas, North Carolina, and Alabama.

Recent trends in the U.S. livestock sector are marked by a decline in the number of farms attributable to ongoing consolidation in the livestock industry. Farms are closing – especially small farming operations – due to competitive pressures from highly specialized – often lower cost – large scale producers. This trend toward fewer and larger livestock operations represents a significant shift in the industry. Both 1992 and 1997 Agriculture Census data highlight the ongoing shift from many small, diversified farms toward fewer large-scale, year-round, intensive breeding and feeding operations.

Another industry trend has been a steady increase in animal production and sales in the U.S. This trend has occurred at the same time there has been a decrease in the number of animals on site. This trend signals continued gains in production efficiency on U.S. farms in the form of higher per-animal yields and quicker turnover of animals prior to marketing.

A detailed industry economic profile is presented in the *Feedlots Point Source Category Study* and covers major commodity sectors, industry trends in the U.S. livestock and poultry farm sectors, recent market trends, farm revenue, farm-gate prices, financial operating conditions, industry marketing chain, and industry employment generated.

Additional geographic and economic information can be found by accessing the 1997 Agriculture Census at http://www.nass.usda.gov/census/ and the National Agriculture Statistics Service at http://www.usda.gov/nass/.

III. SUMMARY OF OPERATIONS, IMPACTS, AND POLLUTION PREVENTION OPPORTUNITIES FOR THE AGRICULTURAL LIVESTOCK PRODUCTION INDUSTRY

This section provides an overview of commonly employed operations and maintenance activities in the agricultural livestock production industry. This discussion is not exhaustive; the operations and maintenance activities discussed are intended to represent the material inputs, major pollution outputs, and associated environmental impacts from agricultural livestock production practices. General pollution prevention and waste minimization opportunities are also discussed in the context of each of the operations and maintenance activities.

The choice of practices or operations influences the material used and the resulting pollution outputs and environmental impacts. Keep in mind that environmental impacts are relative, as some kinds of pollution outputs have far greater impacts than others.

Impact of Agriculture on the Environment

According to the *EPA/USDA Unified National Strategy for Animal Feeding Operations* (March 9, 1999), despite progress in improving water quality, 40 percent of the Nation's waterways assessed by States do not meet goals for fishing, swimming, or both. While pollution from factories and sewage treatment plants has been dramatically reduced, the runoff from city streets, agricultural activities, including AFOs, and other sources continues to degrade the environment and puts environmental resources (i.e., surface water, drinking water) at risk. According to EPA's 1996 305(b) water quality report, the top two pollutants from agriculture were identified as sediment and nutrients, respectively. Additional agricultural pollutants, such as animal wastes, salts, and pesticides, were identified by EPA[1]. The following presents a brief discussion of the environmental impacts or effects of agricultural pollutants.

> The Clean Water Act Plan of 1998 called for the development of the EPA/USDA *Unified National Strategy for Animal Feeding Operations* (AFOs) to minimize the water quality and public health impacts of AFOs.

(1) ***Nutrients***. Excess nutrients in water (i.e., phosphorus and nitrogen) can result in or contribute to low levels of dissolved oxygen (anoxia),

[1] *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, U.S. Environmental Protection Agency, January 1993.

R0074475

eutrophication, and toxic algal blooms. These conditions may be harmful to human health; may adversely affect the suitability of the water for other uses; and, in combination with other circumstances, have been associated with outbreaks of microbes such as *Pfiesteria piscicida*.

- Phosphorus. Phosphorus determines the amount of algae growth and aging that occurs in freshwater bodies. Runoff and erosion can carry some of the applied phosphorus to nearby water bodies.

- Nitrogen. In addition to eutrophication, excessive nitrogen causes other water quality problems. Dissolved ammonia at concentrations above 0.2 mg/L may be toxic to fish. Biologically important inorganic forms of nitrogen are ammonium, nitrate, and nitrite. Ammonium becomes adsorbed to the soil and is lost primarily with eroding sediment. Even if nitrogen is not in a readily available form as it leaves the field, it can be converted to an available form either during transport or after delivery to waterbodies. Nitrogen in the form of nitrate, can contaminate drinking water supplies drawn from groundwater. Nitrates above 10 ppm in drinking water are potentially dangerous, especially to newborn infants.

(2) ***Sediment.*** Sediment affects the use of water in many ways. Suspended solids reduce the amount of sunlight available to aquatic plants, cover fish spawning areas and food supplies, clog the filtering capacity of filter feeders, and clog and harm the gills of fish. Turbidity interferes with the feeding habits of fish. These effects combine to reduce fish and plant populations and decrease the overall productivity of waters. In addition, recreation is limited because of the decreased fish population and the water's unappealing, turbid appearance. Turbidity also reduces visibility, making swimming less safe.

(3) ***Animal Wastes***. Animal waste includes the fecal and urinary wastes of livestock and poultry; process water (such as from a milking parlor); and the feed, bedding, litter, and soil with which fecal and urinary matter and process water become intermixed. Manure and wastewater from AFOs have the potential to contribute pollutants such as nutrients (e.g., nitrogen and phosphorus), organic matter, sediments, pathogens, heavy metals, hormones, antibiotics, and ammonia to the environment. Decomposing organic matter (i.e., animal waste) can reduce oxygen levels and cause fish kills. Solids deposited in waterbodies can

accelerate eutrophication through the release of nutrients over extended periods of time.

Contamination of groundwater can be a problem if runoff results from the misapplication or over application of manure to land or if storage structures are not built to minimize seepage. Because animal feed sometimes contains heavy metals (e.g., arsenic, copper, zinc), the possibility for harmful accumulations of metals on land where manure is improperly or over applied is possible.

Pathogens in manure. Pathogens in manure can cause diseases in humans if people come in contact with the manure. Pathogens in manure also create a food safety concern if manure is applied directly to crops at inappropriate times or if manure contaminates a product (e.g., food, milk). In addition, pathogens are responsible for some shellfish bed closures. Runoff from fields receiving manure may contain extremely high numbers of bacteria (though all of these bacteria may not be harmful) if the manure has not been properly incorporated. Pathogens, such as *Cryptosporidium*, have been linked to impairments in drinking water supplies and threats to human health.

Air pollution is also a concern in relation to animal wastes. Farms on which animals are raised often concentrate odors associated with the microbial degradation of manure and other by-products of the production of meat, milk and eggs. Odors can be a nuisance to neighbors of animal operations, and there is increasing concern about the potential health effects from emissions of odorous compounds.

(4) ***Salts***. Salts are a product of the natural weathering process of soil and geologic material. In soils that have poor subsurface drainage, high salt concentrations are created within the root zone where most water extraction occurs. The accumulation of soluble and exchangeable salts leads to soil dispersion, structure breakdown, decreased infiltration, and possible toxicity; thus, salts often become a serious problem on irrigated land, both for continued agricultural production and for water quality considerations. High salt concentrations in streams can harm freshwater aquatic plants just as excess soil salinity damages agricultural crops.

(5) ***Pesticides.*** The primary pollutants from pesticides are the active and inert ingredients, diluents, and any persistent degradation products. Pesticides and their degradation products may enter groundwater and surface water in solution, in emulsion, or bound to soils. Pesticides may, in some instances, cause impairments to the uses of surface

waters and groundwater. Both the degradation and sorption characteristics of pesticides are highly variable. Some types of pesticides are resistant to degradation and may persist and/or accumulate in aquatic ecosystems. Pesticides may harm the environment by eliminating or reducing populations of desirable organisms, including endangered species.

Within a livestock production establishment, pesticides may be applied directly to livestock or to structures (e.g., barns, housing units) to control pests, including parasites, vectors, and predators.

Pesticides are both suspected and known for causing immediate and delayed-onset health hazards for humans. If exposed to pesticides, humans may experience adverse effects, such as nausea, respiratory distress, or more severe symptoms up to and including death. Animals and birds impacted by pesticides can experience similar illnesses or develop other types of physical distress.

Pollution Prevention/Waste Minimization Opportunities in the Agricultural Livestock Production Industry

The best way to reduce pollution is to prevent it in the first place. Industries have creatively implemented pollution prevention techniques that improve operations and increase profits while minimizing environmental impacts. This can be done in many ways such as reducing material inputs, reusing byproducts, improving management practices, and employing substitute toxic chemicals.

To encourage these approaches, this section provides general descriptions of some pollution prevention advances that have been implemented within the agricultural livestock production industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for establishments interested in beginning their own pollution prevention projects. This section provides information from real activities that may be or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land, and water pollutant releases.

The use of pollution prevention technologies and environmental controls can substantially reduce the volume and concentration of the contaminants released/discharged into the surrounding environment. In some cases, these pollution prevention approaches may be economically beneficial to the agricultural production industries because they decrease the amount of chemicals needed, and therefore the cost of maintaining operations.

Waste minimization generally encompasses any source reduction or recycling that results in either the reduction of total volume or the toxicity of hazardous waste. Source reduction is a reduction of waste generation at the source, usually within a process. Source reduction can include process modifications, feedstock (raw material) substitution, housekeeping and management processes, and increases in efficiency of machinery and equipment. Source reduction includes any activity that reduces the amount of waste that exits a process. Recycling refers to the use or reuse of a waste as an effective substitute for a commercial product or as an ingredient or feedstock in an industrial process.

It should be noted that as individual practices, these pollution prevention and waste minimization practices can significantly reduce the environmental impacts of agricultural operations. However, to get the full effect of the practices and maximize pollution prevention potential, an agricultural operation must consider its individual practices in the context of a system. The practices combine to form an integrated system in which each practice interacts with the others and is affected by the others. That is, outputs from one practice may be inputs into one of the other practices, in effect creating a closed-loop system that both maximizes profits and minimizes environmental impacts. By considering their establishments as systems, operators will be better able to evaluate and implement pollution prevention or waste minimization opportunities.

Operations of Livestock Production

Livestock production generally includes the following activities:

- Feed storage, loading, and unloading
- Housing
- Feeding and watering
- Managing animal waste
- Applying pesticides and pest control
- Maintaining and repairing agricultural machinery and vehicles
- Fuel use and fueling activities

The additional activities of planning and management are required for all of the above processes to occur. Exhibit 17 presents the material inputs and pollution outputs from each of these processes.

Exhibit 17. Livestock Production Activities and Potential Pollution Outputs

Activity		Potential Pollution Outputs
Feed storage, loading, and unloading	➜	– Dust emissions – Unusable or spilled feed – Leachate from silage – Nutrient-contaminated runoff
Housing	➜	– Animal waste – Waste bedding – Air emissions (e.g., odors, methane, ammonia) – Washwater from flushing and washdown of housing areas
Feeding	➜	– Animal waste – Air emissions (e.g., dust, methane) – Moldy feed discard – Spilled feed – Nutrient-contaminated runoff
Watering	➜	– Animal waste – Water contaminated with animal waste – Destruction of stream bank, riparian zone (from animals in streams)

Typically, most of the above activities include the generation of *animal waste*. Animal waste must be managed appropriately because of its potential environmental impacts.

Managing animal waste, includes collecting and transporting; storing and treating; and utilizing animal waste	➜	– Discharges and leaching of wastewater – Manure and urine – Bedding – Air emissions (e.g., ammonia, methane, other gases, odor, dust) – Hair and/or feathers – Carcasses – Pathogens – Heavy metals – Wasted products (e.g., milk, eggs)

R0074480

Exhibit 17. Livestock Production Activities and Potential Pollution Outputs

Activity		Potential Pollution Outputs
Additional activities that occur at agricultural establishments and their potential pollution outputs include:		
Pest control	→	– Discharges and leaching of pesticides – Chemical air emissions
Maintaining and repairing agricultural machinery and vehicles	→	– Used oil – Spent fluids and organic solvents – Used tires – Spent batteries – Metal machining wastes – Scrap metal
Fuel use and fueling activities	→	– Fuel spills or leaks

III.A. Feed Storage, Loading, and Unloading

Feed storage, loading, unloading, and transport are major activities in livestock production. Livestock feed may include hay, grain (sometimes supplemented with protein, vitamins, mineral supplements and antibiotics), and silage -- with grain and hay being the most common feeds. Livestock operations may produce all, a portion, or none of the animal feed. Purchased feed is transported to the livestock operation by truck or, at very large animal operations, by rail. Stored feed must be loaded, transported to the animals' normal feed location, and unloaded.

– Hay that has been cut and partially dried is collected from fields and compacted into small rectangular bales or rolled into large round bales. Hay may be stored in covered and enclosed buildings, in fields, and in outside storage areas where it may or may not be covered. Small rectangular hay bales may be placed in a barn by conveyor.

  Feed hay is often transported on tractor-drawn wagons to feed bunkers, feed rings, and mangers. Small rectangular hay bales may be mechanically or manually placed in bunkers and mangers. Front-end loaders are used to unload round bales and place them in the feed rings.

- Harvested grain is sometimes milled (ground) on site or more commonly sent offsite to a milling facility for grinding prior to being returned to the facility for use. Depending on the livestock species, protein, vitamins, mineral supplements, and antibiotics are often added at the time of milling or mixing. Grain is typically stored in aerated grain bins and handled with augers. High moisture corn is stored in silos. Grain, which is typically placed in feed bunkers, troughs, or feeder units, can be transported using a front-end loader, tractor front bucket, grain wagon, or manually for smaller volumes.

- Silage is usually produced onsite and may consist of chopped green corn or hay. Silage is allowed to ferment in vertical or horizontal silos or storage bunkers prior to use as feed. Silage is removed from silos and then distributed along the feed bunks.

Potential Pollution Outputs and Environmental Impacts

The primary pollution outputs include unusable feed; dust emissions from loading, unloading, and grinding activities; air emissions from transportation to and from sites; and leachate from silage. A minor pollution output is contamination of storm water from spilled feed. Dust emissions pollute the air that agricultural workers and animals breathe and can cause respiratory problems in instances of prolonged exposure. Research indicates that silage materials stored at 65 percent moisture content or higher can produce leachate.

Pollution Prevention/Waste Minimization Opportunities

One potential pollution prevention practice focuses on minimizing unusable feed and consequently maximizing the amount of feed that is consumed by the animal. One way to maximize animal consumption is by grinding the feed in either a grinder-mixer or a tub grinder. Grinding increases the ability of the animal to digest the feed. Where possible, grinders should be used with a dust collector to reduce dust emissions. Silage leachate can be reduced by allowing the material to wilt in the field for 24 hours, varying cutting and harvesting times, cutting or crimping the material, or adding moisture-absorbent material to the silage as it is stored[2].

---

[2] *Farm-A-Syst, Fact Sheet #9, Reducing the Risk of Groundwater Contamination by Improving Silage Storage*, University of Wisconsin, Extension/Cooperative Extension, College of Agricultural and Live Sciences.

III.B. Housing

Livestock housing may consist of feed lots, barns, stables or stalls, corrals, covered loafing areas, pens, poultry houses, and other similar structures that confine the animals in an area and manner best suited to the overall livestock production process. There are three general ways to house livestock:

(1) Enclosed housing (i.e., a roofed and walled structure)
(2) Partially enclosed (i.e., usually roofed with walls on some structure sides)
(3) Open or no structures

The type of housing used for a particular animal type/livestock production is related to animal size, feeding, animal health and biosecurity, climate, and the goal of achieving the optimum weight gain or commodity produced at the lowest cost.

- Dairy cattle. Most dairy operations provide separate housing for different animal groups based on age or milking status (lactating versus dry). Calves may be housed in barns, individual pens within a barn, open fields, and hutches. Heifers may be housed in freestall barns and bedded pack housing. Bedded pack housing is often used with an open feeding area. Dry cows (<3 months to calving) are usually housed on pasture or in freestall barns. Lactating cows are housed in freestall and other types of barns such as stanchion, corrals, structures, and open lots that provide shade[3].

- Beef cattle. Beef cattle are mainly housed in pastures and open feedlots. Calving facilities may consist of an open pasture, a shed with stalls, or an open, wind-protected pen. Bulls are either penned separately or in groups of up to 10. They may be contained in a barn or in an open pen with shade. Cattle feedlots are usually open areas that may have windbreaks and shade. Very few beef cattle are housed in freestall barns with slotted floors for manure collection.

- Sheep. Sheep are maintained primarily on open grazing land, but some are kept in open lots with shelters, facilities with slotted floors for manure collection, and in bedded pens.

[3] *Preliminary Data Summary: Feedlots Point Source Category Study*, U.S. Environmental Protection Agency, Office of Water, Washington, DC, December 1998.

- Horses. Most horses maintained in concentrated numbers are housed in stalls within an enclosed barn. Approximately 70 percent of the horse operations that use stalls have one animal per stall. Horses may also be housed in partially enclosed housing or on pasture.

- Poultry. Poultry including turkeys and ducks are maintained in an enclosed house. Chicken broilers, roasters, and pullets, which may be caged, are usually maintained in houses on a solid floor with bedding. Breeders are usually maintained in houses with a slatted floor generally covering one-third of each side of the house along the length of the side-wall of the house. Most layers are maintained in houses inside of cages with mesh floors, and a few in houses with a litter or slat/litter floor. Turkey poults are reared in enclosed brooder houses, then generally are moved to grower houses and sometimes to range. Turkeys are normally raised on a dirt or clay floor with a bedding cover. Duck housing is normally an enclosed house that has a wire-mesh floor, a solid floor, or a combination of the two.

- Goats. Goats are housed in loose housing common areas that may contain bedded and exercise areas, individual stalls, pens, and corrals. Pregnant does are usually housed in bedded pens.

- Swine. While some swine are raised outdoors with a shelter (e.g., hoop housing), most are housed in an enclosed barn or house. Breed sows may be kept in small group pens and then during farrowing, a sow is usually placed in an individual pen. Young pigs are placed together in larger nursery pens. Finishing operations keep several pigs in the same pen.

The floors of some livestock housing for cattle, swine, and sheep, may be of slotted construction. The floors for some poultry housing may be of wire-mesh or slat construction. The slotted, wire-mesh, and slatted housing floor systems allow the manure to drop into a long-term or temporary storage/collection/transfer area.

Bedding is mostly used in the housing of dairy cattle, poultry, and horses but may be used for the housing of any of the livestock types presented above. Manure and bedding needs to be removed at regular intervals. Methods of removal vary depending on the type of housing. Manure is primarily removed from housing by scraping, scooping, and flushing (see Section III.D. Managing Animal Wastes).

Potential Pollution Outputs and Environmental Impacts
The primary pollution outputs include animal wastes, bedding, wastewater from flushing and washdown of housing areas, and air emissions (e.g., methane, ammonia, and odors). The main impacts of these outputs are soil and water contamination stemming from waste spills, improper storage, and runoff.

From an environmental standpoint, each type of livestock housing (enclosed, partially enclosed or open) has advantages and disadvantages. The move from outdoor housing to confinement housing has removed the weather factor and runoff, which is a substantial problem for outdoor housing, and provided producers the opportunity to manage manure as a resource and not a waste. However, concentrated amounts of manure can be viewed as a disadvantage. While concentrating the animals (and therefore the animal manure) may lead to easier manure management, concentrated amounts of manure have a greater potential to significantly impact the environment in the event of a spill, release, or improper management.

Wastes, including manure and fouled bedding, that are not properly transported from housing could spill and potentially contaminate storm water runoff. Open housing such as feedlots, corrals, and pens, if not scraped as necessary, may also contaminate storm water runoff. Wastes carried in storm water runoff may be discharged to surface waters causing pollution, or may be deposited in low areas and potentially leach to the groundwater.

Animals contained in pasture areas (technically not housing but used for livestock containment) can wear away soil from feeding sites, destroy streambanks at natural watering sites, and, if allowed access, defecate and urinate in surface waters. This results in increased runoff, soil erosion as well as sediments, manure, and urine in the water.

With enclosed or partially enclosed housing areas, odors and other gases (e.g., methane, ammonia, and hydrogen sulfide gases) from animal waste can be concentrated, potentially harming the health of the animals and workers. When the gases are released outside, the odor can affect the surrounding areas and create nuisance problems for neighbors.

Pollution Prevention/Waste Minimization Opportunities
While the majority of the wastes discussed above for housing cannot be prevented, both the wastes and their impacts can be reduced by implementing best management practices.

- *Minimize water use during cleaning.* By cleaning livestock (except poultry) housing on a regular and frequent basis and using minimal amounts of water during cleaning, operations may reduce the volume of wastes to be handled and used. Keeping the waste dry also facilitates its management, reduces runoff potential, and minimizes odors from decomposition.

- *Minimize runoff by cleaning open areas.* Cleaning open areas reduces the potential for the runoff of wastes to surface waters.

- *Reduce odor by preventing ammonia generation.* Ammonia is created by the rapid conversion of urinary nitrogen (urea) to ammonia by microorganisms. By applying various chemicals (e.g., urease inhibitors) on a weekly basis, the conversion of nitrogen to ammonia can be reduced, thus minimizing ammonia emissions and odors, and conserving valuable fertilizer[4].

- *Use tools to minimize odor impacts on the surrounding community.* When considering the installation of a new livestock operation or the expansion of an existing operation, facilities should consider maximizing the distance to neighboring dwellings, the existence of "reverse" setback rules, the potential for new neighbors, and the potential impact neighbors may have on limiting the expansion of the animal housing. Additional methods for reducing odors in other aspects of livestock operations are discussed below.

III.C. Animal Nutrition and Health

There are many activities and considerations when managing animal nutrition and health, including feeding, watering, and biosecurity issues. Animal nutrition is an important consideration for livestock operators for various reasons, including the health of the animals, as well as the nutrient

[4] *Use of Urease Inhibitors to Control Nitrogen Loss From Livestock Waste,* U.S. Department of Agriculture, 1997.

composition of the manure. The nutrient composition of manure (nitrogen and phosphorus) is directly related to the composition of the animal feed, feed supplements, and ability of the animal to digest the feed.

Feeding

Corn, soybean, grasses, hay, silage, and other grains are some of the common food sources for livestock. Most livestock operations adjust the composition of the animals' feed to meet the animals' current protein needs. As an example, dry cows are typically fed a lower protein diet when compared to cattle being milked or nursing calves. Likewise, swine operations often use phase feeding and separation of sexes to best meet the animals' protein needs, lower feed costs, and reduce nutrient levels of the manure. Generally, swine operations feed varying protein diets in relationship to the growth phase and/or need of the animal. As an example, operations provide higher protein feed to farrowing sows, less protein to gilts, and even less to barrows (made possible through separate confinement of sexes). Some livestock operations place swine in confinements recently used for cattle. The swine will receive a portion of its nutrient requirement by feeding on the cattle manure. This provides an overall reduction in the nutrients excreted at the livestock operation.

Feed supplements may include amino acids and enzymes. The supplement of synthetic lysine in swine feed assists in lowering the nitrogen level in the manure. The addition of this amino acid allows feeding of a lower protein diet. Normally, the phosphate in the phytic acid passes through the digestive tract of swine and poultry and is excreted. The addition of phytase, an enzyme, to swine and poultry feed, will allow the animal to digest phytic acid from cereal grains and soybean meal and convert it to phosphate for use by the animal. This reduces the need for supplemental phosphorus in the diet of swine and poultry. Currently, the use of phytase is not feasible due to economic and production concerns.

The ability of the animal to digest the feed can be increased by fine grinding and pelletizing feed. Fine grinding increases the surface area of the feed and thereby increases the portion digested.

Feeding can take place in the housing facility, at a separate feeding facility or feeder unit(s), and from pastureland. Other than grazing, where the animal (e.g., sheep, horses, cattle) goes to the feed, the feed is brought to the animals and placed in a feeding device. The feeding process begins with the feed being transported, by various means, from the storage areas to feeding area or unit. The method of feeding is usually related to the type of animal and the housing structure.

- Most dairy operations feed the animals between milking events and may feed the animals from feed bunks that may be covered or uncovered. Small dairy cattle operations may feed the animals during milking and place them on pasture for grazing between milkings.

- Beef (feeder) cattle operations generally feed the animals from feed bunks that may be covered or uncovered. These operations may also use feed rings for large bales of hay.

- Horses, if maintained inside, are fed from a manger and/or other feed device.

- Housed poultry and swine are generally fed continuously from feeding devices. The two major types of feeding devices for poultry and swine are self feeders, which provide the animal with a constant supply of food, and mechanical feeders, which distribute the feed to the animals at predetermined intervals.

Watering
Watering involves the operation and maintenance of animal drinking systems or access to naturally-occurring surface waters or man-made watering structures (e.g., ponds, reservoirs). It is essential that a constant or on-demand supply of water be provided for livestock.

For those housed or in other types of confined areas, there are many different types of man-made watering devices, each of which can be modified depending on the animal using the system. Some of the most commonly used systems include the following:

- *Animal-operated pumps or drinkers*. Large livestock kept in enclosed and partially enclosed housing can use animal-operated pumps or valves (nose pumps/valves). Livestock-operated on-demand watering devices allow the animal to use its nose to actuate a valve or push a pendulum unit that dispenses water. Small livestock kept in enclosed housing generally have on-demand drinkers that are actuated by the mouth or beak of the livestock.

- *Trough systems*. Large livestock kept in enclosed and partially enclosed housing can also use trough systems. In trough systems, animals drink directly from troughs or tanks. The discharge of water to the trough/tank may be float-controlled or continuous.

Many partially enclosed, open, and pasture/grazing livestock operations perform water hauling or provide access to watering sources to meet livestock watering needs.

- *Water hauling*. Water may also be provided to animals in open pastures and grazing operations through water hauling. By using a truck with a main storage tank and an easily-moved stock tank, the watering point can be relocated as necessary throughout the operation.

- *Access to privately-owned ponds or reservoirs using restricted access ramps*. For grazed cattle and pastured dairies, natural streams and other surface waters provide a source of drinking water. Many partially enclosed, open, and pasture/grazing livestock operations allow animals access to watering sources, such as privately-owned ponds or reservoirs, via restricted access ramps. Access ramps allow the animals to use the water source while minimizing erosion of the banks. While some reservoirs are supplied by natural precipitation, many use water pumping systems. Powered by gas, solar energy, and wind, these systems transport water from the water source to the reservoir or pond.

Biosecurity
Biosecurity consists of the procedures used to prevent the spread of animal diseases from one facility to another. Animal diseases can enter a facility with new animals, on equipment, and on people. Animals, equipment, and people that have recently been at another facility may pose the greatest biosecurity risk. Biosecurity procedures include such general categories as use of protective clothing, waiting periods for new animals and visitors, and cleaning.

Biosecurity is important to livestock owners because some diseases can weaken or kill large numbers of animals at an infected facility. In some cases, the only remedy available to an operation is to sacrifice an entire group of animals in order to prevent the spread of the disease to other parts of the facility or to other facilities. In other words, a failure to conduct biosecurity procedures can cause serious financial and productivity losses for a livestock operation.

The types of biosecurity procedures necessary will depend on the type of animal at a facility, the way the diseases of concern spread to and infect animals, and vulnerability of the animals to each specific disease. For example, if a group of swine has little immunity to a serious virus, and that virus can enter the facility on the skin or clothing of visitors, a facility may need to require visitors to observe a waiting period, take a shower, and change into clean clothing provided by the facility before entering. A different group of swine may have better immunity to the virus, and such biosecurity measures would be unnecessary.

Some of the general types of biosecurity procedures include:

- Controls on the introduction of new animals to a group or facility (such as quarantine periods).
- Controls on equipment entering the farm (such as washing and disinfecting crates).
- Controls on personnel entering the farm (such as requiring service personnel to stay out of animal buildings, or providing protective clothing and footwear).
- Controls on wild or domestic animal access (such as closing holes in buildings to keep undesirable animals out).
- Sanitation in animal housing areas (such as cleaning pens).
- Identification and segregation of sick animals (including adequate removal and disposal of dead animals).

The key to developing adequate biosecurity procedures is to find accurate information about animal diseases and how to prevent them. Potential sources for specific biosecurity information and recommendations include extension services and other agricultural education organizations; veterinarians and veterinary organizations; producer and industry groups; and published information in books, magazines, and World Wide Web sources.

Potential Pollution Outputs and Environmental Impacts

Feeding. When feeding, the potential pollution outputs are soil erosion due to overgrazing, animal wastes (which are partially composed of unabsorbed feed components), spilled feed during feed unloading to feed equipment and by livestock as they feed, mechanical failures with feed equipment (e.g., inoperative cutoff switch), and dust emissions during feed transport. The pollution outputs and potential environmental impacts vary based on the type and location of feed equipment and number of animals.

- *Overgrazing* can contribute to soil losses due to severe erosion, and impoverishment can change the vegetation composition and associated organisms in rangelands.

- *Surface water and groundwater contamination from concentrated wastes*. Totally enclosed feed locations (e.g., barns, poultry houses), when compared to the same livestock types in a partially sheltered or open area, may generate a larger quantity of animal waste per acre of land due to a higher concentration of livestock in a smaller area. Totally enclosed structures are protected from rainfall and should not experience the runoff of livestock wastes and wasted feed that may occur in partially sheltered and open feed locations.

- *Surface water and groundwater contamination from runoff.* Partially sheltered feed locations (e.g., dairy operation free-stall barns and covered loafing areas) and open feed locations (e.g., feeder cattle maintained in an area that has no roofed or walled structures) have a greater pollution potential due to runoff. Areas with no vegetation may experience runoff of livestock waste and spilled feed during rainfall events.

- *Air emissions (e.g., dust).* Areas with no vegetation that are dry may produce dust pollution during the transportation of feed.

Watering. The primary pollution output from watering is excess water, which most likely becomes wastewater that is contaminated with livestock wastes (e.g., manure, urine) and feed. Surface waters and groundwater can become contaminated from wastewater runoff, and surface waters can be directly contaminated with wastes (e.g., manure, urine) from livestock that are allowed access to the water (e.g., during watering).

Properly operated man-made watering systems significantly reduce the environmental impact of livestock. However, continuous watering systems that overflow and cause runoff often cause significant environmental damage. Additionally, livestock with access to creeks, rivers and other natural water sources cause environmental damage by contaminating the water with animal waste, destroying riparian habitat, and eroding the stream banks.

Pollution Prevention/Waste Minimization Techniques
There are many pollution prevention opportunities to reduce or minimize the pollution outputs and impacts from livestock feeding and watering activities. Generation of these wastes can be prevented through management practices, preventive maintenance, appropriate feedlot location, and use of waste minimization technologies.

Feeding. Wastes generated during feeding (e.g., feed spills, unused feed) can be prevented by using troughs or mechanical feeding systems that reduce feed loss and prevent contact with watering areas, weather, and the ground.

- *Use portable and/or covered feeders*. Feeders can be constructed to be portable, eliminating the problem of manure buildup that occurs around stationary feeders. For outdoor or partially enclosed feeding operations, use of covered or protected feeders prevents the feed from being exposed to rain or wind. Examples of such feeders include mineral feeding boxes, and weathervane mineral feeders.

  - A mineral feeding box is simply a trough that is raised off the ground, enclosed on three sides, and covered by a roof.

  - A weathervane mineral feeder consists of a 55-gallon drum with a cut out opening of sufficient size for the animal to reach the feed. The drum pivots on a concrete base that is heavy enough to prevent overturning by cattle or wind. A weathervane is attached to the top of the drum so the feed opening is pushed away from the wind direction, and rain is prevented from reaching the opening.

- *Use specially designed feeders*. For hay feeding operations, using feeders that are specifically designed to accept bales minimizes hay loss and prevents potential nutrient runoff.

- *Use feeders that prevent spills and contact with the ground*. Feeding racks store hay between steel bars, thus minimizing the amount of hay that an animal can pull from the rack and spill on the ground. Totally enclosed racks where the hay is located inside a rectangular or circular enclosure may have diagonally shaped bars containing the hay inside. These bars require the animal to turn its head in order to reach through and remove its head from the hay, thus significantly reducing the amount of hay the animal can pull from the feeder and spill.

Watering. Pollution prevention techniques to prevent environmental impacts from watering include the following:

- *Prevent access to surface waters.* Livestock operations can use physical barriers (e.g., fencing) to prevent animals access to surface waters (e.g., creeks, streams, rivers). This will minimize contamination of these waters caused by animal defecating directly in the water, and runoff carrying waste reaching the water.

- *Reduce excess water use and spills of water.* Preventing overflows of watering devices and excess water use during watering can prevent water becoming mixed with wastes and potential runoff.

- *Use self-watering devices.* The on-demand, self-watering systems that are used in many types of animal operations are an effective method of reducing waste as long as they are well maintained and checked frequently.

III.D. Managing Animal Wastes

Animal wastes are produced at all stages of the livestock production process, including housing, feeding, and watering. *For the purposes of this document, the term animal waste refers to animal manure, urine, and other materials that come in contact with and/or are managed with manure and urine in a typical livestock operation.* These materials may include, but are not limited to, bedding, wastewater from flushing and washdown of housing areas, lot runoff, disinfectants and cleaners, and spilled feed.

Animal manure has been recognized for centuries as an excellent source of plant nutrients and as a soil "builder" in terms of its positive benefits to soil quality. Animal manure is an excellent source of nutrients for plants because it contains most of the elements required for plant growth. Livestock operators today are managing and using manure as an important and valuable resource. If managed and used properly, manure can provide benefits for the livestock operation, such as reduced commercial fertilizer use and increased soil quality.

Overall, the amount of animal wastes to be managed can be extensive. The challenges of animal waste management have been compounded in recent years due to the growth of animal feeding operations. These types of operations have resulted in the concentration of manure production on an ever smaller land area. The consistency and volume of animal waste to be managed at a livestock operation depends on the types of animals at the facility. Generally, dairy cattle, beef cattle, swine, and sheep produce a comparatively wet waste and broiler poultry litter is dry (22-29 percent water). Laying and breeding operations are often considered to have wet manure because of how the waste is handled. Exhibit 18 provides a comparison of the manure production for various animals.

Exhibit 18. Manure Production by Animal Type

Animal Type	Weight of Manure (lbs/day/1000 lbs of animal live weight)	Percent Water Weight
Dairy Cow, Lactating	80.0	75-90
Beef Cow	63.0	20-80
Swine, Grower (40 - 220 lb)	63.4	70-85
Poultry, Broiler	80.0	22-29
Sheep	40.0	70
Horse	50.0	70

Composting Manure and Other Organic Residues, Table III, Cooperative Extension, Institute of Agriculture and Natural Resources, University of Nebraska-Lincoln, March 1997.

Types of Animal Waste Management Systems. Animal waste management systems involve the collection, transport, storage, treatment, and utilization (rather than disposal) of waste, preferably in a manner that is economically and environmentally sound. The type of system that each operation uses

> Additional management activities at livestock operations include controlling or collecting runoff from outdoor lots and waste storage; directing clean water away from lots and storage areas; and disposing of livestock mortalities.

R0074494

depends on the type of animal(s), manure moisture content, size of the operation, acreage and site, available manure utilization methods, and operator's personal preference. Additional information on animal waste management systems, including collection, storage, treatment, transfer, and utilization, can be found in Chapter 9: Agricultural Waste Management Systems of the *Agricultural Waste Management Field Handbook* (USDA, 1992) which can be accessed at http://www.ftw.nrcs.usda.gov/awmfh.html.

Using Best Management Practices. Livestock operators can implement structural and nonstructural best management practices (BMPs) to reduce the volume of animal wastes that must be managed.

- *Structural BMPs* for an animal waste management system may include roof gutters on buildings to collect and divert clean water; vegetated filter strips and riparian buffers to trap sediment; and surface water diversions to move clean water around the areas containing waste.

- *Non-structural (management) BMPs* for an animal waste management system may include reduced frequency and volume of washdown; implementation of a comprehensive nutrient management plan; relocation of manure stacks; and other site-specific land uses that do not involve construction or land movement.

III.D.1. Collecting & Transporting Animal Wastes

The most significant quantities of animal waste are generated at feeding, watering, and housing locations. Waste collection methods vary based on the type of housing and feeding operations, as well as manpower, available equipment, operator training, pen size, and manure moisture content. Some types of manure collection systems used in livestock productions are:

- *Slotted floor systems*. The slotted floor system allows the manure to drop through the slots to a storage tank or area located beneath the floor.

- *Scraping*. Scraping is the primary method of manure collection for open housing and a common method for partially enclosed housing and enclosed housing. Common scraping equipment includes small tractor operated scrapers, tractor-pulled pan scrapers, and automated alley scraper blades on a cable. The manure may be scraped into storage facilities, to treatment, or to utilization equipment.

R0074495

- *Flushing*. Flushing is often used in enclosed and partially enclosed housing. Manual or automated hydraulic flush equipment uses water to flush the manure to collection/storage pits or lagoons.

The following describes the animal waste collection and transport systems used for different types of animals.

- Dairy cattle. Dairy cattle manure is usually collected and transported from sheds and freestall barn alleys by a manual or automated hydraulic flush in warmer climates and alley scrapers in colder climates. Manure dropped in milking parlors is commonly collected by a manual hydraulic flush. Freestall barns and alleys may also have the manure collected by scraping. Manure in open areas such as corrals is primarily collected by scraping; manure in grazed areas is not collected.

- Beef cattle. Manure is usually collected from beef cattle feedlots by scraping. The feedlot area may be unpaved, partially paved around feed and watering areas, or totally paved. Though rare, if beef cattle are kept in enclosed and partially enclosed housing, manure collection is accomplished by a slotted floor system. The manure drops through the slots to a below-floor tank that provides either short-term or long-term storage. In grazed areas, the manure is not collected.

- Sheep. Sheep are primarily maintained on pasture and the manure is not collected. Manure, from sheep kept in enclosed housing, is usually collected by a slotted floor system.

- Horses. Manure from horses housed in enclosed barn stalls, is most often collected by shoveling. The manure and bedding from stalls is often removed daily and placed in stacks.

- Poultry. Poultry manure collection is generally related to the type of operation. Poultry manure is generally dry (22-29 percent water). Broiler, roaster, pullet, turkey, and some duck houses usually raise the birds on the house floor or in cages on beds of shavings, sawdust, rice hulls, or peanut hulls. The manure is allowed to accumulate on the floor where it is mixed with the bedding.

  Many of the poultry broiler houses are only cleaned out completely once a year. Often, they only remove the top two inches or so between flocks (approximately 5-6 flocks per year in broilers houses). The litter is removed with a cruster machine or a small tractor with a front bucket. In layer and duck operations, the operator commonly collects the manure by allowing it to drop through the wire-mesh cage, house floor or slotted floor to a collection area where it is usually removed by a hydraulic flush or belt scraper to a lagoon. Manure is sometimes composted, but can also be stored in stacking sheds, roofed storage areas, outside and covered or uncovered, or occasionally in ponds until it is ready for transport to a disposal or land application area.

- Goats. Goat manure is collected by manual shoveling from small pens or stalls or scraped from larger containment enclosed, partially enclosed, and open areas.

- Swine. Manure from swine in enclosed housing is often collected by allowing it to drop through a slotted floor to a storage area, or it may be collected by a manual or automated flush system. Manure from swine maintained in partially enclosed or open housing is usually collected by scraping.

In housing where animals are confined, frequent manure collection and transport are critical to livestock health. Frequent removal of wastes reduces the naturally occurring volatilization of nitrogen as ammonia and the anaerobic digestion and the subsequent release of gases in the production buildings. This reduction of pit gases, which can be fatal, and odor improves the in-house environment and employee working conditions.

Collection and transport of wastes by flushing is facilitated by slightly sloped, paved floors, alleys, or gutters. Waste collected through slotted floors and wire-mesh cages is usually transported from the below-floor/below-cage collection area by a hydraulic (water) flush or may be scraped. The flushed manure and/or litter may be transported to a storage area or treatment lagoon. Two advantages of the flush system for collecting and transporting manure are that it is non-labor intensive and it provides a safe means to remove manure from confined spaces. The flush, which can be initiated manually or cycled by timer, dosing system, tip tank, or other means, transports the manure from the collection area. Pumping is used to transport liquid and slurry wastes from collection pits to storage or treatment lagoons. High solid wastes are often collected and transported from the housing or feeding areas using tractors with scraper blades and/or bucket loaders. Manure collected in gutters is often transported by automatic scrapers. Some disadvantages of the flush system include a huge increase in the amount of manure, manure cannot be transported very far because of the high cost versus low value, large use of water, problems with overloading when land-applied, and lagoons increasing the volatilization of nitrogen.

Potential Pollution Outputs and Environmental Impacts
For manure collection and transport, the pollution outputs can include manure, urine, litter, bedding, and water. Additional outputs include ammonia emissions from the waste, odors, hair and/or feathers, pathogens, and heavy metals.

Wastewater that may leak from storage areas or transport processes could result in surface water and groundwater contamination. While waste flushing systems aid in removing manure from underground storage basins, flush systems also generate additional manure wastewater that must be managed. Adding water also increases the risk of a manure spill or runoff reaching groundwater or surface water. Frequent collection and transport of manure and collection of surface runoff assists in reducing the nutrient losses and thereby provides greater nutrient availability during utilization. Between 40 to 60 percent of manure's nitrogen content may be lost through volatilization of ammonia NH_3 while the solid manure remains on an open lot[5]. Other nonvolatile nutrients (e.g., organic nitrogen, phosphorus) may be lost through leaching and surface runoff.

Pollution Prevention/Waste Minimization Opportunities
There are many techniques available to reduce pollution caused by animal waste collection and transport activities.

- *Reduce water used in flushing systems*. Alternative technologies, such as low-flow waste flushing systems or no-flow waste scraping systems, use less water than traditional systems, and decrease the amount of liquid that is sent to be treated in the lagoon.

- *Recycle water for flushing*. To minimize the amount of wastewater generated, some means of recycling clarified wastewater for flushing may be desirable. Separation of solids from flush water can be used to reduce the solids in the recycled flush water.

[5] *Generally Accepted Agricultural and Management Practices for Manure Management and Utilization*, Table 5, Nitrogen Losses During Handling and Storage. Adopted by Michigan Agriculture Commission, Lansing, Michigan, June 1997.

III.D.2. Storing & Treating Animal Wastes

Waste Storage

Storage is the temporary containment of manure and wastes. Following collection, animal waste not immediately used may be stored in dry or wet form by various means and structures. Broiler and beef wastes are stored in dry forms while dairy and swine wastes are stored in wet forms.

- Manure stacks, bunkers, and stacking sheds are commonly used for dry wastes.

- Pits, tanks, ponds, and lagoons for liquid or slurry wastes.

Dry manure or litter is often placed in a covered or roofed area so that it does not come into contact with storm water. Storage may be short-term, usually a few days to a few weeks, or long-term, which is usually less than one year. The purpose of short-term storage is typically the retention of manure at the point of collection until transport to long-term storage or treatment. The purpose of long-term storage is retention of the waste until utilization is possible and/or appropriate as determined by the field condition, crop, weather, and other factors. Storage containment must be designed to hold the total volume of manure generated during the maximum length of time between applications. Additionally, federally regulated CAFO liquid storage units that accept storm water runoff must be sized to contain normal precipitation and runoff (less evaporation) for the storage period plus a 25-year, 24-hour storm event flow and still provide adequate freeboard. Waste storage is not treatment and any treatment that occurs is incidental.

Waste Treatment

Following collection and/or storage, livestock production facilities may treat animal wastes. Treatment may include (1) solids separation by gravity, mechanical, or vegetative methods, and (2) stabilization of the waste by anaerobic lagoons, aerobic lagoons, or composting.

- *Solids Separation.* Solids separation is a physical treatment process whereby a portion of the larger solids and fibers are removed from the manure and can be reused. Solids separation is often used preceding a storage or a treatment lagoon to slow the rate of solids accumulation in the basin. Solids separation may be accomplished by settling basins, mechanical separation, and vegetative filter strips.

- Settling basin. Solids separation, in a settling basin, is achieved by discharging the wastestream to a basin where the rate of flow is low enough to cause gravity settling of the solids.

- Mechanical solids separator. A mechanical solids separator unit may be a static screen, vibrating screen, mechanical flat belt (press), or roller press. In solids separation by static or vibrating screen, the flow is generally passed across the screen where the solids are captured and the liquid drops through. The liquid portion from the settling basin and/or mechanical separator is normally sent to storage or treatment or used to irrigate cropland. The collected solids may be used for bedding, feed, soil amendment, or compost.

- *Lagoons (Anaerobic or Aerobic)*. Lagoons can be anaerobic or aerobic (non-mechanical and mechanical), although aerobic lagoons are used less frequently. In contrast to solids separation, lagoons are biological treatment processes used to satisfy the oxygen demand (e.g., BOD, COD) and volatilize nitrogen. Lagoons can convert ammonia nitrogen to nitrate, though this is extremely rare in animal treatment systems.

  Lagoons vary in shape and size, but when properly constructed should have sufficient volume to hold the waste during the treatment period and contain normal precipitation and runoff (less evaporation) for the storage period plus a 25-year, 24-hour storm event flow and still have adequate freeboard. Lagoons should be lined either with clay, naturally occurring high clay content soils, concrete, or a synthetic liner.

  - *Anaerobic lagoons* are commonly used to treat animal waste -- particularly swine, but also cattle and layers. Because anaerobic lagoons do not require free oxygen for treatment, they are usually six to ten feet deep. Anaerobic systems are sometimes operated with two lagoons in series allowing the first lagoon to overflow via pipe or spillway to the second lagoon.

  - *Non-mechanical aerobic lagoons* are shallow, usually two to five feet deep and have a large surface area. This allows more sunlight to reach the algae, which in turn produce oxygen needed for treatment to occur. Non-mechanical aerobic lagoons are rarely used in livestock applications because they require large amounts of land.

- *Mechanical aerobic lagoons* have higher construction costs due to the aeration equipment. The aeration process is expensive to operate; however, digestion occurs at a faster rate and fewer odors are produced. Due to the additional construction and operating costs, mechanical aerobic lagoons are uncommon. Mechanically aerated lagoons are sometimes used to control odors in odor-sensitive areas. Aerobic lagoons will produce more sludge than anaerobic lagoons and thus require additional solids handling.

- *Composting.* Composting is an aerobic biological process that converts organic waste into a stable organic product that can be used onsite or transported offsite for use. Composting reduces the volume of waste and kills pathogens while preserving more of the nutrients for use by crops. The composted material improves soil fertility, tilth (tilled earth), and water holding capacity. Composting is optimized by proper ratios of carbon to nitrogen and carbon to phosphorus; moisture content; temperature; pH; and time.

  In the composting process, a bulking agent (e.g., wood chips, peanut husks, animal bedding, or other materials) is mixed with the manure to provide the proper carbon ratios. Because of its high nutrient to volume ratio, composted animal waste, or compost, is a beneficial agricultural product. Compost can be spread on paddocks, cropland, and nursery stock, or used for landscaping and home gardens. Note: Many poultry and some swine operations also use composting for carcasses.

  There are four general composting methods -- static pile, aerated static, windrow, and in-vessel.

  - Static pile method is the simplest composting operation and requires the least labor, but takes the longest time to complete the process. The static pile operation is not mixed or aerated.

  - Aerated static pile method is not mixed but usually has piping to allow air to reach the interior of the pile.

  - Windrow method involves a long narrow pile that is regularly mixed and aerated.

- In-vessel method is an enclosed operation that allows accurate control of moisture and other parameters, while containing the odors.

Potential Pollution Outputs and Environmental Impacts
During waste storage, livestock production operations may produce stack seepage and storm water runoff which should be directed to the liquid storage ponds and lagoons.

During waste treatment, the pollution outputs and impacts include releases of ammonia and other gases to the air, contaminated runoff to surface waters, leaching resulting in groundwater contamination, and odors. For lagoons, the major pollution output is wastewater that is leached to groundwater through improperly lined lagoons; discharges to surface waters due to overfilling and breakthroughs; or improper transfer of wastes between facilities resulting in surface water contamination.

Pollution Prevention/Waste Minimization Opportunities
There are pollution prevention techniques that can be used during animal waste storage and treatment activities. These include:

- *Proper location*. The location of manure storage systems should consider proximity to water bodies, floodplains, and other environmentally sensitive areas.

- *Cover wastes*. During storage, place dry manure or litter in a covered or roofed area so that it does not come into contact with storm water. When composting, impacts can be significantly reduced by maintaining the compost operation under a roof or in an enclosed area.

- *Prevent spills by regular inspections and maintenance*. Spills and overflows can be prevented by regular inspections and preventive maintenance of lagoons; never filling lagoons beyond treatment capacity; and removing sludge as needed.

- *Use vegetative filters*. Vegetative filters are often used to prevent runoff from lagoon or settling basin liquid overflow from reaching a waterbody. As the water flows across the vegetative strip, the solids drop out of the water, thus reducing

R0074502

the amount of solids that can impact the environment. Vegetative filters are effective when located near the lagoon.

- *Build a reserve lagoon.* While the installation of a reserve lagoon may not be economically viable in all situations, the potential release of lagoon contents to the environment can be reduced by maintaining a spillway to a reserve lagoon. Spillways provide for limited release of overflow, which reduces the tendency for stress-related structural failure. A reserve lagoon is an integral component of a spillway system that prevents contamination of surface water and groundwater.

- *Prevent overtopping.* In preparation of rain events or to prevent exceeding lagoon capacity, livestock operations may hire a contractor to remove liquids from lagoons that are in danger of overtopping.

III.D.3. Utilizing Animal Wastes

Animal wastes (e.g., manure and urine) can be used as sources of plant nutrients. Land application is the most common, and usually most desirable, method of utilizing manure and wastewater because of the value of the nutrients and organic matter. Land application should be planned to ensure that the proper amount of nutrients are applied in a manner that does not adversely impact the environment or endanger public health.

Benefits of Land Application of Animal Wastes. The benefits of proper application include improvement of the physical, chemical, and biological properties of the soil, as well as significant economic returns from the use of manure as a plant nutrient.

Considerations for appropriate land application should include:

R0074503

Nutrient Management Plans[6]. The primary purpose of nutrient management is to achieve the level of nutrients (e.g., nitrogen and phosphorus) required to grow the planned crop by balancing the nutrients that are already in the soil with those from other sources (e.g., manure, biosolids, commercial fertilizers) that will be applied. At a minimum, nutrient management can help prevent the application of nutrients at rates that will exceed the capacity of the soil and the planned crops to assimilate nutrients and prevent pollution.

- Comprehensive Nutrient Management Plans (CNMPs). As discussed in the *USDA-EPA Unified National Strategy for Animal Feeding Operations*, all animal feeding operations should develop and implement technically sound, economically feasible, and site-specific CNMPs to minimize impacts to water quality and public health. In general, a CNMP identifies actions or priorities that will be followed to meet clearly defined nutrient management goals at an agricultural operation. CNMPs should address, as necessary, manure and wastewater handling and storage, land application of manure and other nutrient sources, site management, record keeping, and feed management. CNMPs should also address other utilization options for manure where the potential for environmentally sound land application of manure is limited at the point where it is generated.

- *Timing and Methods of Application:* The timing and methods of application should minimize the loss of nutrients to groundwater or surface water and the loss of nitrogen to the atmosphere. Manure and wastewater application equipment should be calibrated to ensure that the quantity of material being applied is what is planned. Care must be taken when land-applying manure and wastewater to prevent it from

[6] On May 24, 1999, USDA-NRCS released the Policy for Nutrient Management and the revision to the conservation practice standard for Nutrient Management (Code 590). NRCS' directive and supporting technical guide establishes policy for nutrient management, sets forth guidance to NRCS personnel who provide nutrient management technical assistance, and for the revision of the NRCS nutrient management conservation practice standard. These two documents will provide the framework for all nutrient management plans developed by NRCS for the agricultural community, which will be tailored by State Conservationists within a two-year period. Of particular importance is the new policy as it relates to producers that may not have sufficient land available to spread manure at rates that utilize nitrogen and phosphorus and will, as a result, need to pursue off-farm utilization options.

entering streams, other water bodies, or environmentally sensitive areas.

Manure can be land applied as solids, slurries, and liquids. The type of application equipment used depends on the manure moisture content. Box spreaders are typically used for dry manure, flail spreaders and injection for slurries, and irrigation and injection for liquids. Manure application may be by the livestock operation personnel or a custom applicator.

- *Surface application*. Box and flail spreaders apply the manure to the soil surface as the spreader is pulled or driven across the field. If surface applied, the manure may then be incorporated into the soil. Incorporation within 24 hours greatly reduces ammonia volatilization thus retaining nitrogen.

- *Injection*. Injected manure is incorporated into the soil as the equipment is driven or pulled across the field.

- *Irrigation*. Many livestock operations with storage ponds or treatment lagoons use irrigation systems, portable irrigation equipment, or hire custom irrigators. Those establishments with field crops or silviculture often use portable irrigation systems such as traveling guns or center pivots. Operations with several different fields or large acreage on which to apply the waste typically use travelers. Small acreage establishments often use small-nozzle, moderate-pressure, permanent irrigation systems, because they provide low labor costs and more uniform distribution of lagoon liquids.

Potential Pollution Outputs and Environmental Impacts
While properly applied animal wastes provide nutrients and have little negative environmental consequence, improper management and use of animal wastes, such as overapplication, excessive spraying, or application during rain events or on frozen ground, may result in serious impacts to the environment.

The potential pollution outputs of land application include nutrient runoff and leaching, which may cause surface water and groundwater contamination, respectively. Pollutants of concern include (1) nitrates and nitrites that originate from oxidation of nitrogen contributed by the manure, and (2) phosphorus. Groundwater contamination is caused by the nitrates leaching from the crop root zone into the groundwater aquifer. The amount of contaminated runoff depends on factors such as what type of manure is used, how it is handled, type of crop being grown, stage of growth, weather conditions, method of application, and the amount of existing nutrients in the soil.

Overapplication or improper application of animal waste can also lead to aesthetic problems, including odors and vectors. It can also result in polluted runoff resulting in contamination of surface waters. The presence of ammonia, phosphates and organic matter in surface waters can result in increased biochemical oxygen demand and low levels of oxygen. This can cause the death of fish and other aquatic life forms. (Ohio State University, *Ohio Livestock Manure and Wastewater Guide*)

> Vectors are defined as organisms that carry pathogens from one host to another, such as insects or rats/mice.

Pollution Prevention/Waste Minimization Opportunities
In addition to land application, other manure use practices include:

- ✓ Processing and recycling through ruminant feeding programs.
- ✓ Biogas production as an energy source using anaerobic digester technologies.
- ✓ Pyrolysis processes to produce electricity, chars (materials scorched, burned, or reduced to charcoal), and industrial petrochemicals.
- ✓ Microbial and algae production as an animal feed source.
- ✓ Aerobic degradation to produce composted products.

III.E. Other Management Issues

Odor Control

Odors are typically generated throughout the livestock production process. The odor from manure can vary depending on the type and consistency of the manure, how it is stored, and how and where it is applied.

Potential Pollution Outputs and Environmental Impacts
With enclosed or partially enclosed housing areas, odors and other gases (e.g., methane, ammonia, and hydrogen sulfide gases) from animal waste can be concentrated, potentially harming the health of the

R0074506

animals and workers. When the gases are released outside, the odor can affect the surrounding areas and create nuisance problems for neighbors.

Pollution Prevention/Waste Minimization Techniques
There are several ways livestock facilities can reduce odors resulting from their operations and waste management practices. These include:

✓ *Reduce methane emissions*. One method of reducing methane emissions from livestock is to supplement the animal's diet. Scientists have found that supplementing a cow's diet with substances such as urea increases the animal's ability to digest food. With improved digestion, less fermentation takes place during digestion, and methane emissions per unit of forage have been reduced 25-75 percent. In addition, as digestion improves, productivity also improves, as dairy cows produce more milk and beef cattle fatten faster (*Information Unit on Climate Change, 1993*).

✓ *Follow BMPs for land application*. Odors from land application of manure can be minimized by following BMPs that are designed to maximize the nutrients available to the soil and crops. Many of these BMPs may be required by state or local ordinance. These practices include the following:

- Spreading manure within agronomic rates.
- When possible incorporating surface-applied manure within 24 hours.
- Spreading early in the day as the air is warming and rising; this allows the applied waste to dry which reduces odor.
- Avoiding spreading manure on windy days (i.e., blowing towards the neighbor).
- Avoiding spreading manure during holidays and weekends.
- Avoiding spreading waste near heavily traveled roads.

Managing Animal Carcasses

Dead animals should be disposed of in a way that does not adversely affect ground or surface water or create public health concerns. Composting, rendering, and other practices are common methods used to dispose of dead animals.

As with rendering plants, dead animals may be processed for use as pet food, composted, buried, or incinerated. USDA and FDA regulations prohibit the use of mortalities as feed for animals that are to be consumed by humans. *Note: State law or self-imposed industry standards may limit some of these options.* Because rendering must generally occur within 24 hours of an animal's death, it is helpful for the livestock production facility to establish rendering contacts in advance. Where this may not be possible, freezer storage could be used until such time as the rendering facility can collect the animals for processing. Some centrally located rendering facilities may provide pickup services to local livestock operations.

Animal carcass composting is another common method of handling poultry and small animal mortalities. Carcass composting typically takes more time than manure or yard waste composting, but has been shown to be an effective waste management approach. Many poultry and some swine operations use composting for carcasses. Livestock operations may use poultry compost sheds to dispose of their dead birds by mixing the dead birds with bedding and other materials.

As with manure composting, the compost process requires a carbon source to provide the proper carbon/nitrogen ratio for the necessary bacterial processes. Sawdust and straw are typically used as a carbon source due to their small particle size, ease of handling, absorbency, and high carbon content. Sawdust in excess of that required for the ideal carbon/nitrogen ratio is used in the initial stages of composting to provide adequate coverage of the carcasses. Sawdust also helps reduce odors from the composting process.

Potential Pollution Outputs and Environmental Impacts
Animal carcasses must be properly and quickly managed because they are a source of disease and can attract many vectors. Environmental impacts of carcasses depend on the management method used.

- Burial and/or pit disposal of carcasses in coarse textured soils and in areas of a high water table may contribute nutrients to groundwater.

R0074508

- Animal carcasses that are disposed of above ground or insufficiently covered can cause aesthetic and potential human health impacts including odor generation and vector attraction, such as flies and mice.

- Specifically, poultry compost houses can be a potential source of pollution if not managed properly (e.g., kept at the right temperature, moisture content, etc.) because a leachate can form and leak from the compost house.

- The rendering process generates wastewater that must be managed according to the rendering facility's NPDES permit or pretreatment permit.

Pollution Prevention/Waste Utilization Techniques

There are several techniques that can be used to minimize wastes resulting from animal mortalities. As described above, rendering or composting are considered disposal methods that prevent pollution. If these are not available, burying carcasses can be another option. The impact of burying carcasses can be minimized by burying them deep below the surface of the ground, well away and downgrade from any source of drinking water, and covered with a generous supply of quicklime to reduce soil pH before fill dirt is added. If the carcasses must be disposed of onsite, it is preferable to have:

- A burial area at least 100 meters away from houses and watercourses
- The pit base at least 38 inches above the level of the watertable
- Heavy soil of low permeability and good stability
- Good access to the site for earthmoving machinery and stock transport unless the stock are to be walked in for slaughter

> The burial of dead animals is being phased out. In fact, some states prohibit the practice, except under the most extreme circumstances.

It is important to avoid sites sloping toward watercourses and areas that are likely to drain to surface water. Many states may have more strict statutes regulating the burial of dead animals. For example, Oregon requires that the animal carcasses be buried to such a depth that no part of them are nearer than four feet to the natural surface of the ground and they are covered with quicklime and at least four feet of soil.

III.F. Pest Control

Within a livestock production establishment, pesticides may be used for a variety of purposes. They may be applied directly to livestock or to structures, such as barns and housing units, to control pests (e.g., parasites, vectors). Pesticides can also be used to control predators. Vectors are defined as organisms that carry pathogens from one host to another, such as insects or rats/mice.

Livestock. Commonly, pesticides are applied directly to livestock using high-pressure and low-pressure sprayers, mist application equipment (i.e., fumigation and foggers), and dipping vats. In addition, pesticides may be added to ear tags and to gates through which animals commonly pass (i.e., gate wipes/brushes). Spraying or fogging animals, especially high-pressure spraying, allows penetration into fur and wool to control lice, mange, wool maggots, and other parasites and vectors. Portable dipping vats are used for treating external parasites, especially of sheep and swine.

Structures. Pesticides may also be applied directly to or used in and around structures, such as barns or other types of housing units. Sprayers and foggers are the most commonly used methods to apply insecticides, rodenticides, and disinfectants, although other methods may be used, such as injected termite treatments, rat/mouse traps, or other types of insect traps. Such applications are used to control flies, beetles, and manure larvicides, among others.

Predators. Some livestock operations, especially sheep and goat operations, experience problems with predators. Historically, these problems have been addressed by operators through various methods to scare away potential predators. Such methods included scarecrows or bells. Recently, another method, livestock protection collars, have been developed to help combat predators. Livestock protection collars are placed around the necks of the livestock and contain a rubber bladder filled with a pesticide. When predators, primarily coyotes, attack livestock they go for the throat, puncture the bladder on the collar, and ingest the pesticide. The livestock are unhurt, but the coyotes ultimately die from the ingested pesticide.

Potential Pollution Outputs and Environmental Impacts
The potential environmental impacts from pesticide application are runoff or leaching to surface water or groundwater, spills to surface waters, potential human and animal exposure, overtolerance levels on animals and products, and soil contamination that could leave land unproductive. These environmental impacts may all occur if pesticides

R0074510

are not applied in accordance with the label directions. The degree of environmental impact depends on the application method.

- The application of pesticides using spray or fogger systems is more likely to involve releases to air, which may result in human and excessive animal exposure.

- If not disposed of properly, liquids from dipping vats may contaminate both surface water and groundwater.

- If not protected with backflow prevention devices, pesticides applied through spray systems that are connected to water supplies can siphon back to the water source and potentially contaminate drinking water systems.

- In addition to runoff and leaching, spills of pesticides may also negatively impact the environment. The impacts are the same as for runoff and leaching, but may be more significant since the spilled materials will be concentrated in one specific area. Also, improperly cleaned and disposed pesticide containers may cause releases to the soil and/or surface waters.

Pesticides are both suspected and known for causing immediate and delayed-onset health hazards for humans. If exposed to pesticides, humans may experience adverse effects, such as nausea, respiratory distress, or more severe symptoms up to and including death. To help reduce this potential exposure, tolerance levels have been established for residues on agricultural products. Animals and birds impacted by pesticides can experience similar illnesses or develop other types of physical distress. Following label directions for application, protective gear, and disposal will help ensure such environmental impacts do not occur.

Pollution Prevention/Waste Minimization Opportunities
Environmental impacts from pesticides can be minimized by following the label directions and preventing or minimizing their use wherever possible. Pesticide use accounts for a substantial portion of farm production costs. By reducing their use, agricultural establishments can not only reduce production costs, but also reduce environmental impacts of their operations. Pesticide use and impact can be minimized by using general good housekeeping practices, integrated pest management, and good management practices. Examples of these are presented below.

✓ **Integrated Pest Management**. Integrated pest management (IPM) is an effective and environmentally sensitive approach to pest management that relies on a combination of common-sense practices. IPM programs use current, comprehensive information on the life cycles of pests and their interaction with the environment. This information, in combination with available pest control methods, is used to manage pest damage by the most economical means, and with the least possible hazard to people, property, and the environment. Examples of IPM in the livestock production industry could include maintaining structures (e.g., plug holes, place stripping around doors and windows), good housekeeping in barns and other structures, rodent and insect traps, and use of predators (e.g., certain insects, snakes). IPM can involve the use of pesticides. In such cases, the IPM plan should indicate when a pesticide is needed, and its selection is based on persistence, toxicity, and leaching and runoff potential such that the most environmentally friendly pesticide is used.

✓ **Good Management Practices**. In addition to use consistent with the label, there are other general management practices associated with pesticides that can help reduce their environmental impact. Such practices include:

- Buy only the amount needed for a year or a growing season.
- Minimize the amount of product kept in storage.
- Calculate how much diluted pesticide will be needed for a job and mix only that amount.
- Apply pesticides with properly-calibrated equipment.
- Purchase pesticide products packaged in such a way as to minimize disposal problems.
- Work with the state to locate a pesticide handler who can use the excess pesticide.
- Return unused product to the dealer, formulator, or manufacturer.

- Implement setbacks from wellheads for application and storage.

- If possible, choose nonleachable pesticides labeled for the pest.

III.G. Maintaining and Repairing Agricultural Machinery and Vehicles

Day-to-day maintenance and repair activities keep agricultural machinery and vehicles safe and reliable. Maintenance activities include oil and filter changes, battery replacement, and repairs, including metal machining.

Potential Pollution Outputs and Environmental Impacts
The wastes from maintenance and repair activities can include used oil, spent fluids, spent batteries, metal machining wastes, spent organic solvents, and tires. These wastes have the potential to be released to the environment if not handled properly, stored in secure areas with secondary containment, protected from exposure to weather, and properly disposed of. If released to the environment, the impact of these releases can be contamination of surface waters, groundwater, and soils, as well as toxic releases to the atmosphere. Groundwater pollution can also result from discharges of wastes to Class V wells.

Pollution Prevention/Waste Minimization Opportunities
Preventive maintenance programs can minimize waste generation, increase equipment life, and minimize the probability of significant impacts and accidents. Where the wastes cannot be eliminated, safe handling and recycling can minimize environmental impacts. The following presents pollution prevention/waste minimization opportunities for each type of waste.

Used Oil. The impact of oil changes can be minimized by preventing releases of used oil to the environment, and recycling or reusing used oil whenever possible. Spills can be prevented by using containment around used oil containers, keeping floor drains closed when oil is being drained, and by training employees on spill prevention techniques. Oil that is contained rather than released can be recycled, thus saving money, and protecting the environment.

Recycling used oil requires equipment like a drip table with a used oil collection bucket to collect oil dripping from parts. Drip pans can be placed under machinery and vehicles awaiting repairs to capture any leaking fluids. By using catch pans or buckets, rather than absorbent materials to contain leaks or spills of used oil, the used oil can be more easily recycled. To encourage recycling, the publication "How To Set Up A Local Program To Recycle Used Oil" is available at no cost from the RCRA/Superfund Hotline at 1-800-424-9346 or 1-703-412-9810.

Proper Disposal of Oil-Based Fluids. Spent petroleum-based fluids and solids should be sent to a recycling center whenever possible. Solvents that are hazardous waste must not be mixed with used oil or, under RCRA regulations, the entire mixture may be considered hazardous waste. Non-listed hazardous wastes can be mixed with waste oil, and as long as the resulting mixture is not hazardous, can be handled as waste oil. All used drip pans and containers should be properly labeled.

Spent Fluids. Farm machinery and vehicles require regular changing of fluids, including oil, coolant, and others. To minimize releases to the environment, these fluids should be drained and replaced in areas where there are no connections to storm drains or municipal sewers. Minor spills should be cleaned up prior to reaching drains. Used fluid should be collected and stored in separate containers. Fluids can often be recycled. For example, brake fluid, transmission fluid, and gear oil are recyclable. Some liquids are able to be legally mixed with used motor oil which, in turn, can be reclaimed.

During the process of engine maintenance, spills of fluids are likely to occur. The "dry shop" principle encourages spills to be cleaned immediately so that spilled fluid will not evaporate to air, be transported to soil, or be discharged to waterways or sewers. The following techniques help prevent and minimize the impact of spills:

✓ Collect leaking or dripping fluids in designated drip pans or containers. Keep all fluids separated so they may be properly recycled.

✓ Keep a designated drip pan under the vehicle while unclipping hoses, unscrewing filters, or removing other parts. The drip pan prevents splattering of fluids and keeps chemicals from penetrating the shop floor or outside area where the maintenance is occurring.

✓ Immediately transfer used fluids to proper containers. Never leave drip pans or other open containers unattended.

Radiator fluids are often acceptable to antifreeze recyclers. This includes fluids used to flush out radiators during cleaning. Reusing the flushing fluid minimizes waste discharges. If a licensed recycler does not accept the spent flushing fluids, consider changing to another brand of fluid that can be recycled.

Batteries. Farm operators have three options for managing used batteries: recycling through a supplier, recycling directly though a battery reclamation facility, or direct disposal. Most suppliers now accept spent batteries at the time of new battery purchase. While some waste batteries must be handled as hazardous waste, lead acid batteries are not considered hazardous waste as long as they are recycled. In general, recycling batteries may reduce the amount of hazardous waste stored at a farm, and thus reduce the farm's responsibilities under RCRA.

The following best management practices are recommended to prevent used batteries from impacting the environment prior to disposal:

- ✓ Place on pallets and label by battery type (e.g., lead-acid, nickel, and cadmium).
- ✓ Protect them from the weather with a tarp, roof, or other means.
- ✓ Store them on an open rack or in a watertight secondary containment unit to prevent leaks.
- ✓ Inspect them for cracks and leaks as they come to the farm. If a battery is dropped, treat it as if it is cracked. Acid residue from cracked or leaking batteries is likely to be hazardous waste under RCRA because it is likely to demonstrate the characteristic of corrosivity, and may contain lead and other metals.
- ✓ Neutralize acid spills and dispose of the resulting waste as hazardous if it still exhibits a characteristic of a hazardous waste.
- ✓ Avoid skin contact with leaking or damaged batteries.

Machine Shop Wastes. The major hazardous wastes from metal machining are waste cutting oils, spent machine coolant, and degreasing solvents. Scrap metal can also be a component of hazardous waste produced at a machine shop. Material substitution and recycling are the two best means to reduce the volume of these wastes.

The preferred method of reducing the amount of waste cutting oils and degreasing solvents is to substitute with water-soluble cutting oils. If non-water-soluble oils must be used, recycling waste cutting oil reduces the potential environmental impact. Machine coolant can be recycled, either by an outside recycler, or through a number of in-house systems. Coolant recycling is most easily implemented when a standardized type of coolant is used throughout the shop. Reuse and recycling of solvents also is easily achieved, although it is generally done by a permitted recycler. Most shops collect scrap metals from machining operations and sell these to metal recyclers. Metal chips which have been removed from the coolant by filtration can be included in the scrap metal collection. Wastes should be carefully segregated to facilitate reuse and recycling.

III.H. Fuel Use and Fueling Activities

Fuel is used to operate agricultural machinery, equipment, and vehicles that are used throughout the livestock operation. Agricultural machinery and vehicles are typically fueled using an above ground fueling dispenser that is connected to an above ground or underground fuel tank.

Potential Pollution Outputs and Environmental Impacts
Agricultural machinery and vehicles that use fuel most likely emit pollutants to the atmosphere. The activity of fueling itself can emit air pollutants, and spills of fuel can cause water, soil and groundwater contamination. Underground fueling systems that are not monitored or maintained properly can leak into the surrounding soils and eventually contaminate groundwater.

Pollution Prevention/Waste Minimization Opportunities
Properly maintaining fuel tanks, lines, and fueling systems can substantially reduce the probability of accidental fuel spills or leaks. All leaking pipe joints, nozzle connections, and any damage to the fueling hose (e.g., kinks, crushing, breaks in the carcass, bulges, blistering, soft spots at the coupling, deep cracks or cuts, spots wet with fuel, or excessive wear) should be fixed immediately to reduce the amount of pollution to the environment. Spill and overflow protection devices can be installed to prevent fuel spills and secondary

containment can be used to contain spills or leaks. Additional pollution prevention techniques for fueling include the following:

- ✓ Inspect fueling equipment daily to ensure that all components are in satisfactory condition. While refueling, check for leaks.
- ✓ If refueling occurs at night, make sure it is carried out in a well-lighted area.
- ✓ Never refuel during maintenance as it might provide a source of ignition to fuel vapors.
- ✓ Do not leave a fuel nozzle unattended during fueling or wedge or tie the nozzle trigger in the open position.
- ✓ Discourage topping off of fuel tanks.

THIS PAGE LEFT INTENTIONALLY BLANK

IV. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulatory requirements.

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute. For specific agricultural information, contact The National Agricultural Compliance Assistance Center at (888) 663-2155 or visit the website at http://www.epa.gov/agriculture.

IV.A. General Description of Major Statutes

Clean Water Act

The primary objective of the Federal Water Pollution Control Act Amendments of 1972, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA are classified as either "toxic" pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; or "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and "indirect" dischargers (those who discharge to publicly owned treatment works). The National Pollutant Discharge Elimination System (NPDES) permitting program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized state (EPA has authorized 43 states and 1 territory to administer the NPDES program), contain industry-specific, technology-based water quality limits and establish pollutant monitoring and reporting requirements. A facility that proposes to discharge into the nation's waters must obtain a permit prior to initiating a discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

Water quality-based discharge limits are based on federal or state water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technology-based standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from state to state, and site to site, depending on the use classification of the receiving body of water. Most states follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated NPDES permitting regulations for storm water discharges. These regulations require that facilities with the following types of storm water discharges, among others, apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the state determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR §122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; SIC 311-leather tanning and finishing; SIC 32 (except 323)-stone, clay, glass, and concrete; SIC 33-primary metals; SIC 3441-fabricated structural metal; and SIC 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products;

SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program
Another type of discharge that is regulated by the CWA is one that goes to a publicly owned treatment works (POTW). The national pretreatment program (CWA § 307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a state is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than federal standards.

Wetlands
Wetlands, commonly called swamps, marshes, fens, bogs, vernal pools, playas, and prairie potholes, are a subset of "waters of the United States," as defined in Section 404 of the CWA. The placement of dredge and fill material into wetlands and other water bodies (i.e., waters of the United States) is regulated by the U.S. Army Corps of Engineers (Corps) under 33 CFR Part 328. The Corps regulates wetlands by administering the CWA Section 404 permit program for activities that impact wetlands. EPA's authority under Section 404 includes veto power of Corps permits, authority to interpret statutory exemptions and jurisdiction, enforcement actions, and delegating the Section 404 program to the states.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed *through the Ground Water and Drinking Water resource center, at (202) 260-7786.*

Oil Pollution Prevention Regulation
Section 311(b) of the CWA prohibits the discharge of oil, in such quantities as may be harmful, into the navigable waters of the United States and adjoining shorelines. The EPA Discharge of Oil regulation, 40 CFR Part 110, provides information regarding these discharges. The Oil Pollution Prevention regulation, 40 CFR Part 112, under the authority of Section 311(j) of the CWA, requires regulated facilities to prepare and implement Spill Prevention Control and Countermeasure (SPCC) plans. The intent of a SPCC plan is to prevent the discharge of oil from onshore and offshore non-transportation-related facilities. In 1990 Congress passed the Oil Pollution Act which amended Section 311(j) of the CWA to require facilities that because of their location could reasonably be expected to cause "substantial harm" to the environment by a discharge of oil to develop and implement Facility Response Plans (FRP). The intent of a FRP is to provide for planned responses to discharges of oil.

A facility is SPCC-regulated if the facility, due to its location, could reasonably be expected to discharge oil into or upon the navigable waters of the United States or adjoining shorelines, and the facility meets one of the following criteria regarding oil storage: (1) the capacity of any aboveground storage tank exceeds 660 gallons, or (2) the total aboveground storage capacity exceeds 1,320 gallons, or (3) the underground storage capacity exceeds 42,000 gallons. 40 CFR § 112.7 contains the format and content requirements for a SPCC plan. In New Jersey, SPCC plans can be combined with DPCC plans, required by the state, provided there is an appropriate cross-reference index to the requirements of both regulations at the front of the plan.

According to the FRP regulation, a facility can cause "substantial harm" if it meets one of the following criteria: (1) the facility has a total oil storage capacity greater than or equal to 42,000 gallons and transfers oil over water to or from vessels; or (2) the facility has a total oil storage capacity greater than or equal to 1 million gallons and meets any one of the following conditions: (i) does not have adequate secondary containment, (ii) a discharge could cause "injury" to fish and wildlife and sensitive environments, (iii) shut down a public drinking water intake, or (iv) has had a reportable oil spill greater than or equal to 10,000 gallons in the past 5 years. Appendix F of 40 CFR Part 112 contains the format and content requirements for a FRP. FRPs that meet EPA's requirements can be combined with U.S. Coast Guard FRPs or other contingency plans, provided there is an appropriate cross-reference index to the requirements of all applicable regulations at the front of the plan.

For additional information regarding SPCC plans, contact EPA's RCRA, Superfund, and EPCRA Hotline, at (800) 424-9346. Additional documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Coastal Zone Management Act

The Coastal Zone Management Act (CZMA) encourages states/tribes to preserve, protect, develop, and where possible, restore or enhance valuable natural coastal resources such as wetlands, floodplains, estuaries, beaches, dunes, barrier islands, and coral reefs, as well as the fish and wildlife using those habitats. It includes areas bordering the Atlantic, Pacific, and Arctic Oceans, Gulf of Mexico, Long Island Sound, and Great Lakes. A unique feature of this law is that participation by states/tribes is voluntary.

In the Coastal Zone Management Act Reauthorization Amendments (CZARA) of 1990, Congress identified nonpoint source pollution as a major factor in the continuing degradation of coastal waters. Congress also recognized that effective solutions to nonpoint source pollution could be implemented at the state/tribe and local levels. In CZARA, Congress added Section 6217 (16 U.S.C. § 1455b), which calls upon states/tribes with federally-approved coastal zone management programs to develop and implement coastal nonpoint pollution control programs. The Section 6217 program is administered at the federal level jointly by EPA and the National Oceanic and Atmospheric Agency (NOAA).

Section 6217(g) called for EPA, in consultation with other agencies, to develop guidance on "management measures" for sources of nonpoint source pollution in coastal waters. Under Section 6217, EPA is responsible for developing technical guidance to assist states/tribes in designing coastal nonpoint pollution control programs. On January 19, 1993, EPA issued its *Guidance Specifying Management Measures For Sources of Nonpoint Pollution in Coastal Waters*, which addresses five major source categories of nonpoint pollution: (1) urban runoff, (2) agriculture runoff, (3) forestry runoff, (4) marinas and recreational boating, and (5) hydromodification.

Additional information on coastal zone management may be obtained from EPA's Office of Wetlands, Oceans, and Watersheds at http://www.epa.gov/owow or from the Watershed Information Network at http://www.epa.gov/win. The NOAA website at http://www.nos.noaa.gov/ocrm/czm/ also contains additional information on coastal zone management.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint federal-state system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of fluid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized states enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set generally as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is often state/tribe-enforced, since EPA has authorized many states/tribes to administer the program. Currently, EPA shares the UIC permit program responsibility in seven states and completely runs the program in 10 states and on all tribal lands.

The SDWA also provides for a federally-implemented Sole Source Aquifer program, which prohibits federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a state-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

The SDWA Amendments of 1996 require states to develop and implement source water assessment programs (SWAPs) to analyze existing and potential threats to the quality of the public drinking water throughout the state. Every state is required to submit a program to EPA and to complete all assessments within 3 ½ years of EPA approval of the program. SWAPs include: (1) delineating the source water protection area, (2) conducting a contaminant source inventory, (3) determining the susceptibility of the public water supply to contamination from the inventories sources, and (4) releasing the results of the assessments to the public.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding federal holidays. Visit the website at www.epa.gov/ogwdw for additional material.

Resource Conservation and Recovery Act

The Solid Waste Disposal Act (SWDA), as amended by the Resource Conservation and Recovery Act (RCRA) of 1976, addresses solid and hazardous waste management activities. The Act is commonly referred to as RCRA. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (discarded commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. A hazardous waste facility may accumulate hazardous waste for up to 90 days (or 180 days depending on the amount generated per month) without a permit or interim status. Generators may also treat hazardous waste in accumulation tanks or containers (in accordance with the requirements of 40 CFR 262.34) without a permit or interim status.

Facilities that treat, store, or dispose of hazardous waste are generally required to obtain a RCRA permit. Subtitle C permits for treatment, storage, or disposal facilities contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Subparts I and S) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA treatment, storage, or disposal facilities.

Although RCRA is a federal statute, many states implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 states and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Criteria for Classification of Solid Waste Disposal Facilities and Practices** (40 CFR Part 257) establishes the criteria for determining which solid waste disposal facilities and practices pose a reasonable probability of adverse effects on health or the environment. The criteria were adopted to ensure non-municipal, non-hazardous waste disposal units that receive conditionally exempt small quantity generator waste do not present risks to human health and environment.

- **Criteria for Municipal Solid Waste Landfills** (40 CFR Part 258) establishes minimum national criteria for all municipal solid waste landfill units, including those that are used to dispose of sewage sludge.

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) establishes the standard to determine whether the material in question is considered a solid waste and, if so, whether it is a hazardous waste or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste on-site for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including large quantity generators accumulating waste prior to shipment offsite.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that were to be met by December 22, 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and, in some cases, restrict the type of waste that may be burned.

EPA's RCRA, Superfund, and EPCRA Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. Additional documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response or remediation costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more federal or state emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for cleanups. The National Priorities List (NPL) currently includes approximately 1,300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct cleanups and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. Documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The Superfund Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by state and local governments. Under EPCRA, states establish State Emergency Response Commissions (SERCs), responsible for coordinating certain emergency

response activities and for appointing Local Emergency Planning Committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA § 302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance at the facility in an amount in excess of the established threshold planning quantity. The list of extremely hazardous substances and their threshold planning quantities is found at 40 CFR Part 355, Appendices A and B.

- **EPCRA § 303** requires that each LEPC develop an emergency plan. The plan must contain (but is not limited to) the identification of facilities within the planning district, likely routes for transporting extremely hazardous substances, a description of the methods and procedures to be followed by facility owners and operators, and the designation of community and facility emergency response coordinators.

- **EPCRA § 304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance (defined at 40 CFR 302) or an EPCRA extremely hazardous substance.

- **EPCRA § 311 and § 312** requires a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA § 313** requires certain covered facilities, including SIC codes 20 through 39 and others, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media. EPA maintains the data reported in a publically accessible database known as the Toxics Release Inventory (TRI).

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. Documents and resources can be obtained from the hotline's homepage at http://www.epa.gov/epaoswer/hotline. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the states to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAA, many facilities are required to obtain operating permits that consolidate their air emission requirements. State and local governments oversee, manage, and enforce many of the requirements of the CAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are designated as attainment areas; those that do not meet NAAQSs are designated as non-attainment areas. Under §110 and other provisions of the CAA, each state must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and will become effective in 2001.

Title I also authorizes EPA to establish New Source Performance Standards (NSPS), which are nationally uniform emission standards for new and modified stationary sources falling within particular industrial categories. The NSPSs are based on the pollution control technology available to that category of industrial source (*see* 40 CFR Part 60).

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented toward controlling specific hazardous air pollutants (HAPs). Section 112(c) of the CAA further directs EPA to develop a list of sources that emit any of

188 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 185 source categories and developed a schedule for the establishment of emission standards. The emission standards are being developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV-A establishes a sulfur dioxide and nitrogen oxides emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances that are set below previous levels of sulfur dioxide releases.

Title V of the CAA establishes an operating permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States have developed the permit programs in accordance with guidance and regulations from EPA. Once a state program is approved by EPA, permits are issued and monitored by that state.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restricting their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), were phased out (except for essential uses) in 1996. Methyl bromide, a common pesticide, has been identified as a significant stratospheric ozone depleting chemical. The production and importation of methyl bromide, therefore, is currently being phased out in the United States and internationally. As specified in the Federal Register of June 1, 1999 (Volume 64, Number 104) and in 40 CFR Part 82, methyl bromide production and importation will be reduced from 1991 levels by 25 percent in 1999, by 50 percent in 2001, by 70 percent in 2003, and completely phased out by 2005. Some uses of methyl bromide such as the production, importation, and consumption of methyl bromide to fumigate commodities entering or leaving the United States or any state (or political subdivision thereof) for purposes of compliance with Animal and Plant Health Inspection Service requirements or with any international, federal, state, or local sanitation or food protection standard, will be exempt from this rule. After 2005, exceptions may also be made for critical agricultural uses. The United

States EPA and the United Nations Environment Programme have identified alternatives to using methyl bromide in agriculture. Information on the methyl bromide phase-out, including alternatives, can be found at the EPA Methyl Bromide Phase-Out Website:
(http://www.epa.gov/docs/ozone/mbr/mbrqa.html).

EPA's Clean Air Technology Center, at (919) 541-0800 and at the Center's homepage at http://www.epa.gov/ttn/catc, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996 and at http://www.epa.gov/ozone, provides general information about regulations promulgated under Title VI of the CAA; EPA's EPCRA Hotline, at (800) 535-0202 and at http://www.epa.gov/epaoswer/hotline, answers questions about accidental release prevention under CAA §112(r); and information on air toxics can be accessed through the Unified Air Toxics website at http://www.epa.gov/ttn/uatw. In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

Federal Insecticide, Fungicide, and Rodenticide Act

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) was first passed in 1947, and amended numerous times, most recently by the Food Quality Protection Act (FQPA) of 1996. FIFRA provides EPA with the authority to oversee, among other things, the registration, distribution, sale and use of pesticides. The Act applies to all types of pesticides, including insecticides, herbicides, fungicides, rodenticides and antimicrobials. FIFRA covers both intrastate and interstate commerce.

Establishment Registration
Section 7 of FIFRA requires that establishments producing pesticides, or active ingredients used in producing a pesticide subject to FIFRA, register with EPA. Registered establishments must report the types and amounts of pesticides and active ingredients they produce. The Act also provides EPA inspection authority and enforcement authority for facilities/persons that are not in compliance with FIFRA.

Product Registration
Under §3 of FIFRA, all pesticides (with few exceptions) sold or distributed in the United States must be registered by EPA. Pesticide registration is very specific and generally allows use of the product only as specified on the label. Each registration specifies the use site, i.e., where the product may be used, and the amount that may be applied. The person who seeks to register the pesticide must file an application for registration. The application process

often requires either the citation or submission of extensive environmental, health or safety data.

To register a pesticide, the EPA Administrator must make a number of findings, one of which is that the pesticide, when used in accordance with widespread and commonly recognized practice, will not generally cause unreasonable adverse effects on the environment.

FIFRA defines "unreasonable adverse effects on the environment" as "(1) any unreasonable risk to man or the environment, taking into account the economic, social, and environmental costs and benefits of the use of the pesticide, or (2) a human dietary risk from residues that result from a use of a pesticide in or on any food inconsistent with the standard under §408 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 346a)."

Under FIFRA § 6(a)(2), after a pesticide is registered, the registrant must also notify EPA of any additional facts and information concerning unreasonable adverse environmental effects of the pesticide. Also, if EPA determines that additional data are needed to support a registered pesticide, registrants may be requested to provide additional data. If EPA determines that the registrant(s) did not comply with their request for more information, the registration can be suspended under FIFRA § 3(c)(2)(B) and § 4.

Use Restrictions
As a part of the pesticide registration, EPA must classify the product for general use, restricted use, or general for some uses and restricted for others (Miller, 1993). For pesticides that may cause unreasonable adverse effects on the environment, including injury to the applicator, EPA may require that the pesticide be applied either by or under the direct supervision of a certified applicator.

Reregistration
Due to concerns that much of the safety data underlying pesticide registrations becomes outdated and inadequate, in addition to providing that registrations be reviewed every 15 years, FIFRA requires EPA to reregister all pesticides that were registered prior to 1984 (§ 4). After reviewing existing data, EPA may approve the reregistration, request additional data to support the registration, cancel, or suspend the pesticide.

Tolerances and Exemptions
A tolerance is the maximum amount of pesticide residue that can be on a raw product and still be considered safe. Before EPA can register a pesticide that is used on raw agricultural products, it must grant a tolerance or exemption from a tolerance (40 CFR.163.10 through 163.12). Under the Federal Food,

Drug, and Cosmetic Act (FFDCA), a raw agricultural product is deemed unsafe if it contains a pesticide residue, unless the residue is within the limits of a tolerance established by EPA or is exempt from the requirement.

Cancellation and Suspension
EPA can cancel a registration if it is determined that the pesticide or its labeling does not comply with the requirements of FIFRA or causes unreasonable adverse effects on the environment (Haugrud, 1993).

In cases where EPA believes that an "imminent hazard" would exist if a pesticide were to continue to be used through the cancellation proceedings, EPA may suspend the pesticide registration through an order and thereby halt the sale, distribution, and usage of the pesticide. An "imminent hazard" is defined as an unreasonable adverse effect on the environment or an unreasonable hazard to the survival of a threatened or endangered species that would be the likely result of allowing continued use of a pesticide during a cancellation process.

When EPA believes an emergency exists that does not permit a hearing to be held prior to suspending, EPA can issue an emergency order that makes the suspension immediately effective.

Imports and Exports
Under FIFRA §17(a), pesticides not registered in the United States and intended solely for export are not required to be registered provided that the exporter obtains and submits to EPA, prior to export, a statement from the foreign purchaser acknowledging that the purchaser is aware that the product is not registered in the United States and cannot be sold for use there. EPA sends these statements to the government of the importing country. FIFRA sets forth additional requirements that must be met by pesticides intended solely for export. The enforcement policy for exports is codified at 40 CFR 168.65, 168.75, and 168.85.

Under FIFRA §17(c), imported pesticides and devices must comply with United States pesticide law. Except where exempted by regulation or statute, imported pesticides must be registered. FIFRA §17(c) requires that EPA be notified of the arrival of imported pesticides and devices. This is accomplished through the Notice of Arrival (NOA) (EPA Form 3540-1), which is filled out by the importer prior to importation and submitted to the EPA regional office applicable to the intended port of entry. United States Customs regulations prohibit the importation of pesticides without a completed NOA. The EPA-reviewed and signed form is returned to the importer for presentation to United States Customs when the shipment arrives in the United States. NOA forms can be obtained from contacts in the EPA Regional Offices or www.epa.gov/oppfead1/international/noalist.htm.

Additional information on FIFRA and the regulation of pesticides can be obtained from a variety of sources, including EPA's Office of Pesticide Programs homepage at www.epa.gov/pesticides, EPA's Office of Compliance, Agriculture Division at http://es.epa.gov/oeca/main/offices/division/ag.html or The National Agriculture Compliance Assistance Center toll-free at 888-663-2155 or http://www.epa.gov/agriculture. Other sources include the National Pesticide Telecommunications Network toll-free at 800-858-7378 and the National Antimicrobial Information Network toll-free at 800-447-6349.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk. It is important to note that pesticides as defined in FIFRA are not included in the definition of a "chemical substance" when manufactured, processed, or distributed in commerce for use as a pesticide.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical substance is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA § 6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under § 6 authority are asbestos, chlorofluorocarbons (CFCs), lead, and polychlorinated biphenyls (PCBs).

Under TSCA § 8(e), EPA requires the producers and importers (and others) of chemicals to report information on a chemicals' production, use, exposure, and risks. Companies producing and importing chemicals can be required to report unpublished health and safety studies on listed chemicals and to collect and record any allegations of adverse reactions or any information indicating that a substance may pose a substantial risk to humans or the environment.

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding federal holidays.

IV.B. Industry-Specific Requirements for Agricultural Livestock Production Industry

The agricultural livestock production industry discussed in this notebook is regulated by several different federal, state, and local agencies. EPA has traditionally relied on delegation to states to meet environmental standards, in many cases without regard to the methods used to achieve certain performance standards. This has resulted in states with more stringent air, water, and hazardous waste requirements than the federal minimum requirements. This document does not attempt to discuss state standards, but rather highlights relevant federal laws and proposals that affect the agricultural livestock production industry.

Clean Water Act

Under the CWA, there are five program areas that potentially affect agricultural establishments and businesses. These include: point source discharges, storm water discharges, nonpoint source pollution, wetland regulation, and sludge management. Key provisions addressing each of these areas are summarized below:

- **Point Source Discharges**: The CWA establishes a permitting program known as the NPDES program for "point sources" of pollution. The term "point source" includes facilities from which pollutants are or may be discharged to waters of the United States and is further defined at 40 CFR Part 122. If granted, the permit will place limits and conditions on the proposed discharges based on the performance of available control technologies and on any applicable (more stringent) water quality considerations. Usually the permit also will require specific compliance measures, establish schedules, and specify monitoring and reporting requirements.
  - **Concentrated Animal Feeding Operations (CAFOs):** The CWA defines CAFOs as point sources. Therefore, CAFOs are subject to the NPDES permitting program. See 40 CFR Part 122.23 and 40 CFR 122 Appendix B. A CAFO is prohibited

R0074537

from discharging pollutants to waters of the U.S. unless it has obtained an NPDES permit for the discharge.

- Definition of an AFO – An AFO is defined in EPA regulations as a lot or facility where (1) animals have been, are, or will be stabled or confined and fed or maintained for a total of 45 days or more in any 12-month period, and (2) crops, vegetation, forage growth, or post-harvest residues are not sustained in the normal growing season over any portion of the lot or facility.

- Definition of a CAFO – CAFOs are a subset of all AFOs. Whether an AFO is a CAFO under the regulations depends on the number of animals confined at the facility. A CAFO is defined as follows:

  (1) More than 1,000 AUs are confined at the facility [40 CFR 122, Appendix B (a)]; **OR**

  (2) ***From 301 to 1,000 AUs*** are confined at the facility and:

  - Pollutants are discharged into waters of the U.S. through a man-made ditch, flushing system, or other similar man-made device; or

  - Pollutants are discharged directly into waters of the U.S. that originate outside of and pass over, across, or through the facility or come into direct contact with the confined animals. [40 CFR 122, Appendix B (b)] OR

  (3) The facility has been **designated as a CAFO** by the permitting authority on a ***case-by-case basis*** [40 CFR 122.23(c)], based on the permitting authority's determination that the operation is a "significant contributor of pollution." In making this determination, the permitting authority considers the following factors:

  - Size of the operation;
  - Amount of waste reaching waters of the United States;
  - Location of the operation relative to waters of the U.S.;

- The means of conveyance of animal wastes and process wastewater into waters of the United States;
- The slope, vegetation, rainfall, and other factors affecting the likelihood or frequency of discharge of animal wastes and process wastewater into waters of the U.S.; and
- Other relevant factors (e.g.,waste handling and storage, land application timing, methods, rates and areas, etc.).

A permit application shall not be required from a concentrated animal feeding designated under the case-by-case authority until after the Director has conducted an on-site inspection and determined that the operation should and could be regulated under the NPDES permit program.

No animal feeding operation with less than the number of animals set forth in 40 CFR 122, Appendix B shall be designated as a concentrated animal feeding operation unless either (1) pollutants are discharged into waters of the U.S. through a manmade ditch, flushing system, or other similar means, or (2) pollutants are discharged directly into waters of the U.S. which originate outside of the facility and pass over, across, or through the facility, or otherwise come into direct contact with the animals confined in the operation.

The NPDES permit regulations [40 CFR 122, Appendix B] contain an exemption for any AFO from being defined as a CAFO if it discharges only in the event of a 25 year, 24-hour, or larger, storm event. To be eligible for an exemption, the facility must demonstrate to the permitting authority that it has not had a discharge. It must also demonstrate that the entire facility is designed, constructed, and operated to contain a storm event of this magnitude in addition to process wastewater. An operation that qualifies for this exemption from being defined as a CAFO may still be designated as a CAFO by the permitting authority on a case-by-case basis.

A 25-year, 24-hour rainfall event means the maximum precipitation event with a probable occurrence of once in 25 years, as defined by the National Weather Service in Technical Paper Number 40, "Rainfall Frequency Atlas of the United States," May 1961, and subsequent amendments, or equivalent regional or state rainfall probability information developed therefrom [40 CFR Part 412.11(e)].

- **Storm Water Discharges:** Under 40 CFR §122.2, the definition of "point source" excludes agricultural storm water runoff. Thus, such runoff is not subject to the storm water permit application regulations at 40 CFR §122.26. Non-agricultural storm water discharges, however, are regulated if the discharge results from construction over 5 acres or certain other types of industrial activity such as landfills, automobile junk yards, vehicle maintenance facilities, etc.

  - **Concentrated Aquatic Animal Production Facilities**. Under 40 CFR Part 122.24, a *concentrated aquatic animal production facility* is defined and designated as a point source subject to the NPDES permit program.

    - Definition of concentrated aquatic animal production facility (40 CFR Part 122 Appendix C) -- A *concentrated aquatic animal production facility* is a hatchery, fish farm, or other facility that meets one of the following criteria:

      (1) A facility that contains, grows, or holds cold water fish species or other cold water aquatic animals in ponds, raceways, or similar structures which discharge at least 30 days per year. The term does not include (a) facilities which produce less than 9,090 harvest weight kilograms (approximately 20,000 pounds) of aquatic animals per year, and (b) facilities which feed less than 2,272 kilograms (approximately 5,000 pounds) of food during the calendar month of maximum feeding. Cold water aquatic animals include, but are not limited to, the *salmonidae* family (e.g., trout and salmon).

      (2) A facility that contains, grows, or holds warm water fish species or other warm water aquatic animals in

R0074540

ponds, raceways, or similar structures which discharge at least 30 days per year. The term does not include (a) facilities which produce less than 45,454 harvest weight kilograms (approximately 100,000 pounds) of aquatic animals per year or (b) closed ponds which discharge only during periods of excess runoff. Warm water aquatic animals include, but are not limited to, the *Ameiuridae*, *Centrarchidae*, and *Cyprinidae* families of fish (e.g., respectively catfish, sunfish, and minnows).

Designated facility -- A facility that does not otherwise meet the criteria in 40 CFR Part 122 Appendix C (described above) may be *designated* as a concentrated aquatic animal production facility if EPA or an authorized state determines the production facility is a significant contributor of pollution to waters of the U.S. No permit is required for such a designated facility until the EPA or state officials have conducted an onsite inspection and determined that the facility should be regulated under the NPDES permit program.

- **Aquaculture Projects**. Under 40 CFR Part 122.25(b), *aquaculture* means a defined, managed water area that uses discharges of pollutants to maintain or produce harvestable freshwater, estuarine, or marine plants or animals. Discharges into approved aquaculture projects are not required to meet effluent limitations that might otherwise apply. The entire aquaculture project (discharges into and out of the project) is addressed in an NPDES permit.

Wastewater Effluent Guidelines for Dairy Product Processing Establishments. Under 40 CFR Part 405, discharges from twelve categories of dairy products processing are subject to the NPDES permit program. Effluent limitations are established for BOD, TSS, and pH. The effluent guidelines establish technology-based pretreatment standards and effluent limitations for each category.

- **Wastewater Effluent Guidelines for Feedlots (CAFOs)**. Under 40 CFR Part 412, feedlot (beef cattle, dairy cattle, swine, sheep, etc.) point sources are subject to the NPDES permit program. The effluent guidelines establish technology-based pretreatment standards and effluent limitations for this category. In general, the current guidelines for feedlots prohibit any discharge of process wastewater to navigable waters, except in the case of a 25-year, 24-hour rainfall event. CAFOs over 1,000 animal units with NPDES permits may discharge pollutants when chronic or catastrophic rainfall events cause an overflow from a facility designed, constructed, and operated to contain all process wastewater plus the runoff from a 25-year, 24-hour storm for the location of the point source.

- **Nonpoint Source Pollution**. Under the CWA §319 Nonpoint Source (NPS) Management Program and 40 CFR §130.6, states (tribes, and territories) establish programs to manage NPS pollution, including runoff and leaching of fertilizers and pesticides, and irrigation return flows. These NPS management programs must identify: (a) best management practices (BMPs) to be used in reducing NPS pollution loadings; (b) programs to be used to assure implementation of BMPs; (c) a schedule for program implementation with specific milestones; and (d) sources of federal or other funding that will be used each year for the support of the state's NPS pollution management program. Congress provides grant funds to the states annually for the administration of these management programs.

- **Discharges to Publicly Owned Treatment Works (POTWs)**. Under 40 CFR Part 403, facilities, including agricultural establishments, may discharge certain substances to a POTW if the facility has received prior written permission from the POTW and has completed any required pretreatment. Facilities must check with their POTWs for information about permitted discharges and for conditions and limitations.

- **Discharges of Designated Hazardous Substances**. Under 40 CFR Parts 116-117, facilities, including agricultural establishments, must immediately notify the National Response Center (1-800-424-8802) and their state agency of any unauthorized discharge of a designated hazardous substance into (1) navigable waters, (2) the shorelines of navigable waters, or (3) contiguous zones, if the quantity discharged in any 24-hour period equals or exceeds the reportable quantity. A *designated hazardous substance* is any chemical listed in Section 311 of the Clean Water Act. The *reportable quantity* is the amount of the hazardous substance that EPA has determined might cause harm. The list of hazardous substances along with each chemical's reportable quantity is found in 40 CFR Parts 116 and 117. Ammonia and several pesticides are on the list.

- **Discharges of Oil**. Under 40 CFR Part 110, facilities must immediately notify EPA's National Response Center (1-800-424-8802) of any unauthorized discharge of a *harmful quantity of oil* (including petroleum, fuel oil, sludge, oil refuse, or oil mixed with other wastes) into (1) navigable waters, (2) the shorelines of navigable waters, or (3) contiguous zones and beyond. A discharge of oil is considered harmful if it violates applicable water quality standards, causes a sludge or emulsion to be deposited under the surface of the water or on adjoining shorelines, or causes a film or sheen on, or discoloration of, the water or adjoining shorelines. In practice, any quantity of oil or a petroleum product is a harmful quantity, since even small amounts will cause a film or sheen on surface water.

  – **Oil Spill Prevention Control and Countermeasure (SPCC) Program**. Under 40 CFR Part 112, facilities, including agricultural establishments, must comply with EPA's SPCC program when they store oil at their facility. SPCC requirements apply to non-transportation related onshore and offshore facilities of specified size engaged in storing, processing, refining, transferring or consuming oil products, which due to their location, could potentially discharge oil into waters of the U.S. or adjoining shorelines.

    Facilities must comply with the SPCC program: (1) if they have a single aboveground container with an oil storage capacity of more than 660 gallons, multiple aboveground containers with a combined oil storage capacity of more than 1,320 gallons, or a total underground oil storage capacity of more than 42,000 gallons *and* (2) if there is a reasonable expectation that a discharge (spill, leak, or overfill) from the tank will release harmful quantities of oil into navigable waters or adjoining shorelines. The requirements are triggered by tank capacity, regardless of whether tanks are completely filled.

    Facilities subject to the SPCC requirements must prepare an SPCC plan. This plan must include: (1) *prevention* measures that keep oil releases from occurring, (2) *control* measures installed to prevent oil releases from reaching navigable waters, and (3) *countermeasures* to contain, clean up, and mitigate the effects of any oil release that reaches navigable waters. Each plan must be unique to the facility and must be signed by a registered professional engineer.

R0074543

- **Wetlands on Agricultural Lands**. Swamps, marshes, fens, bogs, vernal pools, playas, and prairie potholes are common names for wetlands. Wetlands provide a habitat for threatened and endangered species as well as a diversity of other plant, wildlife, and fish species. In addition to providing habitat, wetlands serve other functions, including stabilizing shorelines; storing flood waters; filtering sediments, nutrients, and toxic chemicals from water; and providing an area for the recharge and discharge of groundwater. It is important to note that not all wetlands will be obvious to the untrained observer. For example, an area can appear dry during much of the year and still be classified as a wetland. Your local Natural Resources Conservation Service (NRCS) office can help to identify and delineate wetlands on your property.

  NRCS, formerly the Soil Conservation Service, is the lead agency for identifying wetlands on *agricultural lands*. According to NRCS, agricultural lands means those lands intensively used and managed for the production of food or fiber to the extent that the natural vegetation has been removed and therefore does not provide reliable indicators of wetland vegetation. Areas that meet this definition may include intensively used and managed cropland, hayland, pastureland, orchards, vineyards, and areas that support wetland crops (e.g., cranberries, taro, watercress, rice). Lands not included in the definition of *agricultural lands* include rangelands, forest lands, woodlots, and tree farms.

  - ***Exemption to Section 404 Permit Requirements***. The placement of dredge and fill material into wetlands and other water bodies (i.e., waters of the United States) is regulated by the U.S. Army Corps of Engineers (Corps) under 33 CFR Part 328. The Corps regulates wetlands by administering the CWA Section 404 permit program for activities that impact wetlands. The 404 permit program requires a permit for point source discharges of dredged and fill material into waters of the United States. However, many normal established farming activities (e.g., plowing, cultivating, minor drainage, and harvesting), silviculture, and ranching activities that involve discharges of dredged or fill materials into U.S. waters are **exempt from Section 404 permits** and do **NOT** require a permit (33 CFR §323.4). In order to be exempt, the activity must be part of an ongoing operation and cannot be associated with bringing a wetland into agricultural production or converting an agricultural wetland to a non-wetland area.

If not covered by the above exemption, a permit is required before discharging dredged or fill material into U.S. waters, including most wetlands (33 CFR Part 323). The Army Corps of Engineers (Corps) reviews Section 404 permit applications to determine if a project is the least environmentally damaging and practicable alternative.

- **POTW Sludge Management - Land Application of Biosolids**. Land application is the application of biosolids to land to either condition the soil or fertilize crops or other vegetation grown in the soil. Biosolids are a primarily organic solid product produced by wastewater treatment processes that can be beneficially recycled.

  EPA regulates the land application of biosolids under 40 CFR Part 503. As described in *A Plain English Guide to the EPA Part 503 Biosolids Rule* (EPA/832/R-93-003, September 1994), the Part 503 rule includes general provisions, and requirements for land application, surface disposal, pathogen and vector attraction reduction, and incineration. For each regulated use or disposal practice, a Part 503 standard includes general requirements, pollutant limits, management practices, operational standards, and requirements for the frequency of monitoring, recordkeeping, and reporting. For the most part, the requirements of the Part 503 rule are ***self-implementing*** and must be followed even without the issuance of a permit covering biosolids use or disposal requirements.

- **Total Maximum Daily Load (TMDL) Program**. There are still waters in the nation that do not meet the CWA national goal of "fishable, swimmable" despite the fact that nationally required levels of pollution control technology have been implemented by many pollution sources. The TMDL program, established under Section 303(d) of the Clean Water Act, focuses on identifying and allocating pollutant loads to these waterbodies. The goal of a TMDL is the attainment of water quality standards.

  A TMDL identifies the amount a pollutant needs to be reduced to meet water quality standards, allocates pollutant load reductions among pollutant sources in a watershed, and provides the basis for taking actions needed to restore a waterbody. It can identify the need for point source and nonpoint source controls.

  Under this provision, States are required to (1) identify and list waterbodies where State water quality standards are not being met following the application of technology-based point source pollution controls; and (2) establish TMDLs for these waters. EPA must review and approve (or disapprove) State lists and TMDLs. If State actions are not adequate, EPA must prepare lists and TMDLs. TMDLs are to be implemented using existing federal, state, and local authorities and voluntary programs.

TMDLs should address all significant pollutants which cause or threaten to cause waterbody use impairment, including:

- Point sources (e.g., sewage treatment plant discharges)
- Nonpoint sources (e.g., runoff from fields, streets, range, or forest land)
- Naturally occurring sources (e.g., runoff from undisturbed lands)

A TMDL is the sum of the individual wasteload allocations for point sources, load allocations for nonpoint sources and natural background pollutants, and an appropriate margin of safety. TMDLs may address individual pollutants or groups of pollutants, as long as they clearly identify the links between: (1) the waterbody use impairment or threat of concern, (2) the causes of the impairment or threat, and (3) the load reductions or actions needed to remedy or prevent the impairment.

TMDLs may be based on readily available information and studies. In some cases, complex studies or models are needed to understand how pollutants are causing waterbody impairment. In many cases, simple analytical efforts provide an adequate basis for pollutant assessment and implementation planning.

Where inadequate information is available to draw precise links between these factors, TMDLs may be developed through a phased approach. The phased approach enables states to use available information to establish interim targets, begin to implement needed controls and restoration actions, monitor waterbody response to these actions, and plan for TMDL review and revision in the future. Phased approach TMDLs are particularly appropriate to address nonpoint source issues.

Numerous TMDLs are under development in many states and TMDLs are likely to impact agricultural activities by prompting states and stakeholders to mitigate water pollution caused by agricultural sources (assuming agriculture-related industries are identified as significant contributors to water quality impairment).

Coastal Zone Act Reauthorization Amendments of 1990

The Coastal Nonpoint Pollution Control Program, which is implemented under the authority of Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990, is administered at the federal level jointly by EPA and the National Oceanic and Atmospheric Administration (NOAA). The Section 6217 program requires the 29 states and territories with NOAA-approved coastal zone management programs to develop and implement coastal nonpoint pollution control programs. These submitted programs must include: (1) management measures that are in conformity with applicable federal guidance and (2) state-developed management measures as necessary to achieve and maintain applicable water quality standards.

On January 19, 1993, EPA issued its *Guidance Specifying Management Measures For Sources of Nonpoint Pollution in Coastal Waters.* The federal guidance specifies management measures for the following agricultural sources: (1) erosion from cropland, (2) confined animal facilities, (3) the application of nutrients to croplands, (4) the application of pesticides to cropland, (5) grazing management, and (6) irrigation of cropland.

Once approved, the programs are implemented through state nonpoint source programs (under CWA §319) and state coastal zone management programs (authorized under §306 of the Coastal Zone Management Act). Agricultural establishments located in coastal states should determine whether their land is included in the state's coastal management area. If so, they must comply with their state's applicable coastal nonpoint programs. Currently, all state coastal nonpoint management programs have been conditionally approved and have begun to be implemented.

Coastal Zone Management Act

The 1996 amendments to the Coastal Zone Management Act that may affect agriculture-related industries include those that relate to aquaculture in the coastal zone. Eligible states may now receive grants for developing a coordinated process among state agencies to regulate and issue permits for aquaculture facilities in the coastal zone. States may also receive grants for adopting procedures and policies to evaluate facilities in the coastal zone that will enable the states to formulate, administer, and implement strategic plans for marine aquaculture. Each state that receives such grants will make its own determination as part of its coastal management plan on how to specifically use the funds. Therefore, persons engaged in aquaculture productivity in the

R0074547

coastal zone may be eligible for technical or financial assistance under their state's plan.

Safe Drinking Water Act

The SDWA, which has been amended twice since 1974, protects the water supply through water quality regulations and source protection, such as underground injection control (UIC) regulations. SDWA requirements apply to all public water systems (PWSs). Currently, 54 of 56 states and territories have been delegated primacy to run the drinking water program.

- **Public Water Systems**. Under 40 CFR Parts 141-143, facilities that operate a PWS or receive water from a PWS and provide treatment to it are subject to SDWA regulations. Prior to 1996, SDWA defined a PWS as "a system for the provision to the public of piped water *for human consumption* if such system has at least 15 service connections or regularly serves at least 25 individuals." The 1996 Amendments expanded the means of delivering water to include not only pipes, but also other constructed conveyances such as ditches and waterways.

  While there are three categories of PWSs, an agricultural establishment will most likely operate a non-transient, non-community system. This type of system serves at least 25 people for over 6 months of the year, but the people generally do not live at the facility. All PWSs must comply with the national primary drinking water regulations (40 CFR 141). Under 40 CFR Part 141 Subpart G, EPA has established drinking water standards for numerous pesticides.

  Establishments that operate a non-transient, non-community system, in general, will need to: (1) monitor for the contaminants the state has established for that type of system, (2) keep records of the monitoring results, (3) report results from all tests and analyses to the state/tribe on a set schedule, (4) take immediate action to correct any violations in the allowable contaminant levels, (5) make a public announcement of any violations to warn people about potential adverse effects and to describe the steps taken to remedy the problem, and (6) keep records of actions taken to correct violations.

- **Comprehensive State Ground Water Protection Program**. Under the SDWA §1429, states/tribes are allowed to establish a Comprehensive State Ground Water Protection Program to protect underground sources of drinking water. Under this program, a state/ tribe can require facilities, including agricultural establishments, to use designated best management practices (BMPs) to help prevent contamination of groundwater by nitrates, phosphates, pesticides, microorganisms, or petroleum products. These requirements generally apply only to facilities that are subject to the public water system supervision program. Persons applying pesticides or fertilizers must know the location of all the public water supply source areas in the vicinity that are protected by state/tribal (and sometimes local) requirements.

- **Source Water and Protection Program**. Under the SDWA, states are required to develop comprehensive Source Water Assessment Programs (SWAP). The statutorily defined goals for SWAPs are to provide for the protection and benefit of public water systems and for the support of monitoring flexibility. These programs plan to identify the areas that supply public tap water, inventory contaminants and assess water system susceptibility to contamination, and inform the public of the result.

- **Wellhead Protection Program**. Under the SDWA §1428, if a facility, has an onsite water source (e.g., well) that qualifies as a PWS, it must take the steps required by the state/tribe to protect the wellhead from contaminants. A wellhead protection area is the surface and subsurface area surrounding a water well or wellfield supplying a PWS through which contaminants are reasonably likely to move toward and reach such water well or wellfield.

  Since drinking water standards (40 CFR Part 141 Subpart G) exist for numerous pesticides, which may be used in various agriculture-related activities, some state/tribe and local wellhead and source water protection programs restrict the use of agricultural chemicals in designated wellhead protection areas. In addition, persons applying pesticides or fertilizers must know the location of all the public water supply source areas in the vicinity that are protected by state/tribal (and sometimes local) requirements, and the requirements for mixing, loading, and applying agricultural chemicals within any designated wellhead or source water protection areas.

- **Sole Source Aquifer Protection Program**. Under the SDWA §1424 and 40 CFR Part 149 Subpart B, EPA can establish requirements for protecting sole source aquifers. EPA designates an aquifer as a ***sole source aquifer*** if it supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer and no alternative drinking water sources are feasible. The Sole Source Aquifer program prohibits federal financial assistance (any grant, contract, loan guarantee, or otherwise) for any project, including agricultural projects, that may result in contamination to the aquifer and create a hazard to public heath. Currently, only a few aquifers have been designated as protected sole source aquifers.

- **Underground Injection Control (UIC) Program**. The UIC program (40 CFR Parts 144 and 146-148) is a permit program that protects underground sources of drinking water by regulating five classes of injection wells (I - V). *Underground injection* means depositing fluids beneath the surface of the ground by injecting them into a hole (any hole that is deeper than it is wide). *Fluids* means any material or substance which flows or moves whether in a semisolid, liquid, sludge, gas, or any other form or state.

  If a facility disposes of (or formerly disposed of) waste fluids onsite in an injection well, it triggers the UIC requirements. In general, a facility may not inject contaminants into any well if the contaminant could cause a violation of any primary drinking water regulation or endanger an underground source of water if the activity would adversely affect the public health. Most deep well underground injections are prohibited without a UIC permit. No Class I, II, or III injection well may be constructed or opened before a permit has been issued. UIC permits include design, operating, inspection, and monitoring requirements. In many states/tribes, EPA has authorized the state/tribal agency to administer the program.

  Class V Wells. Owners/operators of Class V wells (shallow wells that inject fluids above an underground source of water) must not construct, operate, maintain, convert, plug, abandon, or conduct any other injection activity in a manner that allows the movement of fluid containing any contaminant into underground sources of drinking water, if the presence of that contaminant may cause a violation of any primary drinking water regulation (40 CFR Part 142) or may otherwise adversely affect the health of persons. Examples of Class V wells potentially applicable to agricultural establishments include, but are not limited to:

  (1) Drainage wells, such as agricultural drainage wells, primarily used for storm runoff.

  (2) Cesspools with open bottoms (and sometimes perforated sides) and septic system wells used to inject waste or effluent from <u>multiple</u> dwellings or businesses (the UIC requirements do not apply to single family residential septic system or cesspool wells or to non-residential septic system or cesspool wells that

are used solely for the disposal of sanitary wastes and have the capacity to serve fewer than 20 persons per day).

(3) Dry wells used for waste injection.

(4) Recharge wells used to replenish aquifers.

(5) Injection wells associated with the recovery of geothermal energy for heating, aquaculture, and production of electric power.

(6) Floor drains in maintenance shops/work areas.

Agricultural drainage wells typically drain water from low-lying farm land, but some serve to recharge aquifers from which irrigation water is withdrawn. These wells are usually constructed in areas with poor soil drainage, but where underlying geologic formations allow rapid infiltration of water. Sometimes abandoned water supply wells are adapted for use in agricultural drainage. Agricultural drainage wells typically receive field drainage from saturated topsoil and subsoil, and from precipitation, snowmelt, floodwaters, irrigation return flow, and animal feedlots. The types of pollutants injected into these wells include (1) pesticide runoff, (2) nitrate, nitrite, and salts, such as those of calcium, magnesium, sodium, potassium, chloride, sulfate, and carbonate from fertilizer runoff, (3) salts and metals (i.e., iron, lead, cadmium, and mercury) from biosolid sludges and compost, (4) microbes (i.e., bacteria and viruses) from animal waste runoff, and (5) petroleum contaminants, such as fuel and oil, from runoff from roads or equipment maintenance areas.

If a facility has a Class V well, it must furnish inventory information about the well to the appropriate state/tribal agency. If at any time EPA or the state/tribal agency learns that a Class V well may cause a violation of primary drinking water regulations (40 CFR Part 142) or may be otherwise adversely affecting the health of persons, it may require the injector to obtain an individual UIC permit, or order the injector to take such actions (including, where required, closure of the injection well) as may be necessary to prevent the violation.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) was enacted to address problems related to hazardous and solid waste management. RCRA gives EPA the authority to establish a list of solid and hazardous wastes and to establish standards and regulations for the treatment, storage, and disposal of these wastes. Regulations in Subtitle C of RCRA address the identification, generation. transportation, treatment, storage, and disposal of hazardous wastes. These regulations are found in 40 CFR Part 124 and 40 CFR Parts 260-279. Under RCRA, persons who generate waste must determine whether the waste is defined as solid waste or hazardous waste. Solid wastes are considered hazardous wastes if they are listed by EPA as hazardous or if they exhibit characteristics of a hazardous waste: toxicity, ignitability, corrosivity, or reactivity.

Most agriculture-related activities do not generate significant amounts of hazardous waste. Generally, the activities potentially subject to RCRA involve the use of pesticides and fertilizers, and the use and maintenance of different types of machinery.

Hazardous Waste Generator Categories. Facilities that generate hazardous waste can be classified into one of three hazardous waste generator categories as defined in 40 CFR Part 262:

- ***Conditionally exempt small quantity generator (CESQG)***. A facility is classified as a CESQG if it generates no more than 220 lbs (100 kg) of hazardous waste in a calendar month. There is no time limit for accumulating ≤2,200 lbs of hazardous waste onsite. However, CESQGs cannot store more than 2,200 lbs (1,000 kg) of hazardous waste onsite at any time. In addition, CESQGs cannot accumulate onsite more than 2.2 lbs (1 kg) of acutely hazardous waste or more than 220 lbs spill residue from acutely hazardous waste for any period of time.

- ***Small quantity generator (SQG)***. A facility is classified as a SQG if it generates >220 lbs (100 kg) and <2,200 lbs (1,000 kg) of hazardous waste in a calendar month. SQGs can accumulate onsite no more than 13,200 lbs (6,000 kg) of hazardous waste. SQGs can store hazardous waste onsite for up to 180 days (or up to 270 days if the waste treatment/disposal facility is more than 200 miles away).

- ***Large quantity generator (LQG)***. A facility is classified as a LQG if it generates > 2,200 lbs (1,000 kg) of hazardous waste in a calendar month. While there is no limit on the amount of hazardous waste that LQGs can accumulate onsite, they can only store it onsite for up to 90 days.

If a facility is a CESQG and generates ≤2.2 lbs (1 kg) of acutely hazardous waste; or ≤220 lbs (100 kg) of acutely hazardous waste spill residues in a calendar month, and never stores more than that amount for any period of time, it may manage the acutely hazardous waste according to CESQG requirements. If it generates more than 2.2 lbs (1 kg) of acutely hazardous waste or >220 lbs (100 kg) of acutely hazardous waste spill residues in a calendar month, the facility must manage it according to LQG requirements. The hazardous wastes that must be measured are those: (1) accumulated at the facility for any period of time before disposal or recycling, (2) packaged and transported away from the facility, (3) placed directly into a treatment or disposal unit at the facility, or (4) generated as still bottoms or sludges *and* removed from product storage tanks.

Requirements for CESQGs. Based on the quantity of hazardous waste generated per month, most agricultural establishments will qualify as CESQGs. As CESQGs, facilities must comply with three basic waste management requirements:

(1) Identify all hazardous waste generated.

(2) Do not generate per month more than 220 lbs (100 kg) of hazardous waste; more than 2.2 lbs (1 kg) of acutely hazardous waste; or more than 220 lbs (100 kg) of acutely hazardous waste spill residues; and never store onsite more than 2,200 lbs (1,000 kg) of hazardous waste; 2.2 lbs of acutely hazardous waste; or more than 220 lbs of acutely hazardous waste spill residues for any period of time.

(3) Ensure proper treatment and disposal of the waste. This means ensuring that the disposal facility is one of the following:
   - A state or federally regulated hazardous waste management treatment, storage, or disposal facility.
   - A facility permitted, licensed, or registered by a state to manage municipal or industrial solid waste.
   - A facility that uses, reuses, or legitimately recycles the waste (or treats the waste before use, reuse, or recycling).
   - A universal waste handler or destination facility subject to the requirements for universal wastes.

CESQGs are allowed to transport their own wastes to the treatment or storage facility, unlike SQGs and LQGs who are required to use a licensed, certified transporter. While there are no specific RCRA requirements for CESQGs who transport their own wastes, the U.S. Department of Transportation (DOT) requires all transporters of hazardous waste to comply with all applicable DOT regulations. Specifically, DOT regulations require all transporters, including CESQGs, transporting hazardous waste that qualifies as a DOT hazardous material to comply with EPA hazardous waste transporter requirements found in 40 CFR Part 263. CESQGs are not required by federal hazardous waste laws to train their employees on waste handling or emergency preparedness.

Requirements for SQGs and LQGs. Facilities determined to be SQGs or LQGs must meet many requirements under the RCRA regulations. These requirements, found in 40 CFR 260-279, include identifying hazardous waste; obtaining EPA identification numbers; meeting requirements for waste accumulation and storage limits; container management; conducting personnel training; preparing a manifest; ensuring proper hazardous waste packaging, labeling, and placarding; reporting and recordkeeping; and contingency planning, emergency procedures, and accident prevention.

Notes: Facilities that fall into different generator categories during different months may choose to simplify compliance by satisfying the more stringent requirements all the time.

Specific Provisions. RCRA regulations include several specific provisions addressing agriculture-related materials and activities. Key provisions are briefly summarized below:

- ***Exemption for Certain Solid Wastes Used as Fertilizers***. Under 40 CFR §261.4(b), solid wastes generated by (1) growing and harvesting of agricultural crops, or (2) raising animals (including animal manure), and that are returned to the soils as fertilizers are excluded from regulation as hazardous waste.

- ***Exemption for Certain Hazardous Waste Pesticides***. Under 40 CFR §262.70, farmers who generate any amount of hazardous waste pesticides from their own use are excluded from the generator, treatment/storage/disposal facility, land disposal, and permit requirements under RCRA Subtitle C, provided that the farmer: (1) disposes of the waste pesticide in a manner consistent with the label on the pesticide container; (2) triple rinses each empty container in accordance with requirements at 40 CFR §261.7(b)(3); and (3) disposes of the rinsate on his own farm in accordance with the instructions on the label. If the label does not include disposal instruction, or no instructions are available from the pesticide manufacturer, the waste pesticide and rinsate must be disposed of in accordance with Subtitle C hazardous waste requirements. (Also see 40 CFR Part 165 - FIFRA)

- ***Exemption for Commercial Fertilizers***. Under 40 CFR §266.20, commercial fertilizers produced for general public (including agricultural) use that contain recyclable materials are not presently subject to regulation provided they meet the applicable land disposal restriction (LDR) standards for each recyclable material they contain. For example, zinc-containing fertilizers containing K061 (emission control dust from the primary production of steel in electric furnaces) are not subject to regulation.

- ***Fertilizers Made from Hazardous Wastes***. Under 40 CFR Parts 266 and 268, EPA regulates fertilizers containing hazardous wastes as ingredients. Hazardous wastes may be used as ingredients in fertilizers under certain conditions, since such wastes can be a beneficial component of legitimate fertilizers. EPA has established standards that specify limits on the levels of heavy metals and other contents used as fertilizer ingredients. These standards are based on treatment, by the best technology currently available, to reduce the toxicity and mobility of all the contents of the hazardous waste components. These standards are based on waste management considerations and do not include consideration of the potential agronomic or dietary risk.

- ***Food Chain Crops Grown on Hazardous Waste Land Treatment Units***. Under 40 CFR Part 264.276, food chain crops (including feed for animals consumed by humans) may be grown in or on hazardous waste land treatment units under certain conditions and only with a permit. The permit for a facility will list the specific food-chain crops that may be grown. To obtain a permit, the owner/operator of the facility wishing to grow the food-chain crops must demonstrate -- prior to the planting of such crops -- that there is no substantial risk to human health caused by the growth of such crops in or on the treatment zone.

- ***Solid Waste Disposal Criteria***. Under RCRA Subtitle D, 40 CFR 257.3 establishes solid waste disposal criteria addressing floodplains, endangered species, groundwater protection, application to land used for food chain crops, disease vectors, air pollution, and safety. These criteria are largely guidelines used by states in developing solid waste regulations, which control the disposal of waste on a farmer's property.

- ***Land Application of Fertilizers Derived from Drinking Water Sludge***. Under 40 CFR Part 257, EPA regulates the land application of solid wastes, including drinking water sludge applied as fertilizer. These requirements include: (1) cadmium limits on land used for the production of food-chain crops (tobacco, human food, and animal feed) or alternative less stringent cadmium limits on land used solely for production of animal feed; (2) polychlorinated biphenyls (PCBs) limits on land used for producing animal feed, including pasture crops for animals raised for milk; and (3) minimization of disease vectors, such as rodents, flies, and mosquitoes, at the site of application through incorporation of the fertilizer into soil so as to impede the vectors' access to the sludge.

- ***Pesticides That Are Universal Wastes***. Under 40 CFR Part 273, EPA has established a separate set of requirements for three types of wastes called *universal wastes*. Universal wastes include certain batteries, certain pesticides, and mercury thermostats. Pesticides designated as universal wastes include (1) recalled pesticides that are stocks of a suspended or canceled pesticide and part of a voluntary or mandatory recall under FIFRA §19(b); (2) recalled pesticides that are stocks of a suspended or canceled pesticide, or a pesticide that is not in compliance with FIFRA, that are part of a voluntary recall [see FIFRA §19(b)(2)] by the registrant; and (3) stocks of other unused pesticide products that are collected and managed as part of a waste pesticide collection program.

  The Universal Waste rule is *optional* for states/tribe to adopt. In those states/tribes that have not adopted the Universal Waste rule, these wastes must be disposed of in accordance with the hazardous (or acutely hazardous) waste requirements (see 40 CFR Part 262).

- ***Exemption for Small Quantities of Used Oil***. Under 40 CFR §279.20, agricultural establishments that generate an average of 25 gallons or less of used oil per month per calendar year from vehicles or machinery used on the establishment are not subject to the requirements of 40 CFR Part 279.

- ***Exemption for "Farm Tanks" and Tanks of 110 Gallons or Less***. Under the underground storage tank (UST) regulations (RCRA Subtitle I, 40 CFR §280.12), "farm tanks" of 1,100 gallons or less capacity used for storing motor fuel for non-commercial purposes are not regulated as underground storage tanks. *"Farm tanks"* include tanks located on a tract of land devoted to the production of crops or raising animals (including fish) and associated residences and improvements. Also under 40 CFR §280.10, the UST program does not apply to UST systems of 110 gallons or less capacity, or that contain a *de minimis* concentration of a regulated substance.

  Even with the above exemptions, keep in mind that many agricultural establishments may be subject to the UST program (40 CFR Part 280). The UST regulations apply to facilities that store either petroleum products or hazardous substances (except hazardous wastes) identified under CERCLA. UST regulations address design standards, leak detection, operating practices, response to releases, financial responsibility for releases, and closure standards.

Comprehensive Environmental Response, Compensation, and Liability Act

Under CERCLA, there are a limited number of statutory and regulatory requirements that potentially affect agricultural businesses. The key provisions are summarized below:

- **Emergency Release Notification Requirements**. Under CERCLA §103(a), facilities are required to notify the National Response Center about any release of a CERCLA hazardous substance in quantities equal to or greater than its reportable quantity (RQ). Releases include discharges into the air, soil, surface water, or groundwater. Any release at or above the RQ must be reported regardless of whether there is a potential for offsite exposure.

  – ***Hazardous Substances***. The term "hazardous substance" is defined in CERCLA §101(14) and these substances (more than 700) are listed at 40 CFR Part 302, Table 302.4. Several agricultural chemicals are on the CERCLA hazardous substance list, including many pesticides, anhydrous ammonia, and ethylene glycol.

  – ***Reportable Quantities***. For each hazardous substance, EPA has designated a RQ of 1, 10, 100, 1,000, or 5,000 pounds. RQs are listed in 40 CFR Part 355, Appendices A and B and 40 CFR Part 302, Table 302.4.

  – ***When No Notification is Required***. There are several types of releases that are excluded from the requirements of CERCLA release notification. Two of these releases, excluded under CERCLA §§101(22) and 103(e), include the normal application of fertilizer and the application of pesticide products registered under FIFRA. *Keep in mind that spills, leaks, or other accidental or unintended releases of fertilizers and pesticides are subject to the reporting requirements.*

- **Facility Notification and Recordkeeping Requirements - Exemption for Agricultural Producers**. Under CERCLA §§103(c) and (d), certain facilities must notify EPA of their existence and the owners/operators must keep records. However, CERCLA §103(e) exempts agricultural producers who store and handle FIFRA-registered pesticides from the facility notification and recordkeeping requirements. CERCLA does not define the term *agricultural producer*.

- **Liability for Damages**. Under CERCLA §107(a), an owner/operator of a facility that has CERCLA hazardous substances onsite may be liable for cleanup costs, response costs, and natural resource damages associated with a release or threatened release of hazardous substances. Agricultural establishments are potentially liable under this section, and that liability extends to past practices.

Emergency Planning and Community Right-to-Know Act

A summary of the potential applicability of specific sections of EPCRA on the agricultural sector follows below.

- **Emergency Planning and Notification**. Under EPCRA §302, owners or operators of any facility, including agricultural establishments, that have *extremely hazardous substances* (40 CFR Part 355 Appendices A and B) present in excess of the *threshold planning quantity* must notify in writing their state emergency response commission (SERC) and their local emergency planning committee (LEPC) that they are subject to EPCRA planning requirements. Under EPCRA §303, they must also notify the LEPC of the name of a person at their facility whom the LEPC may contact in regard to planning issues related to these extremely hazardous substances. They must also inform the LEPC promptly of any relevant changes, and when requested, must provide information to the LEPC necessary for emergency planning.

  Ammonia, several agricultural pesticides, and certain fuels are included on the list of extremely hazardous substances found in 40 CFR Part 355 Appendices A and B. If a listed substance is a solid, two different planning quantities are listed (e.g., 500 lbs/10,000 lbs). The smaller amount (e.g., 500 lbs.) applies if the substance is in powder form, such as a soluble or wettable powder, or if it is in solution or molten form. The larger quantity (10,000 lbs.) applies for most other forms of the substance. If the extremely hazardous substance is part of a mixture or solution, then the amount is calculated by multiplying its percent by weight times the total weight of the mixture or solution. If the percent by weight is less than one percent, the calculation is not required (40 CFR Part 355.30).

  ✓ Ammonia -- The quantity of anhydrous ammonia that triggers the planning requirement is 500 pounds.

✓ Pesticides -- Examples of pesticides on the list with the quantity in pounds that triggers the planning requirement include: ethion (1,000), nicotine (100), dichlorvos (1,000), parathion (100), chlordane (1,000), methyl bromide (1,000), ethylene oxide (1,000), fenitrothion (500), phorate (10), zinc phosphide (500), aluminum phosphide (500), terbufos (100), phosphamidon (100), demeton (500), ethoprop (1,000), and disulfoton (500).

✓ Solid Pesticides -- Examples of pesticides with dual quantities that trigger the planning requirements include: coumaphos (100/10,000), strychnine (100/10,000), dimethoate (500/10,000), warfarin (500/10,000), azinphos-methyl (10/10,000), methyl parathion (100/10,000), phosmet (10/10,000), methidathion (500/10,000), carbofuran (10/10,000), paraquat (10/10,000), methiocarb (500/10,000), methamidophos (100/10,000), methomyl (500/10,000), fenamiphos (10/10,000), and oxamyl (100/10,000).

- **§304 Emergency Release Notification**. Under 40 CFR 355, facilities must *immediately* notify the SERC and LEPC of releases of EPCRA extremely hazardous substances and CERCLA hazardous substances when the release equals or exceeds the reportable quantity within a 24-hour period and has the *potential* for offsite exposure. There are two notifications required: the initial notification and the written followup notification.

  Exemption for Substances Used in Agricultural Operations. Only facilities that produce, use or store *hazardous chemicals* are subject to EPCRA release reporting. EPCRA §311(e) excludes from the definition of *hazardous chemicals* those substances used in routine agricultural operations. The exemption covers fertilizers and pesticides used in routine agricultural operations and fuels for operating farm equipment (including to transport crops to market). If all the hazardous chemicals present at the facility do not fall within this exemption, the facility must report all releases of any EPCRA extremely hazardous substance or CERCLA hazardous substance. Additionally, spills, leaks, or other accidental or unintended releases of fertilizers and pesticides are subject to the EPCRA release reporting requirements.

- **§311 and §312 Hazardous Chemical Inventory and Reporting**. Under EPCRA §311 and §312, facilities must inventory the hazardous chemicals present onsite in amounts equal to or in excess of the threshold planning quantities, and meet two reporting requirements:

- A one-time notification of the presence of hazardous chemicals onsite in excess of threshold levels (EPCRA §311) to the SERC, LEPC, and the local fire department; and

- An annual notification (Tier I or Tier II report) to the SERC, LEPC, and the local fire department detailing the locations and hazards associated with the hazardous chemicals found on facility grounds (EPCRA §312).

Exemption for Substances Used in Agricultural Operations. As mentioned above, the term "hazardous chemical," as defined in EPCRA §311(e), *excludes* substances used in routine agricultural operations.

Clean Air Act

Agriculture-related industries generally do not include those industry sectors considered to be major sources of air pollution. Nevertheless, some agriculture-related activities are potentially subject to regulation under the CAA. The provisions identified below summarize the CAA requirements applicable to certain agriculture-related activities:

- **Risk Management Program**. Under §112(r) of the Clean Air Act, EPA has promulgated the Risk Management Program Rule. The rule's main goals are to prevent accidental releases of regulated substances and to reduce the severity of those releases that do occur by requiring facilities to develop risk management programs. A facility's risk management program must incorporate three elements: a hazard assessment, a prevention program, and an emergency response program. These programs are to be summarized in a risk management plan (RMP) that will be made available to state and local government agencies and the public.

  Under 40 CFR Part 68, facilities that have more than the threshold quantity of any of the listed regulated substances in a single process are required to comply with the regulation. *Process* means any regulated activity involving a regulated substance, including manufacturing, storing, distributing, or handling a regulated substance or using it in any other way. Any group of interconnected vessels (including piping), or separate vessels located close enough together to be

R0074560

involved in a single accident, are considered a single process. Transportation is not included.

Listed regulated substances are acutely toxic substances, flammable gases, volatile liquids, and highly explosive substances listed by EPA in the Risk Management Program rule. The *threshold quantity* is the amount of a regulated substance that triggers the development of a RMP. The list of regulated substances and their corresponding threshold quantities are found at 40 CFR Part 68. Examples of threshold quantities of listed regulated substances include: formaldehyde -- 15,000 pounds; ethylene oxide -- 10,000 pounds; methyl isocyanate -- 10,000 pounds; anydrous ammonia -- 10,000 pounds; and mixtures containing ammonia in a concentration of 20 percent or greater -- 20,000 pounds.

Exception: Ammonia that farmers are holding for use as fertilizer is not a regulated substance under the risk management program. Farmers are not responsible for preparing a risk management plan if ammonia held for use as a fertilizer is the only listed regulated substance that they have in more than threshold quantities. However, ammonia that is on a farm for any other use, such as for distribution or as a coolant/refrigerant, is not exempt.

Three program levels. The risk management planning regulation (40 CFR Part 68) defines the activities facilities must undertake to address the risks posed by regulated substances in covered processes. To ensure that individual processes are subject to appropriate requirements that match their size and the risks they may pose, EPA has classified them into 3 categories ("programs"):

- **Program 1** requirements apply to processes for which a worst-case release, as evaluated in the hazard assessment, would not affect the public. These are processes that have **not** had an accidental release that caused serious offsite consequences.

- **Program 2** requirements apply to less complex operations that do **not** involve chemical processing.

- **Program 3** requirements apply to higher risk, complex chemical processing operations and to processes already subject to the **OSHA Process Safety Management Standard (29 CFR 1910.119)**.

Risk Management Planning. Facilities with more than a threshold quantity of any of the 140 regulated substances in a single process are required to develop a risk management program and to summarize their program in a risk management plan (RMP). A facility subject to the requirements was required to have submitted a registration and RMP by June 21, 1999, or whenever it first exceeds the threshold for a listed regulated substance after that date.

All facilities with processes in Program 1 must carry out the following elements of risk management planning:

- An offsite consequence analysis that evaluates specific potential release scenarios, including worst-case and alternative scenarios.
- A five-year history of certain accidental releases of regulated substances from covered processes.
- A risk management plan, revised at least once every five years, that describes and documents these activities for all covered processes.

Facilities with processes in Programs 2 and 3 must also address each of the following elements:

- An integrated prevention program to manage risk. The prevention program will include identification of hazards, written operating procedures, training, maintenance, and accident investigation.
- An emergency response program.
- An overall management system to put these program elements into effect.

- **National Ambient Air Quality Standards (NAAQS)/SIPS**. Under the CAA §10, each state must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet federal air quality standards. If the applicable SIP imposes requirements on an agricultural establishment, that facility must comply with the SIP. The most likely pollutant of concern with respect to agriculture-related businesses is particulate matter.

Federal Insecticide, Fungicide, and Rodenticide Act

For agricultural producers, FIFRA is the environmental statute that most significantly impacts day-to-day operations of pesticide use. It also imposes administrative requirements on pesticide users, including agricultural producers. A summary of major provisions applicable to agricultural producers is provided below.

- **Use Restrictions**. The pesticide product label is information printed on or attached to the pesticide container. Users are legally required to follow the label. Labeling is the pesticide product label and other accompanying materials which contain directions that pesticide users are legally required to follow. Under FIFRA §12, each pesticide must be used only in a way that is consistent with its labeling.

  - As a part of the pesticide registration, EPA must classify the product for general use, restricted use, or general for some uses and restricted for others (Miller, 1993). For pesticides that may cause unreasonable adverse effects on the environment, including injury to the applicator, EPA may require that the pesticide be applied either by or under the direct supervision of a certified applicator.

  - It is against the law (Endangered Species Act) to harm an endangered species. Harm includes not only acts that directly injure or kill the protected species, but also significant habitat modification or degradation that disrupts breeding, feeding, or sheltering. Pesticide users must comply with any pesticide labeling restrictions or requirements that concern the protection of endangered species or their habitats.

- **Tolerances and Exemptions**. A tolerance is the maximum amount of pesticide residue that can be on a raw product and still be considered safe. Before EPA can register a pesticide that is used on raw agricultural products, it must grant a tolerance or exemption from a tolerance (40 CFR.163.10 through 163.12). Under the Federal Food, Drug, and Cosmetic Act (FFDCA), a raw agricultural product is deemed unsafe if it contains a pesticide residue, unless the residue is within the limits of a tolerance established by EPA or is exempt from the requirement.

  To avoid being responsible for products being over tolerance, users must be particularly careful to comply with the label instructions concerning application rate and minimum days between pesticide application and harvest (i.e., preharvest interval), slaughter, freshening, or grazing.

- **Worker Protection Standard (WPS) Requirements for Users**. The WPS for Agricultural Pesticides (40 CFR Parts 156 and 170) covers pesticides that are used in the commercial production of agricultural plants on farms, forests, nurseries, and greenhouses. The WPS requires pesticide users to take steps to reduce the risk of pesticide-related illness and injury if they or their employees may be exposed to pesticides used in the commercial production of agricultural plants.

- **Cancellation and Suspension**. EPA can cancel a registration if it is determined that the pesticide or its labeling does not comply with the requirements of FIFRA or causes unreasonable adverse effects on the environment (Haugrud, 1993).

  In cases where EPA believes that an "imminent hazard" would exist if a pesticide were to continue to be used through the cancellation proceedings, EPA may suspend the pesticide registration through an order and thereby halt the sale, distribution, and usage of the pesticide. An "imminent hazard" is defined as an unreasonable adverse effect on the environment or an unreasonable hazard to the survival of a threatened or endangered species that would be the likely result of allowing continued use of a pesticide during a cancellation process.

  When EPA believes and emergency exists that does not permit a hearing to be held prior to suspending, EPA can issue an emergency order that makes the suspension immediately effective.

Toxic Substances Control Act

TSCA has a limited impact on the agricultural sector. TSCA §3, Definitions, specifies that the term chemical substance means any organic or inorganic substance of a particular molecular identity. The definition also states, as declared at subsection (2)(B)(ii), that such term does not include any pesticide (as defined in FIFRA) when manufactured, processed, or distributed in commerce for use as a pesticide. Since the majority of potentially hazardous substances used by agricultural producers are pesticides, they are regulated under FIFRA. Regulation of hazardous substances under other authorities is part of TSCA's overall scheme which allows EPA to decline to regulate a chemical under TSCA if other federal regulatory authorities (e.g., FIFRA) are sufficiently addressing the risks posed from those substances.

- **Asbestos and Asbestos-Containing Material**. Under TSCA §6 and 40 CFR Part 61, Subpart M, EPA regulates the renovation/demolition activities, notification, work practices and removal, and disposal of asbestos-containing material (ACM). ACM should be carefully monitored; however, the mere presence of asbestos in a building is not considered hazardous. ACM that becomes damaged, however, may pose a health risk since it may release asbestos fibers over time. If a material is suspected of containing asbestos and it is more than slightly damaged, or if changes need to be made to a building that might disturb it, repair or removal of the ACM by a professional is needed.

- **Asbestos Brake Pads**. Facilities that repair their own brakes should be aware of asbestos requirements. Asbestos brake pads must be removed using appropriate control measures so that no visible emissions of asbestos will be discharged to the outside air. These measures can include one of the following: (1) wetting that is generally done through the use of a brake washing solvent bath, such as those provided by a service; (2) vacuuming that is usually performed with a commercial brake vacuum specifically designed for use during brake pad changing or pad re-lining operations; or (3) combination of wetting and vacuuming.

  Asbestos brake pads and wastes must be managed by: (1) labeling equipment, (2) properly disposing of spent solvent, (3) properly disposing of used vacuum filters, and (4) sealing used brake pads. The containers or wrapped packages must be labeled using warning labels as specified by OSHA [29 CFR 1910.001 (j) (2) or 1926.58 (k)(2)(iii)].

  Asbestos waste must be disposed of as soon as practical at an EPA-approved disposal site. The asbestos containers must be labeled with the name and location of the waste generator. Vehicles used to transport the asbestos must be clearly labeled during loading and unloading. The waste shipment records must be maintained (40 CFR 61.150) so that the asbestos shipment can be tracked and substantiated.

- **Polychlorinated Biphenyls (PCBs)**. PCBs were widely used in electrical equipment manufactured from 1932 to 1978. Types of equipment potentially containing PCBs include transformers and their bushings, capacitors, reclosers, regulators, electric light ballasts, and oil switches. Any equipment containing PCBs in their dielectric fluid at concentrations of greater than 50 ppm are subject to the PCB requirements.

Under TSCA §6 and 40 CFR Part 761, facilities must ensure through activities related to the management of PCBs (e.g., inspections for leaks, proper storage) that human food or animal feed are not exposed to PCBs. While the regulations do not establish a specific distance limit, any item containing PCBs is considered to pose an unacceptable exposure risk to food or feed if PCBs released in any form have the potential to reach/contaminate food or feed.

- **Lead**. Approximately 1.7 million children have blood-lead levels high enough to raise health concerns. Studies suggest that lead exposure from deteriorated residential lead-based paint, contaminated soil, and lead in dust are among the major existing sources of lead exposure among children in the U.S.

  Section 1018 of the Residential Lead-Based Paint Hazard Reduction Act of 1992 directs EPA and the Department of Housing and Urban Development (HUD) to jointly issue regulations requiring disclosure of known lead-based paint and/or lead-based paint hazards by persons selling or leasing housing constructed before the phaseout of residential lead-based paint use in 1978. Under that authority, EPA and HUD jointly issued on March 6, 1996, regulations titled *Lead; Requirements for Disclosure of Known Lead-Based Paint and/or Lead-Based Paint Hazards in Housing* (40 CFR Part 35 and 40 CFR Part 745). In these regulations, EPA and HUD established requirements for sellers/lessors of residential housing built before 1978.

  Pre-Renovation Lead Information Rule. If conducted improperly, renovations in housing with lead-based paint can create serious health hazards to workers and occupants by releasing large amounts of lead dust and debris. Under TSCA §406 and through a rule published on June 1, 1998 entitled *Lead; Requirements for Hazard Education Before Renovation of Target Housing* (40 CFR Part 745), EPA required the distribution of lead hazard information (i.e., EPA-developed pamphlet) prior to professional renovations on residential housing built before 1978.

IV.C. Proposed and Pending Regulations

Clean Water Act

Feedlots Effluent Limitation Guidelines. EPA is in the process of reviewing and revising the effluent limitation guidelines for feedlots. EPA is

R0074566

under a court-ordered schedule to revise the guidelines for poultry and swine by December 2001 and for beef and dairy cattle by December 2002.

NPDES Implementing Regulations. EPA intends to revise the existing NPDES permitting regulations to clarify expectations and requirements for CAFOs as well as to reflect the changes in the industry. NRCS and other USDA agencies will participate on the regulatory workgroup to advise EPA on the technical and implementation aspects related to any proposed revisions. Revision of the permitting regulations is expected to be closely coordinated with the revision of the Feedlots Effluent Limitation Guidelines (40 CFR Part 412) because of the commonality of issues and the administrative efficiencies for EPA, States and all interested groups. Permits in effect on the date of new regulations will remain in effect until subsequently changed to incorporate the new requirements.

Coastal Zone Act Reauthorization Amendments of 1990

Implementation of Management Measures. Under Section 6217, states/tribes must fully implement the management measures in their Coastal Nonpoint Pollution Control Programs by January 2004. States/tribes are required to perform effectiveness monitoring between 2004 and 2006 and implement other measures between 2006 and 2009.

Safe Drinking Water Act

Management of Class V Wells. EPA plans to propose additional requirements addressing the environmental risks posed by the highest risk Class V wells. This rulemaking potentially affects agricultural operations that use industrial and commercial disposal wells and large capacity cesspools.

Federal Insecticide, Fungicide, and Rodenticide Act

Pesticide Management and Disposal: Proposed Rule - issued on May 5, 1993 (FR26857). The regulations for this rule will be found in the Code of Federal Regulations (CFR) at 40 CFR Part 165 - Regulations for the Acceptance of Certain Pesticides and Recommended Procedures for the Disposal and Storage of Pesticides and Pesticides Containers. This final rule will:

- Describe procedures for voluntary and mandatory recall actions.
- Establish criteria for acceptable storage and disposal plans which registrants may submit to EPA to become eligible for reimbursement of storage costs.
- Establish procedures for the indemnification of owners of suspended and canceled pesticides.

- Amend the Agency's responsibility for accepting for disposal suspended and canceled pesticides.

V. COMPLIANCE AND ENFORCEMENT HISTORY

V.A. Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match air, water, waste, toxics/pesticides, EPCRA, Toxics Release Inventory (TRI), and enforcement docket records for a given facility and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, EPA is developing sector-specific measures of success for compliance assistance efforts.

V.B. Compliance and Enforcement Profile Description

This section uses inspection, violation, and enforcement data from the IDEA system to provide information about the historical compliance and enforcement activity of this sector. While other sector notebooks have used Standard Industrial Classification (SIC) data from the Toxics Release Inventory System (TRIS) to define their data sampling universes, none of the SIC codes associated with the livestock production sector identifies facilities that report to the TRI program. As such, sector-defining data have been provided from EPA data systems

> **Note:** Many of the previously published sector notebooks contained a chapter titled *"Chemical Release and Transfer Profile."* The information and data for that chapter were taken primarily from EPA's Toxic Release Inventory (TRI). Because the industries discussed in this notebook do not, in general, directly report to TRI, that chapter has not been included in this sector notebook.

linked to EPA's Facility Indexing System (FINDS), which tracks facilities in all media databases. This section does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census. With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Before presenting the data, the next section defines general terms and the column heads used in the data tables. The data represent a retrospective summary of inspections and enforcement actions and solely reflect EPA, state, and local compliance assurance activities that have been entered into EPA databases. To identify trends, EPA ran two data queries, one for five calendar years (March 7, 1992 to March 6, 1997) and the other for a twelve-month period (March 7, 1996 to March 6, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and state's efforts within each media program. The presented data illustrate the variations across EPA regions for certain sectors[1]. This variation may be attributable to state/local data entry variation, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

[1]EPA Regions are as follows: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) - assigns a common facility number to EPA single-media permit records, establishing a linkage capability to the permit data. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) - is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of records for that facility. Some of the data systems accessible through IDEA are AFS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS. IDEA also contains information from outside sources, such as Dun and Bradstreet (DUN) and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in this section were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search - based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, or industries in which only a very small fraction of facilities report to TRI, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected - indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections - measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections - provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities With One or More Enforcement Actions - expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal state actions. A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions - describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (i.e., a facility with 3 enforcement actions counts as 3).

State Lead Actions - shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions - shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from state agencies. Many of these actions result from coordinated or joint federal/state efforts.

Enforcement to Inspection Rate - is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. The ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified - expresses the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections - four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

V.C. Livestock Production Industry Compliance History

Exhibit 19 provides an overview of the reported compliance and enforcement data for the livestock sector over a 5-year period (March 1992 to March 1997). These data are also broken out by EPA regions thereby permitting geographical comparisons. A few points evident from the data are listed below.

> **Note:** It should be noted that the data presented in this section represent federal enforcement activity only. Enforcement activity conducted at the state level is not included in this analysis.

- Of the 1,001 facilities identified through IDEA with livestock SIC codes, approximately 20 percent (205) were inspected in the last 5 years.

- Region 4 had more inspections (163) than other regions and the most enforcement actions (9), accounting for 29 percent of the total enforcement actions.

- Region 10 had only 3 percent of the total inspections, but had 16 percent of the total enforcement actions yielding the highest enforcement/inspection ratio of 0.29.

- The total inspections (600) conducted nationwide have resulted in 31 enforcement actions, which results in an enforcement-to-inspection rate of 0.05. This means that for every 100 inspections conducted, there are approximately 5 resulting enforcement actions.

- Enforcement actions were primarily state-led (84%). Regions 7 and 9 had no enforcement actions.

- Several regions (1, 4, 6, 7, 8, 10) had an average time between inspections of greater than 100 months.

Exhibit 19. Five-Year Enforcement and Compliance Summary for the Livestock Industry

Comparison of Enforcement Activity Between Selected Industries

Exhibits 20 and 21 allow the compliance history of the livestock production sector to be compared to other industries covered by the sector notebooks. Comparisons between these exhibits permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering a 5-year period (March 1992 to March 1997) to that of a 1-year period (March 1996 to March 1997). Some points evident from the data are listed below.

- The one-year enforcement-to-inspection ratio (0.01) is one-fifth of the five-year ratio (0.05).
- In the 5-year comparison, the average months between inspections (100) was more than any other sector.
- In Exhibit 20, the livestock production industry data approximate the averages of the industries shown for percent state-lead versus federal-led actions.
- In Exhibit 21, when compared to all sectors over the period March 1996 - March 1997, the livestock sector had the third fewest number of inspections conducted (146) and fewest enforcement actions (2).

Exhibits 22 and 23 provide a more in-depth comparison between the livestock production sector and other sectors by breaking out compliance and enforcement data by environmental statute. As in the previous exhibits (Exhibits 20 and 21), the data cover a 5-year period (Exhibit 22) and a 1-year period (Exhibit 23) to facilitate the identification of recent trends. Points evident from the data are listed below.

- As shown in Exhibit 22, over the past 5 years, more than half (57%) of all inspections conducted at livestock facilities and nearly two-thirds (65%) of all enforcement actions have been under the Clean Water Act. It should be noted that 3 percent of all enforcement actions were taken under the FIFRA/TSCA/EPCRA/Other category although no inspections were conducted within that category. This number is possible because in many EPA regions, media inspectors are being trained to examine the facility from a multimedia viewpoint.
- As shown in Exhibits 22 and 23, Clean Water Act inspections account for more than half (57% and 51%, respectively) of all inspections, with the Clean Air Act representing nearly all of the remaining inspections (38% and 48%, respectively). However, from March 1996 - March

1997, every single enforcement action taken was under the Clean Water Act.

THIS PAGE LEFT INTENTIONALLY BLANK

VI. Review of Major Legal Actions and Compliance/Enforcement Strategies

This section provides summary information about major cases that have affected the livestock production industry, as well as regional highlights of CAFO compliance/enforcement strategies.

Usually, this section also contains information on any supplemental environmental projects (SEPs) that were negotiated. SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. However, no information on SEPs in this sector was discovered during the research process. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility. To learn more about SEPs, go to http://www.epa.gov/oeca/sep.

Review of Major Cases

A review of EPA's FY92 and FY93 *Enforcement Accomplishments Report* and the FY94 through FY98 *Enforcement and Compliance Assurance Accomplishments Report* identified several cases involving the livestock production industry. These cases are discussed below.

- In February 1999, EPA cited David Jaindl, president of Jaindl Land Company, for filling in federally protected wetlands at a turkey farm. EPA has alleged that Mr. Jaindl violated the Clean Water Act by filling three acres of wetlands at the farm in September and October 1998 without a required permit from the U.S. Army Corps of Engineers. EPA is seeking a $44,000 penalty for this violation.

- In October 1996, an Administrative Penalty Order (APO) with a $25,000 penalty was administered against *Del Oro Dairy* of New Mexico for failing to provide a Pollution Prevention Plan as required by the NPDES General Permit for Concentrated Animal Feeding Operations. This violation occurred from 1994 thru 1996. In March 1997, another Administrative Penalty Order and $5,500 fine was issued for failure to complete and implement a Pollution Prevention Plan. These enforcement actions are intended to prevent the pollution of the groundwater by requiring the facility to apply good management practices.

- United States v. Harry James Saul and Ronnie Snead: Harry Saul, part owner and operator of Harry Saul Minnow Farm, Inc., Prairie County, Arkansas, and a company employee, Ronnie Snead, were sentenced on June 19, 1996 by Federal Magistrate Henry Jones for a misdemeanor violation of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). The defendants had mixed furadan, a restricted use pesticide, with minnows and spread the treated minnows on a levee on the minnow farm to control nuisance birds. Saul was ordered to pay a $5,000 fine and Snead a $1,000 fine for use inconsistent with the label. The defendants are appealing the Court's judgement.

- During fiscal year 1996, *Esplin Dairy* allegedly discharged approximately 900,000 pounds per year of animal waste to a slough discharging to Nehalem Bay, Oregon. In response to an EPA order, the dairy set up a system to keep manure from contaminating clean water and installed a 10,000 gallon tank to collect wastewater before pumping it to larger containment facilities. The wastewater is high in fecal coliform bacteria, BOD, TSS, and nutrients.

- The *Four Brothers Dairy* paid a penalty of $7,350 in fiscal year 1996 for the alleged unpermitted discharge of an estimated 561,000 gallons of wastewater from its Shoshone, Idaho dairy to a canal draining to the Snake River. EPA measured fecal coliform levels as high as 180,000 colonies/100ml in the wastewater in the canal.

- *Gienger Farms, Inc.* allegedly discharged approximately 1.3 million gallons of manure-laden wastewater to drainage ditches flowing into the Tillamook Bay, Oregon, without a permit. In fiscal year 1996, in response to an EPA administrative complaint, the farm paid a $20,000 penalty and modified its operations to separate clean water from contaminated material, thereby extending the holding capacity of its wastewater storage lagoon from two to 57 days. In addition, the facility began monitoring and managing its land application practices, thus preventing the discharge of wastewater containing about 6,435 pounds of BOD and TSS to waters of the U.S.

- In fiscal year 1996, *Misty Meadow Dairy* agreed to pay a $6,000 fine for the alleged unpermitted discharge of about 685,000 pounds of manure per year to navigable waters flowing into Tillamook Bay, Oregon. The dairy is expected to sell half of its herd in order to allow more flexibility in managing waste accumulations.

- In fiscal year 1996, *Veeman Dairy* paid a $1,000 penalty for allegedly discharging 52 to 78 million gallons of wastewater to navigable waters flowing into the Willamette River, Oregon. In response to a separate compliance order, the dairy will repair and maintain its wastewater storage ponds to eliminate future discharges.

- In March 1998, a significant criminal enforcement case was taken by the California Resource Board. The U.S. District Court assessed the operator of the *3H Dairy Farm* in Oakdale, CA a $100,000 fine; $101,000 in farm improvements; 90 days in jail; 90 days of home confinement; and 4 years of probation for repeatedly violating state water pollution laws.

Regional Initiatives

According to the FY 1997 and FY 1998 *Enforcement and Compliance Assurance Accomplishments Reports*, several regions targeted their enforcement efforts on agricultural practices during these fiscal years. It should be noted that while CAFOs were the primary focus within the agriculture sector, there were other agriculture activities as well. Some of the Regional initiatives included the following:

- During FY 96, **Region 6** conducted CAFO inspections in the states of Oklahoma, Texas, and New Mexico. These resulted in the EPA issuing five Orders for non-compliance and two Administrative Penalty Orders. The State of Texas also issued penalty actions to three dairies for violation of the State permit. Region 6's emphasis on CAFOs was on the NPDES general permit and its implementation. Six EPA and 24 state CAFO inspections were conducted in FY97 to determine whether facilities were compliant with the CAFO general permit. The region continues to improve its knowledge of the numbers of facilities by the improvement of the database in all states.

- In FY 1997, **Region 7** states took 26 enforcement actions against feedlots for water quality-related violations. In FY 1998, Iowa settled 13 CAFO cases with penalties of $21,238; Kansas settled 4 CAFO cases with $77,520 in penalties; Missouri settled 12 CAFO cases with $20,256 in penalties; and Nebraska settled 2 CAFO cases with $1,700 in penalties.

- In February 1997, **Region 9** initiated a Regional Agriculture Team to complement the Agriculture Initiative team by developing a Regional Agriculture Strategy and incorporating agriculture pollution prevention principles into core agency programs.

- Through the **Region 10** CAFO Whatcom County Initiative, the Region conducted NPDES inspections at 67 targeted facilities; six were issued penalties, three were designated as significant contributors of pollutants, six were issued certificates of merit, and 52 were issued warning letters.

CAFO Compliance/Enforcement Strategies

EPA concluded a total of 93 enforcement cases against this sector in fiscal years 1997, 1998, and 1999 with a total of $163,000 in penalties. In FY 98, Regions conducted 339 compliance inspections. Each Region is working with its NPDES States to develop and implement individual state specific CAFO strategies. Regional highlights include:

- **Region 3** served as the EPA lead on the recently concluded national Poultry Dialog which included recommendations for actions by the poultry industry. Recently, in a key action growing out of the dialog, Perdue Farms Inc. agreed to help farmers dispose of chicken waste in the Delmarva peninsula region.

- **Region 6** held 5 outreach meetings in 4 states in 1998. The Region conducted 95 inspections resulting in 20 administrative orders and 2 administrative penalties.

- **Region 7** initiated a compliance tracking system to collect accurate and readily available information about state CAFO enforcement actions and penalty amounts. The Region also developed maps of CAFO locations in Iowa and Kansas by using state databases.

- **Region 9's** approach combines compliance assistance and inspections/enforcement. The Region is one of 20+ partners of the California Dairy Initiative which seeks to combine education, outreach, nutrient management plans with third party certification. In addition, the Region has developed an inspection targeting approach based on herd size and proximity to surface water. In 1998, the region conducted 133 inspections in 3 counties. The region issued 3 compliance orders and 2 penalty orders against dairy operators.

- **Region 10** expanded its compliance enforcement focus to include an additional 4 other counties in Western Washington State. The Region conducted 58 inspections resulting in 11 compliance orders/penalties; 3 compliance orders only; and 33 warning letters. Facilities found in compliance were issued courtesy letters. EPA's efforts have succeeded in raising public awareness as indicated by real-estate appraisers asking if EPA has any concerns about the facilities they are appraising.

VII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VII.A. Sector-Related Environmental Programs and Activities

There are several federal programs available to the agricultural community to assist agricultural producers in complying with environmental regulations and reducing pollution. The following examples represent some industry initiatives that promote compliance or assess methods to reduce environmental contamination.

National Agriculture Compliance Assistance Center

The U.S. Environmental Protection Agency (EPA), with the support of the Department of Agriculture (USDA), has developed a national Agriculture Compliance Assistance Center (Ag Center) to provide a base for "first-stop shopping" for the agricultural community -- one place for the development of comprehensive, easy-to-understand information about approaches to compliance that are both environmentally protective and agriculturally sound. The Ag Center, a program offered by EPA's Office of Compliance, seeks to increase compliance by helping the agricultural community identify flexible, common sense ways to comply with the many environmental requirements that affect their business. Initial efforts will focus on providing information about EPA's requirements. The Ag Center will rely heavily on existing sources of agricultural information and established distribution mechanisms. The Ag Center is designed so growers, livestock producers, other agribusinesses, and agricultural information/education providers can access its resources easily -- through telephone, fax, mail, and Internet. The Ag Center website can be accessed at http://www.epa.gov/agriculture.

Unified National Strategy for Animal Feeding Operations

As part of President Clinton's Clean Water Action Plan (CWAP), a USDA-EPA unified national strategy has been developed to minimize the water quality and public health impacts of animal feeding operations (AFOs). AFOs are agricultural enterprises where animals are kept and raised in confined situations and have been shown to contribute to significant problems in surface waters. Such problems have included nutrient loading, fish kills, and odors. AFOs are agricultural livestock facilities that confine feeding activities, concentrating livestock and their manure. There are approximately

450,000 AFOs in the U.S. Of these, 6,600 were concentrated AFOs, or CAFOs. CAFOs pose a greater environmental threat, since they confine larger numbers of animals. Less than a quarter of CAFOs have Clean Water Act permits to control the amount of wastes that run off into waterways.

The Unified National Strategy for Animal Feeding Operations presents USDA and EPA's plan for addressing the water quality and public health impacts associated with AFOs. USDA and EPA issued the final Strategy in March 1999. The USDA-EPA Unified National Strategy for Animal Feeding Operations reflects several guiding principles:

- Minimize water quality and public health impacts from AFOs.
- Focus on AFOs that represent the greatest risks to the environment and public health.
- Ensure that measures to protect the environment and public health complement the long-term sustainability of livestock production in the United States.
- Establish a national goal and environmental performance expectations for all AFOs.
- Promote, support, and provide incentives for the use of sustainable agricultural practices and systems.
- Build on the strengths of USDA, EPA, State and Tribal agencies, and other partners and make appropriate use of incentive-base approaches.
- Foster public confidence that AFOs are meeting their performance expectations and that USDA, EPA, local governments, States, and Tribes are ensuring the protection of water quality and public health.
- Coordinate activities among the USDA, EPA, and related State and Tribal agencies and other organizations that influence the management and operation of AFOs.
- Focus technical and financial assistance to support AFOs in meeting the national goal and performance expectation established in this Strategy.

USDA and EPA's goal is for AFO owners and operators to take actions to minimize water pollution from confinement facilities and land application of manure. To accomplish this goal, this Strategy is based on a national performance expectation that all AFOs should develop and implement technically sound, economically feasible, and site-specific Comprehensive Nutrient Management Plans (CNMPs) to minimize impacts on water quality and public health.

This Strategy describes short- and long- term activities to implement and improve the existing regulatory program using a two-phased approach to permitting CAFOs. During Round I, beginning in about 2000, EPA and States will issue permits to CAFOs under the existing National Pollutant Discharge

Elimination System (NPDES) regulations. During Round II, beginning in about 2005, EPA and States will reissue NPDES permits to CAFOs based on revised effluent guidelines for feedlots, as well as revised regulations for NPDES permitting and any other new information. During Round I and Round II, State NPDES permitting authorities will have flexibility to define specific permitting approaches within their existing programs. For more information, the complete unified national strategy can be accessed at http://www.epa.gov/owm/finafost.htm.

Compliance Assurance Implementation Plan For Concentrated Animal Feeding Operations

The Office of Enforcement and Compliance Assurance (OECA) is making implementation of the existing concentrated animal feeding operation (CAFO) regulations a priority. The purpose of the implementation plan is to protect and enhance water quality by ensuring compliance with the Clean Water Act and its implementing requirements. The Plan's major elements are: 1) strong state and regional compliance/enforcement partnerships; 2) effective state specific compliance/enforcement strategies; 3) productive, coordinated compliance assistance activities; 4) strong compliance monitoring programs; 5) effective enforcement; 6) better data/information on CAFOs for targeting compliance assistance and inspections; and 7) plans for developing a feedback mechanism to EPA, states, and other federal agencies. This plan was finalized in March 1998. For more information, refer to http://es.epa.gov/oeca/strategy.html.

VII.B. EPA Programs and Activities

Section 319 Nonpoint Source Management Program
In 1987, Congress amended the Clean Water Act (CWA) to establish the §319 Nonpoint Source Management Program in recognition of the need for greater federal leadership to help focus state and local nonpoint source efforts. Under §319, states, territories, and Indian tribes receive grant money to support a wide variety of activities, including technical assistance, financial assistance, education, training, technology transfer, demonstration projects, and monitoring to assess the success of specific nonpoint source implementation projects. For more information about the Clean Water Act §319 Program refer to EPA's Office of Water website at http://www.epa.gov/OWOW/NPS/sec319.html.

Clean Lakes Program
EPA's Clean Lakes Program supports a variety of lake management activities including classification, assessment, study, and restoration of lakes. The program, authorized in §314 of the Clean Water Act, was established to provide technical and financial assistance to states/tribes for restoring the

quality of publicly owned lakes. The Clean Lakes Program has funded approximately $145 million for grant activities since 1976 to address lake problems, but there have been no appropriations for the program since 1994. EPA has not requested funds for the Clean Lakes Program in recent years, but has encouraged states to use §319 funds to fund "eligible activities that might have been funded in previous years under Section 314." Information on the Clean Lakes Program is available at the following Internet site: http://www.epa.gov/owow/lakes/cllkspgm.html.

National Estuary Program

EPA's National Estuary Program is a national demonstration program, authorized in §320 of the Clean Water Act, that uses a comprehensive watershed management approach to address water quality and habitat problems in 17 estuaries. Nonpoint source pollution is a major contributor of contaminants in the estuary and coastal waters around the country. In this program, EPA and states/tribes develop conservation and management plans that recommend priority corrective actions to restore estuarine water quality, fish populations, and other designated uses of the waters. Information on the National Estuary Program is available at the following Internet site: http://www.epa.gov/owowwtr1/estuaries/nep.html or by contacting the National Estuary Program Office at (202) 260-1952.

Chesapeake Bay Program and The Great Lakes National Program

EPA's Chesapeake Bay Program and the Great Lakes National Program focus substantial resources on understanding the extent of nonpoint source pollution problems in their respective watersheds and supporting State implementation of non-point source pollution controls. Since 1984, the Chesapeake Bay Program, in particular, has supported the implementation of a substantial amount of animal waste management practices through State cost share programs funded jointly by the Bay States and EPA. Information on the Chesapeake Bay Program is available at http://www.epa.gov/owowwtr1/ecoplaces/part1/site2.html. Information on The Great Lakes National Program is available at http://www.epa.gov/glnpo/.

AgSTAR Program

The AgSTAR program is a voluntary program that promotes the use of profitable manure management systems that reduce pollution. The program, a component of President Clinton's Climate Action Plan, is based on a computer model that shows the economic value of capturing the methane naturally produced by manure.

AgSTAR, a joint program of EPA, USDA, and the Department of Energy, helps agricultural producers determine which methane recovery and use technologies will work best for them, and develops financing sources to help with start-up costs. By investing in these technologies, AgSTAR participants realize substantial returns through reduced electrical, gas, and oil bills, revenues from high quality manure by-products, and savings on manure management operational costs. Partners also reduce pollution associated with water resources, odors, and global warming. Information on AgSTAR is available at the following Internet site: http://yosemite.epa.gov/methane/home.nsf/pages/agstar.

Ruminant Livestock Efficiency Program (RLEP)
Ruminant livestock such as cattle and sheep are the largest source of methane emissions resulting from human activity. Methane, produced as part of the animals' normal digestive process, is a potent greenhouse gas that contributes to global climate change. By improving livestock production efficiency, producers can both increase profits and reduce methane emissions.

The RLEP is a joint EPA-USDA program helping livestock producers improve their operations' efficiency, preserve the nation's natural resources and reduce methane emissions. The program focuses on reducing livestock methane emissions and producing economic benefits by offering technical assistance to producers around the country. For more information, review the Program Overview at http://yosemite.epa.gov/methane/home.nsf/pages/rlep to learn how RLEP is helping improve the environment and livestock producers' profits.

Pesticide Environmental Stewardship Program
EPA's Pesticide Environmental Stewardship Program (PESP) is a voluntary program dedicated to protecting human health and preserving the environment by reducing the risks associated with pesticide use. The partnership is a key element of the program, which is sponsored by EPA, USDA, and FDA. Current partners include agricultural producers as well as non-agricultural interests. Partners in PESP volunteer to develop and implement a well designed pesticide management plan that will produce the safest and most effective way to use pesticides. In turn, EPA provides a liaison to assist the partner in developing comprehensive, achievable goals. Liaisons act as "customer service representatives" for EPA, providing the partner with access to information and personnel. EPA also promises to integrate the partners' stewardship plans into its agricultural policies and programs.

So far, agricultural producers have committed to a number of projects, including conducting more research into IPM techniques, developing computer prediction models for more precise pesticide applications, educating their members and the public regarding pesticide use, and working with

Focus on Pesticides
EPA's Endangered Species Protection Program is designed to protect Federally-listed endangered and threatened species from exposure to pesticides.

R0074591

equipment manufacturers to refine application techniques. Information on PESP is available at the following Internet site: http://www.pesp.org, or contact the PESP hotline at (800) 972-7717.

Endangered Species Protection Program
The Endangered Species Protection Program (ESPP) began in 1988. This program is largely voluntary at the present time and relies on cooperation between the U.S. Fish and Wildlife Service (FWS), EPA Regions, States, and pesticide users. ESPP is intended to provide information concerning and regulation for the use of pesticides that may adversely affect the survival, reproduction and/or food supply of listed species. Due to labeling requirements, potential users will be informed prior to making a purchase that there may be local limitations on product use due to endangered species concerns. Information on the Endangered Species Protection Program is available at the following Internet site: http://www.epa.gov/oppfead1/endanger/index.htm.

Energy Star® Buildings and Green Lights® Partnership
In 1991, EPA introduced Green Lights®, a program designed for businesses and organizations to proactively combat pollution by installing energy-efficient lighting technologies in their commercial and industrial buildings. In April 1995, Green Lights® expanded into Energy Star® Buildings— a strategy that optimizes whole-building energy-efficiency opportunities. The energy needed to run commercial and industrial buildings in the United States produces 19 percent of U.S. carbon dioxide emissions, 12 percent of nitrogen oxides, and 25 percent of sulfur dioxide, at a cost of $110 billion a year. If implemented in every U.S. commercial and industrial building, the Energy Star® Buildings upgrade approach could prevent up to 35 percent of the emissions associated with these buildings and cut the nation's energy bill by up to $25 billion annually.

The more than 2,900 participants include corporations, small businesses, universities, health care facilities, nonprofit organizations, school districts, and federal and local governments. As of March 31, 1999, Energy Star® Buildings and Green Lights® Program participants are saving $775 million in energy bills with an annual savings of 31.75 kilowatt per square foot and annual cost savings of $0.47 per square foot. By joining, participants agree to upgrade 90 percent of their owned facilities with energy-efficient lighting and 50 percent of their owned facilities with whole-building upgrades, where profitable, over a seven-year period. Energy Star® participants first reduce their energy loads with the Green Lights® approach to building tune-ups, then focus on "right sizing" their heating and cooling equipment to match their new energy needs. EPA's Office of Air and Radiation is responsible for operating the Energy Star® Buildings and Green Lights® Program. (Contact: Energy Star Hotline, 1-888-STAR-YES (1-888-782-7937) or Maria Tikoff Vargas, Co-Director at (202) 564-9178 or visit the website at http://www.epa.gov/buildings.

WasteWi$e Program
The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection, and the manufacturing and purchase of recycled products. As of 1998, the program had about 700 business, government, and institutional partners. Partners agree to identify and implement actions to reduce their solid wastes by setting waste reduction goals and providing EPA with yearly progress reports for a three-year period. EPA, in turn, provides partners with technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at (800) 372-9473 or Joanne Oxley, EPA Program Manager, (703) 308-0199.)

Climate Wise Program
In October 1993, President Clinton unveiled the Climate Change Action Plan (CCAP) in honor of the United States' commitment to reducing its greenhouse gas emissions to 1990 levels by the year 2000. Climate Wise, a project jointly sponsored by the U.S. Department of Energy and EPA, is one of the projects initiated under CCAP.

Climate Wise is a partnership between government and industry that offers companies a nonregulatory approach to reducing greenhouse gas emissions. Climate Wise state and local government "allies" work with U.S. industries to develop flexible, comprehensive strategies for achieving energy efficiency and pollution prevention. They help local business identify and implement projects that often require little capital investment, but promise a high rate of return. Companies that become Climate Wise partners receive technical assistance and financing information to help them develop and implement cost-effective changes. (Contact: Climate Wise Clearinghouse at (301) 230-4736 or visit the Climate Wise website at http://www.epa.gov/climatewise/allies.htm or http://www.epa.gov/climatewise/index.htm.)

VII.C. USDA Programs and Activities

Environmental Quality Incentives Program
The Environmental Quality Incentives Program (EQIP) is a USDA funded program (led by Natural Resources Conservation Service) that was established in the 1996 Farm Bill to provide a voluntary conservation program for farmers and ranchers who face serious threats to soil, water, and related natural resources. EQIP embodies four of USDA's former conservation programs, including the Agricultural Conservation Program, the Water Quality

Incentives Program, the Great Plains Conservation Program, and the Colorado River Basin Salinity Control Program.

EQIP offers 5 to 10 year contracts that provide *incentive payments* and *cost-sharing* for conservation practices called for in a site-specific conservation plan that is required for all EQIP activities. *Cost-sharing* may include up to 75 percent of the costs of certain conservation practices, such as grassed waterways, filter strips, manure management facilities, capping abandoned wells, and other practices. *Incentive payments* may be made to encourage land management practices such as nutrient management, manure management, integrated pest management, irrigation water management, and wildlife habitat management. These payments may be provided for up to three years to encourage producers to carry out management practices they may not otherwise use without the program incentive.

EQIP has an authorized budget of $1.3 billion through the year 2002. It was funded for $174 million in 1999. Total cost-share and incentive payments are limited to $10,000 per person per year and $50,000 for the length of the contract. Eligibility is limited to persons who are engaged in livestock or agricultural production. Fifty percent of the funds must be spent on livestock production. The 1996 Farm Bill prohibits owners of large confined livestock operations from being eligible for cost-share assistance for animal waste storage or treatment facilities. However, technical, educational, and financial assistance may be provided for other conservation practices on such operations. Further information relating to EQIP may be found on NRCS's website located at
http://www.nhq.nrcs.usda.gov/OPA/FB96OPA/eqipfact.html.

Conservation Reserve Program

The Conservation Reserve Program (CRP) is a highly successful conservation program administered by USDA. Since 1986, CRP has provided financial incentives to farmers and ranchers to take land out of agricultural production and plant trees, grass and other types of vegetation. The result has been reduced soil erosion, improved air and water quality and establishment of millions of acres of wildlife habitat.

With the New Conservation Reserve Program, launched with the final rule published in the Federal Register on February 19, 1997, the Farm Service Agency (FSA) begins a renewed effort to achieve the full potential of government-farmer conservation partnerships. Only the most environmentally-sensitive land, yielding the greatest environmental benefits, will be accepted into the program.

The 36.4-million-acre congressionally mandated cap on enrollments is carried over from the previous program, meaning that the new CRP has authority to enroll only about 15 percent of the eligible cropland. To make the most of the program's potential, a new Environmental Benefits Index (EBI) was developed. The new EBI will be used to select areas and acreages offering the greatest environmental benefits.

Conservation priority areas (CPAs) are regions targeted for CRP enrollment. The four national CPAs are the Long Island Sound region, the Chesapeake Bay and surrounding areas, an area adjacent to the Great Lakes, and the Prairie Pothole region. FSA State Committees may also designate up to 10 percent of a State's remaining cropland as a State Conservation Priority Area. The NRCS is responsible for determining the relative environmental benefits of each acre offered for participation.

Continuous Sign-Up. For certain high-priority conservation practices yielding highly desirable environmental benefits, producers may sign up at any time, without waiting for an announced sign-up period. Continuous sign-up allows farmers and ranchers management flexibility in implementing certain conservation practices on their cropland. These practices are specially designed to achieve significant environmental benefits, giving participants a chance to help protect and enhance wildlife habitat, improve air quality, and improve the condition of America's waterways. Unlike the general CRP program, sign-up for these special practices is open continuously. Provided certain eligibility requirements are met, acreage is automatically accepted into the program at a per-acre rental rate not to exceed the Commodity Credit Corporation's maximum payment amount, based on site-specific soil productivity and local prevailing cash-equivalent rental rates. For more information on the CRP, see USDA's website at http://www.fsa.usda.gov/dafp/cepd/crpinfo.htm.

Conservation Reserve Enhancement Program

The Conservation Reserve Enhancement Program (CREP), a refinement of the CRP, is a state-federal conservation partnership program targeted to address *specific* state and nationally significant water quality, soil erosion and wildlife habitat issues related to agricultural use. The program uses financial incentives to encourage farmers and ranchers to voluntarily enroll in contracts of 10 to 15 years in duration to remove lands from agricultural production. This community-based conservation program provides a flexible design of conservation practices and financial incentives to address environmental issues. For more information about CREP, refer to USDA's website at http://www.fsa.usda.gov/dafp/cepd/crep/crephome.htm.

Wetlands Reserve Program

Congress authorized the Wetlands Reserve Program (WRP) under the Food Security Act of 1985, as amended by the 1990 and 1996 Farm Bills. USDA's Natural Resources Conservation Service (NRCS) administers the program in consultation with the Farm Service Agency and other Federal agencies. WRP is a voluntary program to restore wetlands. Landowners who choose to participate in WRP may sell a conservation easement or enter into a cost-share restoration agreement with USDA to restore and protect wetlands. The landowner voluntarily limits future use of the land, yet retains private ownership.

WRP offers landowners three options: *permanent easements*, *30-year easements*, and *restoration cost-share agreements* of a minimum 10-year duration. In exchange for establishing a *permanent easement*, the landowner receives payment up to the agricultural value of the land and 100 percent of the restoration costs for restoring the wetland. In exchange for the *30-year easement*, the landowner receives a payment of 75 percent of what would be provided for a permanent easement on the same site and 75 percent of the restoration cost. The *restoration cost-share agreement* is an agreement (generally for a minimum of 10 years) to re-establish degraded or lost wetland habitat, in which USDA pays the landowner 75 percent of the cost of the restoration activity. Restoration cost-share agreements establish wetland protection and restoration as the primary land use for the duration of the agreement. In all instances, landowners continue to control access to their land. For more information about WRP, see NRCS's website at: http://wl.fb-net.org.

Conservation Farm Option

The Conservation Farm Option (CFO) is a voluntary pilot program for producers of wheat, feed grains, cotton, and rice. The program purposes include conservation of soil, water, and related resources, water quality protection and improvement, wetland restoration, protection and creation, wildlife habitat development and protection, or other similar conservation purposes. Eligibility is limited to owners and producers who have contract acreage enrolled in the Agricultural Market Transition program. Participants are required to develop and implement a conservation farm plan. The plan becomes part of the CFO contract which covers a ten year period. CFO is not restricted as to what measures may be included in the conservation plan, so long as they provide environmental benefits. During the contract period the owner or producer (1) receives annual payments for implementing the CFO contract, and (2) agrees to forgo payments under the Conservation Reserve Program, the Wetlands Reserve Program, and the Environmental Quality Incentives Program in exchange for one consolidated program.

Wildlife Habitat Incentives Program

The Wildlife Habitat Incentives Program (WHIP) is a voluntary program (administered by NRCS) for people who want to develop and improve wildlife habitat primarily on private lands. It provides both technical assistance and cost-share payments to help establish and improve fish and wildlife habitat.

Under this program, NRCS helps participants prepare a wildlife habitat development plan in consultation with the local conservation district. The plan describes the landowner's goals for improving wildlife habitat, includes a list of practices and a schedule for installing them, and details the steps necessary to maintain the habitat for the life of the agreement. This plan may or may not be part of a larger conservation plan that addresses other resource needs such as water quality and soil erosion.

USDA and the participant enter into a cost-share agreement that generally lasts between 5 to 10 years from the date the agreement is signed. Under the agreement: the landowner agrees to install and maintain WHIP practices and allow NRCS or its agent access to monitor the effectiveness of the practices; and USDA agrees to provide technical assistance and pay up to 75 percent of the cost of installing the wildlife habitat practices.

WHIP is currently budgeted for $50 million total through the year 2002. WHIP funds are distributed to States based on State wildlife habitat priorities, which may include wildlife habitat areas, targeted species and their habitats, and specific practices. WHIP may be implemented in cooperation with other Federal, State, or local agencies; conservation districts; or private conservation groups. For more information, see NRCS's website at http://www.nrcs.usda.gov.

Conservation of Private Grazing Land Initiative

The Conservation of Private Grazing Land initiative will ensure that technical, educational, and related assistance is provided to those who own private grazing lands. It is not a cost share program. This technical assistance will offer opportunities for better grazing and land management; protecting soil from erosive wind and water; using more energy-efficient ways to produce food and fiber; conserving water; providing habitat for wildlife; sustaining forage and grazing plants; using plants to sequester greenhouse gases and increase soil organic matter; and using grazing lands as a source of biomass energy and raw materials for industrial products.

The Wetland Conservation Provision (Swampbuster)

This provision, part of the 1985, 1990, and 1996 farm bills, requires all agriculture producers to protect wetlands on the farms they own or operate if they want to be eligible for USDA farm program benefits. The Swampbuster program generally allows the continuation of most ongoing farming practices as long as wetlands are not converted or wetland drainage increased. The program discourages farmers from altering wetlands by withholding Federal farm program benefits from any person who does the following:

- Plants an agricultural commodity on a converted wetland that was converted by drainage, dredging, leveling or any other means after December 23, 1985.
- Converts a wetland for the purpose of or to make agricultural commodity production after November 28, 1990.

In order to ensure farm program benefits under the Swampbuster provisions, the local NRCS office should be contacted before clearing, draining, or manipulating any wet areas on any farmland.

VII.D. Other Voluntary Initiatives

NICE^3

The U.S. Department of Energy sponsors a grant program called National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). The NICE^3 program provides funding to state and industry partnerships (large and small businesses) for projects demonstrating advances in energy efficiency and clean production technologies. The goal of the NICE^3 program is to demonstrate the performance and economics of innovative technologies in the U.S., leading to the commercialization of improved industrial manufacturing processes. These processes should conserve energy, reduce waste, and improve industrial cost-competitiveness. Industry applicants must submit project proposals through a state energy, pollution prevention, or business development office. Awardees receive a one-time, three-year grant of up to $400,000, representing up to 50 percent of a project's total cost. In addition, up to $25,000 is available to support the state applicant's cost share. (Contact: View the website at http//www.oit.doe.gov/Access/nice3; Steve Blazek, DOE, (303) 275-4723; or Eric Hass, DOE, (303) 275-4728.)

ISO 14000

ISO 14000 is a series of internationally-accepted standards for environmental management. The series includes standards for environmental management systems (EMS), guidelines on conducting EMS audits, standards for auditor qualifications, and standards and guidance for conducting product lifecycle analysis. Standards for auditing and EMS were adopted in September 1996, while other elements of the ISO 14000 series are currently in draft form. While regulations and levels of environmental control vary from country to country, ISO 14000 attempts to provide a common standard for environmental management. The governing body for ISO 14000 is the International Organization for Standardization (ISO), a worldwide federation of over 110 country members based in Geneva, Switzerland. The American National Standards Institute (ANSI) is the United States representative to ISO. Information on ISO is available at the following Internet site: http://www.iso.ch/welcome.html.

VII.E. Summary of Trade Associations

There are more than 200 trade associations that deal with agricultural issues. Many of these are at the national level, while others deal specifically with regions of the country or individual states. The following identify some of the major associations addressing agricultural production.

American Dairy Goat Association
Ronald E. Gelvin, Secretary Treasurer
P.O. Box 865
209 W. Main Street
Spindale, NC 28160
Telephone: 704-286-3801
Fax: 704-287-0476

American Dairy Association
10255 W. Higgins
Rosemont, IL 60018
Telephone: 847-803-2000
Fax: 847-803-2077

American Farm Bureau Federation
Washington DC Office
600 Maryland Avenue, SW
Suite 800
Washington, DC 20024
Telephone: 202-484-3600
Fax: 202-484-3604

American Hereford Association
Craig Huffhines,
Executive Vice President
P.O. Box 014059
Kansas City, MO 64101
Telephone: 816-842-3757
Fax: 816-842-6931

American Horse Council
James J. Hickey, Jr., President
1700 K Street, NW, # 300
Washington, DC 20006
Telephone: 202-296-4031
Fax: 202-296-1970

American Equine Association
Carol Winterburger, Executive Director
Box 658
Newfoundland, NJ 07435
Telephone: 973-697-9668
Fax: 973-697-1538

American Farm Bureau Federation
Headquarters Office
225 Touhy Avenue
Park Ridge, IL 60068
Telephone: 847-685-8600
Fax: 847-685-8896

National Broilers Council
George B. Watts
1015 15th Street, NW, Suite 950
Washington, DC 20005
Telephone: 202-408-1339

National Cattlemen's Beef Assoc.
Charles Schroeder, CEO
1301 Pennsylvania Avenue, NW, Suite 300
Washington, DC 20004-1701
Telephone: 202-347-0228
Fax: 202-638-0607

National Farmers Organization
2505 Elwood Drive
Ames, IA 50010-2000
Telephone: 515-292-2000
Fax: 515-292-7106

American National Cattle Women
4278 Highway 196
Lamar, CO 81052
Telephone: 303-829-4475
Fax: 303-694-2390

American Poultry Association
Lorna Rhodes, Secretary Treasurer
133 Millville Street
Mendon, MA 01756
Telephone and Fax: 508-473-8769

American Sheep Industry Association
Peter Orwick, Executive Director
6911 South Yosemite St.
Englewood, CO 80112-1414
Telephone: 303-771-3500
Fax: 303-771-8200

Association of American Pesticide Control Officials
P.O. Box 1249
Hardwick, VT 05843
Telephone: 802-472-6956
Fax: 802-472-6957

National Pork Producers Council
Jerry King, President
P.O. Box 10383
Des Moines, IA 50306
Telephone: 515-223-2600
Fax: 515-223-2646

National Farmers Union
Leland Swenson, President
11900 E. Cornell Avenue
Aurora, CO 80014-3194
Telephone: 303-337-5500
Fax: 303-368-1390

National Fisheries Institute
Dick Gutting,
Executive Vice President
1901 N. Fort Myer Drive, Suite 700
Arlington, VA 22209
Telephone: 703-524-8880
Fax: 703-524-4619

National Live Stock Producers Association
R. Scott Stuart, CEO
660 Southpointe Court, Suite 314
Colorado Springs, CO 80906
Telephone: 719-538-8843
Fax: 719-538-8847

National Turkey Federation
1225 New York Avenue, NW
Washington, DC 20005
Telephone: 202-898-0100
Fax: 202-898-0203

VIII. CONTACTS/RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the agricultural livestock production industry, a list of contacts and publications are provided below:

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. [A listing of available Sector Notebooks and document numbers is included on the following page.]

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, and local governments, and the media from EPA's National Center for Environmental Publications and Information at (800) 490-9198. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available via Internet on the Enviroene World Wide Web at **http://www.epa.gov/oeca/sector/index.html**. Enviro$ense is a free, public, environmental exchange system operated by EPA's Office of Enforcement and Compliance Assurance and Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization. Direct technical questions to the "Feedback" button on the bottom of the web page.

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution (such as economic sector, and community-based approaches) are becoming an important supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these interrelationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several interrelated topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the references listed at the end of this profile. As a check on the information included, each notebook went through an external document review process.

The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project (2223-A), 401 M St., SW, Washington, DC 20460. Comments can also be sent via the web page or to notebook@epamail.epa.gov.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE AEROSPACE INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the aerospace industry. Facilities described within this document are described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

This industry sector profile provides an overview of the aerospace industry as listed under SIC industry groups 372 and 376. Establishments listed under these codes primarily manufacture and assemble aircraft, space vehicles, guided missiles, and all the associated parts.

Within the industry groups 372, Aircraft and Parts, and 376, Guided Missiles and Space Vehicles and Parts, are the following SIC codes:

- 3721- Aircraft
- 3724- Aircraft Engines and Engine Parts
- 3728- Aircraft Parts and Auxiliary Equipment, Not Elsewhere Classified
- 3761- Guided Missiles and Space Vehicles
- 3764- Guided Missile and Space Vehicle Propulsion Units and Propulsion Unit Parts
- 3769- Guided Missile and Space Vehicle Parts and Auxiliary Equipment, Not Elsewhere Classified

While this notebook covers all of the SIC codes listed above, the large number and variability of the products will not allow a detailed description of each. Instead, commonalities in the industrial processes, pollutant outputs, and pollution prevention opportunities will be identified and described in more general terms. An overview of general manufacturing processes within the industry will be presented, along with descriptions of the actual products and information on the state of the industry. Although certain products covered under these SIC codes may not be specifically mentioned, the economic, pollutant output, and enforcement and compliance data in this notebook covers all establishments producing aerospace products.

SIC codes were established by the Office of Management and Budget (OMB) to track the flow of goods and services within the economy. OMB is in the process of changing the SIC code system to a system based on similar production processes called the North American Industrial Classification System (NAICS). In the NAICS, the SIC codes for the aerospace industry correspond to the following NAICS codes:

R0074622

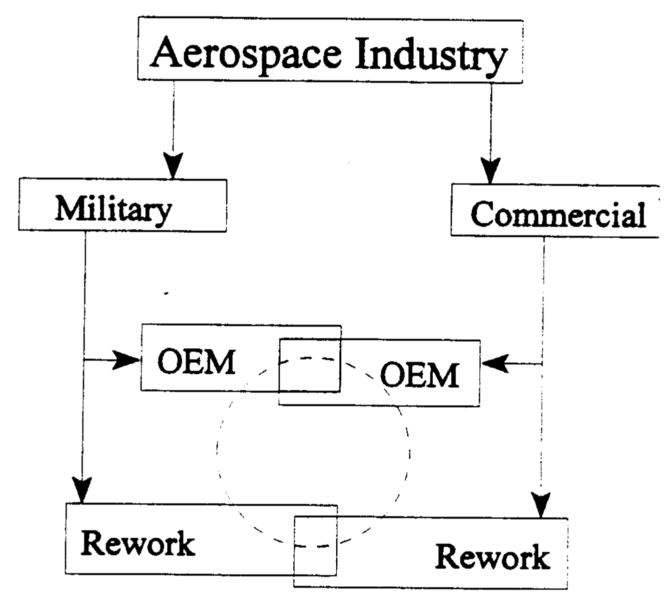
SIC	Industry Sector	NAICS
3721	Aircraft	336411
3724	Aircraft Engines	336412
3728	Aircraft Parts	336413
3761	Guided Missiles and Space Vehicles	336414
3764	Space Vehicle Propulsion Units	336415
3769	Guided Missile and Space Vehicle Parts	336419

II.B. Characterization of the Aerospace Industry

There are many different aerospace products classified under the six aerospace SIC codes. The products produced, geographical distribution, and economic trends of the aerospace industry are discussed below. Figure 1 represents the general structure of the aerospace industry. The aerospace industry operations are often classified as either military or commercial and as either original equipment manufacturers (OEM) or rework. Most aerospace facilities specialize in either military or commercial and either rework or OEM. OEM facilities might do both military and commercial work, and likewise for rework facilities. Some facilities might even work in all areas of the industry, as indicated by the dotted circle in Figure 1.

R0074623

Figure 1: Structure of the Aerospace Industry



Source: NESHAP BID, USEPA/OAQPS, May 1994.

II.B.1. Product Characterization

The aerospace industry consists of manufacturers of aircraft, aircraft engines, aircraft parts, guided missiles and space vehicles, and guided missile and space vehicle propulsion units and parts. Table 1 lists the products included in aircraft, aircraft engines, and space vehicle and missile categories. One source of manufacturer and model information is *The Aerospace Sourcebook*, published by *Aviation Week & Space Technology*.

R0074624

Table 1: Products Included in the Aerospace Industry

Category	Products
Military Fixed-Wing Aircraft	Attack Bombers Cargo/Transport/Refueling Early Warning Electronic Warfare Fighters Observation Patrol ASW Reconnaissance Research/Test Bed Training Utility
Commercial Fixed-Wing Aircraft	Narrow Body Turbofans Wide Body Turbofans Turboprops
Rotary-Wing Aircraft	Naval Scout/Attack Tiltrotor Training Transport Utility
Business & General Aviation Aircraft	Turbofan Turboprop Reciprocating Engine-Powered
Gas Turbine Engines	
Unmanned Aerial Vehicles and Drones	
Space/Launch Vehicles	Manned Systems Unmanned Systems
Missiles	Air-to-Air Air-to-Surface Anti-Armor Anti-Ballistic Anti-Ship Anti-Submarine Surface-to-Air Surface-to-Surface

Source: *Aerospace Source Book, Aviation Week & Space Technology*, 1/12/98.

These manufacturing facilities are classified under SIC codes 372 and 376 as listed above. In order to discuss the production of these parts in a sequential manner, Sections II and III of this profile are divided into four categories: aircraft parts, aircraft assembly, aircraft rework and repair, and space vehicles and guided missiles.

The diverse nature of parts needed to produce these products requires the support of many other major U.S. industries. Many of the parts utilized by aerospace manufacturers are made by other industry sectors such as the plastics and rubber industry, the fabricated metal industry, the metal casting industry, the glass industry, the textile industry, and the electronic components industry. Manufacturing and assembling of complete units in the aerospace industry typically involves prime contractors and several tiers of subcontractors, as follows:

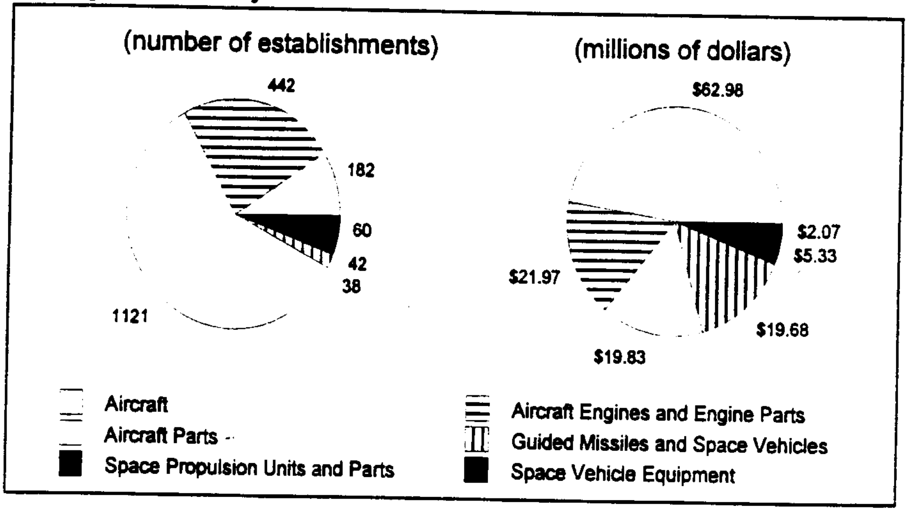
•Prime Contractors-	Design (develop) and assemble or manufacture complete units.
•First Tier Subcontractors-	Do major assembly and/or manufacture of sections of air/space craft without designing or assembling complete units.
•Second Tier Subcontractors-	Make various subassemblies and sections.
•Third Tier Subcontractors-	Produce machined components and sub-assemblies.
•Fourth Tier Subcontractors-	Specialize in the production of particular components and in specific processes.

Typically, those facilities designated as "prime contractors" are included in SIC codes 3721, 3724, 3761 and 3764. Both first and second tier subcontractors correspond to SIC codes 3728 and 3769. Third and fourth tier subcontractors may be included in a variety of industry SIC codes (EPA/OAQPS, 1994).

Figure 2 illustrates the distribution of manufacturing facilities and value of shipments within the aerospace industry. These figures show that while the aircraft parts sector of the aerospace industry is by far the largest in terms of number of establishments, the finished aircraft sector has the largest value of shipments.

The aircraft-related portion of the aerospace industry is much larger than the space vehicle and missile portion. The aircraft portion comprises 93 percent of the establishments and 79 percent of the value of shipments. However, considering the small percentage of facilities engaged in guided missile and space vehicle manufacturing (2 percent), the value of shipments is relatively high (15 percent). In general, facilities which are responsible for assembling the final aerospace products are few and their production rates are low, but the value of each of their products greatly surpasses that of the supporting industries.

Figure 2: Number of Establishments and Value of Shipments for the Aerospace Industry



Source: *1992 Census of Manufacturers*, USDOC, 1995.

Aircraft Engines and Engine Parts and Aircraft Parts and Equipment

The aircraft engines, engine parts, and aircraft parts industry is classified under SIC 3724 and 3728. Facilities producing these parts employ processes similar to many other metal casting, fabricating, and finishing facilities, as well as processes from a wide range of other industries. Typical products manufactured by these facilities include: engines, exhaust systems, motors, brakes, landing gear, wing assemblies, propellers, and many other related products. The primary customers for these industries are the establishments involved in the assembly of aircraft, classified under SIC 3721.

Aircraft Assembly

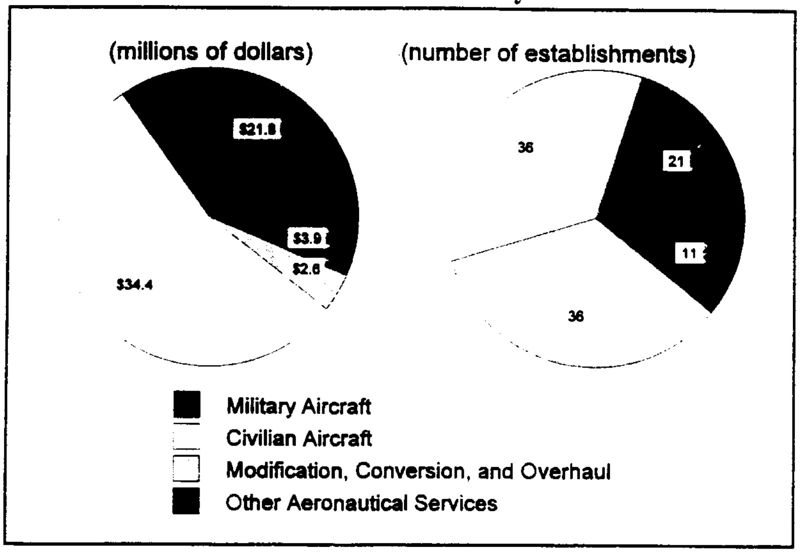
The aircraft industry is made up of establishments primarily engaged in manufacturing or assembling complete aircraft and is classified under SIC 3721. This industry also includes establishments owned by aircraft manufacturers and primarily engaged in research and development on aircraft, whether from enterprise funds or on a contract or fee basis (Census, 1995). There are many different types of aircraft included in this industry, from airplanes and helicopters to blimps and balloons. However, this profile focuses primarily on the production of airplanes since they represent the largest portion of the industry. Typical products include fixed wing aircraft, helicopters, gliders, balloons, and research and development on aircraft.

The major customers of the aircraft industry are commercial airlines and transport companies and the military. Figure 3 shows the distribution within

R0074627

the industry of value of shipments and number of establishments. Civilian aircraft represents the largest percentages in value of shipments and number of establishments. Approximately one-third of the establishments in this industry are involved in the repair and rework of aircraft. These facilities will be discussed in Section III.

Figure 3: Value of Shipments and Number of Establishments for the Aircraft Industry



Source: 1992 Census of Manufacturers, USDOC, 1995.

Guided Missiles and Space Vehicles and Associated Parts

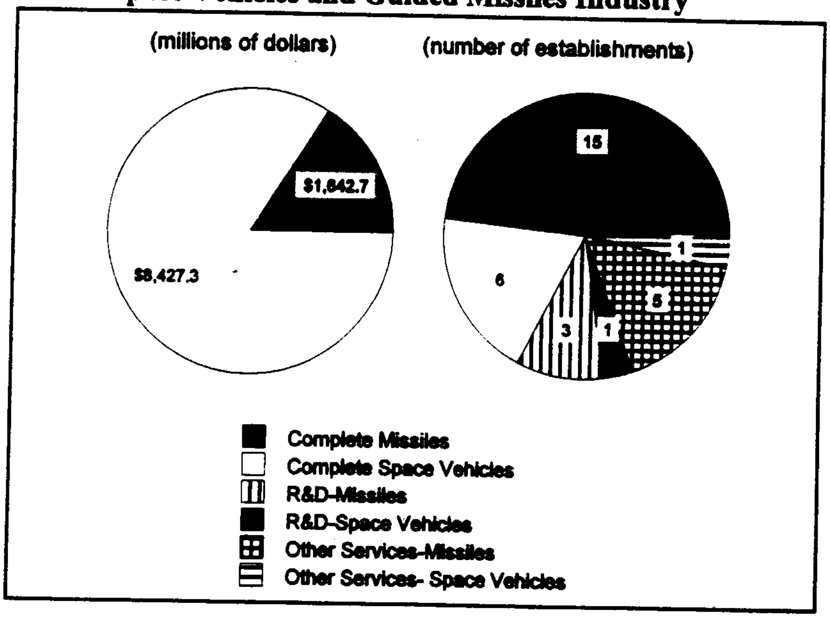
The guided missiles and space vehicles industry includes establishments primarily engaged in manufacturing and research and development on guided missiles and space vehicles, propulsion units, and parts. Typical products covered under SIC 3761, 3764, and 3769 include guided and ballistic missiles, space and military rockets, space vehicles, propulsion units and engines for missiles and space vehicles, airframe assemblies, and research and development on these products. The primary customer for this industry is the military, however space vehicles are also used by commercial entities for releasing communications satellites.

Figure 4 illustrates the specialization within the guided missile and space vehicle industry. The Census of Manufacturers identifies only 31 facilities in this sector. Value of shipment data is not available for facilities providing R&D and other services to protect individual facility confidentiality. Only six facilities, or less than a quarter of the facilities in this industry, are

R0074628

producing complete space vehicles. The value of shipments for these facilities, however, comprised more than three-quarters of the total value of shipments for the industry.

Figure 4: Value of Shipments and Number of Establishments for the Space Vehicles and Guided Missiles Industry



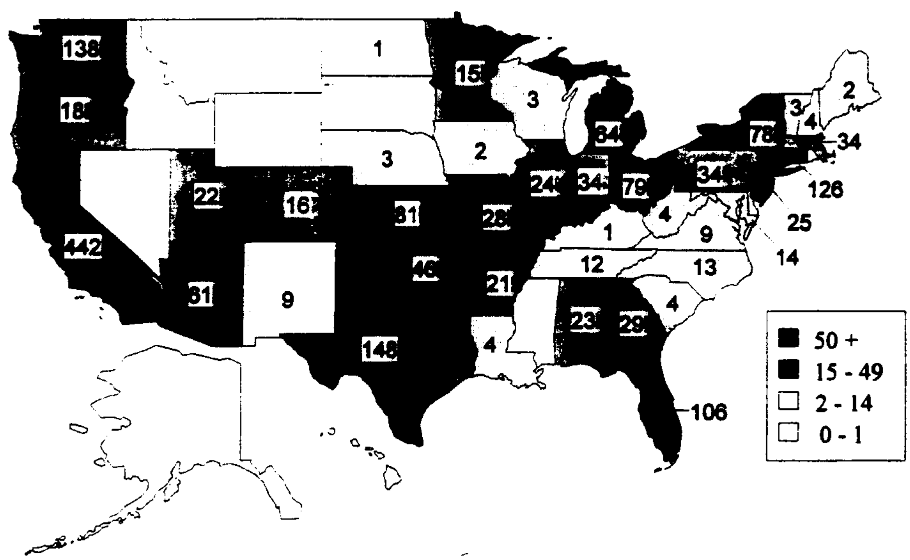
Source: *1992 Census of Manufacturers*, USDOC, 1995.

R0074629

II.B.2. Industry Size and Geographic Distribution

Figure 5 shows the U.S. distribution of aerospace facilities. Generally, the geographic distribution of aerospace facilities is determined by the location of industrialized areas of the country. As with many manufacturing industries, the ease of transportation of materials, products, and skilled workers influence facility location.

Figure 5: Geographic Distribution of Aerospace Manufacturing Facilities



Source: *1992 Census of Manufacturers*, USDOC, 1995.

Table 2 lists the facility size distribution within the aerospace sectors. As previously mentioned, the aircraft and aircraft parts industry (1,745 facilities) is more than ten times larger than the space vehicles, guided missiles, and parts industry (140 facilities). Aircraft and aircraft part manufacturing generally employs less people per facility than space vehicle and guided missile manufacturing. However, the number of employees in the aircraft industries still overshadows that of the missile and space vehicle industries, 645.9 thousand and 149.6 thousand respectively.

R0074630

Table 2: Facility Size Distribution for the Aerospace Industry

	Aircraft and Aircraft Engines and Parts (SIC 372)		Aircraft (SIC 3721)		Aircraft Engines and Engine Parts (SIC 3724)		Aircraft Parts and Equipment (SIC 3728)

R0074632

Readers should note that: (1) companies are assigned a 4-digit SIC code that resembles their principal industry most closely; and (2) sales figures include total company sales, including subsidiaries and operations (possibly not related to aerospace). Additional sources of company specific financial information include Standard & Poor's *Stock Report Service*, *Ward's Business Directory of U.S. Public and Private Companies*, Moody's Manuals, and company annual reports.

The Bureau of the Census publishes concentration ratios, which measure the degree of competition in a market. They compute the percentage of the value of products shipped by establishments classified within an industry of the total value of these products shipped from any establishment. Within the aerospace industry, the aircraft industry and the space vehicle and guided missile industry had the greatest coverage ratios in 1992: 97 percent each. The aircraft engine, aircraft parts, propulsion units, and auxiliary space vehicle equipment coverage ratios were 95, 74, 86, and 40 percent respectively.

II.B.3. Economic Trends

Growth in the U.S. aerospace industry will be influenced by several key factors, including constrained defense spending by the U.S. and foreign governments, increased productivity and technological innovation, foreign competition, continuing expansion of the global economy, investment in research and development, offsets and outsourcing, and support by foreign governments for their industries.

Domestic Trends

In recent years there has been considerable consolidation of aerospace companies, especially those supplying the military. This has resulted in some reductions in labor force and closing of some aerospace facilities in the U.S. However, in constant 1992 dollars, the value of U.S. shipments in 1996 of complete aircraft (all types, civil and military) rose by about six percent over the value of shipments in 1995. The value of those shipments was expected to rise further by about thirty percent in 1997 and about five percent in 1998.

<u>Military</u>
In September 1996, Congress passed a DOD budget for FY 1997 that, for the first time in more than a decade, did not reduce spending from the previous year. In addition, the legislation provided more funding for procurement of aircraft and missiles than DOD had requested. Also, DOD reduced funding for R&D, which means that private companies will have to increase their share of the total amount spent on R&D if the overall level of technology investment and advancement is to be maintained.

In the missiles sector, air-to-surface weapons should experience the most growth relative to other types of missiles. Strong focus will be placed on improving guidance capabilities, mainly through the use of the U.S. Global Positioning System (GPS) (USDOC, 1998).

Commercial

Of all the aerospace sectors, the large civil transport aircraft sector is expected to experience the fastest rate of growth from 1997 through 2001. With the significant increase in production rates undertaken by Boeing in 1996, the value of shipments in 1997 of large civil transports could be as much as sixty percent higher than that of 1996, with another increase of about ten percent expected in 1998 (USDOC, 1998).

Even as U.S. aerospace workers are being laid off because of consolidation in some companies, workers are being hired by other firms because of increasing orders. Sales of large transport aircraft are expected to come from the retirement and replacement of aircraft plus additional aircraft to allow for air traffic growth (USDOC, 1998).

The aircraft engines and parts sectors also should see production and shipments increase as suppliers respond to increased production rates by the manufacturers of commercial transports. The market for commercial transport engines alone is expected to total from $150 billion to $175 billion between 1996 and 2005 (USDOC, 1998).

International Trends

The internationalization of aerospace programs is increasing, and the U.S. aerospace industry is dependent on exports for a third of its market. The U.S. aerospace industry is affected significantly by the economies of foreign countries. The average annual increase in world GDP is expected to be three percent from 1996 through 2005. The main barriers facing U.S. manufacturers are foreign government support for their aerospace industries through direct and indirect subsidies, tariffs, and difficult and expensive licensing procedures. Additional access could be guaranteed if efforts succeed to expand membership and broaden the disciplines of several aircraft-related trade agreements (USDOC, 1998).

Military

The situation for firms in the defense industry is mixed. While some governments, such as those of North America and Europe (with the largest defense budgets), continue to seek ways to reduce their military expenditures, governments in South America (with relatively small defense budgets) are maintaining or increasing their defense spending. However, current economic crises in Asia may reduce exports to some countries. The pace of consolidation in Europe of aerospace and defense companies, which began later than in the U.S., is escalating just as the merger rate in the U.S. appears to be slowing (USDOC, 1998).

Commercial

Overall improvement in the global economy has buoyed the fortunes of the world's airlines. World air passenger traffic rose each year from 1994 to 1996, and increased traffic by airlines all over the world produced a significant turnaround in the large transport aircraft market, the largest part of the aircraft industry. The civil aircraft sector exports 60 percent of its total production and represents about 20 percent of the overall U.S. aerospace industry (USDOC, 1998).

Asian economic problems have not had serious widespread impacts on the aerospace industry to date. Companies such as Lockheed Martin and Boeing estimate that about five percent of their contracts for the next five years are tied to that region. It is possible that, considering the strength of the industry and the economy outside of Asia, other customers may step in and eliminate lower production rates (Smith, 1998).

Commercial space launch providers also are benefiting from the improved economic situation. Consumer demand for direct-to-home television, voice and data transmission, and other satellite services is increasing the demand for satellites and therefore for space launch vehicles to place them in orbit (USDOC, 1998).

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the aerospace industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of resource materials and contacts that are available.

It is important to note that the FAA places very strict "airworthiness" guidelines on manufacturing and rework facilities for safety and quality control purposes, thus new pollution prevention alternatives may require a full evaluation and permitting process before they may be used.

This section contains a description of commonly used production processes, associated raw materials, by-products produced or released, and materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products. Figure 6 shows a general aerospace manufacturing process diagram.

Figure 6: The Aerospace Manufacturing Process

III.A. Aircraft Engines and Parts Industry

Manufacturing processes for aircraft engines and parts may consist of the following basic operations: materials receiving, metal fabricating, machining and mechanical processing, coating application, chemical milling, heat treating, cleaning, metal processing and finishing, coating removal (depainting), composite processing, and testing. Many facilities employ all of these processes in their operations, however, a facility may also employ only a subset of these operations, as with a facility that produces a single component or a facility that provides a service such as painting (EPA/OAQPS, 1997).

In addition, there are a number of operations that may be used at aircraft engine and parts facilities but are not typical and are performed in conjunction with a variety of industries, such as foundry operations and manufacturing of electronic components. For more information on foundry operations, see the *Profile of the Metal Casting Industry*, EPA, 1997. For more information on electronics and computers, see the *Profile of the Electronics and Computer Industry*, EPA, 1995.

III.A.1. Materials

There are many different materials involved in the production of engines and parts. The most common materials are alloys of aluminum, which are used primarily for aircraft structural components and exterior skin sections. Other materials are titanium, stainless steel, magnesium, and non-metallics such as plastics, fabrics, and composite materials. Typical forms of materials are honeycomb, wire mesh, plate, sheet stock, bar cast, and forged materials.

Metallic Alloys

Aluminum is used as a primary structural material in the aerospace industry because of its light weight, and because its alloys can equal the strength of steel. The ability to resist atmospheric corrosion also favors the use of aluminum. The type of alloy metal used depends on the desired characteristics of the finished product such as strength, corrosion resistance, machinability, ductility, or weldability (Horne, 1986).

High strength alloys typically contain copper, magnesium, silicon, and zinc as their alloying elements. Other alloying agents that may be used are: lithium for lightness; nickel for strength and ductility; chromium for tensile strength and elastic limit; molybdenum for strength and toughness; vanadium for tensile strength, ductility, and elastic limit; silicon as a deoxidizer; and powder metallurgy alloys for strength, toughness, and corrosion resistance (Horne, 1986).

R0074637

The development of the gas turbine and the evolution of engines required materials with great resistance to temperature, stress, and oxidation. Nickel-based alloys have a high resistance to oxidation and are used for compressor blades and guide vanes, discs, turbine blades, shafts, casings, combustion chambers, and exhaust systems. Titanium alloys have excellent toughness, fatigue strength, corrosion resistance, temperature resistance, and a lower density than steel. Titanium alloys are frequently used to make hot-end turbine components and turbine rotor blades (Horne, 1986).

Non-Metallic Materials

Plastics, carbon and glass fibers, and synthetic resins and polymers are all used in aerospace manufacturing. There are two types of plastics used, thermoplastics and thermosetting materials. Thermoplastic materials are softened by heating and will harden on cooling and can be extruded (material is pressure forced through a shaped hole), injection molded (soft material is forced into a mold through a screw injector and pressure), or thermoformed (material is cast in a mold with heat and pressure). Thermosetting plastics are hardened by heating and form rigid three dimensional structures through chemical reactions. They are typically compression molded (Horne, 1986). For more information on non-metallic materials, refer to the *Profile of the Rubber and Plastic Industry*, EPA, 1995.

Carbon and glass fibre strands are used to reinforce plastics for strength and stiffness while remaining lightweight. Synthetic resins and polymers are used as adhesives which produce smooth bonds and a stiff structure which propagates cracks more slowly than in a riveted structure (Horne, 1986).

III.A.2. Metal Shaping

Another major process in the manufacturing of aircraft and other aerospace equipment is metal shaping. Shaping operations take raw materials and alter their form to make the intermediate and final product shapes. There are two phases of shaping operations: primary and secondary. Primary shaping consists of forming the metal from its raw form into a sheet, bar, plate, or some other preliminary form. Secondary shaping consists of taking the preliminary form and further altering its shape to an intermediate or final version of the product. Examples of primary and secondary shaping are listed in Table 5 below. Brief descriptions of the most common operations follow the table.

Table 5: Primary and Secondary Shaping Operations

Primary Shaping Operations	Secondary Shaping Operations
Abrasive Jet Machining	Stamping
Casting	Turning
Drawing	Drilling
Electrochemical Machining	Cutting and Shaping
Electron Beam Machining	Milling
Extruding	Reaming
Forging	Threading
Impact Deformation	Broaching
LASER Beam Machining	Grinding
Plasma Arc Machining	Polishing
Pressure Deformation	Planing
Sand Blasting	Deburring
Ultrasonic Machining

Primary Shaping Operations

The most common primary shaping operations include casting, forging, extruding, rolling, cutting, coining, shearing, drawing, and spinning. Each of these operations is briefly described below.

Metal casting involves the introduction of molten metal into a mold or die having the external shape of the desired cast part. The mold or die is removed when the metal has cooled and solidified. Metal casting operations can be classified as either foundries or diecasters. The primary difference is that foundries pour molten metal relying on gravity to fill the mold and die casters use machines to inject molten metal under pressure into the mold. Foundry molds are typically used only once for each part. They are often made of sand grains bound together with chemicals or clay. Die casting molds are often reused thousands of times and are part of a larger diecasting machine that can achieve very high production rates. Foundries typically produce larger airplane parts such as engine blocks, turbine and compressor parts, and other mechanical parts from both ferrous and non-ferrous metals. Die casters typically produce smaller intricate parts from non-ferrous metals (EPA/OECA, 1995). For a more detailed discussion of metal casting operations see the *Profile of the Metal Casting Industry*, USEPA, 1997.

Once the molten metal is formed into a workable shape, shearing and forming operations are usually performed. Shearing operations cut materials into a desired shape and size, while forming operations bend or form materials into

R0074639

specified shapes. Shearing operations include punching, piercing, blanking, cutoff, parting, and trimming. These operations produce holes, openings, blanks, or parts. Forming operations shape parts by forcing them into a specific configuration, and include bending, extruding, drawing, spinning, coining, and forging. Bending is the simplest forming operation; the part is simply bent to a specific angle or shape and normally produce flat-shapes (EPA/OECA, 1995).

Extruding is the process of forming a specific shape from a solid blank by forcing the blank through a die of the desired shape. Complicated and intricate cross-sectional shapes can be produced by extruding. Rolling is a type of extruding that passes the material through a set or series of rollers that bend and form the part into the desired shape. Coining, another type of extruding, alters the form of the part by changing its thickness, producing a three-dimensional relief on one or both sides of the part, as found on coins (EPA/OECA, 1995).

Drawing and spinning form sheet stock into three-dimensional shapes. Drawing uses a punch to force the sheet stock into a die, where the desired part shape is formed in the space between the punch and die. In spinning, pressure is applied to the sheet while it spins on a rotating form so that the sheet acquires the shape of the form (EPA/OECA, 1995).

Forging operations produce a specific part shape, much like casting. The forging process is used in the aerospace industry when manufacturing parts such as pistons, connecting rods, and the aluminum and steel portion of wheels. However, rather than using molten materials, forging uses externally applied pressure that either strikes or squeezes a heated blank into a die of the required shape. Forging operations use machines that apply repeated hammer blows to a red-hot blank to force the material to conform to the shape of the die opening. Squeezing acts in much the same way, except it uses pressure to squeeze rather than strike the blank. Forging typically uses a series of die cavities to change the shape of the blank in increments. Depending on the shape, a forging die can have from one to over a dozen individual cavities (EPA/OECA, 1995).

Secondary Shaping Operations

Shearing (or cutting) operations include punching, piercing, blanking, cutoff, parting, shearing, and trimming. Basically, these are operations that produce holes or openings, or that produce blanks or parts. The most common hole-making operation is punching. Piercing is similar to punching, but produces a raised-edge hole rather than a cut hole. Cutoff, parting, and shearing are similar operations with different applications: parting produces both a part and scrap pieces; cutoff and shearing produce parts with no scrap; shearing is used where the cut edge is straight; and cutoff produces an edge shape rather than a straight edge. Trimming is performed to shape or remove excess material from the edges of parts (EPA/OECA, 1995).

Turning, drilling, and reaming processes typically use a lathe, which holds and spins the workpiece against the edge of a cutting tool. Drilling machines are designed for making holes and for reaming, or enlarging or finishing existing holes. Milling machines use multiple edge cutters to cut unusual or irregular shapes into the workpiece (EPA/ORD, 1990).

Broaching is a process whereby internal surfaces such as holes of circular, square or irregular shapes, or external surfaces like keyways are finished. A many-toothed cutting tool called a broach is used in this process. The broach's teeth are graded in size in such a way that each one cuts a small chip from the workpiece as the tool is pushed or pulled either past the workpiece surface, or through a leader hole. Broaching of round holes often gives greater accuracy and better finish than reaming (EPA/ORD, 1990).

Deburring involves removing metal shavings and burrs clinging to the cut edges of parts after machining has been completed. Deburring is typically done by one of two processes. Small parts can be deburred in a tumbler where the burrs are smoothed off the part by the constant friction with the tumbling media. This process, however, is not appropriate for long parts. Instead, long parts are scrubbed with an abrasive pad by hand or buffed with a power tool. The buffing operation can be performed either by hand or in an automatic operation (EPA/OAQPS, 1994).

Parts may also be honed and buffed to smooth their surfaces; spray-washed with an alkaline cleaner; and blown dry using compressed air. A protective coating of oil may be applied to parts that are stored on-site or shipped off-site to a heat-treating facility (EPA/NRMRL, 1995).

The metal working process creates much heat and friction. If the heat and friction are not reduced, the tools used in the process are quickly damaged and/or destroyed. Also, the quality of the products made is diminished because of inefficient tools and damage to the product while it is being manufactured. Coolants reduce friction at the tool/substrate interface and transfer heat away from the tools and the material being processed, reducing the time to process the metal, increasing the quality of the workmanship, and increasing tool life. The ability to transfer the heat away from the metal working process is why metal working fluids are often called coolants (Ohio EPA, 1993).

Oils are natural lubricants and provide this quality to coolants that are petroleum-based. Other coolants' ability to reduce friction comes from lubricating additives. During the metal working process, heat diffuses into the coolant. The heated coolant flows off the work area into a collection container or sump, where it cools off and then enters the cycle again. Water has excellent cooling characteristics and many coolants contain water or are primarily water. Soluble oils and semi-synthetic oils have both water and oil components. Coolants containing both oil and water require surfactants to form and maintain emulsions, a mixture of the oil and water, so that both properties can work together (Ohio EPA, 1993).

Heat Treating

Heat treating is the modification of the material's or part's metallurgical properties through the application of controlled heating and cooling cycles. For example, aluminum outer skin panels undergo a low temperature oven bake after forming to provide greater stress tolerance. Heat treating can be performed either before or after machining and includes carburizing (impregnating the surface with carbon), annealing (softening), stress relief, tempering, air furnace treating, and salt pot treating. Chemicals, such as methanol, are often used in heat treating ovens to maintain a chemically reducing atmosphere in order to obtain the proper metallurgical properties on the surface of the part being treated. After heat treating, the parts can either be cooled in ambient air or placed in a liquid quenching bath. The quench bath is typically a glycol solution, a chromate solution, or an oil (EPA/OAQPS, 1994).

Heat-treated parts can also be machined, honed, and deburred after they are returned to the plant. After machining, the parts are typically sprayed with a protective oil coating that controls corrosion until they are further processed (EPA/NRMRL, 1995).

III.A.3. Metal Finishing

Metal finishing and electroplating activities are performed on a number of metals and serve a variety of purposes; the primary purpose being protection against corrosion. Without metal finishing, products made from metals would last only a fraction of their unfinished life-span. Metal finishing alters the surface of metal products to enhance properties such as corrosion resistance, wear resistance, electrical conductivity, electrical resistance, reflectivity, appearance, torque tolerance, solderability, tarnish resistance, chemical resistance, ability to bond to rubber (vulcanizing), and a number of other special properties (e.g. electropolishing sterilizes stainless steel) (EPA/ORD, 1994).

These plating processes involve immersing the article to be coated or plated into a series of baths consisting of acids, bases, salts, etc. A wide variety of materials, processes, and products are used to clean, etch, and plate metallic and non-metallic surfaces. Typically, metal parts or work pieces undergo one or more physical, chemical, and electrochemical processes. Physical processes include buffing, grinding, polishing, and blasting. Chemical processes include degreasing, cleaning, pickling, milling, etching, polishing, and electroless plating. Electrochemical processes include plating, electropolishing, and anodizing (EPA/ORD, 1994).

Cleaning/Preparing

Cleaning

Aerospace components are cleaned frequently during manufacturing to remove contaminants such as dirt, grease, and oil, and to prepare the components for the next operation. Cleaning is important in order to ensure the successful application of later surface treatments. There are three main types of cleaning: aqueous, organic solvent, and abrasive. Aqueous cleaning covers a wide variety of cleaning methods such as detergents, acids, and alkaline compounds to displace soil rather than dissolving it as in organic solvent cleaning. Aqueous cleaners are either sprayed or used in cleaning baths, ultrasonic baths, and in steam cleaning. Three types of aqueous cleaning favored by the aerospace industry are:

- emulsification cleaning- emulsification cleaning uses water-immiscible solvents, surfactants, and emulsifiers.
- acid cleaning- sulfuric acid or hydrochloric acid is used to remove scale from metal; acid cleaning is sometimes known as pickling baths.
- alkaline cleaning- alkaline cleaning solutions (usually hot) contain builders (sodium salts of phosphate, carbonate, and hydroxide) and surfactants (detergents and soap) (CARB, 1997).

Abrasive cleaning is mechanical cleaning using abrasives such as rough fabric scrubbing pads, sandpaper, tumbling barrels, buffing wheels, and blasting equipment. Abrasives may be added to acid or alkaline cleaning solutions to improve cleaning action (CARB, 1997).

Masking

Maskants are coatings that are applied to a part to protect the surface from chemical milling and surface treatment processes such as anodizing, plating, and bonding. Maskants are typically rubber- or polymeric-based substances applied to an entire part or subassembly by brushing, dipping, spraying, or flow coating. Two major types of maskants are used: solvent-based and waterborne. After an adequate thickness of maskant has been applied to the part, the maskant is cured in a bake oven. The maskant is then cut following a specific pattern and manually stripped away from selected areas of the part where metal is to be removed. The maskant remaining on the part protects those areas from the etching solution.

Chemical Milling

R0074643

Chemical milling is used to reduce the thickness of selected areas of metal parts in order to reduce weight. The process is typically used when the size or shape of parts precludes mechanical milling or when chemical milling is advantageous due to shorter processing time or its batch capability. Chemical milling is accomplished by submerging the component in an appropriate etchant. Commonly used etchants are sodium hydroxide for aluminum, nitric acid and hydrofluoric acid for titanium, dilute sulfuric acid for magnesium, and aqua regia (a mixture of nitric and hydrochloric acids) for stainless steel. The depth of the cut is closely controlled by the length of time the component is in the etchant and the concentration of the etchant. When the milling has been completed, the part is removed from the etchant and rinsed with water. Some metals may develop a smutty discoloration during the chemical milling process. A brightening solution, such as dilute nitric acid, is typically used as a final step in the process to remove the discoloration. After desmutting, the part either goes back to chemical milling for further metal removal or to the stripping area to have the maskant removed. The maskant may be softened in a solvent solution and then stripped off by hand (EPA/OAQPS, 1994).

Anodizing

Anodizing uses the piece to be coated, generally with an aluminum surface, as an anode in an electrolytic cell. Anodizing provides aluminum parts with a hard abrasion- and corrosion-resistant film. This coating is porous, allowing it to be dyed or to absorb lubricants. This method is used both in decorative application and in engineering applications such as aircraft landing gear struts. Anodizing is usually performed using either sulfuric, boric-sulfuric, or chromic acid often followed by a hot water bath, though nickel acetate or sodium potassium dichromate seal may also be used (EPA/OECA, 1995).

Passivation

Passivation is a chemical process in which parts are immersed in a solution containing a strong oxidizing agent. This forms a thin oxide layer on the part surface, providing corrosion protection and increasing adhesion of subsequent coatings. It is often used before maskant application in the chemical milling process (EPA/OAQPS, 1994).

Pickling

Pickling is a process of chemical abrasion/etching which prepares surfaces for good paint adhesion. The pickling process is used mainly for preparing pipe systems and small parts for paint. However, the process and qualities will vary by facility. The process involves a system of dip tanks. In pickling steel parts, The first tank is used to remove any oil, grease, flux, and other contaminants on the surface being pickled. The part is then immersed into a 5-8% caustic soda and water mixture (pH 8-13) maintained at temperatures of between 180°-200°F. Next, the steel is dipped into a 6-10% acid/water

R0074644

mixture maintained between 140°-160°F (EPA/OECA, 1997). Most carbon steel is pickled with sulfuric or hydrochloric acid, while stainless steel is pickled with hydrochloric, nitric, and hydrofluoric acids (EPA/OECA, 1995). The fourth tank contains an acid rinse tank that is maintained at a pH of 5-7. Finally, the steel part is immersed in a rust preventative 5% phosphoric mixture. The part is then allowed to fully dry prior to paint application (EPA/OECA, 1997).

Polishing

Polishing is used at some facilities to clean and finish the outer skin of the aircraft. The polish is a lightly abrasive metal cleaner that is buffed on the metal surface, then wiped off. The polish gives a mirror-like surface finish and is usually applied instead of paint. Polishing can also be used on other metal parts as a cleaning step.

Conversion Coatings

Conversion coating is the process of changing a metal's surface characteristics by applying a reactive chemical to the metal's surface or by reacting the metal in a chemical bath. The desired result is improved coating adhesion, increased corrosion resistance, or both (EPA/OAQPS, 1994).

Aluminum surfaces are treated with various conversion coatings depending upon the anticipated environmental conditions or performance requirements such as corrosion, electrochemical insulation, and abrasion. Conversion coatings are also used to enhance bond and paint adhesion. Typical treatments include chromate phosphates, chromate oxides, anodizing, and non-chromate formulations (CARB, 1997).

Cadmium surfaces require either a phosphate or a chromate conversion coating prior to painting. The phosphate conversion is designed to be painted; the chromate conversion is designed to add corrosion resistance to the cadmium and it may also be painted (CARB, 1997).

Magnesium must be treated with a conversion coating or anodized before painting to prevent corrosion and to prevent environmental damage by abrasion. Magnesium coatings utilize sodium dichromate solutions (CARB, 1997).

Titanium must be treated with a conversion coating or anodized to protect it from corrosion and to improve adhesion bonding strength. Emersion baths for applying a conversion coating to titanium typically contain sodium phosphate, potassium fluoride, and hydrofluoric acid (CARB, 1997).

Coating/Painting

A coating is a material that is applied to the surface of a part to form a decorative or functional solid film. Coatings are used for corrosion resistance, aircraft identification and improved visibility, and friction reduction. The most common coatings are nonspecialized primers and topcoats, however there are also many specialized primers that provide characteristics such as fire resistance, flexibility, substrate compatibility, antireflection, sealing, adhesion, and enhanced corrosion protection (EPA/OAQPS, 1997).

Coatings are applied by spraying, brushing, rolling, flow coating, and dipping using a variety of application equipment including conventional air spray, high volume low pressure (HVLP) spray, and electrostatic spray. Many of the conventional methods such as rolling, flow coating, dip coating, and brushing are limited to the size and configuration of the part being painted (CARB, 1997).

Painting involves the application of predominantly organic coatings to a work piece for protective and/or decorative purposes. It is applied in various forms, including dry powder, solvent-diluted formulations, and water-borne formulations. Various methods of application are used, the most common being spray painting and electrodeposition. Electrodeposition is the process of coating a work piece by either making it anodic or cathodic in a bath that is generally an aqueous emulsion of the coating material. When applying the paint as a dry powder, some form of heating or baking is necessary to ensure that the powder adheres to the metal. These processes may result in solvent waste (and associated still bottom wastes generated during solvent distillation), paint sludge wastes, paint-bearing wastewaters, and paint solvent emissions (EPA/OECA, 1995).

Spray painting is a process by which paint is placed into a pressurized cup or pot and is atomized into a spray pattern when it is released from the vessel and forced through an orifice. Differences in spray-painting equipment are based on how the equipment atomizes paint. The more highly atomized the paint, the more likely transfer efficiency is to decrease. Transfer efficiency is the amount of paint applied to the object being painted, divided by the amount of paint used. Highly atomized paint spray can more readily drift away from the painting surface due to forces such as air currents and gravity (Ohio EPA, 1994). Cleaning solvent can only be sprayed through a gun for nonatomized and atomized cleaning using specific equipment as specified in the NESHAP.

The viscosity of paint may need adjustment before it can be sprayed. This is accomplished by reduction with organic solvents, or with water for certain water-based coatings. Using solvents for reduction requires the purchase of additional materials and increases air emissions. An alternative method of reducing the viscosity is to use heat. Benefits from the purchase of paint heaters include lower solvent usage, lower solvent emissions, more consistent viscosities, and faster curing rates (Ohio EPA, 1994).

The following types of spray application equipment may be used in the aerospace industry:

- Conventional Spray
- High-Volume/Low-Pressure (HVLP)
- Airless
- Air-Assisted
- Electrostatics
- Rotary Atomization
- Spray Booths

Electroplating

The metals used in electroplating operations (both common and precious metal plating) include cadmium, lead, chromium, copper, nickel, zinc, gold, and silver. Cyanides are also used extensively in electroplating solutions and in some stripping and cleaning solutions (EPA/OECA, 1995).

Electroless plating is the chemical deposition of a metal coating onto a metal object, by immersion of the object in an appropriate plating solution. In electroless nickel plating, the source of nickel is a salt, and a reducer is used to hold the metal ion in the solution. Immersion plating produces a metal deposit by chemical displacement. Immersion plating baths are usually formulations of metal salts, alkalies, and complexing agents (typically cyanide or ammonia) (EPA/OECA, 1995).

Occasionally, touch-up plating is done on an in-house plating line that consists of six separate tanks for cleaning, rinsing, and plating. Following touch-up plating, the parts are typically cleaned in a cold solvent-cleaning tank (EPA/NRMRL, 1995).

Equipment/Line Cleaning

Spray guns and coating lines used to apply the various coatings used at aerospace facilities must be cleaned when switching from one coating to another and when they are not going to be immediately reused. Spray guns can be cleaned either manually or with enclosed spray gun cleaners. Manual cleaning involves disassembling the gun and placing the parts in a vat containing an appropriate cleaning solvent. The residual paint is brushed or wiped off the parts. After reassembling, the cleaning solvent may be sprayed through the gun for a final cleaning. Paint hoses/coating lines are cleaned by passing the cleaning solvent through the lines until all coating residue is removed. Enclosed spray gun cleaners are self-contained units that pump the cleaning solvent through the gun within a closed chamber. After the cleaning cycle is complete, the guns are removed from the chamber and typically undergo some manual cleaning to remove coating residue from areas not exposed to the cleaning solvent, such as the seals under the atomizing cap (EPA/OAQPS, 1997).

III.A.4. Composites Processing

The aerospace industry is increasingly substituting composites for metals in aircraft and space vehicles due to the superior strength-to-weight ratio, corrosion resistance, and fatigue life of composites. Composites are comprised of a resin matrix that bonds together layers of reinforcing material. The resultant structure has mechanical properties superior to each individual component. The resin matrix is usually a polymeric material such as epoxy, polyester, nylon, or phenolic. The reinforcing material or fiber is usually carbon (graphite), fiberglass, or Kevlar. The fibers are oriented at specific angles within the matrix to achieve desired strength characteristics. Methods of forming composites include: injection molding, compression molding, and hand lay-up (or wet lay-up). Hand lay-up can involve applying resin on pre-woven fibers or can involve stacking thin sheets of pre-impregnated (prepreg) fiber material. Steps in hand lay-up are typically: lay-up, debulking, curing, and tear-down (break-out).

Injection molding is the process of shaping a material by applying heat and utilizing the pressure created by injecting a resin into a closed mold. Compression molding is the process of filling a mold with molding compound, closing the mold, and applying heat and pressure until the material has cured. Lay-up is the process of assembling composite parts by positioning reinforcing material in a mold and impregnating the material with resin. With hand lay-up, reinforcing material with resin or prepreg can be added to an open mold until the design thickness and contours are achieved. Debulking is the simultaneous application of low-level heat and pressure to composite materials to force out excess resin, trapped air, vapor, and volatiles from between the layers of the composite, thus removing voids within the composite.

Curing is the process of changing the resin into a solid material so that the composite part holds its shape. This is accomplished by heating the lay-up assembly in order to initiate a polymerization reaction within the resin. Once the reaction is complete, the resin solidifies and bonds the layers of composite materials together. The curing process is typically performed in an autoclave (a pressurized oven), with the composite lay-up enclosed in a bag so that a vacuum can be applied. The vacuum removes air and volatilized components of the resin from within the composite structure which may otherwise be trapped and create voids. Key parameters for curing are time, pressure, vacuum, temperature, and heating and cooling rates.

Break-out is the removal of the composite materials from the molds or curing fixtures (includes the application of release agents prior to filling the mold).

III.B. Aircraft Assembly

Aircraft assembly requires the coordination of thousands of parts coming together to form one large final product. The total assembly process of a complete aircraft can be close to two years. The relatively small number of finished products does not allow for a great deal of automation in the assembly process. Considerable coordination is needed between materials delivery and the production schedule in order to achieve efficient assembly.

Assembly Equipment

Typical materials handling equipment includes conveyors, cranes, industrial vehicles (e.g., forklifts, flatbeds, carts, special lift vehicles, etc.), and containers (EPA/OECA, 1997). Assembly facilities may also use jigs to aid in lining up or joining pieces.

Assembly jigs are essential for the successful assembly or large aerospace products. Their main function is to identify the precise location of fittings for attachment of one component to another. Assembly jigs should be constructed in a manner which allows them to be removed upon completion of the work without breaking down the entire jig structure. They require materials which will not bend or distort over a period of time or during assembly operations. They must also provide easy access to locations where manual joining operations are needed (Horne, 1986).

Pin jigs are used to assemble the curved sheets that form the outside of the fuselage's curved surface. The pin jig is simply a series of vertical screw jacks that support curved pieces during construction. A pin jig is set up specifically for the curved piece under construction. The jig heights are determined from the engineering drawings and plans (EPA/OECA, 1997).

Specially designed locating jigs are required for skins to which stiffeners are to be riveted, such as airplane wings. Stiffeners are first placed in the jigs and then locked in the required position on the completed wings. Wing skins are then placed on the jig and held to a contoured shape with metal bands in order to make contact with the stringers. Holes are drilled through the skin and stringers by using templates to locate hole positions. When all of the holes have been drilled, they are filled with clamping bolts and the metal bands are released. The skin is taken out of the jig and the clamping bolts hold the skin in the desired shape until it is riveted together (Horne, 1986).

Fuselage assembly operations may follow these steps:

- bond stringers to fuselage skin
- fit formers to assembly jig
- assemble skin, drill flanges, and fit riveting clamps
- replace clamps with rivets and remove panel from the jig
- assemble panels and formers on fuselage assembly jig (Horne, 1986).

Welding/Riveting

Fusion Welding

Fusion welding is performed with a metal arc in the presence of an inert gas which prevents the oxidation of the metals to be welded. An alternating or direct current, depending on the type and thickness of the metal, is typically applied through an electrode. The ideal current and pulse duration is selected according to the wire composition, shielding gas, welding position, and wire size (Horne, 1986).

Resistance Welding

Resistance welding requires: a primary electrical circuit from a transformer; a secondary circuit and electrodes to conduct the current to the desired spot; a mechanical system to hold the components and apply force; and control equipment to measure duration and magnitude of the electrical current. Press-type machines have a moveable welding head and force is applied by air through hydraulic cylinders. Seam welding is performed by power-driven roller electrodes instead of the pointed electrodes used for spot welding. Leak-proof and pressure-tight welds are formed by the seam welding process, where each weld overlaps the previous one (Horne, 1986).

Pre-pressure jig welding uses a jig to clamp the components together to relieve the electrodes from clamping stress. This ensures that the desired electrode pressure is available (Horne, 1986).

Electron Beam Welding

Electron beam welding is achieved by concentrating a beam of high velocity electrons onto the surfaces to be joined. The electrons are produced and accelerated by an electron beam gun which consists of a filament emitter, a bias electrode, and a positively charged anode. The electrons are generated by thermionic emission from a filament. Their attraction to an anode gives them speed and direction, and a bias electrode cup surrounding the emitter electrostatically shapes ejected electrons into a beam. An electromagnetic lens system reconverges the beam once its left the anode and focusses it on the work piece (Horne, 1986).

Riveting

Riveted joints are usually in sheet metal parts where the rivets take a shearing load. Riveted joints may be in single, double, triple, or quadruple rows and either chain or zigzag (Horne, 1986).

Sealing/Bonding

Sealants, predominantly composed of polysulfide, are applied throughout the aerospace vehicle structure primarily to seal out moisture and contaminants. This helps prevent corrosion, particularly on faying (i.e., closely or tightly fitting) surfaces, inside holes and slots, and around installed fasteners. Sealants are also used to seal fuel tanks and pressurized components. They are applied using tubes, spatulas, brushes, rollers, or spray guns. Sealants are often stored frozen and thawed before use, and many are two-component mixtures that cure after mixing. Typically, a sealant is applied before assembly or fastener installation, and the excess is squeezed out or extruded from between the parts as the assembly is completed. This ensures a moisture-tight seal between the parts (EPA/OAQPS, 1997).

Adhesive bonding involves joining together two or more metal or nonmetal components. This process is typically performed when the joints being formed are essential to the structural integrity of the aerospace vehicle or component. Bonding surfaces are typically roughened mechanically or etched chemically to provide increased surface area for bonding and then treated chemically to provide a stable corrosion-resistant oxide layer. The surfaces are then thinly coated with an adhesive bonding primer to promote adhesion and protect from subsequent corrosion. Structural adhesives are applied as either a thin film or as a paste. The parts are joined together and cured either at ambient temperature, in an oven, or in an autoclave to cure the adhesive and provide a permanent bond between the components (EPA/OAQPS, 1997).

Nonstructural adhesives are used to bond materials that are not critical to the structural integrity of the aerospace vehicle or component, such as gaskets around windows and carpeting or to nonstructurally joined components. These adhesives are applied using tubes, brushes, and spray guns (EPA/OAQPS, 1997).

Testing

A wide variety of tests are performed by the aerospace industry to verify that parts meet manufacturing specifications. Leak tests are performed on assemblies such as wing fuel tanks. These parts are filled with an aqueous solution or a gas to check seams and seals. Dye penetrant is used following chemical milling and other operations to check for cracks, flaws, and fractures. Many different kinds of penetrants, fluids, dyes, and etchants can be applied to the surface of metal parts to aid in the detection of defects. Hydraulic and fuel system checks are other typical testing operations. Weight checks are performed to verify the balance of certain structures, such as propeller blades and vertical tail rudders. Some critical areas on the assembled components are checked for flaws, imperfections, and proper alignment of parts by X-ray (EPA/OAQPS, 1994).

III.C. Repair/Rework Operations

Repair operations generally include all conversions, overhauls, maintenance programs, major damage repairs, and minor equipment repairs. Although specific repair methods vary from job to job, many of the operations are identical to new construction operations. Repair operations, however, are typically on a smaller scale and are performed at a faster pace. Jobs can last anywhere from one day to over a year. Repair jobs often have severe time constraints requiring work to be completed as quickly as possible in order to get the aircraft, missile, or space vehicle back in service. In many cases, piping, ventilation, electrical, and other machinery are prefabricated prior to the major product's arrival. Typical maintenance and repair operations include:

- Cleaning and repainting the aircraft's surfaces, superstructure, and interior areas
- Major rebuilding and installation of equipment such as turbines, generators, etc.
- Systems overhauls, maintenance, and installation
- System replacement and new installation of systems such as navigational systems, combat systems, communication systems, etc.
- Propeller and rudder repairs, modification. and alignment (EPA/OECA, 1997)

The depainting operation involves the removal of coatings from the outer surface of the aircraft. The two basic types are chemical depainting and blast depainting. Methylene chloride is the most common chemical stripper solvent; however, the particular solvent used is highly dependent on the type of coating to be removed. Chemical depainting agents are applied to the aircraft, allowed to degrade the coating, and then scraped or washed off with the coating residue. Blast depainting methods utilize a media such as plastic, wheat starch, carbon dioxide (dry ice), or high pressure water to remove coatings by physically abrading the coatings from the surface of the aircraft. Grit blasting and sand/glass blasting are also included in this category. High intensity ultraviolet light stripping has been developed for use in conjunction with carbon dioxide methods and is under development at several facilities (EPA/OAQPS, 1994). However, FAA has strict guidelines for safety and quality control purposes which dictate the types of solvents and materials that may be used in aerospace operations. Thus, any alternative must go through a comprehensive study before it is approved for use. *(See Section V- Pollution Prevention Opportunities)*

In addition, some larger facilities are capable of large repair and conversion projects that could include: converting passenger planes to cargo planes, replacing segments of an aircraft that has been damaged, structural reconfiguration and outfitting of combat systems, major remodeling of interiors or exteriors (EPA/OECA, 1997).

III.D. Space Vehicles and Guided Missiles

Many of the industrial processes involved in the production of space vehicles and guided missiles are similar to those discussed above in the production of aircraft parts and assembly. Because the number of establishments involved in the production of space vehicles, guided missiles, and their associated parts is less than 10 percent of the total industry, no additional information on industrial processes will be presented here. Also, due to the confidential nature of some of these products, there is little information available on production technologies.

III.E. Raw Materials Inputs and Pollution Outputs

The Aerospace Industries Association estimates that there are 15,000 to 30,000 different materials used in manufacturing, many of which may be potentially toxic, highly volatile, flammable, contain chloroflourocarbons, or contribute to global warming (AIA, 1994). Material inputs for aerospace manufacturing include metals, solvents, paints and coatings, and plastics, rubbers, and fabrics. Metals used in manufacturing include steel, aluminum, titanium, and many specialty alloys. There is also a wide variety of paints, solvents, and coatings available to the aerospace industry. Many of these materials are specifically required by FAA guidelines.

Pollutants from metal fabricating processes are dependant on the metal and machining techniques being used. Larger pieces of scrap metal are usually recovered and reintroduced to the process, while smaller shavings may be sent off-site for disposal or recovery.

Surface preparation operations generate wastes contaminated with solvents and/or metals depending on the type of cleaning operation. Degreasing operations may result in solvent-bearing wastewaters, air emissions, and materials in solid form. Chemical surface treatment operations can result in wastes containing metals. Alkaline, acid, mechanical, and abrasive cleaning methods can generate waste streams such as spent cleaning media, wastewaters, and rinse waters. Such wastes consist primarily of the metal complexes or particles, the cleaning compound, contaminants from the metal surface, and water. In many cases, chemical treatment operations are used in conjunction with organic solvent cleaning systems. As such, many of these wastes may be cross-contaminated with solvents (EPA/OECA, 1995).

Surface finishing and related washing operations account for a large volume of wastes associated with aerospace metal finishing. Metal plating and related waste account for the largest volumes of metal (e.g., cadmium, chromium, copper, lead, mercury, and nickel) and cyanide bearing wastes (EPA/OECA, 1995).

Air Emissions

Air emissions, primarily volatile organic compounds (VOCs), result mainly from the sealing, painting, depainting, bonding, finishing application processes including material storage, mixing, applications, drying, and cleaning. These emissions are composed mainly of organic solvents which are used as carriers for the paint or sealant and as chemical coating removers. Most aerospace coatings are solvent-based, which contain a mixture of organic solvents, many of which are VOC's. The most common VOC solvents used in coatings are trichloroethylene, 1,1,1-trichloroethane, toluene, xylene, methyl ethyl ketone, and methyl isobutyl ketone. The most common VOC solvent used for coating removal is methylene chloride. The VOC content ranges differ for the various coating categories. Air emissions from cleaning and degreasing operations may result through volatilization during storage, fugitive losses during use, and direct ventilation of fumes. Releases to the air from metal shaping processes contain products of combustion (such as fly ash, carbon, metallic dusts) and metals and abrasives (such as sand and metallic particulates).

Wastewater

Wastewater is produced by almost every stage of the manufacturing process. Metalworking fluids, used in machining and shaping metal parts, are a common source of wastewater contamination. Metalworking fluids can be petroleum-based, oil-water emulsions, or synthetic emulsions that are applied to either the tool or the metal being tooled to facilitate the shaping operation. Waste cooling waters can be contaminated with metalworking fluids (EPA/OECA, 1995).

Surface preparation, cleaning, and coating removal often involves the use of solvents which can also contribute to wastewater pollution. The nature of the waste will depend upon the specific cleaning application and manufacturing operation. Solvents may be rinsed into wash waters and/or spilled into floor drains (EPA/OECA, 1995).

Wastewater may also be generated in operations such as quenching and deburring. Such wastewater can be high in oil and suspended solids. Wastewater from metal casting and shaping mainly consists of cooling water and wet scrubber effluent. The scrubber water is typically highly alkaline (EPA/OECA, 1997).

Wastewater contaminated with paints and solvents may be generated during equipment cleaning operations; however, water is typically only used in cleaning water-based paints. Wastewater is also generated when water curtains (water wash spray booths) are used during painting. Wastewater from painting water curtains commonly contains organic pollutants as well as certain metals (EPA/OECA, 1997).

Electroplating operations can result in solid and liquid waste streams that contain toxic constituents. Aqueous wastes result from work piece rinses and process cleanup waters. In addition to these wastes, spent process solutions and quench baths are discarded periodically when the concentrations of contaminants inhibit proper function of the solution or bath. When discarded, process baths usually consist of solid-phase and liquid-phase wastes that may contain high concentrations of toxic constituents, especially cyanide. Rinse water from the electroplating process may contain zinc, lead, cadmium, or chromium (EPA/OECA, 1995).

Solid/Hazardous/Residual Waste

Solid, hazardous, and residual wastes generated during aerospace manufacturing include contaminated metalworking fluids, scrap metal, waste containers, and spent equipment or materials. Scrap metal is produced by metal shaping operations and may consist of metal removed from the original piece (e.g., steel or aluminum). Scrap may be reintroduced into the process as a feedstock or recycled off-site.

Various solid and liquid wastes, including waste solvents, blast media, paint chips, and spent equipment may be generated throughout painting and depainting operations. These solid and liquid wastes are usually the result of the following operations:

- Paint applications- paint overspray caught by emissions control devices (e.g., paint booth collection systems, ventilation filters, etc.)
- Depainting- spent blast media, chips, and paint and solvent sludges
- Cleanup operations- cleaning of equipment and paint booth area
- Disposal- discarding of leftover and unused paint as well as containers used to hold paints, paint materials, and overspray

Solvents are also used during cleanup processes to clean spray equipment between color changes, and to clean portions of the spray booth. The solvent utilized during cleaning is generally referred as "purge solvent" and is often composed of a mixture of dimethyl-benzene, 2-propanone (acetone), 4-methyl-2-pentanone, butyl ester acetic acid, light aromatic solvent naphtha, ethyl benzene, hydrotreated heavy naphtha, 2-butanone, toluene, and 1-butanol (EPA/OECA, 1995).

Metalworking fluids typically become contaminated and spent with extended use and reuse. When disposed, these oils may contain toxics, including metals (cadmium, chromium, and lead), and therefore must be tested to determine if they are considered a RCRA hazardous waste. Many fluids may contain chemical additives such as chlorine, sulfur, phosphorous compounds, phenols, cresols, and alkalines. In the past, such oils have commonly been mixed with used cleaning fluids and solvents (including chlorinated solvents) (EPA/OECA, 1995).

If metal coating operations use large quantities of molding sand, spent sand may be generated. The largest waste by volume from metal casting operations is waste sand. Other residual wastes may include dust from dust collection systems, slag, and off-spec products. Dust collected in baghouses may include zinc, lead, nickel, cadmium, and chromium. Slag is a glassy mass composed of metal oxides from the melting process, melted refractories, sand, and other materials (EPA/OECA, 1997).

Centralized wastewater treatment systems are common and can result in solid-phase wastewater treatment sludges. Any solid wastes (e.g., wastewater treatment sludges, still bottoms, cleaning tank residues, machining fluid residues, etc.) generated by the manufacturing process may also be contaminated with solvents (EPA/OECA, 1995).

Table 6 summarizes the material inputs and pollutant outputs from the various aerospace manufacturing operations.

Table 6: Material Input and Pollutant Outputs

Process	Material Input	Air Emissions	Wastewater	Solid/Hazardous/ Residual Wastes
Metal Shaping	Cutting oils, degreasing and cleaning solvents, acids, metals	Solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)	Acid/alkaline wastes (e.g., hydrochloric, sulfuric, and nitric acids), waste coolant water with oils, grease, and metals	Scrap metal, waste solvents
Grinding/ Polishing	Metals, abrasive materials, machining oils	Metal shavings/ particulates, dust from abrasive materials	Wastewaters with oil, grease, and metal from machining	Abrasive waste (e.g., aluminum oxide, silica, metal), metal shavings, dust
Plating	Acid/alkaline solutions, metal bearing and cyanide bearing solutions	Volatized solvents and cleaners	Waste rinse water containing acids/alkalines cyanides, and solvents	Metal wastes, solvent wastes, filter sludges (silica, carbides) wasted plating material (copper, chromium, and cadmium)
Painting	Solvent based or water based paints	Paint overspray, solvents	Cleaning water containing paint and stripping solutions	Waste paint, empty containers, spent paint application equipment
Cleaning, depainting, and vapor degreasing	Acid/alkaline cleaners and solvents	Solvent wastes, acid aerosols, paint chips and particulates	Wastewater containing acids/alkalines, spent solvents	Spent solvents, paint/solvent sludges, equipment and abrasive materials, paint chips

III.F. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (PPA) requires facilities to report information about the management of Toxic Release Inventory (TRI) chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1994-1997 and are meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention and compliance assistance activities.

While the quantities reported for 1995 and 1996 are estimates of quantities already managed, the quantities listed by facilities for 1997 and 1998 are projections only. The PPA requires these projections to encourage facilities to consider future source reduction, not to establish any mandatory limits. Future-year estimates are not commitments that facilities reporting under TRI are required to meet

Table 7 shows that the TRI reporting aerospace facilities managed about 37 million pounds of production related wastes (total quantity of TRI chemicals in the waste from routine production operations in column B) in 1996. Production related wastes were projected to continue to decrease slightly in 1997 and 1998. Note that the effects of production increases and decreases on the quantities of wastes generated are not evaluated here, but production has generally been increasing in recent years.

In 1995, about 34 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns C, D, and E, respectively. This decreased to 25 percent in 1996 and was expected to slightly increase to over 30 percent in 1998. The majority of these on-site managed wastes were recycled on-site in 1995. About 39 percent of the industry's TRI wastes were transferred off-site for recycling, energy recovery, or treatment as shown in columns F, G, and H. This increased to 50 percent in 1996. Most of the off-site managed wastes were recycled as well. The remaining portion of the production related wastes, shown in column I, (31 percent in 1995 and 27 percent in 1996) is either released to the environment through direct discharges to air, land, water, and underground injection, or is transferred off-site for disposal.

Table 7: Source Reduction and Recycling Activity for Aerospace Manufacturers Facilities (SICs 372 or 376) as Reported within TRI

A	B	On-Site			Off-Site			I
		C	D	E	F	G	H	
Year	Quantity of Production-Related Waste (10^6 lbs.)[a]	% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated	% Released and Disposed[c] Off-site
1995	40.6	22%	0%	12%	26%	3%	10%	31%
1996	36.5	14%	0%	11%	36%	4%	10%	27%
1997	35.2	14%	0%	12%	36%	4%	10%	24%
1998	33.3	19%	0%	12%	33%	3%	10%	21%

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. For industries that are required to report, the best source of comparative pollutant release information is the Toxic Release Inventory (TRI). A component of the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20 through 39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1996) TRI reporting year (which includes over 600 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries. TRI data provide the type, amount and media receptor of each chemical released or transferred.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1996 Toxic Release Inventory Public Data Release, reported onsite releases of toxic chemicals to the environment decreased by 5 percent (111.6 million pounds) between 1995 and 1996 (not including chemicals added and removed from the TRI chemical list during this period). Reported releases dropped by 48 percent between 1988 and 1996. Reported transfers of TRI chemicals to off-site locations increased by 5 percent (14.3 million pounds) between 1995 and 1996. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

Certain limitations exist regarding TRI data. Within some sectors, (e.g. dry cleaning, printing and transportation equipment cleaning) the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. For these sectors, release information from other sources has been included.

Reported chemicals are limited to the approximately 600 TRI chemicals. A portion of the emissions from aerospace facilities, therefore, are not captured by TRI.

In addition, many facilities report more than one SIC code reflecting the multiple operations carried out on-site. Therefore, reported releases and transfers may or may not all be associated with the industrial operations described in this notebook.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released or the potential exposure to surrounding populations. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by the industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- is the Standard Industrial Classification (SIC) code, a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

R0074661

Releases -- are on-site discharges of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, vents, ducts, or pipes. Fugitive emissions include equipment leaks, evaporative losses from surface impoundments and spills, and releases from building ventilation systems.

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Releases due to runoff, including storm water runoff, are also reportable to TRI.

Releases to Land -- occur within the boundaries of the reporting facility. Releases to land include disposal of toxic chemicals in landfills, land treatment/application farming, surface impoundments, and other disposal on land (such as spills, leaks, or waste piles).

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal. Wastes containing TRI chemicals are injected into either Class I wells or Class V wells. Class I wells are used to inject liquid hazardous wastes or dispose of industrial and municipal wastewaters beneath the lowermost underground source of drinking water. Class V wells are generally used to inject non-hazardous fluid into or above an underground source of drinking water. TRI reporting does not currently distinguish between these two types of wells, although there are important differences in environmental impact between these two methods of injection.

Transfers -- are transfers of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. Chemicals reported to TRI as transferred are sent to off-site facilities for the purpose of recycling, energy recovery, treatment, or disposal. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, the reported quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewater transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment or removal of a chemical from the wastewater depends on the nature of the chemical, as well as the treatment methods present at the POTW. Not all TRI chemicals can be treated or removed by a POTW. Some chemicals, such as metals, may be removed but not destroyed and may be disposed of in landfills or discharged to receiving waters.

Transfers to Recycling -- are wastes sent off-site for the purposes of regenerating or recovery by a variety of recycling methods, including solvent recovery, metals recovery, and acid regeneration. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site to be treated through a variety of methods, including neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal, generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Aerospace Industry

This section summarizes TRI data of aerospace facilities reporting SIC codes within 372 and 376 as the primary SIC code for the facility.

According to the 1996 Toxics Release Inventory (TRI) data, 199 aerospace facilities released (to the air, water, or land) and transferred (shipped off-site or discharged to sewers) a total of approximately 27 million pounds of 65 different toxic chemicals during calendar year 1996. This represents approximately one half of one percent of the 5.6 billion pounds of releases and transfers from all manufacturers (SICs 20-39) reporting to TRI that year. Facilities released an average of 43,862 pounds per facility and transferred and average of 93,503 pounds per facility. The top four chemicals released by weight are solvents-- methyl ethyl ketone, 1,1,1-trichloroethane, trichloroethylene, and toluene. These four account for about 66 percent (5.8 million pounds) of the industry's total releases. Nickel, chromium, sulfuric acid, and methyl ethyl ketone were the four top chemicals transferred by weight. These four account for 55 percent (10.2 million pounds) of the total TRI chemicals transferred by the aerospace industry. Only 22 percent of the 65 chemicals reported to TRI as releases or transfers were reported by more than 10 facilities, evidence of the many different materials used by the industry and the variance between facilities on choice of these materials.

Releases

Table 8 presents the number and weights of chemicals released by aerospace facilities reporting SIC 372 and 376. The total quantity of releases was 8.7 million pounds or 32 percent of the total weight of chemicals released and transferred. The vast majority of air releases were solvents. Air emissions account for 98 percent of total releases, 44 percent as fugitive air emissions and 54 percent as point air releases. Methyl ethyl ketone was the top chemical released by the aerospace industry, accounting for 25 percent of total releases. Releases of 1,1,1-trichloroethane were the second greatest, representing 20 percent of the total. Twenty-four percent of fugitive air emissions were of 1,1,1-trichloroethane, and 32 percent of the point air releases were methyl ethyl ketone. Nitrate compounds accounted for 74 percent of water discharges.

Transfers

Table 9 presents the number and weights of chemicals transferred off-site by aerospace facilities reporting SIC 372 or 376 in 1996. The total amount of transfers was 18.6 million pounds or 68 percent of the total releases and transfers reported to the 1996 TRI by aerospace facilities. Transfers to recycling facilities accounted for the largest percentage, 70 percent, of transfers. The next greatest percentage was 17 percent to treatment facilities. The majority of transfers consisted of metals, spent acids, and solvents. Sixty-six percent (12.3 million pounds) of the total transfers were metals. Nickel represented the largest quantity of transfers, 5.3 million pounds or 29 percent of the total. Chromium composed the second largest quantity of transfers with 12 percent of the total. The chemical with the largest quantity of releases, methyl ethyl ketone, accounted for about 6 percent of the total transfers.

Table 8: 1996 TRI Releases for Aerospace Chemicals Facilities (SICs 372 or 376), By Number of Facilities Reporting (Releases Reported in Pounds/year)

Chemical Name	# Reporting Chemical	Fugitive Air	Point Air	Water Discharges	Underground Injection	Land Disposal	Total Releases	Avg. Releases Per Facility

**Total number of facilities (not chemical reports) reporting to TRI in this industry sector.

R0074666

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases only and not transfers. The top reporting facilities for the aerospace industry are listed below in Tables 10 and 11. Facilities that have reported the primary SIC codes covered under this notebook appear on the first list. Table 11 contains additional facilities that have reported the SIC codes covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations -- some that are under the scope of this notebook, and some that are not. However, only one additional facility appears on the second list, implying that the processes directly relating to the production of aerospace equipment is responsible for releases and transfers reported by aerospace facilities. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Table 10: Largest Quantity TRI Releasing Facilities Reporting Only 372 or 376 SIC Codes to TRI[1]

Rank	Facility	SIC Codes Reported in TRI	Total TRI Releases in Pounds
1	Boeing Commercial Airplane, Everett, WA	3721	784,581
2	Chem-fab Corp., Hot Springs, AR	3728	433,630

[2] Being included on this list does not mean that the release is associated with non-compliance with environmental laws.

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1995 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reduction over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult these sources for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the Hazardous Substances Data Bank (HSDB) and the Integrated Risk Information System (IRIS). The discussions of toxicity describe the range of possible adverse health effects that have been found to be associated with exposure to these chemicals. These adverse effects may or may not occur at the levels released to the environment. Individuals interested in a more detailed picture of the chemical concentrations associated with these adverse effects should consult a toxicologist or the toxicity literature for the chemical to obtain more information. The effects listed below must be taken in context of these exposure assumptions that are explained more fully within the full chemical profiles in HSDB. For more information on TOXNET[3] , contact the TOXNET help line at 1-800-231-3766.

1,1,1-Trichloroethane (CAS: 71-55-6)

Sources. 1,1,1-Trichloroethane is used as an equipment and parts cleaning and degreasing solvent in aerospace manufacturing and is also used as a paint solvent.

[3] TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

Toxicity. Repeated contact of 1,1,1-Trichloroethane (TCA) with skin may cause serious skin cracking and infection. Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations.

Exposure to high concentrations of TCA causes reversible mild liver and kidney dysfunction, central nervous system depression, gait disturbances, stupor, coma, respiratory depression, and even death. Exposure to lower concentrations of TCA leads to light-headedness, throat irritation, headache, disequilibrium, impaired coordination, drowsiness, convulsion and mild changes in perception.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of TCA to surface water or land will almost entirely volatilize. Releases of TCA to air may be transported long distances and may partially return to earth in rain. In the lower atmosphere, TCA degrades very slowly by photo oxidation and slowly diffuses to the upper atmosphere where photodegradation is rapid.

Any TCA that does not evaporate from soils leaches to groundwater. Degradation in soils and water is slow. TCA does not hydrolyze in water, nor does it significantly bioconcentrate in aquatic organisms.

Physical Properties. TCA is a clear, colorless liquid with a mild, chloroform-like odor and slight solubility.

Methyl Ethyl Ketone (CAS: 78-93-3)

Sources. Methyl ethyl ketone (MEK) is used as an equipment and parts cleaning and degreasing solvent and as a paint solvent.

Toxicity. Breathing moderate amounts of methyl ethyl ketone for short periods of time can cause adverse effects on the nervous system ranging from headaches, dizziness, nausea, and numbness in the fingers and toes to unconsciousness. Its vapors are irritating to the skin, eyes, nose, and throat and can damage the eyes. Repeated exposure to moderate to high amounts may cause liver and kidney effects.

Carcinogenicity. EPA does not consider methyl ethyl ketone to be a carcinogen.

Environmental Fate. Most of the MEK released to the environment will end up in the atmosphere. MEK can contribute to the formation of air pollutants in the lower atmosphere. It can be degraded by microorganisms living in water and soil.

Physical Properties. Methyl ethyl ketone is a clear, colorless, flammable liquid which decomposes explosively at 230°F. It has a fragrant mint-like odor detectable at 2 to 85 parts per million.

Trichloroethylene (CAS: 79-01-6)

Sources. Trichloroethylene is used extensively as an equipment and parts cleaning and degreasing solvent and as a paint solvent.

Toxicity. Trichloroethylene was once used as an anesthetic, though its use caused several fatalities due to liver failure. Short term inhalation exposure to high levels of trichloroethylene may cause rapid coma followed by eventual death from liver, kidney, or heart failure. Short-term exposure to lower concentrations of trichloroethylene causes eye, skin, and respiratory tract irritation. Ingestion causes a burning sensation in the mouth, nausea, vomiting and abdominal pain. Delayed effects from short-tern trichlorethylene poisoning include liver and kidney lesions, reversible nerve degeneration, and psychic disturbances. Long-term exposure can produce headache, dizziness, weight loss, nerve damage, heart damage, nausea, fatigue, insomnia, visual impairment, mood perturbation, sexual problems, dermatitis, and rarely jaundice. Degradation products of trichloroethylene (particularly phosgene) may cause rapid death due to respiratory collapse.

Carcinogenicity. Trichloroethylene is considered by EPA to be a probable human carcinogen via both oral and inhalation exposure, based on limited human evidence and sufficient animal evidence.

Environmental Fate. Trichloroethylene breaks down slowly in water in the presence of sunlight and bioconcentrates moderately in aquatic organisms. The main removal of trichloroethylene from water is via rapid evaporation. Trichloroethylene does not photodegrade in the atmosphere, though it breaks down quickly under smog conditions, forming other pollutants such as phosgene, dichloroacetyl chloride, and formyl chloride. In addition, trichloroethylene vapors may be decomposed to toxic levels of phosgene in the presence of an intense heat source such as an open arc welder. When spilled on land, trichloroethylene rapidly volatilizes from surface soils. Some of the remaining chemical may leach through the soil to groundwater.

Physical Properties. Trichloroethylene is a colorless liquid with a chloroform-like odor. It is a combustible liquid, but burns with difficulty, and it has a very low solubility.

Toluene (CAS: 108-88-3)

Sources. Toluene is used as an equipment and parts cleaning and degreasing solvent and as a paint solvent.

Toxicity. Inhalation or ingestion of toluene can cause headaches, confusion, weakness, and memory loss. Toluene may also effect the way the kidneys and liver function.

Reactions of toluene (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Some studies have shown that unborn animals were harmed when high levels of toluene were inhaled by their mothers, although the same effects were not seen when the mothers were fed large quantities of toluene. Note that these results may reflect similar difficulties in humans.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases of toluene to land and water will evaporate. Toluene may also be degraded by microorganisms. Once volatized, toluene in the lower atmosphere will react with other atmospheric components contributing to the formation of ground-level ozone and other air pollutants.

Physical Properties. Toluene, a volatile organic chemical (VOC), is a colorless liquid with a sweet, benzene-like odor. It is a Class IB flammable liquid.

IV.C. Other Data Sources

The toxic chemical release data obtained from TRI captures only about 237 of the facilities in the aerospace industry. However, it allows for a comparison across years and industry sectors. Reported chemicals are limited to the approximately 600 TRI chemicals. A significant portion of the emissions from aerospace facilities, therefore, are not captured by TRI. The EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., total hydrocarbons, SOx, NOx, CO, particulates, etc.) from many manufacturing sources.

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Table 12 summarizes annual releases (from the industries for which a Sector Notebook Profile was prepared) of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Table 12: Air Pollutant Releases by Industry Sector (tons/year)						
Industry Sector	CO	NO_2	PM10	PT	SO_2	VOC
Metal Mining	4,951	49,252	21,732	9,478	1,202	119,761

IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of TRI releases and transfers within each sector profiled under this project. Please note that the following figures and tables do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release Book.

Figure 7 is a graphical representation of a summary of the TRI data for the aerospace industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the vertical axis. Industry sectors are presented in the order of increasing SIC code. The graph is based on the data shown in Table 13 and is meant to facilitate comparisons between the relative amounts of releases and transfers both within and between these sectors. Table 13 also presents the average releases per facility in each industry. The reader should note that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the aerospace industry, the 1995 TRI data presented here covers 237 facilities. These facilities listed SIC 3721, 3724, 3728, 3761, 3764, or 3769 (aerospace industry) as a primary SIC code(s).

Figure 7: Summary of TRI Releases and Transfers by Industry

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasibly. In the waste management hierarchy, if source reduction is not feasible the next alternative is recycling of wastes, followed by energy recovery, and waste treatment as a last alternative.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the aerospace industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be used effectively. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

Pollution Prevention Techniques

This section lists many pollution prevention techniques geared toward the aerospace industry and its related processes. Some techniques may be applicable to a number of different processes such as materials substitution of low-solvent and less hazardous materials exist, while others are specific to a single phase of aerospace manufacturing. Many of the techniques discussed below were obtained from the *Profile of the Shipbuilding and Repair Industry*, EPA, 1997. It is important to note that the FAA places very strict "airworthiness" guidelines on manufacturing and rework facilities for safety and quality control purposes, thus new pollution prevention alternatives may require a full evaluation and permitting process before they may be used. Because military facilities are not subject to FAA guidelines, they have a greater opportunity to implement P2 alternatives. As a result, studies have been conducted at various Air Force, Coast Guard, and Naval facilities which are referenced in Section IX. Excellent information on military facility P2 activities can be found at web sites of the Air Force Center for Environmental Excellence (http://www.afcee.brooks.af.mil), and at the Navy's P2 Library web site (http://enviro.nfesc.navy.mil/p2library).

V.A. Machining and Metalworking

Coolant, or metalworking, fluids account for the largest waste stream generated by machining operations. Waste metalworking fluids are created when the fluids are no longer usable due to contamination by oils or chemical additives. If the contamination rate of the metalworking fluids is reduced, the need to replace them will be less frequent. This will reduce the waste generated.

Preventing Fluid Contamination

Fluid can become hazardous waste if it is contaminated. Although it is not possible to eliminate contamination, it is possible to reduce the rate of contamination and thereby prolong its use.

The primary contaminant in these waste fluids is tramp oil. One way to postpone contamination is to promote better maintenance of the wipers and seals. A preventative maintenance program should be installed and enforced in the machine shop. Scheduled sump and machine cleaning as well as periodic inspections of the wipers and oil seals should be carried out. The responsibility for this should be assigned to some person or group in a position of authority to ensure its success.

Synthetic Fluids

Synthetic fluids have many advantages over their non-synthetic counterparts. Usually the synthetic varieties do not lubricate as effectively, but they are less susceptible to contamination and highly resistant to biological breakdown. Most synthetic fluids have superior longevity and can operate over a large temperature range without adverse side effects. Straight oils should be replaced with synthetic ones when possible.

Recycling Fluids

Once all of the source reduction options have been considered, it is time to explore the possibilities of reuse. It should be noted that in many cases, after the majority of the contaminants have been removed, further treatment with chemicals or concentrated fluid is necessary before the fluids can be recirculated through the machines.

Filtration Filtration is a common way to remove particles from the fluid as well as tramp oils or other contaminants. Many different types of filters can be used depending on the medium to be filtered and the amount of filtration desired. Contaminated cutting fluids can be passed through a bag, disc, or cartridge filter or separated in a centrifuge.

Skimming and Flotation Although it is a slow process, skimming of contaminants is inexpensive and can be very effective. The principle is to let the fluid sit motionless in a sump or a tank, and after a predetermined amount of time, the unwanted oils are skimmed off the surface and the heavier particulate matter is collected off the bottom. A similar technique, flotation, injects high pressure air into contaminated cutting fluid. As the air comes out of solution and bubbles to the surface, it attaches itself to suspended contaminants and carries them up to the surface. The resulting sludge is skimmed off the surface and the clean fluid is reused.

Centrifugation Centrifugation uses the same settling principles as flotation, but the effects of gravity are multiplied thousands of times due to the spinning action of the centrifuge. This will increase the volume of fluids which can be cleaned in a given amount of time.

Pasteurization Pasteurization uses heat treatment to kill microorganisms in the fluid and reduce the rate at which rancidity (biological breakdown) will occur. Unfortunately, heat can alter the properties of the fluid and render it less effective. Properties lost in this way are usually impossible to recover.

Downgrading Sometimes it is possible to use high quality hydraulic oils as cutting fluids. After the oils have reached their normal usable life, they no longer meet the high standards necessary for hydraulic components. At this time they are still good enough to be used for the less demanding jobs. It may be necessary to treat the fluid before it can be reused, but changing fluid's functions in this manner has proven successful in the past.

V.B. Surface Preparation

The majority of wastes generated during surface preparation are spent abrasives and solvents mixed with paint chips. One way the volume of waste generated can be reduced is by using blast media that is relatively easy to reuse.

Improving Recyclability of Abrasive Blasting Media

Often, air powered cleaning equipment is used to screen abrasive to separate it from large paint particles. These systems may also remove lighter dust from the heavy abrasive. This media separation can be especially important when the paint being removed contains heavy metals. An alternative to on-site reclamation is to send it for processing off-site. It is very important that waste streams, especially hazardous waste, are not mixed with used blasting media. Outside debris and other waste could render the media unfit for reuse.

Plastic Media Blasting

As a substitute for other blast media, the military has experimented extensively with plastic media stripping. This process is particularly good for stripping coatings from parts with fragile substrates often found in the aerospace industry such as zinc, aluminum, and fiberglass. It can be a lengthy process because it strips paint layer by layer. The same types and quantities of waste are generated as with grit blasting, but the plastic medium is more recyclable with the use of pneumatic media classifiers that are part of the stripping equipment. The only waste requiring disposal is the paint waste itself. However, the use of plastic media is fairly limited. Plastic blasting media do not work well on epoxy paints. In addition, the blasting equipment is expensive and requires trained operators.

Water Jet Stripping (Hydroblasting)

Hydroblasting is a cavitating high pressure water jet stripping system that can remove most paints. These system may use pressures as high as 50,000 psig. Hydroblasting is an excellent method for removing even hard coatings from metal substrates. Some systems automatically remove the paint chips or stripped material from the water and reuse the water for further blasting. By recirculating the water in this manner, the amount of waste is greatly reduced. Wastewater from this process is usually suitable for sewer disposal after the paint particles are removed. Although this process produces very little waste, it is not always as efficient as other blasting methods, has relatively high capital and maintenance costs, and may not be adequate for fragile substrates.

V.C. Solvent Cleaning and Degreasing

Aerospace manufacturers often use large quantities of solvents in a variety of cleaning and degreasing operations including parts cleaning, process equipment cleaning, and surface preparation for coating applications. The final cost of solvent used for various cleanup operations is nearly twice the original purchase price of the virgin solvent. The additional cost is primarily due to the fact that for each drum purchased, extra disposal cost, hazardous materials transportation cost, and manifesting time and expense are incurred. With the rising cost of solvents and waste disposal services, combined with continuously developing regulation, reducing the quantities of solvents used and solvent wastes generated can be extremely cost effective.

Eliminating the Use of Solvents

Eliminating the use of solvents avoids any waste generation associated with spent solvent. Elimination can be achieved by utilization of non-solvent cleaning agents or eliminating the need for cleaning altogether. Solvent elimination applications include the use of water-soluble cutting fluids, protective peel coatings, aqueous cleaners, and mechanical cleaning systems (USEPA/OECA, 1997).

Water-soluble Cutting Fluids Water-soluble cutting fluids can often be used in place of oil-based fluids. The cutting oils usually consist of an oil-in-water emulsion used to reduce friction and dissipate heat. If these fluids need to be removed after the machining process is complete, solvents may be needed.

In efforts to eliminate solvent degreasing and its subsequent waste, special water-soluble cutting fluids have been developed. Systems are available that can clean the cutting fluid and recycle the material back to the cutting operation. Obstacles to implementing this method are: cost (water-soluble fluids are generally more expensive), procurement (there are only a few suppliers available), and the inability to quickly switch between fluid types without thoroughly cleaning the equipment (USEPA/OECA, 1997).

Aqueous Cleaners Aqueous cleaners, such as alkali, citric, and caustic base, are often useful substitutes for solvents. There are many formulations that are suited for a variety of cleaning requirements. Many aqueous cleaners have been found to be as effective as the halogenated solvents that are commonly employed.

Aqueous stripping agents, such as caustic soda (NaOH), are often employed in place of methylene chloride based strippers. Caustic solutions have the advantage of eliminating solvent vapor emissions. A typical caustic bath consists of about 40 percent caustic solution heated to about 200 degrees Fahrenheit. Caustic stripping is generally effective on alkyl resins and oil paints (EPA, March 1997).

The Douglas Aircraft Division of McDonnell Douglas used a chromic acid solution to clean aluminum parts. However, the solution began to corrode the steel cleaning equipment parts. A scientist at McDonnell Douglas developed a sodium hydroxide-based process which cleaned parts sufficiently to detect cracks in the aluminum parts during testing. The new process saves an estimated $28,000 per year in chemical costs (Boeing, 1998).

In 1990, the Martin Marietta Astronautics Group (now Lockheed Martin) eliminated the use of 1,1,1-trichloroethane (TCA) and methyl ethyl ketone (MEK) for vapor degreasing. Six alternative aqueous cleaners were subjected to a screening process that evaluated health hazards, treatability of wastewater, corrosion potential, degreasing performance, and salt fog corrosion resistance. From this study, Lockheed Martin selected a nontoxic aqueous terpene cleaner. The substitution of this cleaner saves hundreds of thousands of dollars every year in material cost savings and ozone depletion taxes (Dykema, 1993).

Lockheed Martin Tactical Aircraft Systems in Fort Worth, Texas, has substituted low vapor pressure solvent and aqueous cleaning for CFC-113 in all aspects of aircraft manufacturing. The low vapor pressure solvent is a blend of propylene glycol methyl ether acetate, isoparaffins, and butyl acetate. The solvent is effective on a variety of organic soils and is used for wiping the surfaces of aircraft components and assemblies. The substitution of this cleaner completely eliminated CFC emissions and reduced solvent use, solvent cost, VOC emissions, and total air emissions (Evanoff, 1993).

The advantages of substituting aqueous cleaners include minimizing worker's exposure to solvent vapors, reducing liability and disposal problems associated with solvent use, and cost. Aqueous cleaners do not volatilize as quickly as other solvents, thereby reducing losses due to evaporation. Since most aqueous cleaners are biodegradable, disposal is not a problem once the organic or inorganic contaminants are removed (USEPA, March 1997).

The use of aqueous cleaners can also result in cost savings. Although some aqueous cleaners may cost less than an equivalent amount of solvent, the purchase price of each is about the same. The cost of disposal, loss due to evaporation, and associated liabilities, however, favor aqueous cleaners.

The disadvantages of aqueous cleaners in place of solvents may include: possible incompatibilities with FAA guidelines, possible inability of the aqueous cleaners to provide the degree of cleaning required, incompatibility between the parts being cleaned and the cleaning solution, need to modify or replace existing equipment, longer required cleaning time, and problems associated with moisture left on parts being cleaned. Oils removed from the parts during cleaning may float on the surface of the cleaning solution and may interfere with subsequent cleaning. Oil skimming is usually required (USEPA/OECA, 1997).

Mechanical Cleaning Systems Utilizing mechanical cleaning systems can also replace solvents in degreasing and cleaning operations. In many cases, a high pressure steam gun or high pressure parts washer can clean parts and surfaces quicker and to the same degree of cleanliness as that of the solvents they replace. Light detergents can be added to the water supply for improved

R0074683

cleaning. The waste produced by these systems is usually oily wastewater. This wastewater can be sent through an oil/water separator, the removed water discharged to the sewer, and the oil residue sent to a petroleum recycler. Some hot water wash and steam systems can be supplemented by emulsifying solutions to speed the process. Although these additives speed the cleaning process, they can make separation of the oil from the water very difficult and create problems with disposal of the waste.

Cryogenic stripping utilizes liquid nitrogen and non-abrasive plastic beads as blasting shot. This method relies on the freezing effect of the liquid nitrogen and the impact of the plastic shot. Subjecting the surface to extremely low temperatures creates stress between the coating and the substrate causing the coating to become brittle. When the plastic shot hits the brittle coating, debonding occurs. The process is non-abrasive, and will not damage the substrate, but effects of the metal shrinkage, due to extremely low temperatures, should be monitored. The process does not produce liquid wastes, and nitrogen, chemically inert, is already present in the atmosphere (USEPA/OECA, 1997).

Thermal stripping methods can be useful for objects that cannot be immersed. In this process, superheated air is directed against the surface of the object. The high temperatures cause some paints to flake off. The removal results from the drying effects of the air and the uneven expansion of the paint and the substrate. Some paints will melt at high temperatures, allowing the paint to be scraped off manually or with abrasives. Hand-held units are available that produce a jet of hot air. Electric units and open flame or torch units are also used. While this system is easy to implement, it is limited to items that are not heat sensitive and to coatings that are affected by the heat (USEPA/OECA, 1997).

McDonnell Douglas has developed two thermal stripping techniques. The first one, known as FLASHJET™, uses a high-intensity xenon lamp to heat the surface paint and disintegrate it. A stream of dry ice pellets follows to carry away the paint chips. FLASHJET™ was developed for use and tested on helicopters at the McDonnell Douglas Helicopter Systems plant in Mesa, Arizona. FLASHJET™ reduced the manual work required by 10 to 15 percent (Boeing, 1998).

The second technique was adapted from a technique to remove hydrocarbons from engines. The Hot Gaseous Nitrogen (GN2) Purge heats the critical engine surfaces, driving off the volatile hydrocarbons, which then leave the engine through the flow of nitrogen. This method eliminates the use of 1,1,1-trichloroethane for this type of engine cleaning (Boeing, 1998).

Hughes Aircraft Company developed a supercritical carbon dioxide ($SCCO_2$) cleaning system to be used in many cleaning applications in the aerospace industry. At temperatures and pressures close to or above its critical point (88°F and 1,073 psia), CO_2 acts as an ideal solvent. It is also inexpensive and inert, non-combustible, naturally occurring, and does not contribute to smog. Efficient removal of oils, greases, fingerprints, solder flux residues have been achieved by the SUPERSCRUB™ unit at Hughes (Chao).

Reducing the Use of Solvent

By eliminating the use or need for solvent cleaning, the problems associated with disposal of spent solvent are also eliminated. In cases where the elimination of solvent use is not possible or practical, utilization of various solvent waste reduction techniques can lead to a substantial savings in solvent waste.

Methods of reducing solvent usage can be divided into three categories: source control of air emissions, efficient use of solvent and equipment, and maintaining solvent quality. Source control of air emissions addresses ways in which more of the solvent can be kept inside a container or cleaning tank by reducing the chances for evaporation loss. Efficient use of solvent and equipment through better operating procedures can reduce the amount of solvent required for cleaning. Maintaining the quality of solvent will extend the life cycle effectiveness of the solvent.

<u>Source Control of Air Emissions</u> Source control of air emissions can be achieved through equipment modification and proper operation of equipment. Some simple control measures include installation and use of lids, an increase of freeboard height of cleaning tanks, installation of freeboard chillers, and taking steps to reduce solvent drag-out.

All cleaning units, including cold cleaning tanks and dip tanks, should have some type of lid installed. When viewed from the standpoint of reducing air emissions, the roll-type cover is preferable to the hinge type. Lids that swing down can cause a piston effect and force the escape of solvent vapor. In operations such as vapor degreasing, use of lids can reduce solvent loss from 24 percent to 50 percent. For tanks that are continuously in use, covers have been designed that allow the work pieces to enter and leave the tank while the lid remains closed.

In an open top vapor degreaser, freeboard is defined as the distance from the top of the vapor zone to the top of the tank. Increasing the freeboard will substantially reduce the amount of solvent loss. A freeboard chiller may also be installed above the primary condenser coil. This refrigerated coil, much like the cooling jacket, chills the air above the vapor zone and creates a secondary barrier to vapor loss. Reduction in solvent usage, by use of freeboard chillers, can be as high as 60 percent. The major drawback with a freeboard chiller is that it can introduce water (due to condensation from air) into the tank.

In addition to measures that reduce air emissions through equipment modification, it is also possible to reduce emissions through proper equipment layout, operation, and maintenance. Cleaning tanks should be located in areas where air turbulence and temperature do not promote vapor loss.

Maximize the Dedication of the Process Equipment In addition to reduction in vapor loss, reducing the amount of solvent used can be achieved through better operating practices that increase the efficiency of solvent cleaning operations. Maximizing the dedication of the process equipment reduces the need for frequent cleaning. By using a mix tank consistently for the same formulation, the need to clean equipment between batches is eliminated.

Avoid Unnecessary Cleaning Avoiding unnecessary cleaning also offers potential for waste reduction. For example, paint mixing tanks for two-part paints are often cleaned between batches of the same product. The effect of cross-contamination between batches should be examined from a product quality control viewpoint to see if the cleaning step is always necessary.

Proper Production Scheduling Proper production scheduling can reduce cleaning frequency by eliminating the need for cleaning between the conclusion of one task and the start of the next. A simple example of this procedure is to have a small overlap between shifts that perform the same operation with the same equipment. This allows the equipment that would normally be cleaned and put away at the end of each shift, such as painting equipment, to be taken over directly by the relief.

Clean Equipment Immediately Cleaning equipment immediately after use prevents deposits from hardening and avoids the need for consuming extra solvent. Letting dirty equipment accumulate and be cleaned later can also increase the time required for cleaning.

Better Operating Procedures Better operating procedures can minimize equipment clean-up waste. Some of the methods already discussed are examples of better operating procedures. Better operator training, education, closer supervision, improved equipment maintenance, and increasing the use of automation are very effective in waste minimization.

Reuse Solvent Waste Reuse of solvent waste can reduce or eliminate waste and result in a cost savings associated with a decrease in raw material consumption. The solvent from cleaning operations can be reused in other cleaning processes in which the degree of cleanliness required is much less. This will be discussed in more detail in the next section.

Solvent Recycling

Although not as preferable as source reduction, solvent recycling may be a viable alternative for some facilities. The goal of recycling is to recover from the waste solvent, a solvent of a similar purity to that of the virgin solvent for eventual reuse in the same operation, or of a sufficient purity to be used in another application. Recycling can also include the direct use of solvent waste from one waste stream in another operation. There are a number of techniques that facilities can use onsite to separate solvents from contaminants including distillation, evaporation, sedimentation, decanting, centrifugation, filtering, and membrane separation.

V.D. Metal Plating and Surface Finishing

Pollution prevention opportunities in metal plating and surface finishing operations are discussed in the *Profile of the Fabricated Metal Products Industry Sector Notebook*. Readers are encouraged to consult this document for pollution prevention information relating to metal plating and surface finishing. An additional resource for pollution prevention information regarding metal finishing can be found at the National Metal Finishing Resource Center (http://www.nmfrc.org).

V.E. Painting and Coating

Painting and coating operations are typically the largest single source of VOC emissions from aerospace manufacturing and rework facilities. In addition, paint waste can account for more than half of the total hazardous waste generated. Paint waste may include leftover paint in containers, overspray, paint that is no longer usable (Non-spec paint), and rags and other materials contaminated with paint. In many cases, the amount of paint waste generated can be reduced through the use of improved equipment, alternative coatings, and good operating practices. An additional resource for pollution prevention information regarding painting and coating can be found at the Paint and Coatings Resource Center (http://www.paintcenter.org).

Application Equipment

In order to effectively reduce paint waste and produce a quality coating, proper application techniques should be supplemented with efficient application equipment. Through the use of equipment with high transfer efficiencies, the amount of paint lost to overspray is minimized.

High Volume Low Pressure (HVLP) Spray Guns The HVLP spray gun is basically a conventional air spray gun with modifications and special nozzles that atomize the paint at very low air pressures. The atomizing pressure of HVLP systems is often below 10 psi. The design of this gun allows better transfer efficiency and reduced overspray than that of conventional air guns. The low application pressure decreases excessive bounceback and allows better adhesion of the coating to the substrate.

Although improvements are consistently being made to overcome its limitations, most HVLP systems have some definite drawbacks, including difficulty atomizing viscous coatings, sensitivity to variations in incoming pressure, sensitivity to wind, and slow application rates.

Airless Spray Guns Instead of air passing through the spray gun, an airless system applies static pressure to the liquid paint. As the paint passes through the nozzle, the sudden drop in pressure atomizes the paint and it is carried to the substrate by its own momentum. Pressure is applied to the paint by a pump located at a remote supply. These systems have become favorable over conventional air-spray systems for three main reasons:

1) reduced overspray and rebound,
2) high application rates and transfer efficiency,
3) permits the use of high-build coatings with the result that fewer coats are required to achieve specific film thickness.

One major disadvantage of some airless spray systems is the difficulty applying very thin coats. If coatings with less than a millimeter in thickness are required, such as primers applied to objects that require weldability, it may be difficult to use an airless system.

Electrostatic Spray Electrostatic spray systems utilize paint droplets that are given a negative charge in the vicinity of a positively charged substrate. The droplets are attracted to the substrate and a uniform coating is formed. This system works well on cylindrical and rounded objects due to its "wrap-around" effect that nearly allows the object to be coated from one side. Very little paint is lost to overspray, and it has been noted to have a transfer efficiency of over 95%.

In order for an electrostatic system to operate properly, the correct solvent balance is needed. The evaporation rate must be slow enough for the charged droplets to reach the substrate in a fluid condition to flow out into a smooth film, but fast enough to avoid sagging. The resistivity of the paint must also be low enough to enable the paint droplets to acquire the maximum charge.

Although the operating costs of electrostatic spray systems are relatively low, the initial capital investment can be high. This system has been found to work extremely well in small parts painting applications. Sometimes the installation of an electrostatic powder coating system can replace a water curtain spray paint booth.

Heated Spray When paint is heated, its viscosity is reduced allowing it to be applied with a higher solids content, thus requiring less solvent. When the paint is heated in a special container and supplied to the gun at 140° to 160°F, coatings of 2 to 4 millimeters dry-film thickness can be applied in one operation, resulting in considerable savings in labor cost. In addition, much of the associated solvent emissions are eliminated.

Heating the coating prior to application can be used with both conventional and airless spray applications. An in-line heater is used to heat the coating before it reaches the gun. As the coating is propelled through the air, it cools rapidly and increases viscosity after it hits the surface, allowing for better adhesion to the substrate.

Plural Component Systems A common problem that facilities face when working with two-part coatings is overmixing. Once the component parts of a catalyst coating are mixed, the coating must be applied. Otherwise, the excess unused coating will cure and require disposal. Additionally, the coating equipment must be cleaned immediately after use.

One large advantage of plural component technology is the elimination of paint waste generated by mixing an excess amount of a two part coating. This is achieved through the use of a special mixing chamber that mixes the pigment and catalyst seconds before the coating is applied. Each component is pumped through a device that controls the mixing ratio and then is combined in a mixing chamber. From the mixing chamber, the mixed coating travels directly to the spray guns. The only cleaning that is required is the mixing chamber, gun, and the length of supply hose connecting them.

Wet Booth Generally, small-volume painting operations will find the lower purchase cost of a dry filter booth will meet their requirements. One disadvantage in the use of a dry-filter booth is in the disposal of the waste. Typically the majority of this waste is the filter media itself which has been contaminated by a relatively small amount of paint. Reusable filters may decrease waste volume and reduce disposal cost. In some applications, overspray can be collected for reuse.

If overall painting volume can justify the investment, a wet booth eliminates disposal of filter media and allows waste to be reduced in weight and volume. This is achieved by separating the paint from the water through settling, drying, or using a centrifuge or cyclone (Ohio EPA, 1994).

Recycle Paint Booth Water Various methods and equipment are used to reduce or eliminate the discharge of the water used in water-wash booths (water curtain). These methods and equipment prevent the continuous discharge of booth waters by conditioning (i.e., adding detacifiers and paint-dispersing polymers) and removing paint solids. The most basic form of water maintenance is the removal of paint solids by manual skimming and/or raking. This can be performed without water conditioning since some portion of solvent-based paints usually float and/or sink. With the use of detacifiers and paint-dispersing polymer treatments, more advanced methods of solids removal can be implemented. Some common methods are discussed below.

Wet-Vacuum Filtration Wet-vacuum filtration units consist of an industrial wet-vacuum head on a steel drum containing a filter bag. The unit is used to vacuum paint sludge from the booth. The solids are filtered by the bag and the water is returned to the booth. Large vacuum units are also commercially available that can be moved from booth to booth by forklift or permanently installed near a large booth.

Tank-Side Weir A weir can be attached to the side of a side-draft booth tank, allowing floating material to overflow from the booth and be pumped to a filtering tank for dewatering.

Consolidator A consolidator is a separate tank into which booth water is pumped. The water is then conditioned by the introduction of chemicals. Detacified paint floats to the surface of the tank, where it is skimmed by a continuously moving blade. The clean water is recycled to the booth.

Filtration Various types of filtration units are used to remove paint solids from booth water. This is accomplished by pumping the booth water to the unit where the solids are separated and returning the water to the booth. The simplest filtration unit consists of a gravity filter bed utilizing paper or cloth media. Vacuum filters are also employed, some of which require precoating with diatomaceous earth.

Centrifuge Methods Two common types of centrifugal separators are the hydrocyclone and the centrifuge. The hydrocyclone is used to concentrate solids. The paint booth water enters a cone-shaped unit under pressure and spins around the inside surface. The spinning imparts an increased force of gravity, which causes most of the solid particles to be pulled outward to the walls of the cone. Treated water exits the top of the unit and the solids exit from the bottom. Some systems have secondary filtration devices to further process the solids. The centrifuge works in a similar manner, except that the booth water enters a spinning drum, which imparts the centrifugal force needed for separating the water and solids. Efficient centrifugation requires close control of the booth water chemistry to ensure a uniform feed. Also, auxiliary equipment such as booth water agitation equipment may be needed (EPA, 1995).

Alternative Coatings

The use of solvent-based coatings can lead to high costs to meet air and water quality regulations. In efforts to reduce the quantity and toxicity of waste paint disposal, alternative coatings have been developed that do not require the use of solvents and thinners. FAA guidelines may prohibit use of such coatings.

Powder Coatings Metal substrates can be coated with certain resins by applying the powdered resin to the surface, followed by application of heat. The heat melts the resin, causing it to flow and form a uniform coating. The three main methods in use for applying the powder coating are fluidized bed, electrostatic spray, and flame spraying.

In flame spraying, the resin powder is blown through the gun by compressed air. The particles are melted in a high temperature flame and propelled against the substrate. This process is used widely with epoxy powders for aluminum surfaces.

The electrostatic application method uses the same principles as the electrostatic spray. The resin powder is applied to the surface electrostatically. Heat is applied to the covered surface and the powder melts to form the coating. The transfer efficiency and recyclability of this method is very high.

The elimination of environmental problems associated with many liquid based systems is one of the major advantages of powder coatings. The use of powder coatings eliminates the need for solvents and thereby emits negligible volatile organic compounds (VOCs). Powder coatings also reduce the waste associated with unused two-part coatings that have already been mixed. Since powder overspray can be recycled, material utilization is high and solid waste generation is low. Recent case studies demonstrate that powder coating systems can be cleaner, more efficient, and more environmentally acceptable, while producing a higher quality finish than many other coating systems.

Water-Based Paints Water-based coatings are paints containing a substantial amount of water instead of volatile solvents. Alkyd, polyester, acrylic, and epoxy polymers can be dissolved and dispersed by water. In addition to reduction in environmental hazards due to substantially lower air emissions, a decrease in the amount of hazardous paint sludge generated can reduce disposal cost.

UV / EB Coatings Powder coatings require high temperatures for their cure and hence are not applicable to temperature sensitive substrates, such as paper, wood or plastics. For such materials, the use of coatings systems curable by ultra violate light or electron beams (UV/EB) have been developed. The resins used in these coatings are basically the same as those used in conventional high performance coatings which have been modified to make them polymerizable by UV or EB energy. Thus they are liquids that can be applied by conventional techniques such as spraying, roller coating, curtain coating, etc. (in contrast to powder coating which requires specialized application techniques). When exposed to the low level radiant energy, they are instantly and completely cured with no heat application. Because of the diversity of raw materials that can be adapted to this technology, a tremendous range of performance characteristics can be achieved. In addition, because no solvents are used in the coating formulations, there are virtually no volatile organic compounds (VOCs) emitted, making them ecologically preferred. Other advantages include the elimination of curing ovens and incinerators which further aid the cleansing of the air as well as substantial savings of space and fuel costs. The rapid curing cycle without the need of a cool-down cycle allows for higher production rates and therefore lower costs. UV/EB coatings can be used on metals, and are especially useful when coating complex metal products that might contain paper, plastic or wood parts, because of the low temperature curing required by UV/EB. In addition, these, and other advantages which UV/EB provides, have led to rapid increase in their use in the manufacture of electronic components.

Good Operating Practices

In many cases, simply altering a painting process can reduce wastes through better management.

A good manual coating application technique is very important in reducing waste. If not properly executed, spraying techniques have a high potential for creating waste; therefore, proper application techniques are very important.

Reducing Overspray One of the most common means of producing paint waste at facilities is overspray. Overspray not only wastes some of the coating, it also presents environmental and health hazards. It is important that facilities try to reduce the amount of overspray as much as possible. Techniques for reducing overspray include:

1) triggering the paint gun at the end of each pass instead of carrying the gun past the edge of the surface before reversing directions,
2) avoiding excessive air pressure,
3) keeping the gun perpendicular to the surface being coated.

Uniform Finish Application of a good uniform finish provides the surface with quality coating with a higher performance than an uneven finish. An uneven coating does not dry evenly and commonly results in using excess paint.

Overlap An overlap of 50 percent can reduce the amount of waste by increasing the production rate and overall application efficiency. Overlap of 50 percent means that for every pass that the operator makes with the spray gun, 50 percent of the area covered by the previous pass is also sprayed. If less than a 50 percent overlap is used, the coated surface may appear streaked. If more than a 50 percent overlap is used, the coating is wasted and more passes are required to coat the surface.

Paint Proportioning Mixing batches of paint on an as-needed basis, whether through the use of a paint proportioning machine or otherwise, can reduce the amount of paint wasted. Recordkeeping requirements to track the amount of paint and thinner used can also help conserve materials and prevent waste.

General Housekeeping Small quantities of paint and solvents are frequently lost due to poor housekeeping techniques. There are a variety of ways that can be implemented to control and minimize spills and leaks. Specific approaches to product transfer methods and container handling can effectively reduce product loss.

The potential for accidents and spills is at the highest point when thinners and paints are being transferred from bulk drum storage to the process equipment. Spigots, pumps, and funnels should be used whenever possible.

Evaporation can be controlled by using tight fitting lids, spigots, and other equipment. The reduction in evaporation will increase the amount of available material and result in lower solvent purchase cost.

Paint Containers A significant portion of paint waste is the paint that remains inside a container after the container is emptied, and paint that is placed in storage, not used, and becomes outdated or non-spec. By consolidating paint use and purchasing paint in bulk, large bulk containers have less surface area than an equivalent volume of small cans, and the amount of drag-on paint waste is reduced. Large bulk containers can sometimes be returned to the paint supplier to be cleaned for reuse.

If the purchase of paint in bulk containers is not practical, the paint should be purchased in the smallest amount required to minimize outdated or non-spec paint waste. Workers should not have to open a gallon can when only a quart is required. Usually, any paint that is left in the can will require disposal as hazardous waste.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section VI.A. contains a general overview of major statutes
- Section VI.B. contains a list of regulations specific to this industry
- Section VI.C. contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities must obtain a permit either from EPA or from a State agency which EPA has authorized to implement the permitting program if they store hazardous wastes for more than 90 days before treatment or disposal. Facilities may treat hazardous wastes stored in less-than-ninety-day tanks or containers without a permit. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 States and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

•**Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator must follow to determine whether the material in question is considered a hazardous waste, solid waste, or is exempted from regulation.

•**Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

•**Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet LDR treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

•**Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

•RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities that store such waste, including large quantity generators accumulating waste prior to shipment off-site.

•**Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that must be met by December 22, 1998.

•**Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

***EPA's RCRA, Superfund and EPCRA Hotline,** at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.*

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law known commonly as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as removals. EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

•**EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

•**EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release equaling or exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

•**EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

•**EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, known commonly as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The National Pollutant Discharge Elimination System (NPDES) program (CWA §502) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized 42 States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set the conditions and effluent limitations on the facility discharges.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated the NPDES storm water permit application regulations. These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.
Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, consult the regulation.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal

R0074699

mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national pretreatment program (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention, Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities that could reasonably be expected to discharge oil in harmful quantities prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR §112.20) and for PCB transformers and PCB-containing items were revised and finalized in 1995.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, VOCs, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under section 110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and will become effective in 2001.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source (see 40 CFR 60).

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title I, section 112(c) of the CAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV of the CAA establishes a sulfur dioxide nitrous oxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs) and chloroform, were phased out (except for essential uses) in 1996.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Requirements

The aerospace industry is affected by several major federal environmental statutes. A summary of the major federal regulations affecting the aerospace industry follows. Other resources which are useful in understanding industry specific requirements are:

1. The Paint and Coatings Resource Center web page (http://www.paintcenter.org)
2. The Self Audit & Inspection Guide; For Facilities Conducting Cleaning, Preparation, and Organic Coating of Metal Parts, published by the EPA (call NCEPI at 800-490-9198, EPA Doc. #305-B-95-002).
3. California EPA Air Resources Board Web Pages;
   Compliance Handbooks and Pamphlets
   - http://www.arb.ca.gov/cd/cap/handbks.htm

   Compliance Training Courses
   - http://www.arb.ca.gov/cd/training.htm
   - http://www.arb.ca.gov/html/all.htm

Resource Conservation and Recovery Act (RCRA)

The Resource Conservation and Recovery Act (RCRA) was enacted in 1976 to address problems related to hazardous and solid waste management. RCRA gives EPA the authority to establish a list of solid and hazardous wastes and to establish standards and regulations for the treatment, storage, and disposal of these wastes. Regulations in Subtitle C of RCRA address the identification, generation, transportation, treatment, storage, and disposal of hazardous wastes. These regulations are found in 40 CFR Part 124 and 40 CFR Parts 260-279. Under RCRA, persons who generate waste must determine whether the waste is defined as solid waste or hazardous waste. Solid wastes are considered hazardous wastes if they are listed by EPA as hazardous or if they exhibit characteristics of a hazardous waste: toxicity, ignitability, corrosivity, or reactivity.

Some wastes potentially generated at aerospace facilities that are considered hazardous wastes are listed in 40 CFR Part 261. Some of the handling and treatment requirements for RCRA hazardous waste generators are covered under 40 CFR Part 262 and include the following: determining what constitutes a RCRA hazardous waste (Subpart A); manifesting (Subpart B); packaging, labeling, and accumulation time limits (Subpart C); and record keeping and reporting (Subpart D).

Several common aerospace manufacturing operations have the potential to generate RCRA hazardous wastes. Some of these wastes are identified below by process.

Machining and Other Metalworking
•Metalworking fluids contaminated with oils, phenols, creosol, alkalies, phosphorus compounds, and chlorine

Cleaning and Degreasing
•Solvents (F001, F002, F003, F004, F005)
•Alkaline and Acid Cleaning Solutions (D002)
•Cleaning filter sludges with toxic metal concentrations

Metal Plating and Surface Finishing and Preparation
•Wastewater treatment sludges from electroplating operations (F006)
•Spent cyanide plating bath solutions (F007)
•Plating bath residues from the bottom of cyanide plating baths (F008)
•Spent stripping and cleaning bath solutions from cyanide plating operations (F009)

Surface Preparation, Painting and Coating
•Paint and paint containers containing paint sludges with solvents or toxic metals concentrations
•Solvents (F002, F003)
•Paint chips with toxic metal concentrations
•Blasting media contaminated with paint chips

Aerospace manufacturing and rework facilities may also generate used lubricating oils which are regulated under RCRA but may or may not be considered a hazardous waste (40 CFR 266).

Many aerospace facilities store some hazardous wastes at the facility for more than 90 days, and are therefore, a storage facility under RCRA. Storage facilities are required to have a RCRA treatment, storage, and disposal facility (TSDF) permit (40 CFR Part 262.34). Some aerospace facilities are considered TSDF facilities and therefore may be subject to the following regulations covered under 40 CFR Part 264: contingency plans and emergency procedures (40 CFR Part 264 Subpart D); manifesting, record keeping, and reporting (40 CFR Part 264 Subpart E); use and management of containers (40 CFR Part 264 Subpart I); tank systems (40 CFR Part 264 Subpart J); surface impoundments (40 CFR Part 264 Subpart K); land treatment (40 CFR Part 264 Subpart M); corrective action of hazardous waste releases (40 CFR Part 264 Subpart S); air emissions standards for process vents of processes that process or generate hazardous wastes (40 CFR Part 264 Subpart AA); emissions standards for leaks in hazardous waste handling equipment (40 CFR Part 264 Subpart BB); and emissions standards for containers, tanks, and surface impoundments that contain hazardous wastes (40 CFR Part 264 Subpart CC).

Many aerospace manufacturing and rework facilities are also subject to the underground storage tank (UST) program (40 CFR Part 280). The UST regulations apply to facilities that store either petroleum products or hazardous substances (except hazardous waste) identified under the Comprehensive Environmental Response, Compensation, and Liability Act. UST regulations address design standards, leak detection, operating practices, response to releases, financial responsibility for releases, and closure standards.

A number of RCRA wastes have been prohibited from land disposal unless treated to meet specific standards under the RCRA Land Disposal Restriction (LDR) program. The wastes covered by the RCRA LDRs are listed in 40 CFR Part 268 Subpart C and include a number of wastes that could potentially be generated at aerospace manufacturing facilities. Standards for the treatment and storage of restricted wastes are described in Subparts D and E, respectively.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the Superfund Amendments and Reauthorization Act of 1986 (SARA) provide the basic legal framework for the federal "Superfund" program to clean up abandoned hazardous waste sites (40 CFR Part 305). Metals and metal compounds often found in the aerospace industry's air emissions, water discharges, or waste shipments for off-site disposal include chromium, manganese, aluminum, nickel, copper, zinc, and lead. Metals are frequently found at CERCLA's problem sites. When Congress ordered EPA and the Public Health Service's Agency for Toxic Substances and Disease Registry (ATSDR) to list the hazardous substances most commonly found at problem sites and that pose the greatest threat to human health, lead, nickel, and aluminum were all included.

Title III of the 1986 SARA amendments (also known as Emergency Response and Community Right-to-Know Act, EPCRA) requires all manufacturing facilities, including aerospace facilities, to report annual information to the public about over 600 toxic substances as well as release of these substances into the environment (42 U.S.C. 9601). This is known as the Toxic Release Inventory (TRI). EPCRA also establishes requirements for Federal, State, and local governments regarding emergency planning.

Clean Air Act (CAA)

Under Title III of the 1990 Clean Air Act Amendments (CAAA), EPA is required to develop national emission standards for 189 hazardous air pollutants (NESHAP). EPA is developing maximum achievable control technology (MACT) standards for all new and existing sources. The National

R0074707

Emission Standards for Aerospace Manufacturing and Rework Facilities (40 CFR Part 63 Subpart GG) were finalized in 1996 and apply to major source aerospace manufacturing and rework facilities. Facilities that emit ten or more tons of any one HAP or 25 or more tons of two or more HAPs combined are major sources, and therefore are subject to the MACT (NESHAP) requirements. The MACT requirements apply to solvent cleaning operations, primer and topcoat application operations, depainting operations, chemical milling maskant application operations, and handling and storage of waste. The standards set VOC emissions and content limits for different types of solvents, chemical strippers and coatings. In addition, performance standards are set to reduce spills, leaks, and fugitive emissions. Aerospace facilities may also be subject to National Emissions Standards for: Chromium Emissions From Hard and Decorative Chromium Electroplating and Chromium Anodizing Tanks (40 CFR Part 63 Subpart N) if they perform chromium electroplating or anodizing; and Halogenated Solvent Cleaning if they operate a solvent cleaning machine using a halogenated HAP solvent. These NESHAPs require emission limits, work practice standards, record keeping, and reporting.

Under Title V of the CAAA 1990 (40 CFR Parts 70-72) all of the applicable requirements of the Amendments are integrated into one federal renewable operating permit. Facilities defined as "major sources" under the Act must apply for permits within one year from when EPA approves the state permit programs. Since most state programs were not approved until after November 1994, Title V permit applications, for the most part, began to be due in late 1995. Due dates for filing complete applications vary significantly from state to state, based on the status of review and approval of the state's Title V program by EPA.

A facility is designated as a major source for Title V if it releases a certain amount of any one of the CAAA regulated pollutants (SOx, NOx, CO, VOC, PM_{10}, hazardous air pollutants, extremely hazardous substances, ozone depleting substances, and pollutants covered by NSPSs) depending on the region's air quality category. Title V permits may set limits on the amounts of pollutant emissions; require emissions monitoring, and record keeping and reporting. Facilities are required to pay an annual fee based on the magnitude of the facility's potential emissions. It is estimated that as many as 2,869 aerospace facilities will be designated as major sources and therefore must apply for a Title V permit.

Under section 112(r) of CAA, owners and operators of stationary sources who produce, process, handle, or store substances listed under CAA section 112(r)(3) or any other extremely hazardous substance have a "general duty" to initiate specific activities to prevent and mitigate accidental releases. Since the general duty requirements apply to stationary sources regardless of the quantity of substances managed at the facility, many aerospace manufacturing and reworking facilities are subject. Activities such as identifying hazards which may result from accidental releases using appropriate hazard assessment techniques; designing, maintaining and operating a safe facility; and minimizing the consequences of accidental releases if they occur are considered essential activities to satisfy the general duty requirements. These statutory requirements have been in affect since the passage of the Clean Air Act Amendments in 1990. Although there is no list of "extremely hazardous substances," EPA's Chemical Emergency Preparedness and Prevention Office provides some guidance at its website: http://www.epa.gov/swercepp.html.

Also under section 112(r), EPA was required to develop a list of at least 100 substances that, in the event of an accidental release, could cause death, injury, or serious adverse effects to human health or the environment. The list promulgated by EPA is contained in 40 CFR 68.130 and includes acutely toxic chemicals, flammable gases and volatile flammable liquids, and Division 1.1 high explosive substances as listed by DOT in 49 CFR 172.101. Under section 112(r)(7), facilities handling more than a threshold quantity (ranging from 500 to 20,000 pounds) of these substances are subject to chemical accident prevention provisions including the development and implementation of a risk management program (40 CFR 68.150-68.220). The requirements in 40 CFR Part 68 begin to go into effect in June 1999. Some of the chemicals on the 112(r) list could be handled by aerospace manufacturers and reworkers in quantities greater than the threshold values.

Clean Water Act

Aerospace manufacturing and rework facility wastewater released to surface waters is regulated under the CWA. National Pollutant Discharge Elimination System (NPDES) permits must be obtained to discharge wastewater into navigable waters (40 Part 122). Facilities that discharge to a POTW may be required to meet National Pretreatment Standards for some contaminants. General pretreatment standards applying to most industries discharging to a POTW are described in 40 CFR Part 403. In addition, effluent limitation guidelines, new source performance standards, pretreatment standards for new sources, and pretreatment standards for existing sources may apply to some aerospace manufacturing and rework facilities that carry out electroplating or metal finishing operations. Requirements for the Electroplating Point Source Category and the Metal Finishing Point Source Category are listed under 40 CFR Part 413 and 40 CFR Part 433, respectively.

Storm water rules require certain facilities with storm water discharge from any one of 11 categories of industrial activity defined in 40 CFR 122.26 be subject to the storm water permit application requirements (see Section VI.A). Many aerospace facilities fall within these categories. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

VI.C. Pending and Proposed Regulatory Requirements

Clean Water Act

Effluent limitation guidelines for wastewater discharges from metal products and machinery (MP&M) industries are being developed. MP&M industries have been divided into two groups that originally were to be covered under two separate phases of the rulemaking. Effluent guidelines for Phase I industries and Phase II industries (which includes the aerospace industry) will now be covered under a single regulation to be proposed in October 2000 and finalized in December 2002. (Steven Geil, U.S. EPA, Office of Water, Engineering and Analysis Division, (202)260-9817, email: geil.steve@epamail.epa.gov)

Clean Air Act

In December 1997, EPA published Control Technique Guidelines (CTG) for the control of VOC emissions from coating operations at aerospace manufacturing and rework operations. The CTG was issued to assist states in analyzing and determining reasonably available control technology (RACT) standards for major sources of VOCs in the aerospace manufacturing and rework operations located within ozone NAAQS nonattainment areas. EPA estimates that there are approximately 2,869 facilities that could fall within this category. Within one year of the publication of the CTG, states must adopt a RACT regulation at least as stringent as the limits recommended in the CTG. Under Section 183(b)(3) of the Clean Air Act, EPA is required to issue the CTG for aerospace coating and solvent application operations based on "best available control measures" (BACM) for emissions of VOCs. (Barbara Driscoll, U.S. EPA, Office of Air Quality Planning and Standards, (919) 541-0164)

Several National Emission Standards for Hazardous Air Pollutants (NESHAPs) relating to the aerospace industry are being developed for promulgation by November of 2000. They include: Rocket Engine Test Firing, Engine Test Facilities, Miscellaneous Metal Parts and Products, and Plastic Parts and Products. (Contact: In the U.S. EPA Office of Air Quality Planning and Standards, George Smith for information pertaining to the former two, (919)541-1549; and Bruce Moore for the latter two, (919)541-5460)

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within

the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (April 1, 1992 to March 31, 1997) and the other for the most recent twelve-month period (April 1, 1996 to March 31, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across EPA Regions for certain sectors.[4] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of

[4] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

records for that facility. Some of the data systems accessible through IDEA are: AFS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes.

A facility with multiple enforcement actions is counted multiple times, e.g., a facility with 3 enforcement actions counts as 3.

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total

Actions" column.

VII.A. Aerospace Industry Compliance History

Table 14 provides an overview of the reported compliance and enforcement data for the aerospace industry over the past five years (April 1992 to April 1997). These data are also broken out by EPA Regions thereby permitting geographical comparisons. A few points evident from the data are listed below.

• Region IX and Region I had the most enforcement actions (43 and 36 respectively), accounting for 62 percent of the total enforcement actions and only 29 percent of the total inspections. Thus, these two Regions had the highest enforcement/inspection ratios (0.26 and 0.19).

• Region IV had significantly more inspections (325) than the other Regions, 27 percent of the total, but only 13 percent of enforcement actions.

• Enforcement actions were primarily state-lead (75 percent), especially in Regions with the greatest number of enforcement actions.

• Region V had the highest average time between inspections (23 months), which means that fewer inspections, in relation to the number of facilities, were done in Region V than in other Regions.

Table 14: Five-Year Enforcement and Compliance Summary for the Aerospace Industry									
A	B	C	D	E	F	G	H	I	J
Region	Facilities in Search	Facilities Inspected	Number of Inspections	Average Months Between Inspections	Facilities with 1 or More Enforcement Actions	Total Enforcement Actions	Percent State Lead Actions	Percent Federal Lead Actions	Enforcement to Inspection Rate
I	34	28	185	11	16	36	50%	50%	0.19
II	7	6	29	14	3	3	67%	33%	0.10

TOTAL	237	184	1206	12	67	127	75%	25%	0.10

VII.B. Comparison of Enforcement Activity Between Selected Industries

Tables 15 and 16 allow the compliance history of the aerospace sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Tables 15 and 16 permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering the last five years (April 1992 to April 1997) to that of the past year (April 1996 to April 1997). Some points evident from the data are listed below.

• The one-year enforcement/inspection ratio (0.05) is only half of the five-year ratio (0.10).

• The aerospace industry data approximate the averages of the industries shown for enforcement/inspection ratios, state-lead versus federal-lead actions, and facilities with one or more violations and enforcement actions.

Tables 17 and 18 provide a more in-depth comparison between the aerospace industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Tables (Tables 15 and 16), the data cover the last five years (Table 17) and the last one year (Table 18) to facilitate the identification of recent trends. A few points evident from the data are listed below.

• The aerospace industry has the highest percentage of RCRA inspections (54 percent of total) of any industry.

• The one-year versus five-year breakdowns in terms of percent of total inspections do not differ significantly. However, the percent of total actions pertaining to RCRA increased from 42 percent to 55 percent in the past year. CWA actions decreased from 11 percent to zero percent in the last year.

VII.C. Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VII.C.1. Review of Major Cases

As indicated in EPA's *Enforcement Accomplishments Report, FY1995 and FY1996* publications, one significant enforcement action was resolved between 1995 and 1996 for the aerospace industry.

U.S. v. General Electric Company General Electric (GE) operates a facility in Lynn. MA at which the company tests and manufactures aircraft. The enforcement issues arose from GE's failure to obtain prevention of significant deterioration (PSD) permits for one boiler and for four test cells used for the testing of jet engines. The boiler and the test cells emit NOx in quantities that trigger the PSD new source review requirements of the Clean Air Act. GE installed/constructed two new test cells in the early 1980s and modified two test cells in the late 1980s, without obtaining required permits. GE installed/constructed the boiler without obtaining an adequate permit. The boiler also emitted NOx in excess of the levels permissible in EPA's New Source Performance Standards (NSPS).

VII.C.2. Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the internet at the SEP National Database, http://es.epa.gov/oeca/sep/sepdb.

Aerospace Techniques, Inc., in Cromwell, Connecticut, performed a SEP in return for failing to submit a Toxic Release Inventory Form R for 1,1,1-trichloroethane. Aerospace Techniques achieved a 4,500 pound reduction in 1,1,1-trichloroethane releases by replacing the larger of its two vapor degreasers with jet washing machines using heated aqueous cleaning solution. They also plan to scale back degreasing operations to final rinses and replace six interim part-rinsing stations that utilize aqueous cleaner. The cost of this project was $9,766.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

VIII.A.1. Federal Activities

Propulsion Environmental Working Group

The Propulsion Environmental Working Group (PEWG) was formally chartered in 1994 by the Joint Propulsion Coordinating Committee (JPCC), a consortium of industry and Department of Defense participants. PEWG is composed of members from the Army, Navy, and Air Force, and of companies such as Allied Signal, GE Aircraft Engines, Allison Engine, Williams Intl., P&W UTC, Teledyne, Continental, and Sundstrand.

PEWG's chartered objectives include:

•providing an open forum for information exchange on possible technologies to eliminate HAZMATs,

•assisting team members with decisions regarding HAZMATs, identifying HAZMATs, and assisting in prevention and control of HAZMATs,

•assisting engine manufacturers and reworkers with compliance of state and federal regulations,

•ensuring and assisting in the completion of required environmental documentation such as EAs or EIAs,

•establishing committees to address topics of interest for the team members.

Propulsion Product Group

The Air Force Propulsion Product Group (PPG) works to incorporate environmental, safety, and occupational health concerns into multiple weapon systems. The PPG is a participant in the Propulsion Environmental Working Group discussed above. Some of the accomplishment of the PPG are:

•eliminating the use of Class I Ozone Depleting Substances (ODS)

•reducing the use of EPA-17 materials

•facilitating the annual reduction of EPA-17 materials and Class I ODS's used by OEM's.

Airworthiness Assurance Center of Excellence

The FAA created the Airworthiness Assurance Center of Excellence (AACE) in September 1997 in an effort to "make a significant contribution to the reduction of accident rates over the next five years." AACE is based at Iowa State University and Ohio State University. The five principal areas of research are maintenance, inspection and repair, propulsion and fuel systems safety, crashworthiness, advanced materials, and landing gear systems performance and safety. A focus of the work is to develop crack detection methods for particularly small cracks which may be under several layers of skin. Major airlines are also pushing for inspection techniques which do not require disassembly, thus preserving sealants and coatings (*AW&ST*, 3/30/98).

Joint EPA/NASA/USAF Interagency Depainting Study

NASA is conducting a technical assessment of alternative technologies for aerospace depainting operations on behalf of the EPA and the US Air Force. Such technologies are to be used as paint stripping processes which do not adversely affect the environment and which specifically do not involve the use of methylene chloride. The nine techniques subdivided into five removal method categories (abrasive, impact, cyrogenic, thermal, and molecular bonding disassociation).

Thai Airways/Government of Thailand/USEPA Solvent Elimination Project

The Government of Thailand, Thai Airways, and the USEPA Solvent Elimination Project studied methods of eliminating CFC-113 and methyl chloroform use. This project was undertaken as part of the World Bank Global Solvents Project under the Multilateral Fund of the Montreal Protocol. The manual developed under this project describes a step-by-step approach for characterizing the use of ozone-depleting solvents and identifying and evaluating alternatives. For case studies on this topic, see *Eliminating CFC-113 and Methyl Chloroform in Aircraft Maintenance Procedures*, published by the Office of Air and Radiation of the USEPA in October 1993.

VIII.B. EPA Voluntary Programs

33/50 Program

The 33/50 Program is a groundbreaking program that has focused on reducing pollution from seventeen high-priority chemicals through voluntary partnerships with industry. The program's name stems from its goals: a 33% reduction in toxic releases by 1992, and a 50% reduction by 1995, against a baseline of 1.5 billion pounds of releases and transfers in 1988. The results have been impressive: 1,300 companies joined the 33/50 Program (representing over 6,000 facilities) and reached the national targets a year ahead of schedule. The 33% goal was reached in 1991, and the 50% goal -- a reduction of 745 million pounds of toxic wastes -- was reached in 1994. The 33/50 Program can provide case studies on many of the corporate accomplishments in reducing waste (Contact 33/50 Program Director David Sarokin -- 202-260-6396).

Table 19 lists those companies participating in the 33/50 program that reported four-digit SIC codes within 372 and 376 to TRI. Some of the companies shown also listed facilities that are not producing aerospace products. The number of facilities within each company that are participating in the 33/50 program and that report aerospace SIC codes is shown. Where available and quantfiable against 1988 releases and transfers, each company's 33/50 goals for 1995 and the actual total releases and transfers and percent reduction between 1988 and 1995 are presented. Thirteen of the seventeen 33/50 target chemicals were reported to TRI by aerospace facilities in 1995. These 13 chemicals accounted for 77 percent of the total releases and 65 percent of the total transfers reported to the 1995 TRI by aerospace facilities.

Table 19 shows that 47 companies comprised of 506 facilities reporting SIC 372 and 376 participated in the 33/50 program. For those companies shown with more than one aerospace facility, all facilities may not have participated in 33/50. The 33/50 goals shown for companies with multiple aerospace facilities, however, are company-wide, potentially aggregating more than one facility and facilities not carrying out aerospace operations. In addition to company-wide goals, individual facilities within a company may have had their own 33/50 goals or may be specifically listed as not participating in the 33/50 program. Since the actual percent reductions shown in the last column apply to all of the companies' aerospace facilities and only aerospace facilities, direct comparisons to those company goals incorporating non-aerospace facilities or excluding certain facilities may not be possible. For information on specific facilities participating in 33/50, contact David Sarokin (202-260-6907) at the 33/50 Program Office.

With the completion of the 33/50 program, several lessons were learned. Industry and the environment benefitted by this program for several reasons. Companies were willing to participate because cost savings and risk reduction were measurable and no additional record keeping and reporting was required. The goals of the program were clear and simple and EPA allowed industry to achieve the goals in whatever manner they could. Therefore, when companies can see the benefits of environmental programs and be an active part of the decision-making process, they are more likely to participate.

Table 19: Aerospace Industry Participation in the 33/50 Program

Parent Company (Headquarters Location)	Company-Owned Aerospace Facilities Reporting 33/50 Chemicals	Company-Wide % Reduction Goal[1] (1988-1995)	1988 TRI Releases and Transfers of 33/50 Chemicals (pounds)[2]	1995 TRI Releases and Transfers of 33/50 Chemicals (pounds)[2]	Actual % Reduction for Aerospace Facilities (1988-1995)

[1] Company-Wide Reduction Goals aggregate all company-owned facilities which may include facilities not producing aerospace products.
[2] Releases and Transfers are from aerospace facilities only.

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline 202-260-8590, Web: http://www.epa.gov/ProjectXL, or Christopher Knopes in EPA's Office of Reinvention 202-260-9298)

Energy Star® Buildings and Green Lights® Partnership

In 1991, EPA introduced Green Lights®, a program designed for businesses and organizations to proactively combat pollution by installing energy-efficient lighting technologies in their commercial and industrial buildings. In April 1995, Green Lights® expanded into Energy Star® Buildings-- a strategy that optimizes whole-building energy-efficiency opportunities.

The energy needed to run commercial and industrial buildings in the United States produces 19 percent of U.S. carbon dioxide emissions, 12 percent of nitrogen oxides, and 25 percent of sulfur dioxide, at a cost of 110 billion dollars a year. If implemented in every U.S. commercial and industrial building, Energy Star® Buildings' upgrade approach could prevent up to 35 percent of the emissions associated with these buildings and cut the nation's energy bill by up to 25 billion dollars annually.

The over 2,500 participants include corporations, small businesses, universities, health care facilities, nonprofit organizations, school districts, and federal and local governments. As of January 1, 1998, Energy Star®Buildings and Green Lights® Program participants have reduced their annual energy use by 7 billion kilowatt hours and annually save more than 517 million dollars. By joining, participants agree to upgrade 90 percent of their owned facilities with energy-efficient lighting and 50 percent of their owned facilities with whole-building upgrades, where profitable, over a seven-year period. Energy Star participants first reduce their energy loads with the Green Lights approach to building tune-ups, then focus on "right sizing" their heating and cooling equipment to march their new energy needs. EPA predicts this strategy will prevent more than 5.5 MMTCE of carbon dioxide by the year 2000. EPA's Office of Air and Radiation is responsible for operating the Energy Star Buildings and Green Lights Program. (Contact the Energy Star Hotline number, 1-888-STAR-YES (1-888-872-7937) or Maria Tikoff Vargas, Co-Director at (202) 564-9178 or visit the website at http://www.epa.gov/buildings.)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1998, the program had about 700 business, government, and institutional partners. Partners agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports for a three year period. EPA, in turn, provides partners with technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne

Oxley, EPA Program Manager, 703-308-0199)

NICE³

The U.S. Department of Energy sponsors a grant program called *National Industrial Competitiveness through Energy, Environment, and Economics* (NICE³). The NICE³ program provides funding to state and industry partnerships (large and small business) for projects demonstrating advances in energy efficiency and clean production technologies. The goal of the NICE³ program is to demonstrate the performance and economics of innovative technologies in the U.S., leading to the commercialization of improved industrial manufacturing processes. These processes should conserve energy, reduce waste, and improve industrial cost-competitiveness. Industry applicants must submit project proposals through a state energy, pollution prevention, or business development office. The following focus industries, which represent the dominant energy users and waste generators in the U.S. manufacturing sector, are of particular interest to the program: Aluminum, Chemicals, Forest Products, Glass, Metal-casting, and Steel. Awardees receive a one-time, three-year grant of up to $400,000, representing up to 50 percent of a project's total cost. In addition, up to $25,000 is available to support the state applicant's cost share. (Contact: http//www.oit.doe.gov/Access/nice3, Steve Blazek, DOE, 303-275-4723 or Eric Hass, DOE, 303-275-4728)

Design for the Environment (DfE)

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202) 260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at http://www.epa.gov/dfe.

Several DfE projects have been completed pertaining to the aerospace industry. Brief descriptions follow.

The National Science Foundation (NSF), the State of Massachusetts, the Biodegradable Polymer Research Center, the Toxics Use Reduction Institute, and the Center for Environmentally Advanced Materials were partners in a DfE project on aerospace metal degreasing.

EPA established an interagency agreement with the Department of Energy, in partnership with the Joint Association for the Advancement of Supercritical Technology, to determine the suitability of supercritical carbon dioxide as an alternative method for cleaning and degreasing parts. The degree of contaminant removal of the cleaners as well as human health and environmental effects were evaluated under this project. In another agreement with the Department of Energy, EPA obtained the services of the Oak Ridge National Laboratory to perform research and prepare toxicity summaries in support of EPA risk assessment activities conducted on all segments of the aerospace DfE project.

The Experimental Aircraft Association (EAA) was awarded by the EPA for a demonstration project in small aircraft paint stripping. This project, begun as a DfE project jointly run by OPPT and the Coast Guard, explored alternatives to methylene chloride and other hazardous solvent paint strippers. In the summer of 1997, the EAA completely stripped and repainted a small plane using products that contained no chemicals on the EPA's Hazardous Air Pollutant list and that met the definition of low volatile organic chemical (VOC) releases (P2 Newsletter, 1997).

Small Business Compliance Assistance Centers

The Office of Compliance, in partnership with industry, academic institutions, environmental groups, and other federal and state agencies, has established national Compliance Assistance Centers for four specific industry sectors heavily populated with small businesses that face substantial federal regulation. These sectors are printing, metal finishing, automotive services and repair, agriculture, painted coatings, small chemical manufacturers, municipalities, and transportation.

The purpose of the Centers is to improve compliance of the customers they serve by increasing their awareness of the pertinent federal regulatory requirements and by providing the information that will enable them to achieve compliance. The Centers accomplish this by offering the following:

•"First-Stop Shopping" - serve as the first place that small businesses and technical assistance providers go to get comprehensive, easy to understand compliance information targeted specifically to industry sectors.

•"Improved Information Transfer" - via the Internet and other means, create linkages between the small business community and providers of technical and regulatory assistance and among the providers themselves to share tools and knowledge and prevent duplication of efforts.

•"Compliance Assistance Tools" - develop and disseminate plain-English guides, consolidated checklists, fact sheets, and other tools where needed by small businesses and their information providers.

•"Links Between Pollution Prevention and Compliance Goals" - provide easy access to information and technical assistance on technologies to help minimize waste generation and maximize environmental performance.

•"Information on Ways to Reduce the Costs of Compliance" - identify technologies and best management practices that reduce pollution while saving money.

For general information regarding EPA's compliance assistance centers, contact Lynn Vendinello at (202)564-7066, or go to http://www.epa.gov/oeca/mfcac.html.

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Industry Research Programs

NASA Langley Research Center and the Tidewater Interagency P2 Program

NASA's Langley Research Center (LaRC) is devoted to aeronautics and space research and has initiated a broad-based pollution prevention program guided by a Pollution Prevention Program Plan and implemented through specific projects. The Program Plan contains an environmental baseline, opportunities for P2, and establishes a framework to plan, implement, and monitor specific prioritized P2 projects. LaRC is one of the participants in the Tidewater Interagency Pollution Prevention Program (TIPPP). TIPPP was developed under an interagency agreement and designed to integrate P2 concepts and practices at Federal installations in the Tidewater, Virginia area.

Air Force Center for Environmental Excellence

The Air Force Center for Environmental Excellence (AFCEE) is working toward environmental leadership and pollution prevention. The Environmental Quality Directorate of the AFCEE has developed a Base Pollution Prevention Management Action Plan (PPMAP). Each base environmental manager must submit a PPMAP for his/her shop. Many Air Force Bases have also completed Pollution Prevention Opportunity Assessment Reports (OARs) which outline alternative approaches that a Base can use for P2 in Base-specific operations, including rework of aircraft.

Lean Aircraft Initiative Program

The Lean Aircraft Initiative (LAI) is a three-year program which strives to define and foster dynamic, fundamental change in both the U.S. defense aircraft industry and government operations over the next decade. LAI is a cooperative venture of private industry, the U.S. Air Force, and the EPA, supported by the analytical and research expertise of the Massachusetts Institute of Technology. By building on and extending the "lean" paradigm through an organized process of research, the program seeks to develop the knowledge base that will lead to greater affordability of systems, higher quality, and increased efficiency including efficient use of materials.

Chemical Strategies Partnership

The Chemical Strategies Partnership (CSP), funded by the Pew Charitable Trusts, began a pilot project with Hughes Missile Systems Company and Nortel. The CSP project aims to reduce their use and release of toxic chemicals in manufacturing while improving production efficiency and competitiveness.

Joint Depot Environmental Panel (JDEP)

The Joint Policy Coordinating Group on Depot Maintenance in the Department of Defense chartered the Joint Depot Environmental Panel (JDEP) in 1988 to facilitate information exchange on environmental issues, technologies, and processes with potential application in the depot maintenance community. The JDEP's functions are to review the depot's current environmental program, compile information on techniques and processes with potential application, coordinate the development and implementation of environmental initiatives, and establish liaisons with federal agencies. The JDEP has hosted over 37 meetings and distributed over 500 technical briefings. Total dismantling of JDEP will occur in October 1998. *(see JASPPA below.)*

Joint Group on Acquisition Pollution Prevention (JGAPP)

The Department of Defense has developed the Joint Group on Acquisition Pollution Prevention (JGAPP) as a military/industry initiative to reduce the use of hazardous material in manufacturing processes. The initiative involves seven major corporations and their related services. The JGAPP is working with manufacturers at their facilities to reduce the use of specific hazardous materials in all of the programs at the facility.

Joint Acquisition & Sustainment Pollution Prevention Activity (JASPPA)

The Joint Logistics Commanders of the Department of Defense tasked the JGAPP and JDEP to explore the possibility of a single pollution prevention activity. Since then the JDEP and the Joint Pollution Prevention Advisory Board (JPPAB, which JGAPP is part of) have been working and meeting together to develop various avenues of consideration for that tasking. As a result, the JDEP and JPPAB have decided to merge to form a single integrated group called the Joint Acquisition & Sustainment Pollution Prevention Activity (JASPPA). The JASPPA will function as a single integrating activity for all pollution prevention efforts for both the acquisition and sustainment communities. (For more information, contact Carl Adams in the Joint Depot Maintenance Activities Group, (937)656-2771.)

Aerospace Environmental Roundtable

The Aerospace Environmental Roundtable is an informal monthly meeting coordinated by the Aerospace Industries Association(AIA). Attendees include other trade associations, contractors, and anyone else interested in discussing environmental issues, increasing awareness, and sharing information pertaining to the aerospace industry. (For more information, contact Glynn Rountree, (202)371-8401.)

VIII.C.2. Trade Associations

Aerospace Industries Association of America (AIA)
1250 Eye St. NW, Suite1200 (202)371-8400
Washington, DC 20005 (202)371-8401 FAX
John Douglass, Pres.

AIA was founded in 1919 as a trade association which represents the nation's manufacturers of commercial, military and business aircraft, helicopters, aircraft engines, missiles, space craft, and related components and equipment. AIA maintains the AIA Aerospace Research Center to compile statistics on the industry. AIA's annual budget is roughly seven million dollars. They publish *Aerospace Facts and Figures* annually which contains statistical and analytical information on aircraft production, missile programs, space programs, and air transportation, as well as an annual report and an AIA newsletter.

Aircraft Electronics Association (AEA)
PO Box 1963 (816)373-6565
Independence, MO 64055-0963 (816)478-3100 FAX
Monte Mitchell, Pres.

AEA was founded in 1958 by companies engaged in the sales, engineering, installation, and service of electronic aviation equipment and systems. AEA works to advance the science of aircraft electronics, promote uniform and stable regulations and standards of performance, gather and disseminate technical data, and educate the aircraft electronics community and the public. They publish *Avionics News*, a monthly trade magazine. The annual budget is one million dollars.

American Helicopter Society (AHS)
217 N. Washington St. (703)684-6777
Alexandria, VA 22314 (703)739-9279 FAX
Morris E. Flatter, Exec. Dir.

AHS was founded in 1943 and is composed of aircraft designers, engineers, government personnel, operators, and industry executives in over forty countries interested in V/STOL aircraft. AHS conducts research and educational and technical meetings concerning professional training and updated information. They publish an annual composite of technical papers presented at the AHS forum, a quarterly journal, *Journal of the American Helicopter Society,* A bimonthly magazine, *VertFlite*, and other technical papers. They operate on a one million dollar budget.

Aviation Distributors and Manufacturers Association (ADMA)
1900 Arch St. (215)564-3484
Philadelphia, PA 19103-1498 (215)564-2175 FAX
Patricia A. Lilly, Exec. Dir.

ADMA was founded in 1943 as an association of wholesalers and manufacturers of general aviation aircraft parts, supplies, and equipment. They publish *ADMA News* bimonthly, *Aviation Education News Bulleting* bimonthly, and an annual directory.

Council of Defense and Space Industry Associations (CODSIA)
2111 Wilson Blvd., Suite 400 (703)247-9490
Arlington, VA 22201-3061
Peter Scrivner, Exec. Sec.

CODSIA was founded in 1964 and is comprised of the Aerospace Industries Association of America, Contract Services Association of America, Electronic Industries Association, National Security Industrial Association, Shipbuilders Council of America, American Electronics Association, Professional Services Council, and Manufacturers' Alliance for Productivity and Innovation. CODSIA holds three meetings per year in order to simplify, expedite, and improve industry-wide communications regarding policies, regulations, and problems.

Flight Safety Foundation (FSF)
2200 Wilson Blvd. Ste. 500 (703)522-8300
Arlington, VA 22201 (703)525-6047 FAX
Stuart Matthews, Pres.

FSF was founded in 1945 to represent aerospace manufacturers, domestic and foreign airlines, insurance companies, fuel and oil companies, schools, and miscellaneous organizations having an interest in the promotion of safety in flight. They have an annual budget of 2.5 million dollars and publish several bimonthly newsletters, studies, and an annual membership directory.

General Aviation Manufacturers Association (GAMA)
1400 K St. NW, Ste. 801 (202)393-1500
Washington, DC 20005 (202)842-4063 FAX
Edward W. Simpson, Pres.

GAMA was founded in 1970 as an association of manufacturers of aviation airframes, engines, avionics, and components. They strive to create a better climate for the growth of general aviation. GAMA publishes quarterly and annual reports as well as films and printed material on the aviation industry.

Helicopter Safety Advisory Conference (HSAC)
PO Box 60220 (713)960-7654
Houston, TX 77205 (713)960-7660 FAX
Dick Landrum, Chm.

HSAC is comprised of helicopter operators, manufacturers, and others involved in the transport of workers by helicopter. HSAC promotes safety and seeks to improve operations through establishment of standards of practice. HSAC was founded in 1979.

International Society of Transport Aircraft Trading (ISTAT)
5517 Talon Ct. (703)978-8156
Fairfax, VA 22032-1737 (703)503-5964 FAX
Dawn O'Day Foster, Exec. Dir.

ISTAT was founded in 1983 as a society of professionals engaged in the purchase, sale, financing, manufacturing, appraising, and leasing of new and used commercial aircraft. ISTAT publishes a quarterly newsletter, *JeTrader*, and an annual membership directory.

Light Aircraft Manufacturers Association (LAMA)
22 Deer Oaks Ct. (510)426-0771
Pleasanton, CA 94588
Lawrence P. Burke, Pres.

LAMA was founded in 1984 as an association of manufacturers of experimental and ultralight aircraft, suppliers to the homebuilt aircraft community, media and other professionals involved with the light aircraft industry. LAMA works to assure that the interests of the industry are properly represented to the FAA and to Congress and provides uniform standards of manufacturing quality and airworthiness. Lama publishes newsletters, standards, and a membership directory.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS

For further information on selected topics within the aerospace industry a list of contacts and publications are provided below.

Contacts[5]

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, and local governments, and the media from EPA's National Center for Environmental Publications and Information at (800) 490-9198. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

AIR TRANSPORTATION INDUSTRY
(SIC 45)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Integrated environmental policies based upon comprehensive analysis of air, water, and land pollution are a logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was originally initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information on major industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded to its current form. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process who enabled us to develop more complete, accurate and up-to-date summaries.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at (202) 564-2395.

II. INTRODUCTION TO THE AIR TRANSPORTATION INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the air transportation industry. Facilities described within this document are described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

This notebook pertains to the transportation industry as classified within SIC code 45 (Transportation by Air). (Please note that this section provides both the SIC code and the new North American Industrial Classification System (NAICS) code, which went into effect January 1, 1997. While the NAICS code is identified in this section, the remainder of the document will refer to the SIC codes for specific air transportation activities.)

The transportation industry includes other modes of transport, such as trucking, railroad, pipeline, and water, which make up an important portion of overall transportation activity in the United States. These modes are addressed in two sector notebooks. Trucking, railroad, and pipeline transportation are addressed in *Ground Transportation Industry* [EPA/310-R-97-002], and water transportation is addressed in *Water Transportation Industry* [EPA/310-R-97-003].

The air transportation industry (SIC 45) includes establishments engaged in furnishing domestic and foreign transportation by air and also operating airports and flying fields and furnishing terminal services. Specifically, this notebook includes the following groups:

SIC 4512 - Air Transportation, Scheduled (NAICS 481111 and 481112). This sector includes establishments primarily engaged in furnishing air transportation over regular routes and on regular schedules. This industry includes Alaskan carriers operating over regular or irregular routes.

SIC 4513 - Air Courier Services (NAICS 49211). This sector includes establishments primarily engaged in furnishing air delivery of individually addressed letters, parcels, and packages (generally under 100 pounds), except by the U.S. Postal Service. Separate establishments of air courier companies which provide pick-up and delivery only, "drop-off points," or distribution centers are all classified in this industry.

SIC 4522 - Air Transportation, Nonscheduled (NAICS 481211, 481212, 48799, 62191). This sector includes establishments engaged in furnishing nonscheduled air transportation. Also included in this industry are establishments primarily engaged in furnishing airplane sightseeing services, air taxi services, and helicopter passenger transportation services to, from, or between local airports, whether scheduled or not scheduled.

SIC 4581 - Airports, Flying Fields, and Airport Terminal Services (NAICS 488111, 488119, 56172, 48819). This sector includes establishments primarily engaged in operating and maintaining airports and flying fields; in servicing, repairing (except on a factory basis), maintaining, and storing aircraft: and in furnishing coordinated handling services for airfreight or passengers at airports. This industry also include private establishments primarily engaged in air traffic control operations (except government).

II.B. Characterization of the Air Transportation Industry

II.B.1. Industry Characterization

The transportation industry affects nearly every American. Either through the necessity of traveling from one place to another, shipping goods and services around the country, or working in a transportation-related job, transportation's share of the national economy is significant. According to the Eno Transportation Foundation, for all transportation-related industries, total transportation expenditures in the U.S. accounted for 16.1 percent of the gross national product in 1993.

The airline industry in particular provides transportation of passengers, cargo, mail and perishable goods. American citizens have come to rely on domestic and international air transportation more and more every year. Airline travel in the United States has been getting safer over the years and is the safest in the world. The National Safety Council's latest fatality totals for 1995 show 175 deaths caused by United States airline accidents. By contrast, five times as many people died in boating accidents and accidents involving bicycles and tricycles.

II.B.1.1. Types of Aircrafts and Airports

Generally, the air transportation sector can be broken down into two categories: (1) facilities providing scheduled, non-scheduled, and air courier services using aircraft, and (2) airports and airport operations. It is these two major topics (i.e., aircraft facilities and airports) and the activities and operations that occur within each of these areas that are the primary focus of this notebook.

Categories of Aircraft

There are five types of aircraft that compose the aviation industry: commercial, air taxi operations, commuter, general, and military.

Commercial aircraft encompass air carriers and air taxi flights. Air carriers are airlines holding a certificate issued of public convenience and necessity under Section 401 of the Federal Aviation Act of 1958 authorizing them to perform passenger and cargo services. Air carriers operate aircraft designed to have a maximum seating capacity of more than 60 seats, to have a maximum payload capacity of more than 18,000 pounds, or to conduct international operations. The four different types of air carriers (and their annual operating revenues) are:

- Majors (greater than $1 billion)
- Nationals ($100 million to $1 billion)
- Large regionals ($20 million to $100 million)
- Medium regionals (Up to $20 million).

Air taxi operations are those in which departure time, departure location, and arrival location are specifically negotiated with the customer or by the customer's representative and are conducted with airplanes or rotorcraft having a seating configuration of 30 or fewer seats.

Commuter aircraft are noncertified small regionals who perform scheduled service to smaller cities and serve as feeders to the major hub airports. They generally carry 60 or fewer passengers.

General aviation is all aviation that is not commercial or military. General aviation is the segment of civil aviation that encompasses all facets of aviation except air carriers and commuters. General aviation includes corporate-executive transportation, instruction, rental, aerial application, aerial observation, business, pleasure, and other special uses.

Military refers to the operators of all military (e.g., Air Force, Army, Navy, U.S. Coast Guard, Air National Guard, and military reserve organizations) aircraft using civil airports.

Classification of Airports

The system of airports in the U.S. is the largest and most complex in the world. As of 1990, there were 17,451 civil landing areas (e.g., airports, heliports, seaplane bases, etc.) in the U.S. The activity and services at individual airports vary greatly. Regardless of size, many activities occur at airports including fueling, aircraft maintenance, aircraft washing, and deicing. In addition, two primary activities at most airports are enplaning passengers and enplaning air cargo. Enplaning passengers is defined as the total number of passengers departing on aircraft at the airport. Enplaning air cargo includes the total tonnage of priority, nonpriority, and foreign mail, express, and freight (property other than baggage accompanying passengers) departing on aircraft at an airport.

Airport Ownership. Public airports in the U.S. are owned and operated under a variety of organizational and jurisdictional arrangements. Commercial airports might be owned and operated by a city, county, or State; or by more than one jurisdiction. Additionally, some airports may be operated by a separate public body, such as an airport authority. Regardless of ownership, legal responsibility for day-to-day operations can be vested in any of five kinds of governmental or public entities:

- Municipal or county government. Municipally operated airports are city owned and run as a department of the city.
- A multipurpose port authority. Port authorities are legally chartered institutions with the status of public corporations.
- An airport authority.
- State government.

Classification of airports with scheduled services. Airports with scheduled passenger service have several classifications:

- Commercial service airports are those airports receiving passenger service and having 2,500 or more annual enplanements.

- Primary airports are commercial service airports having 10,000 or more enplanements.

- Hub airports are airports that serve as a transfer point for passengers changing flights. Commercial service airports are classified as large, medium, or small hub airports or non-hub airports, depending on the percentage of total national enplanements for which they account.

- General aviation airports encompass the bulk of civil aircraft operations. The general aviation system includes 98% of all registered civil aircraft and 95% of all airports.

- Reliever airports are a special category of general aviation airports. Located in the vicinity of major air carrier airports and classified by the Federal Aviation Administration as a reliever, these airports are designed to provide relief to congested major airports.

Terminal Facilities. The terminal and associated landside facilities such as the parking areas and access roads provide the transition zone for passengers between surface and air transportation. Landside facilities are long-term installations and are largely independent of activities that occur airside. Concession and food service operations provide food and materials goods for passengers.

II.B.1.2. Requirements Pertaining to the Aviation Industry

The Federal Aviation Administration's (FAA's) major responsibilities include overseeing aircraft safety and the competency of pilots and mechanics. The FAA does this by providing mandatory safety rules, conducting safety inspections, and setting high standards for civil aviation.

Noise Abatement. In addition to safety, the FAA also addresses issues such as noise abatement. As a result of complaints against aircraft noise, which increased dramatically with the introduction of jet aircraft, the *Federal Aviation Act of 1958* was amended to include noise abatement regulations designed to establish noise levels which aircraft manufacturers cannot exceed in the development of new aircraft. In 1979, the *Aviation Safety and Noise Abatement Act* authorized the FAA to help airport operators develop noise mitigation abatement programs.

The *Airport Noise and Capacity Act of 1990* authorized DOT/FAA to reduce aircraft engine noise by requiring an aircraft fleet replacement program. The estimated effect of the phase out of larger, noisier aircraft is estimated to reduce the number of people exposed to significant noise levels of aircraft noise in the U.S. from 2.7 million in 1990 to 400,000 by the year 2000, when the phaseout is complete. The law also limited airport operators' abilities to place noise or access restrictions on airports in the interest of avoiding an overly burdensome patchwork of individual operating limitations across the United States.

Standards for Aircraft Design. The FAA works closely with aircraft manufacturers while examining designs for new planes. The FAA sets very high standards for aircraft designs. Once the design has been thoroughly examined and the first model has completed a grueling series of flight tests and evaluations, the model is certificated for production by the FAA (http://www.faa.gov/publicinfo.htm).

Monitoring and Maintenance of Existing Aircraft. Once the aircraft has been certified and put into service, the FAA continues to monitor its performance. When necessary, the FAA will issue repair notices known as "Airworthiness Directives" to the manufacturers and airlines when problems are spotted. The FAA issues several hundred notices a year. In addition, manufacturers often issue Service Bulletins to advise aircraft carriers of safety improvements or procedures that will enhance safety.

FAA airworthiness requirements specify materials to be used during maintenance or other technical specifications and standards (e.g., cleaning, deicing) that limit the airlines' ability to change materials, procedures, or processes.

Flight Personnel. The FAA sets standards for training, health, experience, number of hours worked, and qualifications for pilots and other flight personnel. Because pilots play such a vital role in maintaining aircraft operations safety, they are especially heavily regulated by the FAA. Pilots must have their health examined every six months. They must pass special examinations and flight tests, and those serving as captains are required to possess hundreds of hours of additional flying time. FAA tests their flying skills on a regular basis. DOT and FAA safety policies and rules expressly place the ultimate legal authority for aircraft operation fully and solely on the pilot in command of the aircraft (14 CFR §91.3(a)).

Air Traffic Control Operations. FAA is responsible for developing, maintaining, and operating the nation's Air Traffic Control System, which is in charge of ensuring the safe separation of aircraft during flight and sequencing aircraft for taxiing, takeoff, and landing.

Maintenance Personnel. Airline mechanics and technicians must be certified by the FAA. In addition, repair stations must obtain an FAA operating certificate and are subject to regular inspection by the agency.

For more information about FAA airworthiness requirements, see the FAA website at http://www.faa.gov/publicinfo.htm.

II.B.1.3. International Aviation

After 1945, commercial air transportation began to transcend domestic markets into the international arena, therefore, the standardization of operational practices for international services, such as navigational aids and weather reporting systems, became essential. There were also many political and technical problems that needed to be solved. For example, there was the issue of commercial rights: what arrangements were needed for the airlines of one country to fly into and through territories of another? For more information relating to International Civil Aviation Organization (ICAO) and other international milestones, refer to *Memorandum on ICAO,* January 1994.

II.B.2. Industry Size and Geographic Distribution

Industry Size

According to Dun & Bradstreet, there were an estimated 16,282 air transportation establishments in the U.S. as of April 1997. Exhibit 1 provides information on each of the SIC codes in the air transportation industry, including total number of establishments and employees, and total annual sales.

Exhibit 1. Market Size Analysis of Air Transportation Industry

SIC Code	No. of Establishments	No. of Employees	Annual Sales (millions)
4512	3,638	320,837	147,858.6
4513	2,252	75,493	15,172.9
4522	3,321	39,253	7,019.0
4581	7,071	220,986	15,616.8
Total	16,282	656,569	185,667.3

Source: Dun & Bradstreet Marketplace (www.dnb.imarketinc.com), December 1997

Exhibit 2 displays the percentages of establishments per air transportation sector discussed above.

Exhibit 2: Distribution of Establishments by Sector

Geographic Distribution

The air transportation industry is widely dispersed. Of the total of 16,282 U.S. establishments in the air transportation industry, most are located in California, Texas, Florida, Illinois, and New York. Exhibits 6 and 7 identify the five states with the most establishments and employees by air transportation SIC code.

Exhibit 6. Top Five States with Air Transportation Establishments					
SIC Code	States (Number of Establishments)				
Air transportation, scheduled (SIC 4512)	CA (426)	FL (369)	NY (321)	TX (258)	IL (200)
Air transportation, nonscheduled (SIC 4522)	CA (348)	FL (314)	TX (236)	NY (151)	AK (146)
Air courier services (SIC 4513)	CA (328)	NY (308)	FL (208)	TX (194)	IL (91)
Airports, flying fields, & services (SIC 4581)	CA (747)	TX (641)	FL (551)	NY (304)	IL (264)

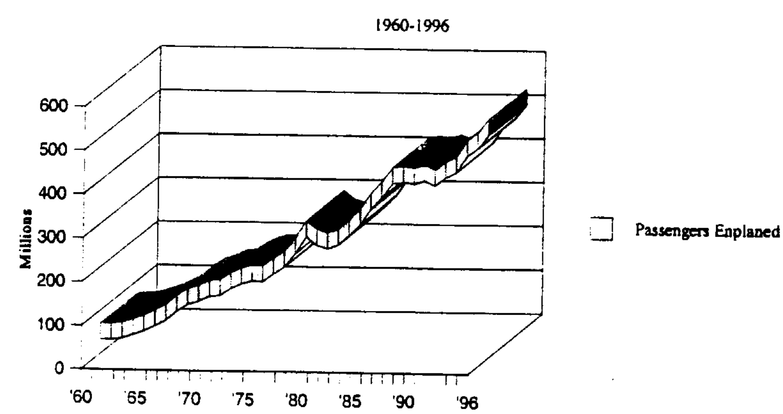
II.B.3. Economic Trends

Aviation Trends and Forecasts

The aviation industry has been growing steadily and is expected to continue. U.S. commercial air carrier passenger enplanements, which had averaged less than 1.0 percent growth between 1990 and 1993, grew at an annual rate of 6.2 percent over the last 3 years. In 1996, the large U.S. air carriers increased their system capacity by only 2.9 percent, while passenger demand increased by 6.1 percent. Exhibit 9 presents the trends for U.S. scheduled airlines in passengers enplaned and domestic cargo from 1960 to 1996.

Exhibit 9: Summary of Domestic Passenger Traffic



Source: ATA Airline Traffic Stats 1960-1996

R0074765

The FAA predicts that domestic departures for commercial carriers will increase from 7.1 in 1997 to 9.2 million by 2008. Exhibit 10 presents additional FAA forecasts for the aviation industry.

Exhibit 10. Forecast for U.S. Commercial Carriers and Regionals/Commuters FY1998 - 2009

Year	Passengers (Millions) [1]	Revenue Passenger Miles (Billions) [1]	Jet Aircraft[2]	Aircraft Operations (Millions)[3]
1998	656.1	635.3	5,092	24.7
1999	676.3	660.7	5,224	25.1
2000	699.1	688.5	5,444	25.5
2001	724.7	720.3	5,698	26.2
2002	753.2	755.2	5,913	26.9
2003	782.9	791.7	6,119	27.5
2004	813.7	829.7	6,361	28.1
2005	845.6	869.7	6,574	28.7
2006	878.8	911.6	6,778	29.4
2007	913.4	955.6	6,983	30.0
2008	949.4	1,001.9	7,203	30.7
2009	986.7	1,050.2	7,419	31.4

Impacts of Deregulation

Before 1978, the United States airline economy was tightly regulated by the federal government. However, due to complaints of high airfares and growing concerns that government regulation was inhibiting the growth of the airline industry, the Deregulation Act of 1978 was passed. Since then, several important trends have characterized the airline industry.

Rapid expansion of overnight delivery of mail. Air cargo was deregulated a year before the passenger airlines. Deregulation was responsible for dramatic results for all aspects of the cargo business, but particularly for express package delivery for high value and time sensitive packages. Deregulation gave express carriers operating freedom, and the direct result was outstanding growth for that part of the aviation industry over the next decade.

Increase of Total Revenue Sales. Total sales revenues for the industry as a whole (in adjusted dollars) have increased each consecutive year except for a brief decline from 1989 through 1991. This brief decline can be explained largely by two factors: (1) Northwest Air Lines was private during those same years, so its revenues were not included in the industry data, and (2) Eastern Air Lines experienced a major labor strike that began in March 1989. As indicated by its financial data from 1989 to 1991, Eastern was able to continue operation, in spite of the labor strike, by charging fares below its costs. Eastern's unusually low fares may have caused other airlines to reduce fares in a similar fashion, and this reduced the total revenue earned by the industry as a whole. Current projections are that industry revenues will continue to rise due to the strengthened economy and a predicted 5% increase in airline traffic.

Increased number of airlines. Following deregulation in 1978, the number of companies increased dramatically from about 36 carriers in 1978 to a total of 123 such carriers in 1984. This initial increase resulted from the market becoming more accessible to new companies that sought to operate below the costs of older, established airlines with higher cost structures. However, a clear decline in the number of air carriers in the late 1980s followed this initial increase due to weaker airlines being forced out of business or being taken over by the stronger companies. Then by 1993, the numbers increased again as numerous small airlines emerged, offering direct, low cost, no-frills service. To compete with these lower cost airlines, many of the larger airlines are initiating their own low cost divisions. The Brookings 1986 Report estimated that the traveling public was saving $5.7 billion a year (measured in 1977 dollars) as a result of deregulation (www.air-transport.org/handbk/chaptr02.htm).

Expanded market. A major development since deregulation was the creation of hub and spoke networks. The hubs are strategically located airports used as transfer points for passengers traveling from one location to another. The hub and spoke systems were developed in order to enable airlines to serve far more markets, with the same size fleet, than the traditional direct, point-to-point service.

Deregulation also sparked marketing innovations used by most major airlines and many smaller airlines that equate to fare discounts, such as the frequent flyer program that is designed to reward repeat customers with free tickets and other benefits.

The appearance of new airlines, combined with the rapid expansion into new markets by many of the established airlines, resulted in unprecedented popularity and competition in the airline industry. In 1977, the last full year of government regulation of the airline industry, the US airlines carried 240 million passengers. By 1993 they were carrying nearly 490 million. A study by the Department of Transportation a decade after deregulation found that well over 90% of airline passengers had a choice of carriers compared to only two-thirds in 1978 (www.air-transport.org/handbk/chaptr02.htm)

III. DESCRIPTION OF OPERATIONS

This section describes the major operations and maintenance activities within the air transportation industry. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the relationship between the industrial process associated with air transportation, and the associated environmental aspects and potential impacts of the processes. This section is not exhaustive; the operations and maintenance activities discussed are intended to represent the air transportation practices and activities with potentially significant environmental impacts. These activities are presented in two categories:

(1) *Aircraft operations*, including maintenance, cleaning, fueling, and deicing; and

(2) *Airport operations*, including terminal activities, loading and off loading.

This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section VIII for a list of resource materials that are available.

III.A. Aircraft Operations and Associated Environmental Aspects

III.A.1. Aircraft and Aviation-Support Vehicle Maintenance

Aircraft maintenance activities include scheduled preventive maintenance, repairs required as a result of inspections, and aircraft refurbishing. When an aircraft is built, the manufacturer creates a maintenance program for the operator of the plane. Representatives from the manufacturer, the Federal Aviation Administration (FAA), subcontractors, and the airline that purchases the aircraft form a review board that develops minimum requirements of a maintenance program. This maintenance program is then documented and followed throughout the aircraft's life.

Together, scheduled maintenance and day-to-day preventive activities are necessary to keep the aircraft safe and reliable. In general, aircraft maintenance is the function of three factors: (1) hours of flight time, (2) number of landing and take off cycles, and (3) calendar length of time from prior maintenance. Aircraft preventive maintenance starts with daily inspections of items such as tires, brakes, and fluid levels. The aircraft then continues to receive many levels of maintenance that include fluid and filter changes, detailed testing, inspections for cracks and corrosion, and after many hours of flying (usually over 100,000), complete refurbishing of the aircraft to return the plane to its original condition.

Aviation-support vehicles undergo a similar, yet less rigorous schedule of inspections, testing, and maintenance that includes oil and fluid changes, battery replacement, and repairs including metal machining.

Environmental Aspects and Potential Impacts of Aircraft Maintenance

Environmental aspects of aircraft maintenance include the use and disposal of aircraft and vehicle fluids such as:

- Wastewater from parts cleaning, metal finishing, or coating applications
- Generation of hazardous wastes consisting of flammable and metals-contaminated solvents, used hand-wipes, and sludges collected during all maintenance operations
- Hazardous air pollutant (HAP) emissions from solvent-based cleaners and coatings used in all activities.

Wastes generated as a result of aircraft and aviation-support vehicle maintenance and repair activities can include used oil, spent fluids, batteries, metal machining wastes, organic solvents, and tires. Some of these wastes can be toxic or otherwise hazardous, and uncontrolled releases can contaminate surface water, groundwater, and soils. Typical materials used in each operation and the potential impacts of use and disposal of these materials are identified in Exhibit 11. A description of these operations and associated environmental impacts appear below.

Lubrication and Fluid Changes. Lubrication and fluid changes are part of the aircraft standard maintenance program. These activities occur at regular intervals, and as inspections indicate they are necessary. In conducting aircraft lubrication and fluid changes, these operations may generate waste oil and greases. These materials have the potential to contaminate water supplies and soil if not properly stored. By storing these materials in secure containers or tanks with secondary containment, the potential for releases to impact the environment is significantly reduced.

Exhibit 11. Maintenance and Refurbishing Operations: Activities and Potential Environmental Impacts		
Operation	**Activities**	**Environmental Aspects and Potential Impacts**
Lubrication and Fluid Changes	Storage, transfer, and disposal of petroleum products	Potential to contaminate soil, groundwater, and surface waters, if spilled or allowed to enter storm drains
Battery repair and replacement	Storage of batteries containing sulfuric acid	Potential to contaminate soil, groundwater, and surface waters with hazardous material, if not contained and covered from weather
Chemical Milling Maskant Application and Chemical Milling	Use and disposal of maskants containing either toluene/xylene mixture or perchloroethylene	Air pollution from organic HAP emissions, waste maskant
Parts Cleaning	Aqueous, semi-aqueous, and solvent-based cleaner use and disposal	Water pollution from wastewater containing cleaners, waste solvents; metals, oil, and grease Air pollution from organic HAP emissions
Metal Finishing	Use and disposal of processing solutions, cyanide, heavy metal baths	Air pollution from HAP emissions; contaminated wastewater including cyanide solutions, corrosive acid and alkali solutions; heavy metal sludges
Coating Application	Primer and topcoats application and disposal	Air pollution from organic HAP emissions; waste paint; waste solvent thinner
Depainting	Chemical or blast depainting agents use and disposal	Contaminated sludge (stripper solution and paint residue); air contamination from VOC emissions from paints; solid waste containing paint chips and spent blasting media.
Painting	Paint use, storage, and disposal	Soil or water contamination from disposal of waste paint, thinners, solvents, resins; air contamination by VOC emissions.

Battery repair and replacement. Battery repair and replacement involve removing, repairing, and recharging aircraft and vehicle batteries. These operations have the potential to impact the environment if sulfuric acid in the batteries is released. Acid has the potential to contaminate soil and groundwater supplies, and to cause personnel injury if used batteries are not properly handled. By using proper safety equipment during handling, and storing batteries in a contained and covered area that is not exposed to rain water, batteries are less likely to cause a significant impact.

Chemical Milling Maskant Application and Chemical Milling. This operation uses etchant solutions to reduce the thickness of selected areas of metal parts in order to reduce weight. Chemical milling maskants are typically rubber- or polymeric-based coatings applied to an entire part or subassembly by brushing, dipping, spraying, or flow coating. After the chemical milling maskant is cured, it is removed from selected areas of the part where metal is to be removed during the chemical milling process.

Chemical milling maskants typically contain either a toluene/xylene mixture or perchloroethylene as solvent constituents. These chemical solvents vaporize when exposed to air, and if not stored in tightly sealed containers, become a source of hazardous air pollutants (HAPs). These organic HAP emissions also occur as the solvent evaporates as the chemical milling maskant is applied and cured.

Parts Cleaning. Aircraft components are cleaned frequently to remove contaminants such as dirt, grease, and oil. Cleaning is performed using a wide variety of cleaning materials, including aqueous, semi-aqueous, or, in some cases, solvent-based cleaners. Recently, many aircraft maintenance facilities have substituted solvent-based cleaners with water-based cleaning materials. Many components are cleaned with soap and water.

Parts cleaning operations can include immersion, flush, spray gun cleaning, or hand wiping of aircraft components. For most parts, cleaning is typically performed by a hand wiping process. However, parts that are either too large or too intricate to hand wipe are cleaned by immersion in large solvent baths or parts cleaning machines. Assemblies and parts with concealed or inaccessible areas may be cleaned by pouring the cleaning material over or into the part. The cleaning material is then drained from the part and the procedure is repeated as many times as necessary to ensure the required cleanliness.

The potential environmental impact of parts cleaning operations is dependent on the type of cleaning solution used. Halogenated, solvent-based cleaning materials potentially have the most significant impact. These solvents can generate organic HAP emissions from the evaporation of solvents during the cleaning process, including: (1) evaporation of solvent from open containers and solvent-soaked cloth and paper, and (2) emissions from storage tanks used to store cleaning solvents. In addition, solvent spills have the potential to contaminate soil, groundwater, or surface water. Contamination can be caused by hazardous constituents found in solvents themselves, as well as in metals, oils, and other potential contaminants found in the parts being cleaned. Spent hazardous solvents must be managed as hazardous wastes. Typically, they are reclaimed by a RCRA permitted hazardous waste recycler.

Facilities that use aqueous or semi-aqueous cleaning materials have a much less significant potential environmental impact because they do not generate hazardous air emissions. They do, however, generate metals, oil, and grease in the aqueous system that have the potential to contaminate water supplies. Wastewater from these cleaning processes is required to be treated onsite in accordance with the facility's wastewater discharge permit (known as a National Pollutant Discharge Elimination System or NPDES permit) or according to standards set by any local pretreatment programs.

Metal Finishing. Metal finishing processes are used to prepare the surface of a part for better adhesion, improved surface hardness, and improved corrosion resistance. Typical metal finishing operations include chemical conversion coating, anodizing, electroplating, and any operation that chemically affects the surface layer of a part. Each of these metal finishing operations has the potential to significantly impact the environment by discharging metals, cyanides, phosphates, acids, and other contaminants to waterways, soil, or groundwater.

HAP emissions and contaminated wastewater are the most significant environmental aspects of metal finishing operations. As the organic chemicals in the processing solutions evaporate, they generate hazardous vapors and emissions. Evaporation of solution also occurs from refurbished parts as they are removed from the processing tanks. Wastewater from these operations includes cyanide solutions, corrosive acid, and alkali solutions. This water is typically treated prior to discharge, in accordance with a facility's NPDES permit or applicable pretreatment requirements. For more details on metal finishing processes and the associated environmental aspects, see EPA's Sector notebook titled *Profile Of The Fabricated Metal Products Industry* (EPA 310-R-95-007).

Coating Application. A coating is a material that is applied to the surface of a part to form a decorative or functional solid film. The most common coatings are primers and topcoats. Coatings are applied to aircraft components using several methods of application. The methods most commonly used are spraying, brushing, rolling, flow coating, and dipping. Nearly all coatings contain a mixture of organic solvents. Spray guns and other components of coating units must be cleaned when switching from one coating to another. The cleaning of spray guns involves disassembling the gun and placing the parts in a vat containing an appropriate solvent. The residual coating is brushed or wiped off the parts.

Organic HAP emissions from coating application are generated from evaporation of solvents during mixing, application, and from overspray, which is exhausted from spray booths or hangars. Coating operations also produce waste paint and waste solvent thinner that are typically drummed and shipped offsite as RCRA hazardous waste.

Depainting. Depainting involves the removal of coatings from the outer surface of aircraft. Two methods are chemical stripping and blast depainting. During chemical stripping, stripping agents are applied to the aircraft, allowed to degrade the coating, and then scraped or washed off with the coating residue. Blast depainting methods use a media such as plastic, wheat starch, carbon dioxide, or high pressure water to remove coatings by physically abrading the coatings from the surface of the aircraft. Depainting operations can produce either a liquid or solid waste stream. depending on the type of process used.

Air pollution and soil or water contamination are potential impacts from depainting. Chemical depainting generates organic HAPs from evaporation of the solvents in the stripping solution, while particulate emissions occur from the blasting media. Depainting operations can produce either a liquid or solid waste stream, depending on the type of process. Chemical depainting processes produce a liquid sludge that consists of the stripper solution and paint residue. Blast depainting processes produce a solid waste stream that consists of paint chips and spent blasting media. These wastes are required to be characterized as hazardous or nonhazardous and disposed of appropriately.

Painting. Aircraft painting generally occurs in an enclosed area to minimize potential environmental and human health impacts. High pressure, low volume, and electrostatic painting systems can reduce the amount of paint needed for a job.

Aspects of painting with potential environmental impacts include management of unused paints, spray paint booth air filters, and spent paint thinner, and emissions of volatile organic compounds (VOCs) from thinners and solvents. Spent paint filters often must be handled as hazardous waste because of the presence of wet paint or paint containing lead or chromium. Through proper training of employees and the use of high efficiency equipment, painting operations have been able to reduce paint waste, minimize air emissions, and protect the health of employees.

III.A.2. Fueling

An essential part of any airport operation is the fueling of aircraft. Fueling is conducted either by tank trucks or a central underground fueling system. In both operations, fueling involves the transfer of a potentially hazardous liquid to the aircraft. Aviation fuels are broken down into two classes. The reciprocating engines use various grades of aviation gasoline, while the jet class, which includes gas turbines, utilizes jet fuels. There are grades of aviation gasoline that are readily identified by the color-coded dyes added to them. The color-coded system aids maintenance personnel in finding fuel leaks when they occur and prevents fueling mixups.

For jet fuel, there are two basic grades of jet fuel, Jet-A and Jet-B. Jet-A fuel, a narrow cut kerosene product, is the standard commercial and general aviation grade available in the United States. It usually contains no additives but may be additized with an anti-icing chemical. Jet-A1 is identical to Jet-A except that it has a lower freeze point. It is used outside the United States and is the fuel of choice for long haul flights where the fuel temperature may fall to near the freeze point. It often contains a static dissipator additive. Jet-B fuel is a wide cut kerosene with lighter gasoline-type naphtha components. It is not used by the commercial air transportation sector, however, it is used by the military.

Fuel tanks are generally located in the wings of light aircraft. However, depending on the make and model of the aircraft, it is also common to find fuel tanks in the main fuselage. Fuel lines range in diameter from 1/8 of an inch to as large as 4 inches on very large aircraft. Fuel lines of aircraft using wing tanks are located back from the leading edge of the wing. With fuselage tank model twin-engine aircraft, the fuel lines run from the fuselage tanks out through the wing structure along the wing spar into the engine compartment. On single-engine aircraft, the fuel lines are routed from the fuel tank to the firewall, and then to the engine.

Environmental Aspects and Potential Impacts of Fueling

The major environmental aspect of fueling operations is managing the fuel so that it is not released to the environment, either to the air, water, or soil. Leaking pipes or improper connections between fueling lines and the aircraft can allow fuel vapors to be released to the air, causing air contamination. Leaks, improper connections, and improperly monitored storage tanks also can lead to fuel spills. As a contingency measure, many airports and airlines employ vacuum sweeper trucks as well as hand operated sweeper units for spill response. Vacuum sweepers allow the spilled material to be removed quickly from the site while minimizing the spill's potential to impact the environment. If spills are not contained or diverted to an established treatment system, they may end up being discharged to soil and groundwater either directly through storm drains, or as sheet runoff during rain events.

Underground fueling systems that are not maintained properly can leak into the surrounding soils and eventually contaminate groundwater. EPA regulations for underground storage tanks require tanks to be upgraded and monitored to reduce the probability of leaks to groundwater.

By conducting activities to prevent releases such as maintaining fuel tanks, lines, and fueling systems, and by assuring proper training of employees, the possibility of leaking tanks, equipment leaks, or accidental spillage is reduced substantially.

III.A.3. Aircraft Cleaning

Exterior cleaning of aircraft typically consists of washing with detergent solutions and a water rinse. Small aircraft cleaning is carried out using hand held spray nozzles, hoses and brushes. For larger aircraft, wet cleaning usually is limited to wheel wells and landing gear and is conducted to facilitate inspections. In addition, wet cleaning sometimes is performed on wing structure and flap-sequencing carriage areas for overhaul and inspection processes and on the lower aircraft fuselage for removal of accumulations of oil and grease.

Because it can be more economical (e.g., lower water costs) to dry polish aircraft fuselages rather than wash them with water and cleaning solutions, aircraft are cleaned using dry methods whenever possible.

Environmental Aspects and Potential Impacts of Cleaning

The primary environmental aspect of aircraft cleaning is the generation and disposal of wastewater from cleaning aircraft exteriors. If high pressure steam cleaners are used, water use may range from 10-20 gallons for washing small aircraft, and between 100 and 200 gallons for large aircraft.[2] Wastewater from cleaning activities may contain diluted cleaning chemicals; low concentrations of metals, oil and grease, solvents, dirt and grit, or other materials that are used as detergents, or are found in the aircraft itself. If not treated, the washwater has the potential to pollute the soil, groundwater, and surface waters.

---

[2] A Boeing 727 is an example of a narrow-body aircraft, while MD-11's, Boeing 747's and 767's are examples of wide-body aircraft.

To prevent such contamination, wastewater from cleaning operations usually drains to catch basins where it is mixed with other airport wastewater and discharged at an onsite treatment facility prior to discharge in accordance with the facility's NPDES permit. Prior to discharge, the wastewater may also pass through a holding tank where metals, dirt, and grit settle to the bottom, oil and grease are skimmed off the water surface, and the remaining water is discharged. If the washwater is not treated onsite, it may be discharged to a publicly owned treatment works (POTW), where it is treated prior to discharge. Washwater discharged to the POTW may be subject to pretreatment requirements established by EPA and the POTW.

III.A.4. Aircraft Deicing and Anti-Icing

As noted earlier, FAA regulations govern every aspect of airline and airport operations, including procedures and standards for aircraft maintenance and airworthiness, including aircraft deicing. Aircraft deicing and anti-icing are key components in assuring cold weather aircraft safety. Deicing and anti-icing remove from and inhibit for a period of time the formation of ice and snow on wings, fuselages, and other parts of the airplane that provide lift during takeoff. Common practice is to deice (remove accumulation) then anti-ice (protect from further accumulation) aircraft before takeoff. These processes use glycol-based materials, including ethylene glycol, diethylene glycol, or propylene glycol.

Aircraft deicing is carried out either at the departure gate area or at a central or remote facility in the vicinity of the runway to minimize the amount of time between treatment and takeoff. Central and remote deicing areas facilitate collection of deicing fluids for recycling and treatment.

Deicing is almost performed exclusively using hand held nozzles and hoses. Automatic deicer spray machines, called "deicing gantries", have been developed in recent years. However, there are some limitations on the practicality of such equipment and the associated capital investment.

Environmental Aspects and Potential Impacts of Deicing

Deicing operations generate spent deicer fluids. These fluids drain from the aircraft surfaces or from the runway surfaces to drains that direct the fluids to onsite water treatment facilities, to storm drains, or simply to paved surfaces where they may be discharged to local waterways or groundwater as sheet runoff. In some cases, deicing fluids may be released directly to the environment through runoff to surface waters or infiltration to groundwater. Glycol-based fluids deplete oxygen from the waters in which they are disposed and have toxic effects on life forms in those waters (*Aviation Week and Space Technology*, January 1995).

In general, each airport has its own distinct characteristics and drainage systems and collecting deicing fluid for reuse or recycling may not be practical. However, some airports have constructed deicing fluid collection systems that prevent discharge to storm water sewers and segregate spent deicer from other wastewater for reclamation, recycling, onsite treatment, or disposal offsite. FAA allows the reuse of deicing fluids that are reformulated and re-certified to meet appropriate aircraft deicing fluid specifications. However, at this time, the aviation industry has not recycled glycols for reuse on aircraft or runways due to cost. Some reclaimed deicing fluids may be sold in secondary markets (e.g., windshield deicers for automobiles). In compliance with Clean Water Act requirements, spent deicing fluids are treated either in the facility wastewater treatment system, discharged to publicly owned wastewater treatment plants, or discharged directly to surface waters in accordance with permit conditions.

III.A.5. General Aircraft Operational Activities

As discussed earlier, the FAA has jurisdiction over all aircraft operations and prohibits states and local governments from regulating in the areas of aircraft operations and airspace management. In addition, the exclusive jurisdiction also extends to environmental statutes as they relate to the aviation industry. For example, Section 233 of the Clean Air Act specifically prohibits states from regulating air pollution from aircraft engines.

Aircraft Operation. The mode of operation of the aircraft can be broken down into five stages: idling at gate and runway; engine power up; taxiing; takeoff and climb out; and approach and landing. Depending on the type of engine and aircraft, these activities can consume varying amounts of resources and produce various pollutants. Because fuel is the airline industry's second largest expense, increasing fuel efficiency of aircraft engines has been a top priority of U.S. airlines. Over the past two decades, U.S. airlines have increased fuel efficiency nearly 50% by lowering cruising speeds, using computers to determine optimum fuel loads and to select altitudes and routes that minimize fuel burn; and keeping aircraft exteriors trimmed (i.e., stowed) to minimize aerodynamic drag.[3]

The environmental aspects of aircraft operation are related to the use and burning of fuel. Fuel has the potential to cause varying environmental impacts depending on the type of fuel, the efficiency of burning, and the manner in which excess fuel is discarded. During aircraft operations, engines emit hydrocarbons, carbon monoxide, and nitrogen oxides (NOx). Hydrocarbon and carbon monoxide emissions result from incomplete combustion at the lower power settings for descent, or when idling or taxiing

---

[3] *The Airline Handbook*, Chapter 9: Airlines and the Environment from the Air Transport Association, 1997.

on the ground. NOx, the result of combustion products mixing with nitrogen in the air, is produced when engines are at their hottest, such as during takeoffs and, to a lesser extent, during cruise when jet engines also produce carbon dioxide and water vapor.

Aircraft loading and off loading. Aircraft loading and off loading includes all activities associated with the movement of materials, items, and people in and out of airplanes. Regardless of the type of airport, aircraft loading and off loading occur an infinite number of times daily throughout the U.S. Aircraft cargo loads consist of several different items, including but not limited to passengers, baggage, mail, live animals, dangerous goods (including hazardous materials), and wet cargo (e.g., fresh fish, seafood, meat, casings, etc.).

The primary loading and off loading activity with a potentially significant impact on human health and the environmental is the loading and off loading of hazardous materials. Though a rare occurrence, these loading activities have the potential to contaminate soil, groundwater, or surface water in the event of a spill or release. Facilities minimize and control these impacts through development and implementation of spill prevention control and countermeasures plans, storm water pollution prevention plants, and other emergency response programs.

If hazardous materials are transported by aircraft, the materials are subject to U.S. Department of Transportation (DOT) requirements that regulate aircraft inspections, placement of materials, packaging, and shipping papers (e.g., waybills, manifests). If hazardous materials are loaded onto an airplane, containers should be inspected for proper labeling/placarding, any signs of leakage, and compatibility with other hazardous materials. If damage or spillage of a package containing hazardous materials is observed on board an aircraft or during loading/off loading, immediate action must be taken in accordance with company or airport procedures.

Transportation of Dangerous Goods. Once hazardous materials are loaded onto aircraft, they are transported to their destination. In preparation for transport, they are stored, segregated and secured to assure safety during the transportation process. If improperly stored and secured, dangerous goods have the potential to not only impact the health of workers and passengers, but also to impact the safety of the aircraft itself.

To assure that these goods are transported in a safe manner, regulations have been established by DOT and the International Civil Aviation Organization (ICAO) Dangerous Goods Panel. These standards regulate the types of materials that can be transported, and the types of aircraft in which they can be transported. The ICAO Dangerous Goods regulations include a detailed list of individual articles and substances specifying the United Nations classification of each article or substance, their acceptability for air transport, and the conditions for their transport.

According to the regulations, dangerous goods may be transported in one of the following ways: they may not be carried on any aircraft under any circumstances; they are forbidden under normal circumstances, but may be carried with specific approvals from the States concerned; they may be carried only on cargo aircraft; or they may be safely carried on passenger aircraft, provided certain requirements are met. It should be noted that most dangerous goods fall into the latter transport category.

The ICAO Dangerous Goods regulations also provide packing instructions for all dangerous goods acceptable for air transport with a wide range of options for inner, outer, and single packaging. In addition, all individuals involved in the preparation or transport of dangerous goods must be properly trained to carry out their responsibilities. Information on the goods must be conveyed by the pilot to air traffic services to aid in the response to any aircraft incident or accident. Finally, dangerous goods accidents or incidents must be reported, so that an investigation by the relevant authorities can establish the cause and take corrective action.

Aircraft Noise. Another type of pollution generated from the operation of aircraft is noise pollution. Noise from airports is a significant negative impact for many people in the airport vicinity. Federal noise regulations require all large aircraft to meet noise standards. FAR Part 150 regulations address the issue of aircraft noise and provide a comprehensive scheme for planning and mitigation measures funded by aviation trust funds intended to reduce noise impacts on the public (US EPA Office of Federal Activities, *Pollution Prevention/Environmental Impact Reduction Checklist for Airports*).

Air Pollutants from Transportation

The EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., total hydrocarbons, SOx, NOx, CO, particulates, etc.) from many transportation sources. The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. Exhibit 12 summarizes annual releases (from the industries for which a Sector Notebook Profile was prepared) of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM_{10}), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 12. Annual Air Pollutant Releases by Industry Sector (tons/year)

Industry Sector	CO	NO_2	PM_{10}	PT	SO_2	VOC	TOTALS
Power Generation	366,208	5,986,757	140,760	464,542	13,827,511	57,384	20,843,162

III.B. Airport Operations

Airport operations include all activities related to operating and maintaining the airport. These activities include operation and maintenance of runways, control towers, maintenance facilities, aircraft gates, baggage handling facilities, and general airport operations. This section focuses on two of these activities: runway deicing and general operations.

III.B.1. Runway Deicing

Airport runways, taxiways, and gate areas are sprayed with deicer and anti-icer to remove and prevent the buildup of ice and snow that would inhibit taxing, takeoff, and landing. Pavement deicing/anti-icing breaks the bond holding ice and compacted snow to the surfaces of runways and taxiways, facilitating mechanical ice and snow removal, and allowing aircraft to maintain adequate friction between aircraft tires and the runway. Runway and ramp deicing is usually done with one or more substances (e.g., glycol, urea, sodium formate, and/or potassium acetate). Sand is usually reserved to prevent slippage at the gate area, but not on taxiways and runways due to potential engine ingestion hazards.

Environmental Aspects and Potential Impacts of Runway Deicing

Deicing mixtures have the potential to contaminate groundwater and surface water supplies as they flow from airport runways to storm drains or to waterways as sheet runoff. Sand has the potential to clog storm water drains and contaminate water bodies through increased erosion and sediment buildup. Deicing chemicals that mix with storm water discharges must be managed according to the facility's NPDES storm water permit. In an effort to control water contamination, many facilities direct storm water to an onsite treatment facility prior to discharge.

III.B.2. General Airport Operations

General airport operations encompass many activities including passenger and vehicle traffic, ticketing, baggage handling, passenger security, and concessions and food services. Airports, like other administrative offices, can generate large quantities of waste paper and consume large amounts of energy from lighting, heating and cooling systems, and computers. Concession shops and food service operations can generate significant quantities of solid waste, such as corrugated cardboard, paperboard, office paper, newspapers, magazines, wooden pallets, aluminum, plastic, and glass containers, as well as leftover food. Groundskeeping and landscaping activities can generate waste pesticides and herbicides. Airport traffic congestion can generate significant air emissions.

Environmental Aspects and Potential Impacts of General Operations

The operation of airports can have a variety of impacts on the environment. These impacts include erosion, sedimentation, soil compaction, noise pollution, chemical pollution resulting from aircraft maintenance and deicing, aircraft emissions, contaminated runway and grounds runoff, generation of waste construction materials, and litter and other debris from administrative and food service operations.

In regards to wildlife, there is typically no significant destruction of wildlife habitat. FAA is, however, aware of the problem that certain species (e.g., large waterfowl, birds that flock, deer) cause aviation. As a result, FAA encourages, and in some cases requires, airport sponsors to work with wildlife agencies to manage the habitat attracting these species. Such measures are needed to reduce the number of collisions between these species and aircraft to protect human and wildlife populations.

IV. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. Airlines and airports are reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some operations are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies. ***While implementing pollution prevention techniques, it is important that the facility assure that the techniques are conducted in accordance with FAA safety regulations and airworthiness requirements. FAA's Advisory Circular entitled, "Management of Airport Industrial Waste"(AC#150/5320-15), provides guidance on managing industrial wastes that airport operations generate.***

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasibly. In the waste management hierarchy, if source reduction is not feasible, the next alternative is recycling of wastes, followed by energy recovery, and as a last alternative, waste treatment.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the air transportation industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be used effectively.

Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be considered carefully when pollution prevention options are evaluated, and the full impacts of each option must be evaluated for its effects on air, land, and water pollutant releases.

Waste minimization generally encompasses any source reduction or recycling that results in either the reduction of total volume or the toxicity of hazardous waste. Source reduction is a reduction of waste generation at the source, usually within a process. Source reduction can include process modifications, feedstock (raw material) substitution, housekeeping and management processes, and increases in efficiency of machinery and equipment. Source reduction includes any activity that reduces the amount of waste that exits a process. Recycling refers to the use or reuse of a waste as an effective substitute for a commercial product or as an ingredient or feedstock in an industrial process.

IV.A. Air Transportation Operations

Pollution prevention/waste minimization opportunities in the air transportation industry are available for many operations including aircraft and vehicle maintenance and repair, washing and cleaning, deicing, fueling, aircraft modification, and airport layout and operations. These areas are addressed in the following sections.

IV.A.1. Maintenance and Refurbishing Operations

Aircraft maintenance activities generate wastes that are of great environmental concern to the air transportation industry. The major wastestreams from aircraft maintenance and refurbishing are lubricants, batteries, scrap metal, parts cleaning wastes (e.g., solvents), depainting wastes (e.g., chemical paint stripping wastes, abrasive blast and surface preparation wastes), and painting/painting equipment cleaning wastes. Source reduction is the best pollution prevention approach for reducing the amount of wastes produced. Source reduction can be achieved through material substitution, process or equipment modification, recycling, or better operating practices. ***Note: Such modifications must be made in accordance with FAA requirements, as well as the extraordinarily specific maintenance practices recommended by airframe and engine manufacturers.*** The following material presents pollution prevention/waste minimization opportunities for each type of waste.

Used Oil and Lubricants. Most airline maintenance facilities recycle used oil. Recycling used oil requires equipment like a drip table with a used oil collection bucket to collect oil dripping off parts. Drip pans can be placed under aviation-support vehicles awaiting repairs in case they are leaking fluids. Some facilities use absorbent materials (e.g., "pigs" or "quick dry") to catch drips or spills during activities where oil drips may occur. While absorbents prevent oil from impacting the environment, they actually create more solid and potentially hazardous waste in the form of contaminated absorbent materials. Preventing small spills in the first place, using drip pans, or cleaning spills with rags, soap and water can prevent the generation of additional waste. Recycling used oil by sending it to a commercial recycling facility saves money and protects the environment.

R0074784

To encourage recycling, the publication *How To Set Up A Local Program To Recycle Used Oil* is available at no cost from the RCRA/Superfund Hotline at 1-800-424-9346 or (703) 412-9810.

Spent petroleum-based fluids and solids should be sent to a recycling center whenever possible. Solvents that are hazardous waste must not be mixed with used oil. If they are mixed, the entire mixture may be considered hazardous waste, and thus subject to more stringent regulation. Non-listed hazardous wastes will be mixed with waste oil, and as long as the resulting mixture is not hazardous, can be handled as waste oil. All used drip pans and containers should be labeled properly.

Fluids. Aircraft and aviation-support vehicles require regular changing of fluids, including oil, coolant, and others. To minimize releases to the environment, these fluids should be drained and replaced in areas where there are no connections to storm drains or municipal sewers. Minor spills should be cleaned prior to reaching drains. Used fluid should be collected and stored in separate containers. Fluids can often be recycled. For example, brake fluid, transmission gear, and gear oil are recyclable. Some liquids are able to be legally mixed with used motor oil which, in turn, can be reclaimed.

During the process of engine maintenance, spills of fluids are likely to occur. The "dry shop" principle encourages spills to be cleaned immediately, without waiting for the spilled fluids to evaporate into the air, to transmit to land, or to contaminate other surfaces. The following techniques help prevent spills:

✓ Collect leaking or dripping fluids in designated drip pans or containers. Keep all fluids separated so they may be properly recycled.

✓ Keep a designated drip pan under the vehicle while unclipping hoses, unscrewing filters, or removing other parts. The drip pan prevents splattering of fluids and keeps chemicals from penetrating the shop floor or outside area where the maintenance is occurring.

✓ Immediately transfer used fluids to proper containers. Never leave drip pans or other open containers unattended.

Radiator fluids from aviation-support vehicles are often acceptable to antifreeze recyclers. This includes fluids used to flush out radiators during cleaning. Reusing the flushing fluid minimizes waste discharges. If a licensed recycler does not accept the spent flushing fluids, consider changing to another brand of fluid that can be recycled. Many maintenance facilities have purchased antifreeze recycling systems that connect directly to a vehicle so that the antifreeze is taken from the vehicle, cleaned, and then put back into the same vehicle.

If the maintenance facility services air conditioners in aviation-support vehicles, special equipment must be used to collect the freon or other refrigerant because it is not permissible to vent the refrigerant to the atmosphere. Air conditioner maintenance activities require employee training, specifically for handling refrigerants. Reusing refrigerants onsite is less costly than the only other legal alternative, sending the refrigerant to an offsite recycler.

Batteries. Facilities have many battery disposal options: recycling onsite, recycling through a supplier, or direct disposal. Facilities should explore all options to find one that is right for the facility. Many waste batteries must be handled as hazardous waste. Lead acid batteries are not considered hazardous waste as long as they are recycled. In general, recycling batteries may reduce the amount of hazardous waste stored at a facility, and thus the facility's responsibilities under RCRA. The following best management practices are recommended when sorting used batteries:

✓ Place on pallets in a contained area, and label by battery type (e.g., lead-acid, nickel, and cadmium).

✓ Protect them from the weather with a tarp, roof, or other means.

✓ Store them on an open rack or in a watertight, secondary containment unit to prevent leaks.

✓ Inspect them for cracks and leaks as they are removed from the vehicle or aircraft. If a battery is dropped, treat it as if it is cracked. Acid residue from cracked or leaking batteries is likely to be hazardous waste under RCRA because it is likely to exhibit the characteristic of corrosivity, and may contain lead and other metals.

✓ Avoid skin contact with leaking or damaged batteries.

✓ Neutralize acid spills and dispose of the resulting waste as hazardous if it still exhibits a characteristic of a hazardous waste.

Machine Shop Wastes. The major hazardous wastes from metal machining are waste cutting oils, spent machine coolant, and degreasing solvents. However, scrap metal also can be a component of hazardous waste produced at a machine shop. Material substitution and recycling are the two best means to reduce the volume of these wastes.

The preferred method of reducing the amount of waste cutting oils and degreasing solvents is to substitute them with water-soluble cutting oils. Recycling of waste cutting oils also is possible if nonwater-soluble oils must be used. Machine coolant can be recycled, and a number of proprietary systems are available to recycle the coolant. Coolant recycling is implemented most easily when a standardized type of coolant is used throughout the shop. Reuse and recycling of solvents also are achieved easily, as mentioned above. Most shops collect scrap metals from machining operations and sell these to metal recyclers. Metal chips which have been removed from the coolant by filtration should be drained and included in the scrap metal collection. Wastes should be segregated carefully to facilitate reuse and recycling.

Small Parts Cleaning. Solvents are commonly used for small parts cleaning. Spent solvents are often toxic and/or hazardous and should be disposed of in an environmentally safe manner. Spent solvent, if hazardous, must be treated and disposed of as hazardous waste, unless recycled properly. There are several options for reducing the amount and/or toxicity of spent solvents:

- ***Switch to non-hazardous substances.*** Switch from hazardous, organic-based to non-hazardous, aqueous-based solvents. In addition, certain aqueous parts washers can use detergents instead of solvents. While water-based parts washers may be more expensive than solvent-based parts washers (costs range from $1,000 to $3,000 for water-based washers capable of washing small parts), the cost of the parts washer can be quickly recovered as the cost of disposing or recycling of hazardous solvent as well as the cost of any required training for workers handling the solvent are eliminated. This will reduce the amount of hazardous waste generated from cleaning operations.

- ***Keep lids closed when not in use.*** For solvents that contain volatile organic compounds, keeping containers closed except when parts actually are being cleaned reduces solvent emissions to the atmosphere, improves worker safety, and allows the solvent to be used longer, rather than simply to evaporate.

- ***Reuse.*** Solvents can be reused if quality requirements are met and until their effectiveness is compromised. and then they can be recovered and recycled.

- ***Recycle.*** Solvent recycling also can decrease hazardous waste production from small parts cleaning. Spent solvents can be cleaned and recycled with a solvent still. Processes for recycling solvents are well established and widely used in many industrial sectors. Solvents should not be poured down sewer drains, mixed with used oil, or stored in open containers to allow them to evaporate. Solvent stills (e.g., distillation units) may only be installed in appropriately fire rated areas.

- ***Use good housekeeping practices.*** To minimize solvent waste generation, facilities should use good housekeeping practices including labeling of all chemicals and wastes to avoid misuse and potential injury or contamination; keeping containers of hazardous solvents closed to prevent air emissions; providing storage area leak control and containment; and making improvements in drum location, product transfer leak collection, and drum transport procedures. If solvents are used, care should be taken to wear protective safety gear and follow good housekeeping practices.

Depainting

Chemical Stripping Wastes. Chemical stripping operations must be conducted according to the appropriate and relevant requirements associated with the original equipment manufacturers' specifications. Chemical stripping wastes consist primarily of stripping agent and paint sludges. Methylene chloride is the most commonly used paint stripping agent, although the industry increasingly is using less toxic agents such as dibasic esters, semi-aqueous, terpene-based products, aqueous solutions of caustic soda, and detergent-based strippers that currently are available on the market. In order to reduce compliance costs, many facilities are replacing methylene chloride with nonhalogenated strippers.

The Aerospace National Emission Standards for Hazardous Air Pollutants (NESHAP) (effective September 1998) places stringent limitations on the use of chemical strippers containing hazardous air pollutants. (See discussion in Section V.C Pending and Proposed Regulatory Requirements.)

Storing and reusing or recycling used strippers also are effective waste minimization techniques. Solvent strippers, particularly stripping baths, generally can be reused several times before their effectiveness is diminished. Both spent caustic and organic stripping solutions can be treated to remove contaminants. Segregating the spent stripping wastes from other waste streams will help facilitate cost-efficient reuse and recycling of contaminated strippers.

Abrasive Blasting and Surface Preparation Wastes. Abrasive blasting is being used as an alternative for chemical paint stripping. Although blasting does not require disposal of chemical strippers, it does create a large amount of water runoff and air pollution, and the presence of paint chips containing hazardous metals and organometallic biocides can make abrasive blasting wastes potentially hazardous. Research and testing are underway on a number of innovative alternative paint removal and surface preparation techniques including: plastic media blasting, steel shot slingers, water jet stripping, thermal stripping, dry ice pellets, laser paint stripping, and cryogenic stripping. However, an alternative as economically viable and easy as chemical paint stripping has not been found.

- Plastic media blasting has had mixed results. The same types and quantities of solid wastes are generated as with grit blasting, but the plastic media tend to be more easily recyclable through the use of pneumatic media classifiers that are part of the stripping equipment. The abrasion eventually turns the plastic media to dust, making the waste paint the main waste to be disposed. However, it will not work on epoxy or urethane paints. In addition, the blasting equipment is more expensive and requires more highly trained operators.

- Cavitating water jet stripping systems remove most paints, separate the paint chips from the water, and treat the water to eliminate dissolved toxic materials. Although relatively little hazardous waste is generated by this process, it is not as efficient as grit blasting, and the equipment has higher capital and operating costs.

- The thermal stripping process softens the paint so it can be peeled relatively easily. Although it generates only one waste stream (waste paint), it is more labor-intensive than other stripping methods and can only be used on non-heat-sensitive surfaces.

- Carbon dioxide pellets can be used as a blast medium leaving only paint chips that can be swept up and placed in containers for disposal (the dry ice evaporates). However, the cost of the dry ice, storage, and handling equipment can be substantial.

- A pulsed carbon dioxide laser controlled by an industrial robot to remove paint produces no residue. However, the method is complex, capital intensive, and requires highly skilled operators.

- Cryogenic stripping using liquid nitrogen baths followed by gentle abrasion or plastic shot blasting is useful for small parts or objects, but requires special equipment for handling the liquid nitrogen.

Blasting cannot be used as a paint stripping method on certain substrate because the abrasive media will cause damage, especially to composite materials.

Painting and Painting Equipment Cleanup Wastes. Methods for minimizing paint and painting equipment cleanup wastes include tight inventory control, material substitution, and minimization of fugitive oversprays. Tight inventory control techniques such as monitoring employee operations or limiting access to raw materials storage areas force employees to stretch the use of the raw materials. Use of less toxic types of paints can reduce the amount of hazardous paint waste as well as painting equipment cleanup waste (i.e., solvent wastes). Also, the use of powder coatings based on finely pulverized plastics that are baked on at 400°F has been tried as a substitute for paint for some industrial applications.

Minimizing overspray has benefits in terms of both inventory control and elimination of surface water runoff. For inventory control, overspray can be minimized by using air-assisted, airless, high volume, low pressure turbine, air-atomized electrostatic, and airless electrostatic application techniques. In addition, overspray can be minimized by maintaining a fixed distance from the surface while triggering the paint gun, and releasing the trigger when the gun is not aimed at the target. Overspray control for minimizing runoff can be achieved by using plastic sheeting under and around the aircraft being painted, or using a paint booth for smaller parts.

To reduce the amount of wastes created by painting operations, all paint should be used until containers are completely empty. Containers that are considered empty under the Resource Conservation and Recovery Act (RCRA) may be disposed of as solid waste (40 CFR 265). However, they may face requirements under DOT regulations depending on the amount of hazardous waste remaining in the container. Used containers of paint may need to be disposed of as hazardous wastes if they are not completely empty. Also, paint may be purchased in recyclable and/or returnable containers to reduce disposal costs.

IV.A.2. Fueling

Pollution prevention opportunities for aircraft and vehicle refueling operations primarily focus on the prevention of fuel spillage and the associated air, water, and hazardous waste pollution. Fuel tank monitoring and automatic shutoff devices are key spill prevention measures. Although not permitted for jet fuel, using color-coded dyes to identify fuel grades of aviation fuel is commonly used to prevent mixtures of fuel and to find fuel leaks. One technique to prevent fuel spills is to install catchment basins, including containment at hydrant pits. All leaking pipe joints, nozzle connections, and any damage to the fueling hose (e.g., kinks, crushing, breaks in the carcass, bulges, blistering, soft spots at the coupling, deep cracks or cuts, spots wet with fuel, or excessive wear) should be reported immediately to reduce their potential impact on the environment. Using dry cleanup methods for the fuel area reduces water runoff and associated contamination of groundwater and surface water supplies.

Pollution prevention techniques for aircraft fueling include:

✓ Inspect fueling equipment daily to ensure that all components are in satisfactory condition.

✓ Employ proper grounding and bonding techniques for a safe fueling operation.

✓ If fueling of an airplane occurs at night, assure it is carried out it in well lit areas.

✓ Where possible, avoid fueling an aircraft during aircraft maintenance activities that might provide a source of ignition to fuel vapors. Similarly, assure that all radio and radar equipment is off during the refueling process.

✓ While fueling, check for leaks and assuring that the fueling operator has a clear view of control panel.

✓ Never leave the nozzle unattended during overwing fueling, or wedge or tie the nozzle trigger in the open position.

✓ Discourage topping off of fuel tanks, except when required for compliance with FAA safety regulations.

✓ Sump of hydrant pits.

Vehicle fueling. Self-locking fueling nozzles minimize the risk of both fuel spillage and air pollution by ensuring a secure seal between the fuel source and tank.

Fuel in vehicle operations. Use of battery-operated or alternative fuel vehicles provides two ways to reduce emissions from aviation-support vehicles. Natural gas vehicles, for example, are a viable alternative to gasoline- and diesel-powered transportation. Almost any gasoline-powered vehicle can be converted to run on natural gas by installing a natural gas fuel system and storage tanks without removing any existing equipment. Diesel conversions are somewhat more complicated because they also involve reducing compression and adding a sparked-ignition system. Other fuels suitable for vehicles include methanol, ethanol, and propane.

In 1997, there were alternative fuel vehicle programs at virtually every major airport in the United States. The alternative vehicle usage at airports runs the gamut from taxis, shuttle buses, passenger busses, transport busses, minivans, trucks, cars, tugs, tractors, belt loaders, and ground power units, to catering vehicles. The use of natural gas vehicles is being driven by both cost effectiveness and regulation. Many states require companies with fleets of twenty or more vehicles to phase in alternative fuel vehicles. The 1990 Clean Air Act also contains incentives to encourage the use of alternative fuels. Federal (and in some areas, State) tax deductions for "alternative fuel vehicles" and related refueling equipment are available. The maximum tax deductions range from $2,000 to $50,000 for each alternative fuel vehicle and up to $100,000 on refueling stations.

IV.A.3. Aircraft and Vehicle Exterior Cleaning

Pollution prevention opportunities for aircraft and aviation-support vehicle cleaning focus on the reduction of wastewater discharges.

> Note: Air worthiness requirements may dictate the quantity of water used in certain cleaning operations.

- ***Aircraft Cleaning.*** For washing aircraft, it is best to utilize a designated cleaning area, recycle washwater (if possible), and use phosphate-free detergents. Washwater should be contained and an oil/water separator should be used. Washwater can be captured, filtered, and reused in aircraft washing and other activities. If the washwater is reused for washing aircraft, ***it must meet the manufacturer's specifications for washwater***. Washwaters containing contaminants can result in corrosion of potentially critical aircraft parts.
  Another water reduction tool, a flow restrictor, can be used to control the amount of water being used to wash aircraft. A reduction in water usage will translate into a reduction in the volume of generated wastewaters. (Note that technologies for water reduction are only suggestions and should be evaluated individually to address the circumstances appropriate to each site.)

- ***Vehicle Washing.*** Vehicle washing has become a major environmental compliance issue for most companies that operate a fleet of vehicles. While pollutants from vehicle washing are generally controlled by routing the water through an oil and water separator.

many techniques are available that prevent the water from being generated at all. The following pollution prevention activities will help ensure that a facility is addressing potential sources of pollution:

- ✓ Wastewater discharge can be prevented by dry washing vehicles using a chemical cleaning and waxing agent, rather than detergent and water. The dry washing chemical is sprayed on and wiped off with rags. No wastewater is generated. Dry washing is labor intensive and creates solid waste that must be disposed of properly.

- ✓ Wastewater can be contained by washing at a low point of the facility, blocking drains from the facility using a containment dike. or blanket, or washing on a built-in or portable containment pad.

- ✓ Wastewater can be disposed of by evaporation from a containment area, or by discharging the wastewater to a sanitary sewer system. Permission must be obtained from the POTW before washwater can be drained. pumped. or vacuumed to a sanitary sewer connection.

IV.A.4. Aircraft Deicing

As noted earlier, FAA regulations and advisory circulars govern in detail virtually every aspect of airline and airport operations, particularly with respect to procedures and standards for aircraft maintenance and airworthiness, including aircraft deicing. Potential pollution prevention opportunities for aircraft deicing operations include (1) providing the appropriate training on the use of glycol products to ensure they are efficiently applied to reduce polluting airport runoff and (2) collecting deicing fluid to prevent direct discharges to surrounding surface water and groundwater along with facility storm water. Appropriate liquid aircraft deicers include ethylene glycol, propylene glycol, and di-ethylene glycol.

Recycling deicing fluid. In general, the reuse of deicier fluid *on aircraft* is problematic and usually prohibited due to quality control and the cost issues associated with storage and treatment. However, recycling deicing fluid is a method employed by some airports and airlines as recycled deicing fluid can be used for *nonaircraft applications*. There are two main processes used to recycle deicing fluid. The first process involves filtering collected fluid, demineralizing it, removing salts, and then evaporating the water to leave a higher glycol concentration.

The second process uses reverse osmosis membrane technology to recover glycol by preconcentrating dilute runoff prior to distillation. In order to make recycling practical and economically feasible, it is necessary to collect concentrations that contain more than 10% glycol. Traditionally to allow recycling, only one type of chemical glycol (ethylene or propylene) could be used at an airport. However, newer methods are available to handle mixtures. The benefits of recycling fluids include recovery of the cost of glycol, recovery of the utility cost for water, and reduced disposal cost for spent glycol.

The most widespread collection method involves the collection of deicer through separate drainage areas around aircraft deicing operations, which minimizes the mixing of storm water and deicing fluid. The collection systems can be located either at the gate area or at a remote deicing area. Deicer fluid at gate area surfaces can be collected using vacuum sweeping machines, sponge rollers, and pumps.

Alternative deicing methods. Additional technology-based, alternative deicing methods currently are being developed by industry. While some of these have yet to be proven cost effective, they do present viable alternatives as technology is improved.

- FAA has approved site-specific procedures for infra-red equipment designed to de-ice aircraft.
- Deicing truck with a cab. This type of enclosure for the operator reduces overspray since the operator can get closer to the job. However, minimum safe distances must be maintained to avoid accidents and damage to aircraft or personnel. Customers of such a system have reported up to 30% reductions in consumption of glycol-based and other anti-deicing fluids.
- More advanced computerized ice detection protection systems. For example, a system that takes electronic measurements from a wing-mounted sensor disc to identify the type and thickness of ice contamination has been developed. The system also can tell when the deicing fluid is in a transition stage and about to fail as a protective coat. Such a mechanism would be useful in determining when and where the aircraft needs to be deiced.

Segregation of Wastestreams. Wastewater segregation can be an effective technique that often does not require significant process or equipment modifications. In some cases, wastewater streams can be treated more effectively and economically if they are segregated from other streams which do not require the same degree of treatment. Highly contaminated wastewater streams, oily wastewater streams, and wastewater streams containing contaminants requiring a specific treatment method (e.g., metals removal) can be segregated to reduce the volume of wastewater receiving certain treatment steps. Wastewater treatment can also be improved by adding stages to existing wastewater treatment systems. Additional stages, such as biological treatment, chemical precipitation, filtration, ion exchange, and sludge dewatering, improve system effectiveness and treatment costs through reduced sludge generation, recovery of metals for resale, and replacement of more costly treatment stages. By segregating wastestreams, facilities can provide the appropriate treatment to each wastewater stream. (Note: Wastestream segregation should be considered as a preferred alternative at a new or existing facility when it can be accomplished at a reasonable cost.)

IV.A.5. General Aircraft Operations

Modifications. Pollution prevention opportunities for aircraft modification primarily focus on improving the efficiency of the engine. Engine manufacturers are being encouraged or required to research and develop cleaner, quieter, and more fuel-efficient aircraft. Air pollution is a function of both the type of aircraft engine and the mode of operation of the aircraft, which can be broken down into the following stages: idling at gate and runway; engine power up; taxiing; takeoff and climb out; and approach and landing. With respect to the type of engine, one mechanism that can improve air quality in and around airports is for airlines and associated personnel to encourage and support aviation research that would reduce aircraft emissions. In the meantime, airlines have the option of buying and leasing aircraft that meet or exceed the strictest requirements while retiring, replacing, or retrofitting older equipment as rapidly as possible to reduce both the amount of air and noise pollution.

Operations. Pollution prevention opportunities for aircraft operations at the airport include the following:

✓ Utilize more efficient aircraft. By operating more efficient aircraft, airlines have been able to reduce fuel consumption and decrease the cost of operations. Since 1976, the introduction of more fuel efficient aircraft has reduced fuel consumption per passenger mile by approximately 50%.[4]

---

[4] *Airline Fuel Consumption*, The Boeing Company, 1997.

R0074795

✓ Retrofit gate facilities to centralized ground power in order to reduce aircraft engine running and prevent extraneous air emissions associated with engine and auxiliary power unit usage.

✓ Reduce holdover time from deicing to takeoff to eliminate the need for a plane to require deicing more than once.

✓ Checking cargo prior to loading for leaking or otherwise damaged shipments will prevent the leakage of wastes. This is of particular importance for loading dangerous goods, wet cargo, live animals, or other cargo prone to leakage. After unloading, it is useful to check the cargo compartments to ensure that all of the load for a given station has been removed. Inspecting any traces of leakage at once will enable the operator to establish the source of such leakage.

IV.B. Airport Operations

IV.B.1. Runway Deicing

In addition to collection and recycling of deicing fluids, pollution prevention opportunities include the use of alternative, less polluting deicers such as magnesium acetate and potassium acetate. These fluids have been approved by FAA on both safety and environmental grounds, and have no significant impact on water quality. It should be noted that although they have received FAA approval, magnesium acetate and potassium acetate have caused safety problems by damaging aircraft lighting systems. As in all cases where alternative technologies are used to minimize environmental impacts, aircraft safety is a major concern and must be addressed.

IV.B.2. General Airport Operations

Pollution prevention opportunities for airports focus primarily on alleviating air and noise pollution by implementing layout modifications and changes in airport operations. These improved practices can reduce the amount of air and noise pollution generated by aircraft and associated airport activities.

- For existing airports, engage in comprehensive noise mitigation planning and implement feasible measures to reduce noise impacts on densely populated regions. For new airports, if possible, choose an optimal site for the airport that is away from large communities.

- Use proper land use planning, which is a local government responsibility, for the areas affected by airport noise. For examples, airports may choose to purchase land surrounding the airport for airport use or acquire land as aviation easements. Airports may also work with local zoning boards and encourage them to zone land near airports for airport compatible uses. In particular. FAA is concerned about sanitary landfill locations near airports because landfills attract certain bird species that are hazards to aviation due to their size and/or flocking behavior.

Additional Airport Activities Impacting Air Quality. Air pollution resulting from airport operations is dependent on both mobile sources of pollution such as airplanes, ground-service vehicles, and automobiles accessing the airport as well as point sources of pollution such as power plants. fueling systems, fuel storage facilities, aircraft maintenance facilities, and deicing facilities.

Airport Traffic. Air quality in and around the airport vicinity is related not only to aircraft using the airport but to travelers and employees accessing the airport and maintenance vehicles that service the airport. Automobiles and busses used by motorists that enter and leave airports create a large source of air pollution through automobile exhaust. To reduce emissions from private vehicles, airports can link or improve public transport access. provide express bus services, and institute bus/high occupancy vehicle lanes on access roads.

Employee Programs. Initiating employee programs can reduce air pollution in and around the airport. For instance, modifying airport employee work weeks to a revised schedule that limits trips made by employees will decrease air emission (e.g., an airport may implement a 9 day/80 hour two-week schedule). Other options are voluntary employee Rideshare Programs or day care services to prevent employees from having to travel unnecessary miles, which in turn reduces the quantity of auto emissions associated with airport operations.

Recycling solid waste. Recycling all paper, cardboard, plastics. metal, and airport-specific items such as wood and film plastic will prevent pollution. In addition, distributing recycling literature and educational materials to employees and travelers will encourage more recycling of these materials.

Pest Management. Food waste from the large number of concessionaires at major airports create pest management problems at airports. Various pesticides, fumigants, and other pest management techniques are used at airports to control pests.

Landscaping. Airport erosion control projects should use environmentally and economically beneficial landscaping methods. Any plantings near runways should avoid attracting hazardous wildlife (e.g., geese, gulls, large mammals, or prey species that attract large mammals). However. careful planting can reduce the use of pesticides, herbicides insecticides, and rodenticides; control erosion; reduce water usage; reduce energy usage; reduce runoff and air emissions from mowers; and associated exposure to workers and the public.

V. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section V.A. contains a general overview of major statutes
- Section V.B. contains a list of regulations specific to this industry
- Section V.C. contains a list of pending and proposed regulations

The descriptions within Section V are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

V.A. General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity, and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities must generally obtain a permit either from EPA or from a State agency which EPA has authorized to implement the permitting program if they store hazardous wastes for more than 90 days (or 180 or 270 days depending on the amount of waste generated and the distance the waste will be transported) before treatment or disposal. Facilities may treat hazardous wastes stored in less-than-ninety-day tanks or containers without a permit. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.101) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA treatment, storage, and disposal facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 States and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261 and 262) provides definitions and lays out the procedure every generator must follow to determine whether the material in question is considered a hazardous waste or solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establish the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Providing they meet additional requirements described in 40 CFR 262.34, generators may accumulate hazardous waste for up to 90 days (or 180 or 270 days depending on the amount of waste generated and the distance the waste will be transported) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet LDR treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Virtually all hazardous wastes are subject to LDR requirements. Generators of waste subject to the LDRs must provide notification of such to the designated treatment, storage, and disposal facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities that store such waste, including large quantity generators accumulating waste prior to shipment off-site.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that must be met by December 22, 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

***EPA's RCRA, Superfund and EPCRA Hotline** at 1-800-424-9346 responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding Federal holidays.*

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law known commonly as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs (including remediation costs) incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as removals. EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

***EPA's RCRA, Superfund and EPCRA Hotline** at 1-800-424-9346 answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding Federal holidays.*

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release equal to or exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, known commonly as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline *at 1-800-424-9346 answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding Federal holidays.*

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters.

Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The National Pollutant Discharge Elimination System (NPDES) program (CWA §502) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized 42 States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set the conditions and effluent limitations on the facility discharges.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated the NPDES storm water permit application regulations. These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, consult the regulation.

Category I: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; SIC 311-leather tanning and finishing; SIC 32 (except 323)-stone, clay, glass and concrete; SIC 33-primary metals; SIC 3441-fabricated structural metal; and SIC 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly owned treatment works (POTWs). The national pretreatment program (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if the State develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities that could reasonably be expected to discharge oil in harmful quantities prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR §112.20) and for polychlorinated biphenyl (PCB) transformers and PCB-containing items were revised and finalized in 1995.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Groundwater and Drinking Water Resource Center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable, health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at 1-800-426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and PCBs.

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms.

Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, sulfur dioxide, and volatile organic compounds (VOCs). Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under Section 110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and may go into effect as early as late 1997.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source.

Under Title III, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title I, section 112(c) of the CAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV of the CAA establishes a sulfur dioxide and nitrogen oxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs) and chloroform, were phased out (except for essential uses) in 1996.

EPA's Clean Air Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at 1-800-296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at 1-800-535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities (www.epa.gov/ttn then select Directory and then CATC).

V.B. Industry Specific Requirements

As noted earlier, several government entities regulate specific transportation sectors. The air transportation industry is regulated by several different Federal, State, and local agencies. The air transportation industry is regulated by DOT's largest agency—the Federal Aviation Administration (FAA). The DOT has traditionally established national standards that are not affected by local or State laws.

EPA has traditionally relied on delegation to States to meet environmental standards, in many cases without regard to the methods used to achieve certain performance standards. This has resulted in States with more stringent air, water, and hazardous waste requirements than the Federal minimum requirements. This document does not attempt to discuss State standards, but rather highlights relevant Federal laws and proposals that affect the air transportation industry.

Clean Water Act

NPDES Requirements. Wastewater from air transportation facilities discharging to surface waters is regulated under the Federal Water Pollution Control Act (FWPCA). National Pollutant Discharge Elimination System (NPDES) permits must be obtained to discharge wastewater into navigable waters. The airport is usually considered the "discharger" for regulatory control and permitting purposes, and the individual tenants may not hold specific discharge permits. However, in some cases, the airport is the permittee and the tenants are the co-permittees. In the event of a discharge problem, a tenant who is a co-permittee contributing wastewater to an airport's discharge may be subject to action on the part of the airport or regulators (EEA, 1996).

As mandated by Section 304(m) of CWA, EPA is developing effluent limitation guidelines for certain industrial wastewater discharges from operations. At this time, there are no effluent limitation guidelines established specifically for aviation operations, however. other wastewater discharge restrictions may apply. For example, existing categorical guidelines for metal finishing currently apply to certain discharges from this industry sector. In addition, EPA is in the process of establishing effluent limitation guidelines for the transportation equipment cleaning, which will include operations such as exterior cleaning. These guidelines are scheduled to be promulgated in 2000. (Contact: Gina Matthews or Jan Goodwin, Office of Water, (202) 260-6036 and (202) 260-7152, respectively).

Storm Water Requirements. As discussed under the general description of the Clean Water Act, EPA published storm water regulations on November 16, 1990, which require certain dischargers of storm water to waters of the U.S. to apply for NPDES permits. According to the final rule, facilities with a "storm water discharge associated with industrial activities" are required to apply for a storm water permit. The rule states that transportation facilities classified in SIC 40 through 45, and 5171 which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations are considered to have a storm water discharge associated with industrial activity. However, only those portions of the facility that are either involved in vehicle maintenance (including vehicle refurbishing, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under paragraphs (b)(14)(I)-(xi) of Section 122.26 are considered to be associated with industrial activity. It is also important to that co-permittee permitting is available if appropriate to a specific tenant/airport relationship for covering storm water run off.

Facilities covered by this rule must submit one of the following permit applications:

- Individual permit application.
- Group permit application. A group permit application can be filed by facilities with like operations and discharges. In 1991, a group storm water permit application that covered airports was filed by the American Association of Airport Executives and the Airport Research and Development Foundation. On the application, airports were identified as the permittee and all tenants as co-permittees (EEA, 1996).
- Notice of Intent for general permit coverage.

SPCC. The CWA requires facilities to develop Spill Prevention Control and Countermeasure (SPCC) plans for petroleum products, such as oil or any substance, that cause a sheen on water, if they are stored in large quantities at a particular site. The SPCC program requires reporting spills to navigable waters and the development of contingency plans that must be kept onsite. SPCC plans document the location of storage vessels, types of containment, dangers associated with a major release of material from the tanks, types of emergency equipment available at each site, and procedures for notifying the appropriate regulatory and emergency agencies. No SPCC plan is considered complete until it has been reviewed and certified by a registered Professional Engineer.

Resource Conservation and Recovery Act

Air transportation facilities generate a variety of RCRA-regulated wastes in the course of normal operations and utilize underground storage tanks for fuel storage. However, underground airport hydrant fuel systems have been deferred from the bulk of federal UST requirements pursuant to an exclusion set forth in 40 CFR §280.10. Aircraft refurbishing and maintenance operations generate hazardous wastes such as certain spent solvents and caustics, and paints and paint sludges. Additional common materials from aviation maintenance facilities that may be hazardous include:

- Rechargeable nickel-cadmium batteries and lead-acid motor vehicle batteries
- Vehicle maintenance fluids
- Fluorescent light bulbs
- Scraps of metals (cadmium, chromium, lead, mercury, selenium, and silver) and materials containing these metals (e.g., high-grade stainless steel or paint waste) (exempt if recycled)
- Waste solvents
- Near-empty paint cans and spray cans
- Paint stripping residue.

Note that petroleum products and petroleum-containing wastes (e.g., waste oil, contaminated fuel, or fuel spill clean-up wastes) are specifically exempted from RCRA regulations, unless they exhibit any of the hazardous waste characteristics (EEA, 1996). Many air transportation facilities qualify as hazardous waste generators under RCRA law. Under RCRA, it is the facility's responsibility to determine whether a waste is hazardous. A list of EPA hazardous wastes can be found in 40 CFR §§261.31-261.33. Wastes are also hazardous if they exhibit a characteristic described in 40 CFR §§261.21-261.24. RCRA wastes are subject to the hazardous waste regulations of 40 CFR Parts 124, 261-266, 270-273, and 302. Used oil and USTs are subject to different rules.

Oil Pollution Act

The 1990 Oil Pollution Act (OPA) establishes strict, joint and several liability against facilities that discharge oil or which pose a substantial threat of discharging oil to navigable waterways. OPA imposes contingency planning and readiness requirements on certain facilities that may include vehicle maintenance shops. These requirements may affect some air transportation maintenance establishments. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and facility response plans to oil discharges (40 CFR Part 112) were revised and finalized in 1994.

Comprehensive Environmental Response, Compensation, and Liability Act

A number of wastes generated from the air transportation refurbishing and maintenance processes contain CERCLA hazardous substances. Therefore, past spills and on-site releases of such substances may require remedial clean-up actions under Superfund.

Emergency Planning and Community Right-to-Know Act

CERCLA/EPCRA Emergency Release Notification. Any person in charge of a facility is required to immediately notify the LEPCs and SERCs likely to be affected if there is a release into the environment f a hazardous substance that exceeds the reportable quantity for that substance. Substances subject to this requirement include those on the list of "extremely hazardous substances" (40 CFR Part 355) as well as more than 700 hazardous substances subject to the emergency notification requirements under CERCLA Section 103(a) (40 CFR Section 302.4).

Many materials commonly used in the aviation industry fall into this category of CERCLA hazardous substances, including many solvents, ethylene glycol, methanol, methylene chloride, and 1,1,1-trichloroethane. With regard to the obligation to report releases of ethylene glycol being used for aircraft deicing at airports, the "facility" may include the truck applying the deicer, the aircraft to which the deicer is applied, or the entire airport. The person in charge of the "facility" must report a release into the environment of 5,000 pounds or more of ethylene glycol in any 24-hour period (EPA, 1996).

Federally Permitted Release Exemption. CERCLA Section 103(a) exempts those persons in charge of facilities from reporting releases that are federally permitted. On February 4, 1992, EPA issued OSWER Directive 9360.4-12 regarding *CERCLA Reporting Requirements for Releases of Ethylene Glycol From Airplane Deicing Operations*. This Interpretative Memorandum and OSWER Directive allows the airline industry to classify releases of the ethylene glycol as nonreportable (or exempt) discharges if a facility (1) has an NPDES permit covering ethylene glycol, (2) has applied for an NPDES permit, or (3) discharges to a publicly-owned treatment works (POTW) meeting the applicable pretreatment standards. Since most if not all fluid discharges resulting from aircraft deicing operations usually fit into one of the permitted release exemptions found in CERCLA Section 101(10), most water discharges of ethylene glycol-based deicing fluids will not result in a reporting requirement. (EPA, 1992)

Emergency Planning. Under EPCRA, a facility must notify authorities if it has onsite at any time a listed hazardous substance in an amount over the substance's threshold planning quantity. Extremely hazardous substances that may be present in aviation-related facilities include nitric acid, sulfuric acid, phenol and ammonia (EEA, 1996).

Clean Air Act

Sections 231-234 of the Clean Air Act gives exclusive jurisdiction to the federal government and preempts any state or local regulation with respect to emissions of any air pollutant from any aircraft or engine.

Air Quality Standards - Ozone Non-Attainment Areas. The most important pollutant affected by air quality standards is ozone. In attainment areas, a major source emits or has the potential to emit more than 100 tons per year of any criteria pollutant or 10 tons per year of any hazardous air pollutant or 25 tons per year of any combination of hazardous air pollutants (emission thresholds differ for various categories of nonattainment areas). Large aircraft maintenance facilities performing aircraft painting or using large amounts of solvents may exceed these limits. Emission rates are dependent on the types of chemicals and methods used and the types of air emission control equipment used. Some regulations apply to substances (e.g., solvent degreasers) regardless of the size of the source. These regulations are designed to reduce emissions from solvent evaporation (EEA, 1996).

To assist State and local agencies in establishing regulations that reduce VOC emissions from the air transportation industry, EPA developed a control technique guideline. This guideline offers an incentive of reduced recordkeeping requirements for facilities that use only approved cleaning agents, and requires vapor pressure limits for non-listed cleaning agents. Additionally, the guideline requires unused cleaning agent and solvent-laden rags to be stored in containers to prevent evaporation. (EEA, 1996) Airports located in ozone non-attainment areas may be subject to restrictions applicable to motor vehicles. These restrictions may affect the type and use of both airside and landside vehicles.

NESHAPs/MACT Standard. National emission standards for hazardous air pollutants (NESHAP) attempt to control several hundred compounds, the most notable for airports being asbestos. Airports must comply with the NESHAP requirements for asbestos when demolishing, or significantly remodeling, a building containing asbestos. Asbestos is commonly found in ceiling tile, floor tile, boiler room insulation, and sprayed-on insulation installed more than 20 years ago.

As stated earlier, MACT is the control technology achieving the maximum reduction in the emission of the hazardous air pollutants, taking into account cost and other factors. A MACT standard for coating operations conducted by aerospace manufacturing and reworking facilities was finalized by EPA in 1996. The emission limit from primers is 2.9 pounds per gallon and the topcoat emission limit is 3.5 pounds per gallon. Generally, HAP emissions are not permitted during paint removal operations (except during spot stripping and decal removal) (EEA, 1996). However, a number of exceptions may apply which permit such emissions under circumstances addressed in the NESHAP. According to the aerospace NESHAP, the provisions restricting HAP emissions during paint removal do not apply to the removal of paint from parts or units normally removed from the plane.

New Source Performance Standards (NSPS). Some facilities subject to NSPS may be found at airports, including industrial and utility boilers, vehicle maintenance facilities, and fuel storage and delivery facilities.

State Implementation Plans (SIPs). SIPs regulate stationary sources, such as buildings and other permanent installations, and mobile sources, such as automobiles. Typical airport facilities and activities which may be subject to stationary source regulations include heating and refrigeration plants; fueling systems; fuel storage facilities; aircraft maintenance facilities; deicing; roadways, garages, and parking lots; landside development; building demolition; and building construction. SIPs may also control mobile sources such as fleet vehicles and other vehicles using the airport. Airports are large parking areas for automobiles, trucks, and aircraft. SIPs may have to limit motor vehicle emissions through "transportation control measures." These measures are designed to reduce congestion and the number of vehicle miles traveled in a region. Measures which affect airports include improved public transit, measures to encourage uses of buses and other high occupancy vehicles, mandatory trip reduction, and traffic flow improvements.

Where applicable, SIPs must address the requirements of general air conformity (40 CFR Part 93). In addition, FAA is required to ensure compliance with general air conformity requirements for federal airport actions planned for nonattainment or maintenance areas.

Ozone-Depleting Substances. The amended CAA is phasing out the production and restricting the use and distribution of ozone-depleting chemicals. One ozone-depleting chemical widely used in the air transportation industry for fire suppression is halon. Halon production has ceased and future purchases must be from recycled stock. For consistency with these regulations, FAA has revised its policy and no longer requires halon use during firefighting drills conducted under FAR 121.417 and FAR 135.331 (EEA, 1996).

Additionally, EPA has established requirements for servicing and disposal of air conditioning and refrigeration equipment containing regulated ozone-depleting refrigerants. Certified, self-contained recovery equipment must be available during refrigeration equipment servicing. Additional recordkeeping and reporting requirements apply for appliance owners/operators and technicians. Facilities with refrigeration equipment containing ozone-depleting chemicals must comply with 40 CFR Part 82 (EEA, 1996).

Federal Insecticide, Fungicide, and Rodenticide Act

FIFRA regulations are applicable to air transportation facilities and operations where herbicides are used to control weeds and brush, or when pesticides and rodenticides are used for pest control in buildings. Air transportation operations should only apply herbicides, both general and restricted use, according to label instructions. Certification is required for use of restricted use herbicides.

V.C. Pending and Proposed Regulatory Requirements

Clean Water Act

Presently, there are no effluent limitations guidelines specific to the air transportation industry. Effluent guidelines are currently being developed for tank interior cleaning, including aircraft cleaning, by the Office of Water. These guidelines are to be proposed in January 1998 and issued in final by February 2000 (Contact: Gina Matthews or Jan Goodwin, Office of Water, (202) 260-6036 and (202) 260-7152, respectively).

On January 31, 1997, EPA proposed a package of negotiated amendments, including deadline extensions, to the effluent guidelines plan set forth in a 1992 Consent Decree. For metal products and machinery industry guidelines, which are applicable to certain maintenance and refurbishing activities, the proposed modifications would allow EPA to combine the current two-phase guideline development process into one streamlined effluent guideline procedure. The new combined rule is scheduled to be finalized by December 2002.

The modified consent decree also targets airport deicing operations. The consent decree allowed EPA to remove deicing discharges from the scope of the categorical rulemaking, and instead initiate a study of water pollution problems associated with airport deicing operations and storm water runoff. Recently issued FAA guidelines on aircraft deicing and the recent EPA storm water rules are likely to have a significant effect on airport deicing operations.

In addition, the EPA Office of Water will also work with the Department of Defense to study deicing operations at military installations. Depending on the results of this study, guidelines specific to deicing at military installations may be developed.

EPA's five-year-old baseline general permit for industrial storm water dischargers expired on September 30, 1997. EPA suggests that industries covered by the baseline permit should explore their permit options. Most State five-year industrial permits expired along with the EPA Baseline General Permit on September 30, 1997. Most permits contain a provision stating that the expired permit remains effective and enforceable until replaced. However, the permits also contain a provision requiring permittees to submit a new Notice of Intent (NOI) prior to permit expiration to remain covered. Once an airport is without a permit, it generally cannot reapply for coverage under the expired permit.

Emergency Planning and Community Right-to-Know Act

Under EPCRA 313, Toxic Release Inventory (TRI) reporting is required by manufacturing and certain other facilities. Air transportation facilities are currently not subject to TRI reporting requirements. EPA recently expanded the TRI program and did not include airports (62 FR 23834), however, they may be added in the future.

Clean Air Act

EPA has completed its final amendments to the Aerospace NESHAP under the CAA which will be implemented September 1, 1998. The Aerospace

NESHAP establishes work practice, equipment, and pollution control standards for maintenance procedures.

EPA will issue its final Control Techniques Guidelines document for the aerospace industry addressing reasonably available control technology (RACT) for volatile organic compounds (VOC) emissions, which will address the maintenance issues discussed in the document.

EPA's Clean Air Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. In addition, the Clean Air Technology Center's website includes recent CAA rules and EPA guidance documents (www.epa.gov/ttn then select Directory and then CATC).

VI. COMPLIANCE AND ENFORCEMENT HISTORY

Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (see Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (April 1, 1992 to March 31, 1997) and the other for the most recent twelve-month period (April 1, 1996 to March 31, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across EPA Regions for certain sectors.[5] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of

[5] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

records for that facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times, e.g., a facility with 3 enforcement actions counts as 3.

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/ EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); and Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance.
Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections" or the "Total Actions" column.

VI.A. Air Transportation Industry Compliance History

Exhibit 13 provides an overview of the reported compliance and enforcement data for the air transportation industry over the past five years (April 1992 to April 1997). These data are also broken out by EPA Regions thereby permitting geographical comparisons. A few points evident from the data are listed below.

As shown, there were 444 facilities identified through IDEA with air transportation SIC codes. Of these, 52 percent (231) were inspected in the last 5 years.

- Over the 5 years, 973 inspections were conducted at those 231 facilities. On average, each facility was inspected between 4 and 5 times, or about once a year.

- The 973 inspections resulted in 48 facilities having enforcement actions taken against them. At those 48 facilities, there were a total of 97 enforcement actions, meaning each facility averaged approximately 2 enforcement actions over the past 5 years.

- The average enforcement to inspection rate is 0.10. This average rate means that for every 10 inspections conducted, there is 1 resulting enforcement action taken. Across the regions, this rate ranged from 0.03 to 0.30.

Exhibit 13. Five-Year Enforcement and Compliance Summary for the Air Transportation Industry

VI.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 14 and 15 allow the compliance history of the air transportation sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Exhibits 14 and 15 permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering the last five years (April 1992 to April 1997) to that of the past year (April 1996 to April 1997). Some points evident from the data are listed below.

- Overall, the air transportation sector enforcement numbers are mostly consistent, on a percentage basis, with the other sectors.

- As shown in Exhibit 14, the air transportation enforcement-to-inspection rate is 0.10 over the past 5 years. Over the last year, as shown in Exhibit 15, the air transportation enforcement-to-inspection rate is 0.08.

Exhibits 16 and 17 provide a more in-depth comparison between the air transportation industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous exhibits, the data cover the last five years (Exhibit 16) and the last year (Exhibit 17) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- As shown, over the past 5 years, nearly half of all inspections conducted and resulting in enforcement actions at air transportation facilities have been under RCRA.

- Over the past year, while RCRA accounted for more than half of all inspections, only 25 percent of the enforcement actions were under RCRA.

VI.C. Review of Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VI.C.1. Review of Major Cases

As shown in the previous tables, there have been only 97 enforcement actions taken against air transportation industries over the past 5 years. Stemming from those 97 actions are at least 34 cases, some of which are discussed in more detail below. The 34 cases can be categorized as follows:

- 1 Clean Air Act case (new source performance standards)
- 2 Clean Water Act cases (pretreatment and NPDES permit violations)
- 21 RCRA (USTs, unpermitted storage units, etc.)
- 5 CERCLA
- 4 TSCA (PCBs)
- 1 EPCRA (release reporting).

Of these 34 cases, 16 were against federal facilities and 2 were criminal cases. Supplemental environmental projects were negotiated in 3 of the cases. (These are discussed in more detail in the following section.) The following cases are examples of EPA's enforcement against air transportation industries.

- Pacific Southwest Airmotive, Inc. (PSA) owned and operated a jet engine overhaul facility in San Diego, California. EPA brought an enforcement action against PSA (and ultimately its new owner U.S. Air) under the Clean Water Act for violations of the pretreatment standard for metal finishing operations. During operations, PSA discharged an average of 73,000 gallons per day of regulated industrial wastewater through the sewers to San Diego's Point Loma wastewater treatment plant. The court entered a civil consent decree in which U.S. Air agreed to pay $335,000 in civil penalties.

- Grumman St. Augustine Corporation strips, paints, and refurbishes aircraft at its St. Augustine, Florida, facility. EPA brought an enforcement action against Grumman in 1991 as part of the RCRA Land Disposal Restrictions Initiative. A consent decree in 1993 settled the enforcement action. The decree calls for a civil penalty of $2.5 million, of which Grumman will initially pay $1.5 million in cash. The penalty would be reduced by $1 million if Grumman completed several innovative pollution prevention projects.

The pollution prevention provisions would substantially reduce or eliminate several highly toxic waste streams, including a paint stripper, methylene chloride, and ozone-depleting chemicals (e.g., CFCs). EPA estimated that up to 240,000 pounds of hazardous emissions per year will be eliminated and toxic sludge will be reduced if Grumman complied with RCRA. Furthermore, if compliance with RCRA is achieved, approximately 2.4 million gallons of potable water will be conserved.

- As a result of an imminent and substantial endangerment situation, EPA issued Reese Air Force Base in Lubbock, Texas, an administrative order under RCRA Section 7003. In March 1993, EPA learned that Reese had detected trichloroethylene above safe drinking water standards in some privately-owned drinking water wells near the base. After confirming the data, EPA issued the administrative order. The order requires the base to conduct the following activities:

  (1) Collect samples from wells in a 36-square-mile area (within a 2-mile perimeter of the base) to determine the extent of the contamination
  (2) Notify the owners of any contamination
  (3) Supply an alternate source of drinking water to the residents with contaminated wells
  (4) Monitor the ground water in and adjacent to the plume.

  Reese has completed the initial sampling of about 950 wells, provided carbon filters for all the impacted water wells, and connected some of the users to the City of Lubbock's water system. The city is in the process of connecting its water lines to the residents that live within the city limits. The residents living outside the city limits may use the water from the wells after it has been carbon filtered.

- Region II conducted a major consolidated multimedia inspection of Kennedy International Airport in New York City, which is operated by the Port Authority of New York and New Jersey. A number of violations were documented, both at facilities operated by the Port Authority itself, as well as at some facilities operated by airline or service companies. In 1993 a complaint was issued to the Port Authority citing it for TSCA violations and proposing a penalty of $289,000. On June 28, 1994, Region II issued three additional administrative complaints to Ogden Aviation Services, Inc., citing that company for violations of the federal underground storage tank regulations, and proposing penalties totaling $109,125.

VI.C.2. Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the Internet at EPA's EnviroSen$e website: http://es.inel.gov/sep.

The following are examples of three SEPs negotiated with air transportation facilities.

- In response to violations of EPCRA Section 304 and CERCLA Section 103 at the Memphis/Shelby County Airport (Tennessee), the County Airport Authority agreed to implement a $475,000 pollution prevention SEP. The SEP involves the purchase of equipment that will assist in the deicing of runways. The use of this equipment will reduce the amount of deicing fluid required, which results in a substantial reduction in the use of ethylene glycol. In addition, the Authority agreed to pay a $9,000 penalty to resolve its past violations.

- EPA achieved a comprehensive settlement of a TSCA administrative complaint against the Port Authority of New York and New Jersey, which is a joint State agency that operates Kennedy and LaGuardia Airports in New York City. The Region had cited the Authority for multiple violations of PCB regulations at the airports. The settlement provides that the port authority will pay a civil penalty of $19,500 and conduct two SEPs. One SEP consists of a 3-year fluorescent bulb recycling program for all Port Authority facilities in the New York metropolitan area. The total cost to implement the SEP is $130,000. The second SEP is a storm water management training program that will be conducted at the airports over a 2-year period. This SEP will cost $90,000.

- American Airlines, Inc. was charged with violations of the RCRA land disposal restrictions for discharging degreasing solvents, which are hazardous waste, into their onsite injection wells. A consent order was filed against American Airlines, in which it agreed to pay a cash penalty of $20,000, take affirmative actions to prevent further injection of restricted wastes, and conduct a SEP in the amount of $385,235. The SEP reduces chrome wastes by subjecting them to a chrome waste recovery system. The system reduces the waste by 98 percent or, in this case, 6,969 pounds per year. In addition, this system results in the elimination of 26 million gallons of wastewater annually into injection wells.

VII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VII.A. Sector-Related Environmental Programs and Activities

VII.A.1. EPA Voluntary Programs

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative developed by EPA that focuses on improving environmental performance, encouraging voluntary compliance, and building working relationships with stakeholders. EPA initiated a one year pilot program in 1995 by selecting 12 projects at industrial facilities and federal installations that demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, pollution prevention, community involvement, and mentor programs. In return for participating, pilot participants received public recognition and were given a period of time to correct any violations discovered during these experimental projects.

EPA is making plans to launch its full-scale Environmental Leadership Program in 1998. The full-scale program will be facility-based with a 6-year participation cycle. Facilities that meet certain requirements will be eligible to participate, such as having a community outreach/employee involvement programs and an environmental management system (EMS) in place for 2 years. (Contact: http://es.inel.gov/elp or Debby Thomas, ELP Deputy Director, at (202) 564-5041)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the April 23, 1997 Federal Register Notice. (Contact: Fax-on-Demand Hotline (202) 260-8590, Web: http://www.epa.gov/ProjectXL, or Christopher Knopes at EPA's Office of Policy, Planning and Evaluation at (202) 260-9298.)

Climate Wise Program

EPA's ENERGY STAR Buildings Program is a voluntary, profit-based program designed to improve the energy-efficiency in commercial and industrial buildings. Expanding the successful Green Lights Program, ENERGY STAR Buildings was launched in 1995. This program relies on a 5-stage strategy designed to maximize energy savings thereby lowering energy bills, improving occupant comfort, and preventing pollution—all at the same time. If implemented in every commercial and industrial building in the United States, ENERGY STAR Buildings could cut the nation's energy bill by up to $25 billion and prevent up to 35% of carbon dioxide emissions. (This is equivalent to taking 60 million cars of the road). ENERGY STAR Buildings participants include corporations; small and medium sized businesses; local, federal and state governments; non-profit groups; schools; universities; and health care facilities. EPA provides technical and non-technical support including software, workshops, manuals, communication tools, and an information hotline. EPA's Office of Air and Radiation manages the operation of the ENERGY STAR Buildings Program. (Contact: Green Light/Energy Star Hotline at 1-888-STAR-YES or Maria Tikoff Vargas, EPA Program Director at (202) 233-9178 or visit the ENERGY STAR Buildings Program website at http://www.epa.gov/appdstar/buildings/)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program saves money for businesses and organizations and creates a cleaner environment by reducing pollutants released into the atmosphere. The program has over 2,345 participants which include major corporations, small and medium sized businesses, federal, state and local governments, non-profit groups, schools, universities, and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. As of March 1997, participants had lowered their electric bills by $289 million annually. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and an information hotline. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Green Light/Energy Star Hotline at 1-888-STAR-YES or Maria Tikoff Vargar, EPA Program Director, at (202) 233-9178.)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1997, the program had about 500 companies as members, one third of whom are Fortune 1000 corporations. Members agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports. To member companies, EPA, in turn, provides technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne Oxley, EPA Program Manager, (703) 308-0199.)

NICE^3

The U.S. Department of Energy is administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 45 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, and demonstrate new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the forest products, chemicals, petroleum refining, steel, aluminum, metal casting and glass manufacturing sectors. (Contact: Chris Sifri, DOE at (303) 275-4723 or Eric Hass, DOE at (303) 275-4728 or http//www.oit.doe.gov/access/nice3.)

Design for the Environment (DfE)

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202) 260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at http://es.inel.gov/dfe.

VII.A.2. Trade Association/Industry Sponsored Activity

Industry Working Group on Deicing

A deicing working group was formed by the American Association of Airport Executives and the Airports Council International - North America to (1) study the use of deicing chemicals on aircraft; (2) study the feasibility of locating deicing facilities away from airport gates; and (3) provide information to both industry members and the federal government on ways in which deicing operations can be improved upon. As part of their investigation, the working group sent out surveys to the major airports to determine which deicing procedures and chemicals are being used by the industry. Some of the survey questions relate to environmental effects of deicing and recovery, reuse, and recycling of waste deicer. The results of the survey indicated that a number of air carriers are using alternative chemicals, and have constructed remote deicing facilities with deicer recovery systems. (Contact: Carter Morris, American Association of Airport Executives, (703) 824-0500.)

ISO 14000

ISO 14000 is a series of internationally-accepted standards for environmental management. The series includes standards for environmental management systems (EMS), guidelines on conducting EMS audits, standards for auditor qualifications, and standards and guidance for conducting product lifecycle analysis. Standards for auditing and EMS were adopted in September 1996, while other elements of the ISO 14000 series are currently in draft form. While regulations and levels of environmental control vary from country to country, ISO 14000 attempts to provide a common standard for environmental management. The governing body for ISO 14000 is the International Organization for Standardization (ISO), a worldwide federation of 110+ country members based in Geneva, Switzerland. The American National Standards Institute (ANSI) is the United States representative to ISO.

VII.B. Summary of Trade Associations

American Association of Airport Executives
4212 King Street
Alexandria, VA 22302
Phone: (703) 824-0500
Fax: (703) 820-1395

The American Association of Airport Executives (AAAE) is comprised of airport management personnel and representatives of companies serving the civil airport industry. The AAAE sponsors educational seminars, conducts examinations, and maintains a speakers' bureau. AAAE has an Environmental Service/Environmental Affairs Committee that provides assistance on complying with environmental regulations (e.g., regulation interpretations, training seminars, and manuals). Environmental compliance assistance is focused on the storm water rules. Publications are the bimonthly *Airport Executive Magazine* and the *Airport Report Newsletter*. Separate yearly conferences are held on topics such as national airports, legislative issues (semiannual), international facilities, and general annual issues.

Airports Association Council International
1220 19th Street NW, Suite 200
Washington, D.C. 20036
Phone: (202) 293-8500
Fax: (202) 331-1362

The Airports Association Council International (AACI) is comprised of operators of public airport facilities. The group also includes government bodies that own and operate major airports. The association provides compliance assistance to members through seminars, meetings, conferences, regulation interpretations, and manuals. One day conferences are frequently held on environmental management and auditing techniques. Committees include planning and environmental, safety and security, and U.S. government affairs. Publications are the weekly *Airport Highlights*, the annual *Worldwide Airport Traffic Report*, and the *Airport Environmental Management Handbook.* The AACI holds an annual meeting in September or October.

National Air Transportation Association
4226 King Street
Alexandria, VA 22302
Phone: (703) 845-9000
Fax: (703) 845-8176

The National Air Transportation Association (NATA) represents the interests of aviation services companies such as fixed-based operators and on-demand air taxis. NATA provides compliance assistance to members in the form of guidelines, explanations of regulations, and seminars. Most of NATA's work relates to Federal Aviation Administration regulations; however, environmental services are also provided. Environmental aspects of deicing and aircraft cleaning are not a major focus, because the membership does not include the carrier companies, however, some fixed-based operators carry out deicing operations. Publications include an annual membership directory, an annual report, and the monthly *ATAnews*.

Airports Council International - North America
1775 K Street, NW Suite 500
Washington, D.C. 20006
Phone: (202) 293-8500
Fax: (202) 331-1362

Airports Council International - North America (ACI-NA) is the "voice of airports" representing local, regional, state, and national governing bodies that own and operate commercial airports in the U.S. ACI-NA member airports enplane more the 90 percent of the domestic and virtually all of the international airliner passenger and cargo traffic in North America.

Aerospace Industries Association
1250 Eye Street, NW
Washington, D.C. 20005
Phone: (202) 371-8400

Member companies of Aerospace Industries Association (AIA) represent the primary manufacturers of military and large commercial aircraft, engines, accessories, rockets, spacecraft, and related items.

General Aviation Manufacturers Association
1400 K Street, NW Suite 801
Washington, D.C. 20005
Phone: (202) 393-1500

The General Aviation Manufacturers Association (GAMA) is a national trade association, headquartered in Washington, D.C., representing 53 manufacturers of fixed-wing aircraft, engines, avionics, and components. In addition to building nearly all U.S. general aviation aircraft, GAMA member companies also operate aircraft fleets, airport fixed-based operations, pilot schools, and training facilities.

Air Transport Association of America
1709 New York Ave., NW
Washington, D.C. 20006
Phone: (202) 626-4000
Fax: (202) 626-4181

The Air Transport Association of America (ATA) represents 22 major scheduled airlines in the U.S. engaged in transporting persons, goods, or mail by aircraft. ATA serves its membership by providing aviation safety, advocating industry positions, conducting designated industry-wide programs and monitoring public understanding. ATA publishes annually *Air Transport* as well as fact sheets, press releases, studies, speeches, and references pertaining to air transport. The ATA holds quarterly meetings.

Air Line Pilots Association
535 Herndon Parkway
P.O. Box 1169
Herndon, VA 20170
Phone: (703) 689-2270
Fax: (703) 689-4370

The Air Line Pilots Association (ALPA) is a union representing 46,000 airline pilots at 45 U.S. airlines. ALPA provides lobbying of airline pilot views to Congress and government agencies, and devotes approximately 20 percent of its dues income to support aviation safety.

Regional Airline Association
1200 19th Street, N.W. Suite 300
Washington, D.C. 20036
Phone: (202) 857-1170
Fax: (202) 429-5113

The Regional Airline Association (RAA) represents regional air carriers and suppliers of products and services that support the industry before the Congress, Federal Aviation Administration, Department of Transportation and other federal and state agencies. RAA member airlines transport between 90-95 percent of all regional airline passengers. RAA developed an *Environmental Compliance Handbook* addressing compliance issues.

Aircraft Owners & Pilots Association
421 Aviation Way
Frederick, MD 21701
Phone: (301) 695-2000

With over 270,000 members, the Aircraft Owners & Pilots Association (AOPA) represents the interests of general aviation pilots. It provides insurance plans, flight planning, and other services, and sponsors large fly-in meetings.

Helicopter Association International
1619 Duke Street
Alexandria, VA 22314
Phone: (703) 683-4646
Fax: (703) 683-4745

The members of Helicopter Association International (HAI) represent rotocraft operators and manufacturers.

National Association of State Aviation Officials
8401 Colesville Road, Suite 505
Silver Spring, MD 20910
Phone: (301) 588-0587
Fax: (301) 585-1803

The National Association of State Aviation Officials (NASAO) represents departments of transportation and state aviation departments and commissions from 49 states, Puerto Rico, and Guam.

National Business Aircraft Association
1200 18th Street, NW, Room 200
Washington, D.C. 20036
Phone: (202) 783-9000

The National Business Aircraft Association (NBAA) represents 361 companies that own and operate aircraft flown for corporate purposes. NBAA is affiliated with the International Business Aircraft Council.

Flight Safety Foundation
2200 Wilson Boulevard
Arlington, VA 22201
Phone: (703) 739-6700
Fax: (703) 739-6708

The Flight Safety Foundation (FSF) promotes air transport safety. Its members include airport and airline executives and consultants.

Experimental Aircraft Association
EAA Aviation Center
Oshkosh, WI 54903
Phone: (414) 426-4800

The Experimental Aircraft Association (EAA), with over 700 local chapters, promotes the interests of home-built and sport aircraft owners.

Aviation Distributors & Manufacturers Association
1900 Arch Street
Philadelphia, PA 19103
Phone: (215) 564-3484
Fax: (215) 564-3484

The Aviation Distributors & Manufacturers Association (ADMA) represents the interests of a wide variety of aviation firms including FBOs and component parts manufacturers.

International Air Transport Association
2000 Peel Street
Montreal, PQ, Canada H3A2R4
Phone: (514) 844-6311
Fax: (514) 844-5286

The International Air Transport Association (IATA) is an association of 105 international air carriers whose main functions include coordination of fares and operations.

Cargo Airline Association
1220 19th Street, N.W. Suite 400
Washington, D.C. 20036
Phone: (202) 293-1030
Fax: (202) 293-4377

The Cargo Airline Association (CAA) is a nationwide trade organization with members made up of all segments of the air cargo community. The Association is responsible for promoting the use of air freight services; monitoring regulatory activity; representing the industry before Congress, various agencies, and courts; providing educational programs; and keeping members up-to-date on all issues affecting air cargo.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviro$enSe Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the EnviroSenSe World Wide Web, set your World Wide Web Browser to the following address:

http://es.epa.gov/sector/index.html

or use

www.epa.gov/oeca - then select the button labeled Industry and Gov't Sectors and then select EPA Sector Notebooks . The Notebooks will be listed.

EPA Office Of Compliance Sector Notebook Project

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line EnviroSen$e Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE DRY CLEANING INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the dry cleaning industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

This notebook covers the entire dry cleaning industry which includes three distinct types of operations: commercial, industrial and coin-operated. The dry cleaning industry is covered by three Standard Industrial Classification (SIC) codes, the codes the Department of Commerce uses to track the flow of goods and services. The commercial sector is included in SIC 7216 (dry cleaning plants except rug cleaning). Commercial plants typically receive small quantities of clothes from individuals and usually do not clean furs or leathers although they offer non-dry cleaning services, such as refreshing garments. The industrial dry cleaning sector is included in SIC code 7218 (industrial launderers). According to the 1987 Census of Service Industries, there are 1,379 industrial laundry facilities. Of these, the Agency estimates that 325 have dry cleaning capacity (USEPA, 1993a) while the remainder are exclusively wet laundries. Industrial dry cleaners primarily clean uniforms and may also rent uniforms and other industrial clothing such as gloves. Coin-operated dry cleaning is included in SIC 7215 (coin-operated laundries and dry cleaning). The Census of Service Industries indicates that there are 27,180 coin-operated laundries (with and without payroll) in 1987. Of these, the Agency estimated that about 3,000 offer dry cleaning services of some kind (USEPA, 1993a) although some estimate that there are fewer than 100 of such cleaners in operation. Coin-operated dry cleaners may be self-service units located in laundromats or may be run by an attendant but located in a self-service laundromat.

II.B. Characterization of the Dry Cleaning Industry

The dry cleaning industry provides garment cleaning services and in most cases will provide related services such as clothes pressing and finishing. The dry cleaning process is physically very similar to the home laundry process, except that clothes are washed in dry cleaning solvent instead of water. Fabric or garment cleaning consists of three basic functions: cleaning, drying and finishing. Garments are pre-treated for stains, and then machine washed in a solution of a solvent, soaps and detergents. The solvent is extracted by first draining, and then spinning the clothes. Finally, the garments are dried through a combination of aeration, heat and tumbling, and then they are pressed.

These functions are the core of any fabric cleaning process, although the details vary and steps may be minimized or even omitted. All three functions are readily recognizable in the full-service dry cleaning process. Dry cleaners will also "refresh" a garment, concentrating mainly on finishing.

II.B.1. Industry size and geographic distribution

The number and size of dry cleaning firms varies within the three basic categories of dry cleaning operations. The commercial facilities are by far the most prevalent and include full service, retail operations located in shopping centers and near densely populated areas. The industrial dry cleaners operate the largest facilities which are often part of a business that rents uniforms, towels or other garments. The coin-operated sector of the market is typically associated with a laundromat that may provide either full-service retail dry cleaning similar to the commercial sector, or customer operated dry cleaning equipment. All sectors, however, provide a single basic service, clothes cleaning.

Commercial dry cleaning accounts for the majority of the firms with 30,494 facilities, as well as the majority of dry cleaning volume, 630,520 tons of clothes per year as shown in the exhibit below. The average commercial facility cleans approximately 19.7 tons of clothes per year. Industrial facilities while fewer in number, 325, have a larger average cleaning output of 578 tons of clothes per facility per year. Total dry cleaning volume of the industry sector is 187,991 tons per year. The coin-operated sector accounts for the smallest portion of the industry with 3,044 facilities processing 4,914 tons of clothes per year for an average 1.6 tons per facility.

R0074860

Exhibit 1: Commercial Dry Cleaners Dominate Industry

	Commercial	Industrial	Coin- Operated	Total
# of Facilities[a]	30,494	325	3,044[b]	33,863
Volume of Clothes Cleaned[c] (Tons/Year)	630,520	187,991	4,914	825,425
Mean Output per Facility[d] (Tons/year)	19.7	578	1.6	not applicable
Sales[e]	$4.8 billion	$385 million	$29 million	$5.2 billion

[a] USEPA, 1991b
[b] The number of coin-operated dry cleaning facilities estimated in USEPA, 1991b is high compared to a more recent estimate of <100 (Torp, 1994).
[c] Estimated values based on USEPA, 1991a and USEPA, 1991b.
[d] Volume/Number of facilities.
[e] USEPA, 1991b, some values were rounded (1993 dollars). Values indexed from 1989 dollars using the CPI for Apparel and Upkeep.

The size of dry cleaners varies by industrial sector. Most commercial dry cleaners are single facility "mom and pop" operations, although there is considerable variation in the size of these businesses. Classic family-owned-and-operated commercial cleaners typically have two or three full-time employees (including the owner) and perhaps some additional part-time employees. A typical firm might consist of a single small store front operation, with customer pickup and delivery in the front, and cleaning and finishing in the back. The store usually has one or two dry cleaning units (either a separate washer and dryer, or a combined "dry-to-dry" machine), and perhaps a water-based laundry machine for shirts and other washables.

Commercial dry cleaning is not a high profit business, and many dry cleaners are barely able to stay in business. Typical start-up costs in 1993 were $113,000, and over 60 percent of dry cleaners had annual revenues below $113,000; however, there is wide variation in the receipts. Official Census figures indicate one-quarter of the firms had annual revenues which were less than $28,000, and six percent had receipts over $564,000 in 1993 dollars (USEPA, 1991). The exhibit below shows the revenue distribution for commercial dry cleaners. The receipts must cover labor costs (by far the largest cost category), rent, capital depreciation, solvent and other supplies. Wages are typically low; the industry average operator wage is less than $7.00

R0074861

per hour. Many dry cleaners have difficulty paying competitive wages and earning any profit.

Exhibit 2: Very Small and Very Large Establishments Dominate Commercial Dry Cleaning (1993 dollars)

Annual Receipts ($/year) per Establishments	Number of Establishments	Percent	Total Annual Receipts ($1,000/year)	Percent
0-28,000	8,026	26%	160,474	53%
28,000-56,000	5,024	17%	229,611	5%
56,000-85,000	3,096	10%	233,950	5%
85,000-113,000-	3,096	10%	327,530	7%
>113,000	11,251	37%	3,857,651	80%
Total	30,494	100%	4,809,217	100%

Source: USEPA, 1993a

Coin-operated dry cleaners are gradually being phased out of the dry cleaning market. New coin-operated equipment is reported to be no longer available on the market (SRRP, 1990). The coin-operated segment of the dry cleaning industry resides in laundromats. There are two basic types of operations, including: commercial dry cleaners operating a laundromat and self-service dry cleaning operations. Commercial dry cleaners operating at a laundromat are classified as coin-operated because the dominant business at the location is the coin-operated laundromat. The dry cleaning side of the business can be fully staffed and provide the full services of a commercial dry cleaner. Alternatively, it can provide more limited service, with an operator receiving, cleaning, and returning batches of clothes to the customer, but not providing pressing, spotting or other services. The second type of coin-operated dry cleaning facility is the self-serve dry cleaning machine. These are truly coin-operated, with the customer operating the dry cleaning equipment. The exhibit below shows the total dry cleaning output and the average output per establishment as categorized by the coin-operated sector income. Comparing the total coin-operated dry cleaning sales from the first exhibit to total coin-operated sales below, shows that dry cleaning makes up only about 10 percent of the receipts in this sector, a much smaller fraction than for commercial or industrial laundries (USEPA, 1993a).

R0074862

Exhibit 3: Medium-Sized Establishments Dominate Coin-operated Dry Cleaning and Laundries
(1993 dollars)[a]

Annual Receipts ($/year) per Establishment	Number of Establishments[b]	Percent	Total Annual Receipts ($1,000/yr)	Percent
0-28,000	523	17%	10,425	4%
28,000-56,000	1,451	48%	66,180	23%
56,000-85,000	475	16%	35,888	12%
85,000-113,000	169	5%	17,664	6%
>113,000	426	14%	158,468	55%
Total	3,044	100%	288,627	100%

[a] Based on payroll converted to 1993 dollars using the CPI for Apparel and Upkeep.
[b] The distribution of establishments is based on the distribution of all coin-operated laundries with payroll (including those without dry cleaning capacity) reported in the 1987 Census of Service Industries.
Source: U.S. Environmental Protection Agency. 1993a. Economic Analysis of Regulatory Controls in the Dry Cleaning Industry. Final. EPA 450/3-91-021b. September.

Industrial dry cleaners tend to be larger than commercial establishments. They service institutional, professional and industrial customers by providing cleaning services for uniforms, restaurant linens, wiping towels, floor mats and work gloves. In many cases industrial dry cleaning firms offer rental as well as cleaning services. According to Census data, 1,379 industrial laundry facilities were operating in 1987 of which 325 were estimated to have dry cleaning operations. While sales for all operations at these facilities totaled $1.1 billion, only about 35 percent ($385 million) of the receipts were related to dry cleaning. The balance of receipts were from water washing or other activities (USEPA, 1993a).

Dry cleaners are spread throughout the United States although their location depends on both the type of operation and the solvent used. Commercial dry cleaners are distributed in a six to one ratio of urban to rural as a result of the greater demand for dry cleaning in urban settings. Their distribution roughly follows the population as shown in the exhibit below. Industrial laundries, however, tend to be located in medium to small cities to take advantage of the lower capital and labor costs. Industrial laundries are also less reliant upon being in their customer's immediate neighborhood. Coin-operated laundries tend to be in rural areas where commercial dry cleaning is not available. The type of solvent used for dry cleaning also varies by geographic region. Petroleum dry cleaners are concentrated in the Gulf states, particularly Texas and Louisiana, partly due to the availability of petroleum in these locations and partly because local fire regulations prohibit petroleum cleaners in many other regions.

Wyoming	0.1	4,168	50	51	454
Alaska	0.1	17,679	51	52	550
Total	100	5,069,031			248,710

[a] Number of facilities comes from the 1992 Census of Service Industries. Drycleaning plants, except rug cleaning (SIC 7216).
[b] Populations are from 1990 Census, Summary Population and Housing Characteristics, Table I: US Summary. Total may vary due to rounding.

Ward's Business Directory of U.S. Private and Public Companies, produced by Gale Research Inc., compiles financial data on U.S. companies including those operating within the dry cleaning industry. Ward's ranks U.S. companies, whether they are a parent company, subsidiary or division, by sales volume within the 4-digit SIC codes that they have been assigned as their primary activity. Readers should note that: 1) companies are assigned a 4-digit SIC that most closely resembles their principal industry; and 2) sales figures include total company sales, including subsidiaries and operations not related to dry cleaning. Additional sources of company specific financial information include Standard & Poor's *Stock Report Services*, Dun & Bradstreet's *Million Dollar Directory*, Moody's Manuals, and annual reports.

Exhibit 6: Top U.S. Companies with Dry Cleaning Operations

Rank[a]	Company[b]	1993 Sales (millions of dollars)
1	Initial USA, Inc. - Atlanta, GA	170
2	Concord Custom Cleaners - Richmond, KY	25
3	Dryclean USA, Inc. - Miami, FL	25
4	Pride Cleaners, Inc. - Leawood, KS	16
5	Fashion Care, Inc. - Atlanta, GA	10
6	Spic and Span, Inc. - Milwaukee, WI	10
7	Al Phillips the Cleaner, Inc. - Las Vegas, NV	8
8	Admiral, Inc. - Annapolis, MD	7
9	Walker, Inc. - Omaha, NE	3
10	WH Christian and Sons, Inc. - Brooklyn, NY	3

Note: [a] When Ward's Business Directory lists both a parent and subsidiary in the top ten, only the parent company is presented above to avoid double counting. Not all sales can be attributed to the companies dry cleaning operations.
[b] Companies shown listed SIC 7216 as primary activity.

II.B.2. Product characterization

The dry cleaner's product is the service of cleaning clothes conveniently. The products may also include services such as pressing and finishing. The market is divided into two parts, those customers who shop for price and will accept adequate quality and those who are buying quality cleaning with price being less of a concern. The latter are more steady dry cleaning customers while the former will forego dry cleaning during financial downturns.

II.B.3. Economic trends

In 1992, the total dry cleaning market generated $5.2 billion in revenues, with $4.8 billion generated by the commercial sector and $385 million and $29 million generated by the industrial and coin-operated sectors respectively. Current industry estimates indicate a zero growth rate for the commercial sector through 1996 while both the industrial and coin-operated sectors are anticipated to continue their decline during this period. More clothes are being made of launderable fabrics which reduces the demand for commercial dry cleaning. Self-service coin-operated dry cleaning machines are no longer manufactured and those currently in use are being phased out as they age. The trend toward launderable fabrics will inevitably reduce the need for industrial dry cleaning as well.

Convenience is the driving force in commercial dry cleaning. Location near the consumer and fast turnaround on their clothes as well as the cleanliness of the item are important to dry cleaning success. Consumers care little about what solvent is used to clean their clothes as long as the cleaning service is convenient, fast and effective. While the switch to launderable fabrics reduces the need for dry cleaning, the other services such as laundering, pressing and finishing may still be in demand.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the dry cleaning industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A. Industrial Processes in the Dry Cleaning Industry

Dry cleaning processes garments in a way that avoids saturating fabrics with water. If thoroughly saturated with water, agitated and heated, certain fabrics (especially wool, silk and rayon) may shrink or the dye may run. Other garments that are constructed from several materials can be damaged if the various layers react differently to the cleaning process. Because dry cleaning solvents do not saturate the fibers of the fabric, the swelling and shrinking from water saturation is avoided, allowing nearly all types of fabrics and garments to be safely dry cleaned.

Four solvents dominate the dry cleaning market: perchloroethylene (PCE), petroleum solvents, chlorofluorocarbons (CFC-113) and trichloroethane (TCA). The manufacture of the latter two will be banned in 1995 under the Clean Air Act Amendments. The exhibit below shows that PCE dominates the commercial sector while petroleum solvent is used in the majority of industrial machines.

One important characteristic of the dry cleaning industry is that the machinery used with these solvents has evolved over time. The development encompasses four "generations" of machines, all of which are still in use. The first generation of equipment has separate washers and dryers, thus the operator must transfer the clothes between the two. The second generation machine design eliminates the stand-alone dryer and combines both washing and drying into a single machine. The third generation of equipment includes added control technology to reduce the vapor emissions. The fourth generation of machine design modifies the third generation by recycling the air in the machine to further reduce emissions. Each generation is described further below.

Exhibit 7: Number of Dry Cleaning Facilities by Process and Industrial Sector[a]

Process Solvent	Industrial Sector			
	Commercial	Industrial	Coin-operated	Total
PCE	24,947	130	3,044	28,121
Petroleum	4,548[b]	195	0	4,743
CFC-113	949[b]	0	0	949
Trichloroethane	50[c]	0	0	50
Total	30,494	325	3,044	33,863

[a] USEPA, 1991b, unless otherwise indicated.
[b] Estimate based on USEPA, 1991a.
[c] Wolf, 1992.

First Generation Machines

The first generation of dry cleaning machines had separate washers and dryers. These transfer machines (so-called because the wet clothes were transferred from the washer to the dryer) were the predominant type of machine used until the late-1960s, when dry-to-dry machines were developed that reduced solvent loss and improved dry cleaning economics. In a typical transfer process, the clothes are loaded into the washer, where the solvent is combined with a water and detergent charge, and the clothes and solvent are agitated by rotation of the washer's drum. After washing, the drum is rotated at high speeds to extract the residual solvent. The clothes are then manually transferred to a dryer where recirculating warm air causes most of the remaining solvent to vaporize. To reduce wrinkling, the drying cycle is followed by a brief cool-down cycle during which unheated air is circulated through the clothes (USEPA, 1991). A flow diagram for a typical PCE transfer machine is shown below. The advantages of using transfer equipment are: (a) more production since a new load is being washed while the previous one is being dried; (b) less complicated construction with less automation and thus greater ease of repair; and (c) reduction of fabric damage since the cylinder remains cool after the prior load is removed. The disadvantages are:

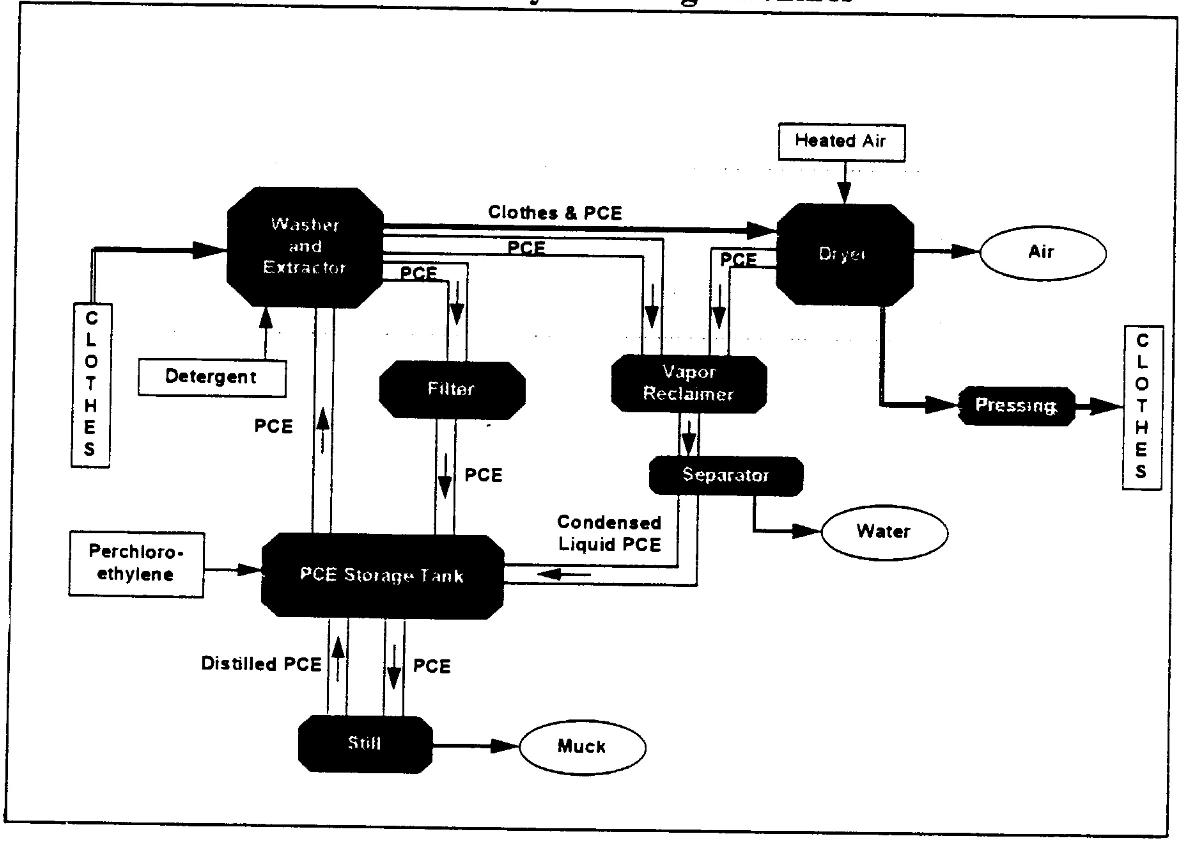
(a) the additional labor required to handle the heavy volume; (b) the solvent vapors that escape to the atmosphere during transfer; (c) exposure of the worker to the solvent; and (d) the garments that can fall on the floor during transfer. Currently, about 34 percent of dry cleaning machines in the U.S. are transfer units (Brown, 1993). However, the National Emissions Standards for Hazardous Air Pollutants (NESHAP) for PCE dry cleaning facilities will not allow new transfer machines that use PCE (USEPA, 1993b). Transfer machines cannot be converted to dry-to-dry machines, but they can be retrofitted with vapor control devices and with impermeable enclosures to capture fugitive emissions. Two technologies that can capture the solvent that escapes during clothing transfer are hamper enclosure and room enclosures.

Hamper enclosures consist of a hood or canopy usually made of polyethylene -- impervious plastic that encloses the clothing hamper and the open door of the washer when clothing is removed from the washer of a transfer machine and placed in the dryer. The same canopy is used when transferring the clothes from the hamper to the dryer (Environmental Reporter, 1992).

Room enclosures usually consist of a metal frame covered with clear impervious plastic that encloses both the washer and dryer of a transfer machine. During clothing transfer, a fan is turned on to draw air from outside the room enclosure through louvered door openings in the enclosure and then to a vapor emission control device.

R0074871

Exhibit 8: Process Flow Diagram for Perchloroethylene Solvent Transfer Dry Cleaning Machines



Source: Adapted from USEPA, 1991b

Second Generation Machines

Transfer units were used exclusively until the late 1960s, when a second generation of equipment was introduced to reduce the amount of space the machines occupied and to decrease solvent consumption. Called "dry-to-dry" machines, these units integrate the washing and drying into the same unit. This saves space, requires less labor (because the operator does not have to transfer garments), reduces the amount of solvent vapor that escapes, lowers worker exposure to solvent vapor, and generates a higher solvent mileage (the quantity of solvent needed to clean a quantity of clothes). The disadvantages are lower production and less flexibility, since each machine is committed to a single load during its entire wash-dry cycle. Dry-to-dry machines currently comprise 66 percent of the units used in the U.S. (Brown, 1993). Of these, 32 percent are the vented units (2nd generation machines) that are designed

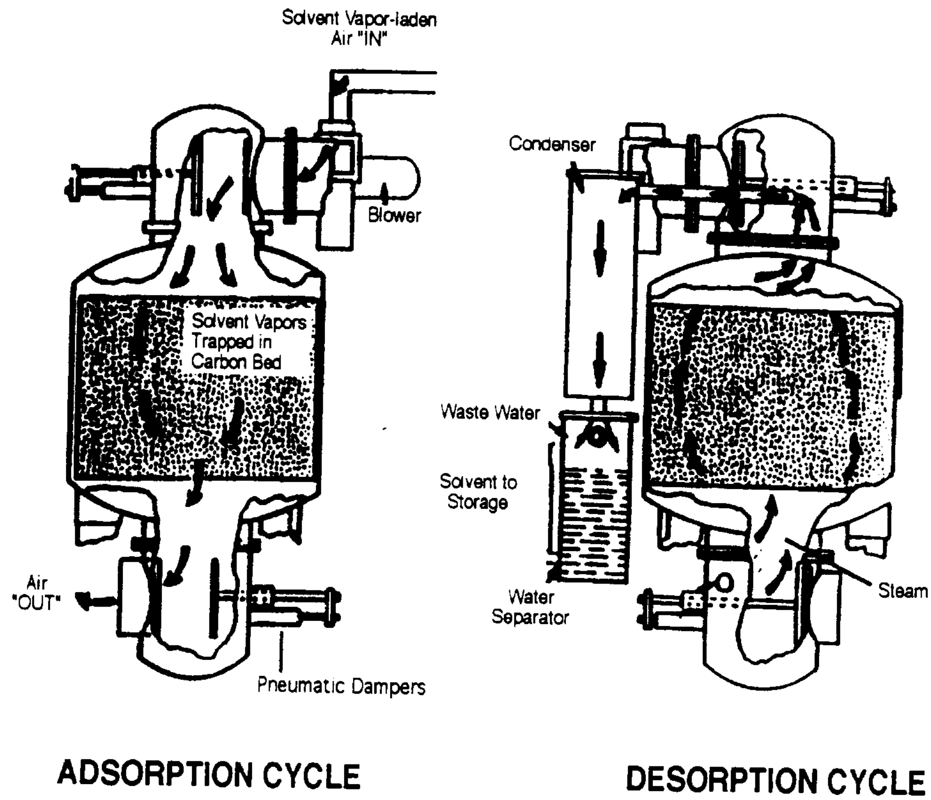
R0074872

to send residual vapors to the atmosphere or an external control device (Brown, 1993). The remainder are third or fourth generation machines as described below. Second generation machines can be retrofitted with control devices such as carbon adsorbers (not allowed under current regulations) and refrigerated condensers.

Carbon adsorbers recover solvent by sending contaminated air through a bed of activated carbon that then adsorbs[a] the solvent vapors as shown below. The adsorbed solvent is recovered by passing low-pressure steam (new designs use hot air) through the carbon bed. The mixed steam and solvent vapors are then passed through a water-cooled condenser and are collected in a phase separator.[b] The carbon is dried and reused while the recovered solvent is returned to the dry cleaning system (SRRP, 1990). Carbon adsorbers can be retrofitted to both dry-to-dry and transfer machines. In tests of carbon adsorbers, the removal efficiencies were above 95 percent (USEPA, 1991). However,.subsequent data from the California Air Resources Board led the Agency to believe that in actual practice the removal efficiencies are much lower. As a result, the NESHAP does not allow them as an option for primary control except in certain large facilities where carbon adsorbers were installed prior to the promulgation of the regulation, September 22, 1993.

[a] The system will hold molecules on its surface (adsorb) and then release them (desorb) when steam is passed through the bed.

[b] PCE and water are reasonably insoluble in the liquid phase. The cooled PCE/water mixture will enter the phase separator where two layers will form. The PCE will then be drawn off for recycling.



Source: USEPA 1991a

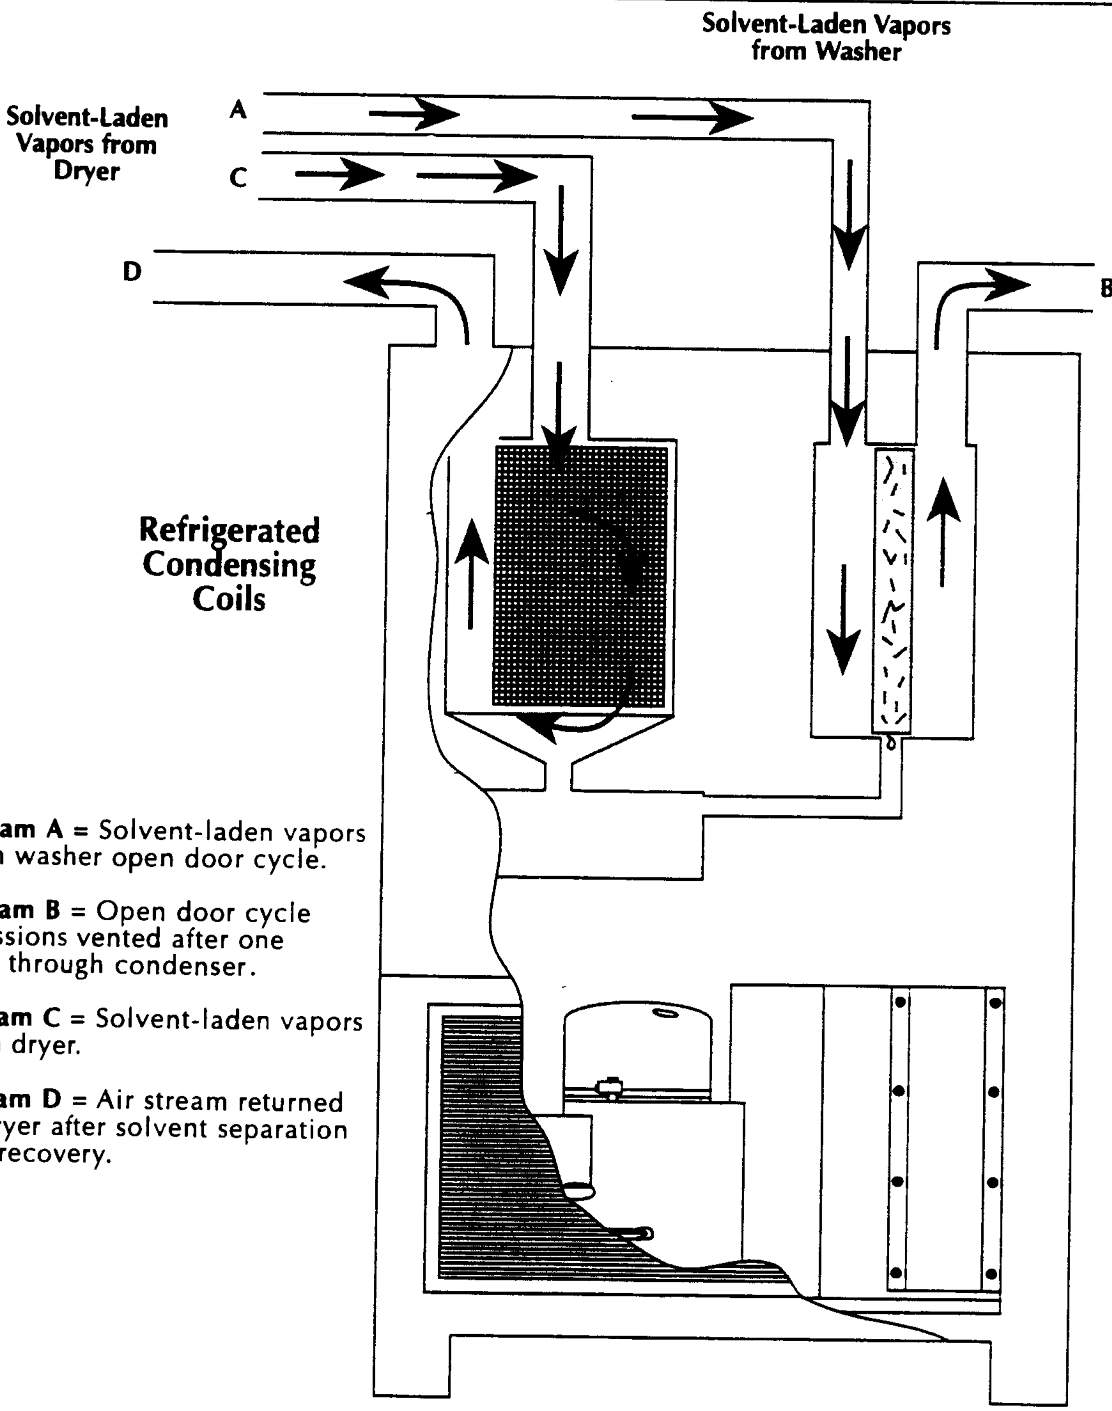
Exhibit 9: Flow Diagram of a Carbon Adsorber

Refrigerated condensers have both an advantage and a disadvantage when compared to carbon adsorbers. They require less maintenance because the refrigerant only needs to be replaced yearly while carbon adsorbers must be desorbed daily.[c] The disadvantage of refrigerated condensers compared to carbon adsorbers is that they cannot be used to control low concentration emission streams (USEPA, 1991a).

[c] The desorption of solvent is accomplished by passing steam (or hot air) through the carbon bed.

Refrigerated condensers remove vapors from the exhaust stream by cooling them to below their dew points. Most new machines have built-in refrigerated condensers, but the condensers can be retrofitted to both transfer and dry-to-dry machines (USEPA, 1991a). Refrigerated condensers achieve about 95 percent control of HAPs when compared to uncontrolled machines (Smith, 1995). The figure below shows a typical refrigerated condenser that can accommodate two HAP (hazardous air pollutant such as PCE)-laden streams. In transfer machines, a stream (Stream A) from the exhaust fan used when the washer door is opened will feed through the condenser and be vented (Stream B) and a stream from the dryer (Stream C) passes through the condenser, and after separation and recovery of the solvent returns the air stream to the dryer (Stream D). Dry-to-dry machines only have the second stream. In transfer machines, the exhaust vapors from the washer are vented (in one pass) through the condenser to the atmosphere, and thus the system can achieve only about 85 percent control of HAPs compared to an uncontrolled machine (USEPA, 1991a).

Exhibit 10: Flow Diagram of a Refrigerated Condenser



Stream A = Solvent-laden vapors from washer open door cycle.

Stream B = Open door cycle emissions vented after one pass through condenser.

Stream C = Solvent-laden vapors from dryer.

Stream D = Air stream returned to dryer after solvent separation and recovery.

A refrigerated condenser as applied to a transfer dry cleaning machine.

Source: USEPA 1991a

R0074876

Third Generation Machines

The third generation of machines that were designed in the late 1970s and early 1980s are dry-to-dry with built-in refrigerated condensers. These are closed loop machines. A closed-loop machine does not vent air to the atmosphere but recycles it continuously throughout the dry cleaning cycle. The only air exchange with the atmosphere occurs during loading and unloading. Thirty-four percent of the machines currently in use in the U.S. are of this design (Brown, 1993). The advantage is a single unit that will release smaller amounts of vapor. The disadvantage is the greater complexity of machine design which could lead to higher maintenance costs and more frequent breakdowns. The principles of operation are the same as for the second generation machines that use refrigerated condensers.

Fourth Generation Machines

The fourth generation machine is a non-vented, closed loop process with an additional internal vapor recovery device. The control technologies used in these machines are refrigerated condensers and carbon adsorbers. In non-vented, closed loop machines, refrigerated condensers can match carbon adsorber's 95 percent control efficiency (USEPA, 1991a).

Technological Trends

The recent technological trends have been to increase mileage and to reduce emissions. The increased mileage decreases solvent costs for the facility while the reduced emissions are driven by both environmental and worker protection laws. In September, 1993 the Agency promulgated a National Emission Standard for Hazardous Air Pollutants (NESHAP) for Perchloroethylene Dry Cleaners. These regulations require both existing and new facilities that meet certain size requirements to use designated vapor control technologies and undertake leak detection and equipment repair to prevent fugitive emissions. Occupational Safety and Health Act regulations have imposed limits on worker exposure to perchloroethylene which has led to machine designs that reduce emissions from opening the door after operation. For petroleum solvents the trend has been towards development of solvents with higher flash points to reduce the explosion potential and to solvents with lower volatile organic compound content to reduce VOC emissions.

One of the most important current developments in the industry is the commercialization of aqueous alternatives for a portion of the clothes currently dry cleaned. Multi-process wet cleaning is a method of hand cleaning clothes using a controlled application of water. It is called "multiprocess" because a number of different steps can be included in the process depending upon the fabric type and the soil and stains on the garment. A cleaning technician inspects incoming garments for the degree of soiling and based on that and the fiber type a cleaning process is chosen. The process could be spotting, localized steaming, hand washing or machine washing. A flow diagram of multi-process wet cleaning is shown below. The second aqueous alternative is machine wet cleaning. This process uses a specially designed washing machine that reduces the agitation the clothes are subject to in a traditional laundering process and adds proprietary chemicals (that satisfy the German environmental regulations) to reduce fiber swelling. These machines have been used profitably in Europe (primarily Germany) and are now being introduced into the U.S. market by several manufacturers. The process is diagramed below. The critical test for market acceptance will be the percent of the current U.S. dry cleaning clothes stream that these processes can clean effectively without damaging the garments. Two firms in New York City currently are using a combination of the two aqueous processes and report eighty percent repeat business.

III.B. Raw Material Inputs and Pollution Outputs

The primary dry cleaning releases are to air (through both fugitive emissions and direct release at the end of the cycle), water (from water that was contained in the clothes and from regenerating carbon adsorbers) and solid waste (such as the muck from stills used to evaporate solvent-contaminated water, the residue remaining after contaminated solvent is filtered, and the carbon from an adsorber). There is an active recycling market for solvent recovered from dry cleaning facilities, although the overall percentage of solvent recovered is not known.

R0074880

Exhibit 13: Pollution Releases from Dry Cleaning Operations

Release Medium	Emissions
Air	Solvent spills Fugitive leaks from piping Vapor released with transferring or removing clothes from machines Vapor release from clothes dryers Residual vapor release from clothes after they are removed from the dryer
Water	Water from separator
Hazardous/Solid Waste	Residue from solvent still Filters

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7 percent between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 800-535-0202), or directly from the Toxic Release Inventory System database. (For user support call 202-260-1531)

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weights to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- is the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20 through 39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emission occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

R0074883

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for storm water runoff and non-point losses must also be included.

Releases to Land -- includes disposal of toxic chemicals in waste to on-site landfills, land treated or incorporation into soil, surface impoundments, spills, leaks. or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Dry Cleaning Industry

The Toxics Release Inventory (TRI) covers only manufacturers categorized in two-digit SIC codes 20 through 39. Therefore dry cleaning facilities which are categorized as service industry establishments (SIC 72) are not required to report to TRI. However, solvent releases from dry cleaners were estimated by the Agency for two regulatory actions, the 1993 NESHAP for HAPs (excluding petroleum solvents) and the 1984 Petroleum Dry Cleaners New Source Performance Standard. The information is explained below.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear on the first list. The second list contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations -- some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time are available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), and the Hazardous Substances Data Bank (HSDB), accessed via TOXNET. TOXNET is a computer system run by the National Library of Medicine. It includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health.[d] HSDB contains chemical-specific information on manufacturing and use.

[d] Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Release Inventory).

chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB. For more information on TOXNET, contact the TOXNET help line at 800-231-3766.

Perchloroethylene (tetrachloroethylene) (CAS: 127-18-4)

Toxicity. Chronic exposure to perchloroethylene (PCE) has been linked to damage to the central nervous system and to a lesser extent, the lungs, liver, and kidneys. Exposure to PCE is irritating to the eyes, skin, and respiratory system.

Ecologically, experimental application of PCE to a freshwater pond led to the local extinction of several phytoplankton and zooplankton species.

Carcinogenicity. PCE is a possible human carcinogen via oral exposure.

Environmental Fate. PCE released to surface water or the soil rapidly evaporates. PCE is not expected to significantly biodegrade, bioconcentrate in aquatic organisms, hydrolyze, or significantly adsorb to sediments or soil particles. PCE released to the atmosphere degrades rapidly in the presence of sunlight. It may be subject to washout in rain.

IV.C. Other Data Sources

The primary releases from the dry cleaning industry are associated with the many solvents used. As mentioned in Section III.A., four solvents dominate: perchloroethylene, petroleum solvents, chlorofluorocarbons and trichloroethane. Estimates of national releases of hazardous air pollutants (HAPs) (excludes petroleum solvents) from the baseline estimate prior to the 1993 NESHAP are 90,200 tons/year from the commercial sector, 4,800 tons/year from the industrial sector and 990 tons/year from the coin-operated sector for a total of 95,900 tons/year. The total quantity of HAPs disposed of off-site is 47,500 tons per year and is primarily from filtration residue. The recent NESHAP will reduce the air emissions by prohibiting the sale of new transfer equipment, requiring control devices on existing equipment, and requiring new equipment to be fitted with controls. The most recent petroleum solvent emission data available for the dry cleaning industry are from 1982 in support of the 1984 New Source Performance Standards. Applying the release factor

R0074886

of 23 pounds of solvent per 100 pounds of clothes cleaned to the total petroleum-based facility throughput yields total petroleum solvent releases of 51,000 tons per year. These releases are distributed approximately equally between commercial and industrial plants (there are no coin-operated petroleum plants). Over 75 percent of the releases are from dryers with the remainder from a combination of evaporation from filters, still releases and fugitive emissions. These values may slightly overestimate current releases because vapor control technologies such as carbon adsorbers or condensers may have been added to existing machines.

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. Exhibit 14 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM_{10}), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 14: Pollutant Releases (short tons/year)

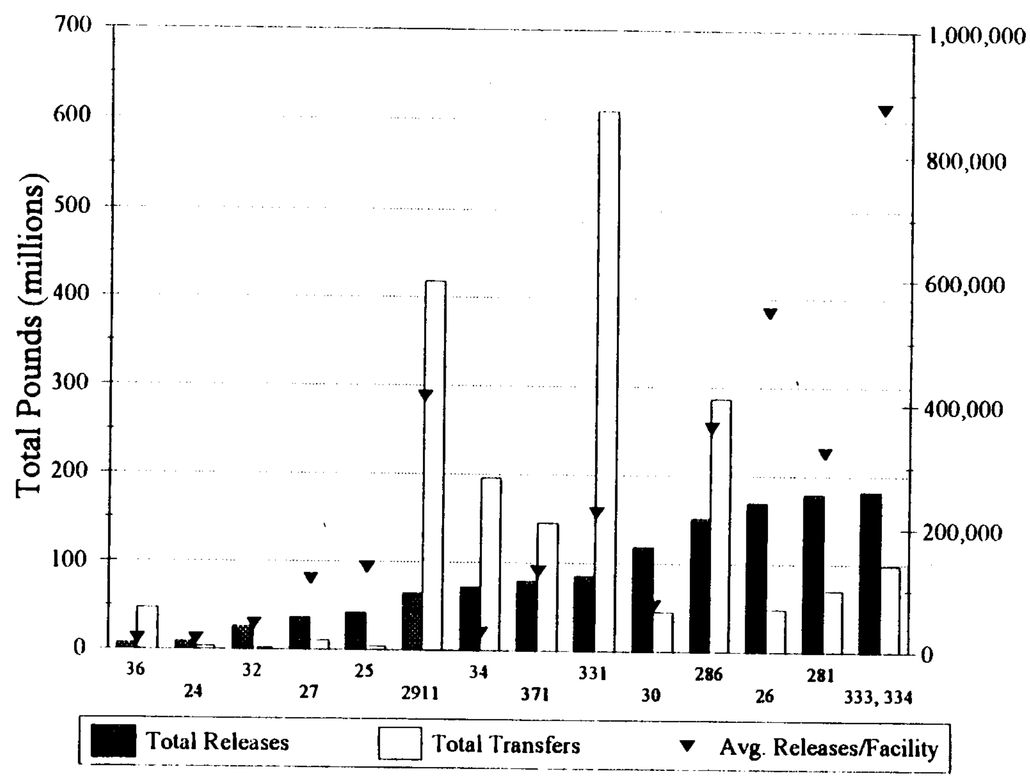
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following figure and table do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. In addition, the dry cleaning industry sector is not subject to TRI reporting and therefore is not presented in Exhibits 14 and 15. Similar information is available within the annual TRI Public Data Release Book.

Exhibit 15 is a graphical representation of a summary of the 1993 TRI data for the dry cleaning industry and the other sectors profiled in these notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 16 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors.

Exhibit 15: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg.
24	Lumber and Wood Products	34	Fabricated Metals	26	Pulp and Paper
32	Stone, Clay, and Concrete	371	Motor Vehicles, Bodies, Parts, and Accessories	281	Inorganic Chemical Mfg.
27	Printing	331	Iron and Steel	333, 334	Nonferrous Metals
25	Wood Furniture and Fixtures	30	Rubber and Misc. Plastics		

Exhibit 16: Toxics Release Inventory Data for Selected Industries

Industry Sector	SIC Range	# TRI Facilities	1993 TRI Releases: Total Releases (million lbs.)	1993 TRI Releases: Average Releases per Facility (pounds)	1993 TRI Transfers: Total Transfers (million lbs.)	1993 TRI Transfers: Average Transfers per Facility (pounds)	Total Releases + Transfers (million lbs.)	Average Releases + Transfers per Facility (pounds)
Stone, Clay, and Concrete	32	634	26.6	42,000	2.2	4,000	28.8	46,000

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the dry cleaning industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

V.A. Pollution Prevention Opportunities for the Dry Cleaning Industry

A number of major changes within the dry cleaning industry are pushing dry cleaners toward pollution prevention. Projects such as the Design for the Environment, the import of European technologies, and increased attention on the part of state and federal regulators to dry cleaning have caused trade associations, technical assistance offices, and individual establishments to investigate possible techniques for reducing the environmental releases associated with dry cleaning. Pollution prevention approaches over the short term for existing facilities and equipment include: improved operating practices or "good housekeeping" and process and equipment retrofits. Over the long-term, there are several new fabric cleaning processes under development, some of which are commercially available while others are still in the research stage. Market forces might take longer than command and control regulations to influence cleaning technologies, as new technologies will only be adopted as existing equipment is retired and replaced.

R0074892

As pointed out in Section IV.C, air releases of perchloroethylene and petroleum solvents used to clean the fabric are the primary environmental release from dry cleaning. Spills, inadequate storage and drain disposal of solvents have led to groundwater contamination. In addition, (improper) disposal of solvent laden material, such as filters, as nonhazardous solid waste is of concern.

Because chemicals constitute a large cost for dry cleaners, particularly if drying exhaust is vented directly to the atmosphere, there are significant opportunities to reduce chemical use and possibly reduce operating costs. Reduced chemical use can, in turn, reduce the waste management costs associated with regulatory requirements as well as reduce potential financial liability. Some pollution prevention strategies may reduce risk but involve a higher energy consumption.

Several operating practices can reduce potential solvent exposure if they are used regularly. The practices of importance will vary based on the type of machine. For example, the major release in a transfer machine occurs when clothes are transferred. Because dry-to-dry machines wash and dry in a single container there are no such releases. Listed below are several specific practices that may reduce releases.

Improved Operating Practices- Specific to Transfer Machines

Conduct transfer of solvent saturated clothes from washer to dryer as quickly as possible.

Close dryer door immediately upon completion of transfer.

Improved Operating Practices - All Machines

Clean the filters that precede the carbon filters weekly.

Clean lint screens to avoid clogging fans and condensers.

Open button traps and lint baskets only long enough to clean.

Check baffle assembly in cleaning machine bi-weekly.

Use closed containers for collection and storage of recovered or new solvent.

Equipment Maintenance

Clean drying sensors weekly.

Replace seals regularly on dryer deodorizer and aeration valves.

Replace door gasket on button trap.

Replace gaskets around cleaning machine door or tighten enclosure.

Repair holes in air and exhaust duct.

Secure hose connection and couplings.

Clean lint buildup on cooling condenser coils weekly.

Equipment Modification

Use a hamper enclosure or a room enclosure of impermeable construction to reduce solvent release during transfer. The enclosure should be a complete vapor barrier, especially if the dry cleaner is located in a mixed use residential setting.

Use local exhaust ventilation through washer and dryer doors or exhaust hoods between washer and dryer. The exhaust velocity should be 100 feet per minute. In addition, a supplemental door fan local exhaust system should be included on third generation equipment. This should vent through a small carbon adsorber designed to control PCE emission levels between 5-20 ppmv.

Install general ventilation that changes the air every five minutes.

Place dry cleaning equipment in separate room at negative pressure and operate a separate exhaust system to control the vapors.

Place washer and dryer close together to minimize solvent losses during transfer.

Replace the cartridge filters with spin disk filters that can be cleaned without opening. This would produce fewer fugitive emissions and less hazardous waste.

Install distillation equipment where the still bottoms can be removed without opening the still. This reduces fugitive emissions.

Use carbon adsorber that is regenerated with hot air stripping rather than steam stripping. This reduces the waste stream.

Use double carbon waste water treatment devices to clean up PCE contaminated waste waters. Recycle the treated waste water to the process boiler.

Chemical Substitutions

Alternative petroleum solvents are being developed with higher flash points to reduce the fire hazard.

Alternative petroleum solvents are being developed with lower VOC content (the drawback, however, is the longer drying time).

Use wet cleaning processes.

Major Equipment Upgrades

Add a refrigerated condenser to the machine for primary control, followed perhaps by a carbon adsorber for secondary control.

Replace a transfer machine with a dry-to-dry machine.

Upgrade a dry-to-dry machine with additional control equipment such as a spill container that will catch and recycle solvent spills from the machine.

Replace current machine with a dry-to-dry closed-loop-non-vented machine that contains an integral refrigerated condenser and an integral carbon adsorber.

Technological Innovation

The majority of the hazardous solid waste is generated by the carbon adsorbers. Several technologies are being developed that use a polymer surface for adsorbing the solvent vapor. The surface can be regenerated by heating and, unlike carbon, does not need to be replaced, thus reducing the hazardous waste.

New aqueous processes that do not use organic solvents as the primary solvent were mentioned in Section III.B. Multiprocess wet cleaning and machine wet cleaning have both been introduced in several sites in the U.S.

New processes that use other cleaning methods are also under development. Both ultrasonic cleaning and a clothes cleaning method that uses liquid carbon dioxide are under development.

Both pollution prevention and end-of-pipe controls have the potential to substantially reduce the risk from toxic chemical release. The primary difference is the size of the initial investment. For example, to retrofit a dry-to-dry perchloroethylene machine with a refrigerated condenser costs about $7,500 while replacing the existing unit with a fourth generation machine that is closed-loop with a built-in refrigerated condenser and secondary controls is about $47,000 (35 pound machine). However, the total cost per pound of clothes cleaned over a fifteen year lifetime is nearly identical ($0.48 to $0.50) when the solvent savings are considered. The fourth generation machine also produces lower solvent releases to air and water and creates less hazardous waste. However, with 25 percent of commercial dry cleaners taking in annual receipts of less than $28,000, the initial investment required for a new machine may be prohibitive. (Information developed for OPPT's Design for the Environment Program.)

The aqueous processes have recently been introduced to the U.S. market. They reduce pollution considerably by not introducing toxic chemicals as the primary solvent. The multiprocess wet cleaning method is cost competitive with conventional dry cleaning although in preliminary short term testing it is more labor intensive. The performance of these cleaning methods has yet to be determined on a broad scale although the Agency's Design for the Environment (DfE) test site should provide this data within two years.

Liquid carbon dioxide and the ultrasonic cleaning are currently in the development stage. While neither of these technologies uses toxic chemicals, the technical and economic feasibility must be demonstrated before they are true market options.

Most commercial dry cleaners are small shops. Over twenty-five percent of dry cleaners have owners of Korean descent. Commercial dry cleaners may not be in compliance with current regulations because of lack of familiarity with the law or communication barriers. Dry cleaners get much of their technical information from their trade associations and their equipment suppliers who may only have information on their products. This could limit the dissemination of information on innovative alternatives such as machine wet cleaning which tends to be manufactured by washing machine makers rather than dry cleaning machine makers.

The Agency's Design for the Environment program has already participated in a number of outreach activities. These include attending trade shows to discuss alternatives, conducting a demonstration of multiprocess wet cleaning and arranging for a demonstration of several alternative technologies over the next two years. A full description of the program is provided in Section VIII.A.

Showing the commercial viability of alternatives is likely to produce the largest leverage for pollution prevention since dry cleaners are skeptical that new technologies will clean as well as the current process. However, current fashion trends, the introduction of new washable fabrics and the increased use of casual (washable) clothes in the work place have created opportunities for new processes and the increased use of traditional laundry.

Pollution prevention will reduce the releases of solvents to air and water and reduce the quantity of solid waste produced. Controlling releases will reduce worker exposure, customer exposure and the exposure of residents in multi use buildings that contain dry cleaners. Some pollution prevention efforts may also be cost effective for the dry cleaner if the solvent savings are significant. Finally, the fact that a dry cleaner is environmentally sound could be used in marketing. If customers prefer such "green cleaning," the fact that a cleaner is practicing pollution prevention could increase sales.

VI. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section VI.A. contains a general overview of major statutes
- Section VI.B. contains a list of regulations specific to this industry
- Section VI.C. contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting

R0074898

program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and record keeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil** storage and disposal regulations (40 CFR Part 279) do not define **Used Oil Management Standards** impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

R0074901

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compiie the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES

permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.
A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing, or raw material storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards.

R0074905

The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control** (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide

R0074906

available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Regulatory Requirements

The dry cleaning industry is becoming increasingly regulated at the Federal, State and local levels. Some of the regulations are directed specifically at dry cleaners such as the new National Emission Standard for Hazardous Air Pollutants (NESHAP) for Perchloroethylene Dry Cleaning. Other regulations are more general but are also likely to affect a significant part of the industry such as standards on underground tank storage. The major Federal laws that affect dry cleaners are identified below, as well as a few state regulations that may be indicators of national trends.

Occupational Safety and Health Act

The Occupational Safety and Health Administration proposed a 25 part per million permissible exposure level (PEL) for perchloroethylene that was to take effect on January 19, 1989. Before December 31, 1993, the PEL could be met by using personal protective equipment; however, after that date the PEL needed to be met by controls. Development of new dry cleaning machines (fourth generation) with recycling air and additional controls was underway to meet the requirement when the proposed limit was remanded in March 23, 1993, because of legal and administrative technicalities. The PEL reverted to 100 ppm; however, some states have already included the 25 ppm level in their regulations.

Clean Air Act Amendments of 1990

A number of provisions of the Clean Air Act Amendments (CAAA) of 1990 affect the dry cleaning industry. The most recent is the September 1993 promulgation of the National Emission Standards for Hazardous Air Pollutants (NESHAP) for the Perchloroethylene Dry Cleaning Industry covering the 80 percent of the industry that uses perchloroethylene solvent. These standards prohibit the sale of new transfer machines (although existing, those machines installed prior to December 1993, transfer machines are allowed), require retrofitting of existing (defined as installed prior to December 1993) dry cleaning equipment with control devices (if they fall under the large area and major source classifications) and require new machines to be sold with such technology (40 CFR §63.320). Title VI of the Clean Air Act Amendments of 1990 calls for a ban on chlorofluorocarbons in the year 2000 and on trichloroethane in 2002 because of their ozone depleting potential. In February of 1992, President Bush announced that the ban on CFCs and TCA would be effective in the United States on December 31, 1995. The Agency also issued New Source Performance Standards (NSPS) for petroleum-based dry cleaners in 1984 (petroleum-based dry cleaners represent less than 15 percent of the market) (49 FR 37328). These are applicable in CAA non-attainment areas and may also have been adopted by individual states. They set limits on solvent loss from drying, set standards on the use of filters, and require leaks to be repaired in a timely fashion. Dry cleaners must add control devices to reduce solvent loss from the washer and dryer as well as the filters. In addition, they must monitor their machines more closely for leaks.

Comprehensive Environmental Response, Compensation and Liability Act (1980) and Superfund Amendments and Reauthorization Act (1986)

Dry cleaners or their landlords may be held joint and severally liable for perchloroethylene contamination of the site under the Comprehensive Environmental Response, Compensation and Liability Act (Superfund) (40 CFR §305). The contamination may occur by having PCE containing waste water leak through sewer pipes or by leaks of PCE during normal operation.

Resource Conservation and Recovery Act

Under the Resource Conservation and Recovery Act (RCRA) dry cleaners who generate 100 kilograms (220 pounds) or more of perchloroethylene solid wastes (hazardous waste code D039) such as still bottoms, cartridge filters and filter muck each month are regulated under RCRA and must dispose of their wastes at a licensed hazardous waste facility (40 CFR. §260-270). Small quantity generators are defined as those who generate less than 100 kilograms and are exempt from this regulation (40 CFR §261.5). The slightly contaminated waste water generated by dry cleaners from various sources is considered hazardous waste under RCRA because it was derived from an F002 waste. The toxicity characteristic leaching procedure (TC) cutoff for perchloroethylene is 0.7 ppm. Typical separator water contains about 150 ppm and is therefore considered hazardous because it exceeds the TC level.

Underground Storage Tanks

Dry cleaning facilities that store either petroleum or perchloroethylene in an underground storage tank are subject to the Agency's underground storage tank regulations which require that the tank must be protected from corrosion, be equipped with devices that prevent spills and overfills and must have a leak detection method that provides monitoring for leaks at least every 30 days (40 CFR §265.190-196).

Clean Water Act

Discharges to a POTW - Facilities discharging wastewater to a sewer are often subject to restrictions required under the Clean Water Act (CWA). These restrictions are established by the local sewerage authority to prevent significant interference with the treatment facility or pass-through of pollutants not removed by treatment (40 CFR §125). The specific requirements include: notifying the POTW of discharges that could cause problems at the POTW, monitoring and record keeping as established by the POTW and a one-time notice of the discharge of hazardous waste, specifically if more than 33 pounds/month.

State Regulations

Several states have developed additional dry cleaning regulations. New York and California serve as examples.

New York

A negotiating committee of organizations representing dry cleaners, equipment manufacturers, consumer interests and regulatory agencies reached conceptual agreement in March 1994 on revised regulations to control emissions from dry cleaning facilities in New York State. The regulations include requirements for operator training and certification, equipment certification, inspection and monitoring, and stringent new equipment standards which include the retrofitting of existing equipment. A finalized draft will be released before the end of the year for public comment.

The agreement calls for the phased replacement of older dry cleaning equipment with state-of-the-art closed-loop machines that use a refrigerated condenser and an integrated carbon adsorber. The regulations call for the complete phase out of older transfer machines by 1996, the addition of vapor barriers or room enclosures by late 1995 for dry cleaners using older machines, and room ventilation systems providing a complete air exchange every five minutes.

The agreement specifies that manufacturers and/or vendors of new dry cleaning equipment must have their equipment tested and certified that it meets certain standards before it can be installed. The committee is developing new standards covering the operation and maintenance of dry cleaning facilities that will go into effect in 1996. (Contacts: Lenore Kuwik 518-457-2224 and Michael Barylski 607-753-3095 at the NY State Department of Environmental Conservation)

California

The California regulations are contained in the Airborne Toxic Control Measure (CATCM) for Emissions of Perchloroethylene from Dry Cleaning Operations (17 and 25 CCR §93109). The requirements for existing and new facilities regarding dry cleaning equipment include initial notification of installation, annual reporting to the state, maintenance of good operating practices to reduce emissions, and fugitive emissions control when applying water repellent using PCE as the solvent. Existing facilities must use either a converted closed-loop machine with a primary control system or a closed-loop machine with a primary control system. New facilities are required to use a closed-loop machine with both primary and secondary control systems once their district's have approved the ATCM.

Districts within California are allowed to supersede the ATCM if district regulations are more stringent than State regulations. At this time, only the Bay Area and the South Coast Air Quality Management Districts have proposals to supersede the ATCM; other districts are assumed to be following the ATCM. (Contact: Todd Wong, California Air Resources Board, 916 322-8285)

The **Bay Area Air Quality Management District** (BAAQMD) has proposed stricter controls than the ATCM including secondary controls and vapor barrier rooms in residential facilities and ventilation systems in non-residential facilities. They also allow evaporators to be used with certain minor criteria attached. (Contact: Scott Lutz, Bay Area Air Quality Management District, 415-749-4676)

The **South Coast Air Quality Management District** (SQAQMD) Proposal 1421 includes the control requirements in California's ATCM while keeping the NESHAP requirements for record keeping, inspection, and repair. Reporting requirements are derived from a combination of both the NESHAP and the ATCM. Specifically, Proposal 1421 requires that relocating facilities obtain a permit as if they were new facilities, waste water elimination systems be used, and facilities keep records of their solvent use for five years.

The SCAQMD is also creating the requirements for establishing a list of approved equipment. The basic structure is that the manufacturers/distributors will demonstrate the 1421 compliance of their equipment. Once the equipment has been approved, it will be added to the list of equipment considered in compliance with the regulations. The SCAQMD hopes this will facilitate dry cleaner adherence to the regulations. (Contact: Pierre Sycip, South Coast Air Quality Management District, 909-396-3095)

VI.C. Pending and Proposed Regulatory Requirements

Petroleum solvents are currently regulated under the new source performance standards for VOCs and will be listed as a source category for toxic substances in the year 2000. (Contact: Steve Shedd, U.S. EPA, 919-541-5397)

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within

R0074913

the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[e] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

This section provides summary information about major cases that have affected this sector, and a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

The final part of this section provides highlights from interviews with several knowledgeable EPA inspectors. These interviews provide the inspector's viewpoint on where compliance problems occur, why they occur, and possible solutions to eliminate these problems. The reader should not reach any definitive conclusions about an industry sector's ability or willingness to

[e] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

comply based on these interviews. These interviews provide only anecdotal information about the interactions occurring between inspectors and the facilities they inspect.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with three enforcement actions counts as one). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with three enforcement actions counts as three).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Reported inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and TSCA.

Facilities with One or More Violations Identified -- indicates the number percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column may exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Dry Cleaning Industry Compliance History

Exhibit 17 provides an overview of the reported compliance and enforcement data for the dry cleaning industry over the past five years (August 1990 to August 1995). These data are also broken out by EPA Region thereby permitting geographical comparisons. A few points evident from the data are listed below.

- Within the limited universe of dry cleaning facilities retrieved from the database search, the number of dry cleaning facilities inspected was only 26 percent of those identified. In the past five years, the facilities identified were inspected on average every seven to eight years.

- A significantly larger proportion of facilities identified in the database search had been inspected than had enforcement actions brought against them.

- State lead enforcement actions accounted for almost all of the enforcement actions brought against dry cleaning facilities over the five year period.

Exhibit 17: Five-Year Enforcement and Compliance Summary for Dry Cleaning

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 18 and 19 allow the compliance history of the dry cleaning industry to be compared to the other industries covered by the industry sector notebooks. Comparisons between Exhibits 18 and 19 permit the identification of trends in compliance and enforcement records of the industry by comparing data covering the last five years to that of the past year. Some points evident from the data are listed below.

- Of those sectors listed, the dry cleaning industry has been the least frequently inspected industry over the past five years. The average time between inspections for the facilities identified is 88 months.
- The industry has a relatively small percentage of facilities with violations and enforcement actions, in comparison to the other sectors.
- The rate of enforcement actions per inspection over the past five years is relatively high for the industry, but has decreased over the past year.

Exhibits 20 and 21 provide a more in-depth comparison between the dry cleaning industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Exhibits (Exhibits 18 and 19), the data cover the last five years (Exhibit 20) and the last one year (Exhibit 21) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- The number of inspections carried out under each environmental statute as a percent of the total number of inspections has changed only slightly between the average of the past five years and that of the past year.
- The number of enforcement actions taken under RCRA dominate both the percentage of inspections as well as the percentage of enforcement actions.
- In the past year there has been a significant drop in the proportions of enforcement actions taken under RCRA from the average of the past five years, primarily resulting from an increase in enforcement actions taken under CWA.

VII.C. Review of Major Legal Actions

This section provides summary information about major cases that have affected this sector, and a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

VII.C.1. Review of major cases

Historically, OECA's Office of Regulatory Enforcement does not regularly compile information related to major cases and pending litigation within an industry sector. The staff are willing to pass along such information to Agency staff as requests are made. In addition, summaries of completed enforcement actions are published each fiscal year in the Enforcement Accomplishments Report. To date, these summaries are not organized by industry sector. (Contact: Office of Enforcement Capacity and Outreach, 202-260-4140)

VII.C.2. Supplementary Environmental Projects (SEPs)

Each Region's summary of Supplemental Environmental Projects (SEPs) undertaken in federal fiscal years 1993 and 1994 were reviewed. None was identified as being applied to a dry cleaning operation or establishment. Many process changes have been demonstrated which may be suitable for use as SEPs (see Pollution Prevention Opportunities - Section V.). However, because federal enforcement actions within the dry cleaning industry are few (one during the period from 1989-1994), the chances that SEPs are recommended or adopted for dry cleaners is reduced.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

Design for the Environment

The Environmental Protection Agency's Design for the Environment (DfE) program uses a non-regulatory, voluntary, and pro-active approach in working with industry and environmental and human health groups to reduce risk. The Design for the Environment (DfE) program was created by the Office of Pollution Prevention and Toxics of the U.S. Environmental Protection Agency in 1992 to promote the incorporation of pollution prevention principles in the design of products and processes through voluntary partnerships with industry, professional organizations, state and local governments, other federal agencies, and the public. The DfE provides businesses with the information needed to design for the environment and to help businesses use this information to make environmentally informed choices. The DfE program also works to make sure that the information reaches the people who make the choices - from buyers to industrial design engineers.

The Dry Cleaning (DfE) program has identified control technologies and alternative solvents and processes that might be used to reduce solvent releases from the industry. The Agency is evaluating the risks, costs and benefits of each alternative (including setting up an alternative process demonstration) and will publicize the results so that individual dry cleaners can understand the pros and cons of each alternative. Examples of the DfE's work in the dry cleaning industry include the following:

The DfE convened the International Roundtable of Pollution Prevention and Control in the Dry Cleaning Industry. Researchers, industry representatives, and government officials met to exchange information on issues related to the dry cleaning industry, including exposure reduction, regulation, and information dissemination.

The DfE program is producing a Cleaner Technologies Substitute Assessment (CTSA) for the dry cleaning industry to examine both existing and emerging technologies. The Agency expects to release a draft CTSA on existing technologies and another on emerging technologies sometime in 1995. The first phase of the CTSA will examine traditional, solvent-based technologies.

The new or alternative technologies, such as multiprocess wet cleaning, machine wet cleaning, liquid carbon dioxide technology, and microwave drying will be addressed in the second phase of the CTSA.

In November and December of 1992, the DfE program, in collaboration with the dry cleaning industry, conducted a short term, high volume demonstration to compare the costs and performance of an aqueous alternative process (multiprocess wet cleaning) to the traditional dry cleaning method that uses perchloroethylene.

As part of the Agency's outreach program, the DfE partnership produced a wet cleaning brochure entitled *Summary of a Report on Multiprocess Wet Cleaning*, to assist dry cleaners and consumers in learning more about how their choices and actions can affect the environment. The Agency also has distributed brochures and fact sheets on alternative cleaning processes, compiled case studies and success stories, and produced exhibits at trade shows to keep the public and the dry cleaning industry informed of the DfE project's activities.

To further test the viability of the wet cleaning process, the Agency has launched a two-year demonstration project in three demonstration sites around the United States that will establish the performance of wet cleaning methods under "real world" conditions. Two demonstration sites will test the full range of garments typically handled by professional clothes cleaners using only various wet cleaning technologies/techniques; while the one site will offer both wet and dry cleaning services. Technologies to be tested include: multiprocess wet cleaning; machine-based wet cleaning; and microwave drying to be used in combination with both cleaning methods.

The DfE project is developing a certification program centered around solvent use reduction, worker safety, and consumer awareness.

The Agency currently is working with the Federal Trade Commission on the labeling of "Dry Clean Only" garments. Public comments are being reviewed regarding proposed changes that attempt to allow for other forms of cleaning without increasing the liability of the dry cleaner. Currently, if a "Dry Clean Only" garment is damaged when cleaned using an alternative method, the dry cleaner is held liable. If the same garment is damaged during the dry cleaning process, the manufacturer is held liable. Proposed changes will make the garment label less restrictive and allow other forms of cleaning to be used without penalty. (Contact: Pollution Prevention Clearinghouse, PPIC, 202-260-1023)

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases of eighteen chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases by 33 percent as of 1992 and by 50 percent as of 1995. Certificates of Appreciation have been given out to participants meeting their 1992 goals. The list of chemicals includes seventeen high-use chemicals reported (including perchloroethylene) in the Toxics Release Inventory and dioxin. Because dry cleaning is a service, dry cleaners are not eligible for the 33/50 program even though perchloroethylene is covered by the program. (Contact: Mike Burns 202-260-6394 or 33/50 Program 202-260-6907)

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and state agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentor programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. At this time, no dry cleaning operations are ELP participants. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, U.S. EPA, 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995, Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis 202-260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Maria Tikoff at 202-233-9178 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA, in turn, provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn 202-260-0700 or the WasteWi$e Hotline at 800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman 202-260-4407)

Office of Enforcement Compliance Assurance

The Office of Compliance is compiling a list of resource materials on pollution prevention and contacts in the dry cleaning industry. This is the first of several projects planned to help reduce risk from dry cleaners. (Contact: Joyce Chandler 202-564-7073)

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Environmental programs

Several trade associations including the Neighborhood Cleaner's Association, the International Fabricare Institute (IFI) and the state and regional affiliates of IFI have instituted environmental programs. Theses include: introducing an environmental certificate program that provides members information on good environmental practices and then tests them on this knowledge, training sessions in alternative technologies, and information pamphlets on environmental laws and compliance. The additional trade association activities are listed below.

VIII.C.2. Summary of trade associations

Neighborhood Cleaners Association (NCA)
252 West 29th Street
New York, NY 10001-5201
Tel: (212) 967-3002 Contact: Bill Seitz

The NCA is a worldwide trade organization with over 4,000 members. NCA provides outreach to its members through monthly bulletins, through the NCA's Consumer Education Program, and educational courses on dry cleaning issues. NCA also offers representation for its members at all levels of government including the Federal Trade Commission.

R0074929

Federation of Korean Drycleaners Association (FKDA)
25606 Alicia Pkwy
Lagona Hills, CA 92653
Tel: (714) 770-8613 Contact: Hank Kim

The FKDA was founded in 1986 and is an umbrella organization representing 30 regional Korean dry cleaning associations throughout the U.S. It represents approximately 12,000 members, and educates its members by providing FKDA newsletters as well as organizing educational seminars on subjects such as pollution prevention and other critical issues.

International Fabricare Institute (IFI)
12251 Tech Road
Silver Spring, Maryland 20904
Tel: (301) 622-1900 Contact: Joe Meijer

The association is a worldwide organization of dry cleaners and launderers as well as organizations and individuals concerned with professional garment cleaning, care and serviceability. There are currently over 12,000 members. The association provides publications to aid members technically and in business, represents cleaners' interest in legislative activities, as well as provides testing services for products and training for employees.

State Fabricare Institutes

Many states or regions have trade associations that are affiliated with the International Fabricare Institute. For more information call the IFI.

Textile Care Allied Trade Association, Inc. (TCATA)
200 Broadacres Drive
Bloomfield, NJ 07003
Tel: (201) 338-7700 Contact: David Cotter

TCATA has existed since 1920 and represents manufacturers and distributors of commercial laundry and dry cleaning equipment and supplies. There are currently 275 members. Its primary concern is addressing issues that affect the industry's allied trades exclusively. The association provides newsletters to its members; coordinates an annual convention; co-sponsors a biennial trade show; and provides information on machinery requirements and certain market information.

Fabricare Legislative And Regulatory Education (FLARE)
P.O. Box 5157
Naperville, IL 60567-5157
Tel: (708) 416-6221 Contact: Manfred Wentz

FLARE is a volunteer organization led by members of International Fabricare Institute, Neighborhood Cleaners Association, R.R. Streets and Co.(a dry cleaning supply company), and the Textile Care Allied Trade Association. FLARE is committed to ensuring favorable treatment by local media and providing representation at all levels of government. The majority of their attention currently is given to environmental legislation and regulation affecting the fabric care industry; however, the FLARE organization is designed to address a much broader spectrum of legislation and regulation as well as public relations issues affecting the industry.

Center for Emission Control (CEC)
2001 L Street, N.W.
Suite 506A
Washington, DC 20036
Tel: (202) 785-4374 Contact: Steve Risotto

The CEC is an independent not-for-profit organization established in October 1990 to act as a clearinghouse for information about, and to encourage the development and use of, safe and effective work practices, process modifications, control technologies, and other methods to reduce emissions of chlorinated solvent. The CEC has developed a control option document on solvent applications in the dry cleaning industry. The organizations also may undertake and support research and development projects for the creation or application of new technologies or products that will reduce emissions of chlorinated solvents.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the Dry Cleaning Industry a list of publications and contacts are provided below:

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

Superintendent of Documents, Mail Stop: SSOP, Washington, DC 20402-9328
ISBN 0-16-048269-0

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviro$ense Bulletin Board and via Internet on the Enviro$ense World Wide Web. Downloading procedures are described in Appendix A of this document.

ELECTRONICS AND COMPUTER INDUSTRY (SIC 36)

I. Introduction to the Sector Notebook Project

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE ELECTRONICS/COMPUTER INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Electronics/Computer industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

The electronics/computer industry is classified by the U.S. Bureau of Census as SIC code 36. SIC 36 includes manufacturers of electrical distribution equipment, household appliances, communication equipment, electrical industrial apparatus, radio and television receiving equipment, electronic components and accessories, electrical wiring and lighting equipment, and other electrical equipment and supplies. The electronics/computer industry is comprised of five major sectors: telecommunications, computers, industrial electronics, consumer electronics, and semiconductors. Many segments of the electronics/computer industry are interdependent and share common manufacturing processes.

The Department of Commerce provides the following three-digit breakout for industries in SIC 36:

- SIC 361 - Transformers
- SIC 362 - Motors/Generators
- SIC 363 - Household Appliances
- SIC 364 - Electrical Wiring and Lighting Equipment
- SIC 365 - Household Audio and Video Equipment and Audio Recordings
- SIC 366 - Communication Equipment
- SIC 367 - Printed Wiring Boards (also commonly called Printed Circuit Boards), Semiconductors, Integrated Circuits, and Cathode Ray Tubes
- SIC 369 - Storage Batteries, Primary Batteries (wet and dry).

In 1988, the U.S. Bureau of Census reclassified some of the manufacturing of computer parts, such as semiconductors, printed wiring boards, and integrated microcircuits, and included them with the component industries in SIC code 36. For the purpose of this profile, computer equipment (SIC 35) and the electronics/computer industry (SIC 36) have been combined because of the overlapping industry segments. Currently there is no SIC code for electronic assemblies manufactured by the electronic manufacturing services industry (EMSI), otherwise known as contract assemblies. Electronic assemblies are sometimes classified under SIC 3679 as indicated by the Institute for Interconnecting and Packaging Electronic Circuits (IPC).

Due to the vast size of the electronics and computer industries, this profile will focus on the distinct equipment and products that raise environmental concerns.

II.B. Characterization of the Electronics/Computer Industry

The electronics/computer industry produces a variety of products such as batteries, televisions, computer chips/components, and household appliances. During the manufacture of many of these products, chemicals are released into the environment. This profile will focus on three products:

SIC 3674 - Semiconductors and Related Devices
SIC 3672 - Printed Wiring Boards (PWBs)
SIC 3671 - Cathode Ray Tubes (CRTs).

The profile focuses on semiconductors and not integrated circuits because integrated circuits are used to produce semiconductors and most electronic devices manufactured today are multiple devices/circuit chips. Semiconductors, although accounting for only a small portion of total industry sales, are crucial to all electronic products and to the U.S. economy and pose numerous environmental concerns. PWBs and CRTs also raise environmental concerns from their manufacturing processes.

The following sections describe the size and geographic distribution, product characterization, and economic trends of the electronics/computer industry and specifically semiconductors, PWBs, and CRTs. The information provided in the following sections was compiled from a variety of sources including the Bureau of Census, documents developed by The World Bank, U.S. International Trade Commission, and the U.S. Department of Commerce.

II.B.1. Industry Size and Geographic Distribution

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

Size Distribution

The U.S. has the largest electronics (including computer) workforce in the world, although Japan, the Republic of Korea, and other Asian nations are experiencing rapid growth in their electronics workforces. The size of the U.S. domestic electronics workforce for SIC 36 was estimated to be 2.39 million in 1991, while the number of worldwide employees was estimated to be four million. In addition, the electronics/computer industry is estimated to provide four million additional jobs to people who support and service U.S. electronics firms. The electronics/computer industry provides more jobs than any other manufacturing sector in the U.S., three times as many jobs as automotive manufacturing, and nine times more than the steel industry. The electronics/computer industry has not, however, experienced growth in domestic employment for the past two and one-half years. In fact, since 1989, the industry has lost 210,000 jobs.

IPC states that this stagnation in job growth is caused primarily by two factors: increased productivity and increased competition by foreign manufacturers that may have fewer government regulations. IPC also notes that the U.S. electronic manufacturing services industry or contract assembly industry is one of the fastest growing industries in the country, employing over 150,000 people.

The following exhibit lists the segments of the industry highlighted in this profile, as well as the number of facilities with fewer than and greater than 20 employees. Just under 50 percent of semiconductor and PWB manufacturing facilities have greater than 20 employees.

Exhibit 1
Facility Size Distribution of Electronics/Computer Industry

SIC Code	Number of Facilities with <20 Employees	Number of Facilities with > 20 Employees	Percentage of Facilities with > 20 Employees
3674 Semiconductors and Related Devices	484	439	48%
3672 Printed Wiring Boards	734	591	45%
3671 Cathode Ray Tubes	120	69	37%

Source: Based on 1992 Bureau of the Census data, Preliminary Report Industry Series.

Exhibit 2 lists the top ten electronics/computer industry companies worldwide according to a 1992 addition of *Electronic News*. The companies are listed in descending order of electronic sales during the latest available four quarters in 1992. Many of these top ten companies are not from the United States. However, a representative from the Electronic Industries Association (EIA) noted that many of these international companies have manufacturing facilities in the United States. Corporations that are among the top 25 in terms of electronic sales include AT&T, General Motors, Xerox, Apple Computer, Hewlett Packard, Motorola, and General Electric.

Exhibit 2
Top 10 Worldwide Electronics/Computer Industry Companies

Company Name	1992 Electronic Sales in Millions of Dollars
IBM	$53,600
Matsushita Electric	$48,668
Toshiba	$29,232
NEC	$28,375
Fujitsu	$25,879
Philips	$25,747
Hitachi	$25,107
Siemens	$24,550
Sony	$22,959
Alcatel Alsthom	$20,892

Source: Based on 1992 Electronic News.

Geographic Distribution

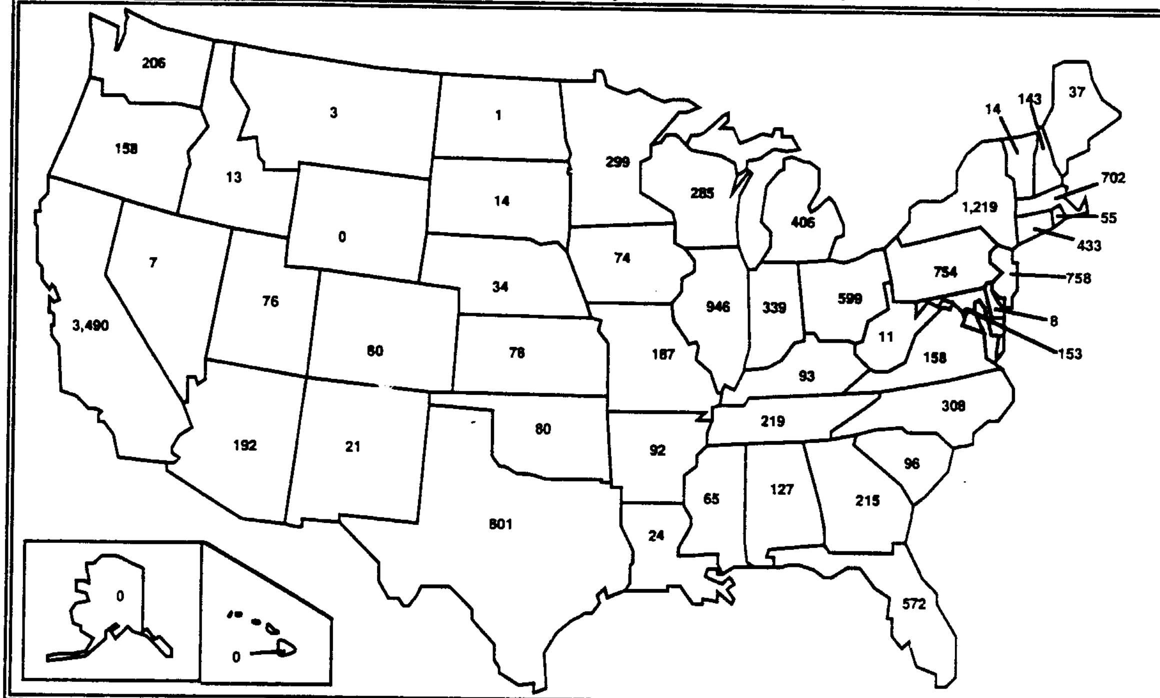
Exhibit 3 displays the number of electronics/computer industry facilities in each State for SIC 3671, 3672, and 3674. As seen in Exhibit 4, approximately 38 percent (3,689) of the facilities in the electronics/computer industry are located in EPA Region IX[1]. Region V has approximately 13 percent of the electronics/computer industry facilities. Across the U.S., approximately 60 percent of the facilities in the electronics/computer industry are located in six States: California (34 percent), Texas (6.5 percent), Massachusetts (6.4 percent), New York (4.5 percent), Illinois (4.4 percent), and Pennsylvania (4 percent).

The U.S. semiconductor industry is concentrated in California, New York, and Texas, specifically to be near primary users, transportation routes, utility and telecommunication infrastructures, and engineering experts. Texas, Oregon, and Colorado also received a large portion of capital investments by semiconductors producers during 1986-1992. Manufacturers have selected these States because of low tax rates, land values, and energy prices.

California has the largest concentration of industry workers, accounting for almost one-third of the semiconductor industry's employment. Texas, Arizona, New York, and Massachusetts also have high employment in the semiconductor industry. The majority of PWB manufacturers are located in Texas, California, Illinois, New York, Minnesota, and Massachusetts. According to Dun & Bradstreet, approximately 51 manufacturers produce cathode ray tubes (CRTs) in the U.S.; most of them are located in Illinois, Indiana, Ohio, Kentucky, Pennsylvania, and California (1994).

[1]EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

Exhibit 3
Geographic Distribution of and Number of Companies in the Electronics/Computer Industry (SIC 3671, 3672, and 3674)



Source: Based on 1992 Bureau of the Census data.

Exhibit 4
Percentage of Companies in the Electronics/Computer Industry (SIC 3671, 3672, and 3674) by Region

Region I:	10.8%	Region VI:	7.2%
Region II:	8.0%	Region VII:	1.4%
Region III:	6.0%	Region VIII:	3.4%
Region IV:	7.6%	Region IX:	37.6%
Region V:	13.1%	Region X:	4.8%

II.B.2. Product Characterization

Semiconductors

Although semiconductors account for only a small portion of electronics/computer industry sales, this product is crucial to all electronic products and to the U.S. economy. Semiconductors can serve one of two purposes: they act as a conductor, by guiding or

R0074959

moving an electrical current; or as an insulator, by preventing the passage of heat or electricity. Semiconductors are used in computers, consumer electronic products, telecommunication equipment, industrial machinery, transportation equipment, and military hardware. Typical functions of semiconductors in these products include information processing, display purposes, power handling, data storage, signal conditioning, and conversion between light and electrical energy sources. According to EPA's Design for the Environment (DfE) initiative, computers are the principal end use of semiconductors, constituting 40 percent of the market in 1992.

Printed Wiring Boards

Computers are also the major U.S. market for PWBs, with communications being the second largest application market. The Institute for Interconnecting and Packaging Electronic Circuits (IPC) indicates that nearly 39 percent of printed wiring boards produced in 1993 were used by the computer market, while 22 percent were used by the communication industry. PWBs and assemblies are used in many electronic products such as electronic toys, radios, television sets, electrical wiring in cars, guided-missile and airborne electronic equipment, computers, biotechnology, medical devices, digital imaging technology, and industrial control equipment.

Cathode Ray Tubes

According to EPA's Common Sense Initiative (CSI) subcommittee, the CRT industry produces tube glass, color picture tubes and single phosphor tubes, television sets, and computer displays. Currently, nearly all projection television tube and computer display manufacturers and the majority of CRT glass manufacturers are located outside the United States. Therefore, this CRT industry profile focuses on the production of color picture tubes, single phosphor tubes, and rebuilt tubes (collectively called CRTs and categorized under SIC 3671). These products are the video display component of televisions, computer displays, military and commercial radar, and other display devices.

II.B.3. Economic Trends

For the past two decades, worldwide production of electronics (including computers) has grown faster than any other industrial sector. The American Electronics Association (AEA) estimates that domestic sales of U.S. electronics companies increased from $127 billion to $306 billion during the period from 1980 to 1990. According to the U.S. Department of Commerce, the value of shipments (sale of computer products and services) in the computer industry declined during the 1990-1991 recession, but has experienced growth since then. The value of shipments increased two percent in 1993 to $8.3 billion and is expected to increase another two percent in 1994, to $8.48 billion. U.S. exports of the electronics/computer industry have increased at an average rate of 18 percent since 1977.

EIA indicates that the U.S. electronics/computer industry has experienced a 13 percent growth in production in 1994. Japan now holds the largest share of global consumer electronics production; 49 percent in 1990. Although the U.S. produced a little over 10 percent of global consumer electronics equipment, it is one of the two largest consumers of such products, with purchases totaling $33 billion in 1990.

Semiconductors

The U.S. semiconductor industry has experienced growth since 1992. The U.S. global market share of semiconductors, semiconductor processing equipment, and computer systems fell between 1980 to 1991. Japanese firms gained most of the market share lost by U.S. firms. Although the U.S. continues to be the world's largest consumer of electronics products, as a result of Japan's growth in consumer electronics production, Japan is now the world's largest consumer of semiconductors. The U.S. is the second largest market in the world for semiconductors, with consumption at $17.4 billion in 1990. The five largest U.S. producers are Motorola, Intel, Texas Instruments, National Semiconductor, and Advanced Micro Devices. According to the Department of Commerce, the value of shipments of U.S. semiconductors is estimated to be $37.6 billion in 1993 and is expected to grow 12 percent in 1994 to over $42.1 billion.

Printed Wiring Boards/Electronic Assemblies

Japan and the U.S. now have equal market shares, 27 percent each. IPC notes that the U.S. was the largest PWB market in the world with a value of approximately $5.5 billion in 1993. According to the Department of Commerce, the value of printed wiring board shipments produced in the U.S. was $6.75 billion in 1993 and is expected to grow by three percent, to $6.95 billion, in 1994. According to IPC, the U.S. electronic manufacturing services industry or contract assemblies industry generates over $9 billion in revenue.

Cathode Ray Tubes

According to 1994 U.S. Industrial Outlook data, the total value of CRT shipments was $3 billion in 1993 and is expected to increase six percent to $3.2 billion in 1994. The total value of CRT shipments is expected to increase more than 3.5 percent per year due to a projected rising demand for television sets and computer displays.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the electronics/computer industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the processes. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Electronics/Computer Industry

The products discussed in this section, semiconductors, printed wiring boards (PWBs), and cathode ray tubes (CRTs), pose significant environmental concerns during the manufacturing processes and/or comprise a large portion of the electronics/computer industry. This section will describe and distinguish these products as well as the steps followed to manufacture them. This discussion also includes an explanation of the wastes generated during the manufacturing processes.

III.A.1. Semiconductor Manufacturing

Semiconductors are made of a solid crystalline material, usually silicone, formed into a simple diode or many integrated circuits. A simple diode is an individual circuit that performs a single function affecting the flow of electrical current. Integrated circuits combine two or more diodes. Up to several thousand integrated circuits can be formed on the wafer, although 200-300 integrated circuits are usually formed. The area on the wafer occupied by integrated circuits is called a chip or die.

Information in this section is from a variety of sources including the following: U.S. EPA's DfE initiative, U.S. EPA Common Sense Initiative (CSI), California Department of Toxic Substances Control, McGraw Hill Encyclopedia of Science and Technology, *Integrated Circuits, Making the Miracle Chip, Microchip Fabrication: A Practical Guide to Semiconductor Processing*, and Microelectronics and Computer Technology Corporation (MCC). The semiconductor manufacturing process is complex and may require that several of the steps be repeated to complete the process. To simplify this discussion, the process has been broken down into five steps:

- Design
- Crystal processing
- Wafer fabrication
- Final layering and cleaning
- Assembly.

The primary reason that semiconductors fail is contamination, particularly the presence of any microscopic residue (including chemicals or dust) on the surface of the base material or circuit path. Therefore, a clean environment is essential to the manufacture of semiconductors. Cleaning operations precede and follow many of the manufacturing process steps. Wet processing, during which semiconductor devices are repeatedly dipped, immersed, or sprayed with solutions, is commonly used to minimize the risk of contamination.

Step One: Design

As with any manufacturing process, the need for a particular type of product must be identified and process specifications must be developed to address that need. In the case of semiconductors, the circuit is designed using computer modeling techniques. Computer simulation is used to develop and test layouts of the circuit path. Then, patterning "masks," which are like stencils, are fabricated, manufacturing equipment is selected, and operating conditions are set. All of these steps occur prior to actually producing a semiconductor.

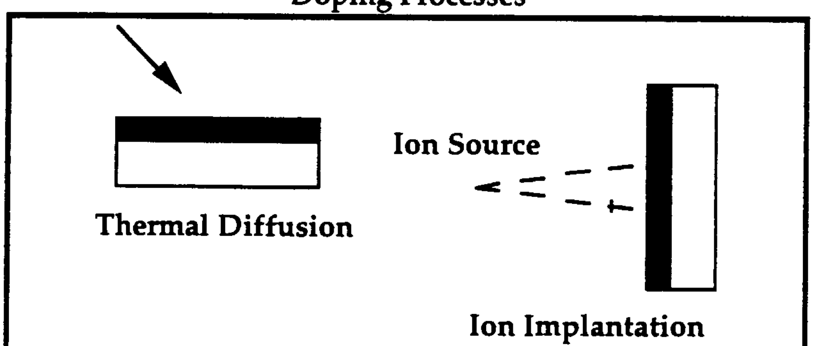
Step Two: Crystal Processing

Wafers, which consist of thin sheets of crystalline material, are the starting point of semiconductor production. Silicon, in the form of ingots, is the primary crystalline material used in the production of 99 percent of all semiconductors. Silicon crystals are actually "grown" using controlled techniques to ensure a uniform crystalline structure. Because crystals of pure silicon are poor electrical conductors, controlled amounts of chemical impurities or **dopants** are added during the development of silicon ingots to enhance their semiconducting properties. Dopants are typically applied using **diffusion** or **ion implantation** processes (See Exhibit 5). Dopants eventually form the circuits that carry the flow of current.

- Diffusion is a chemical process which exposes the regions of the silicon surface to vapors of the metal additive (dopant) while maintaining high temperatures. The process ends when the additives (represented by the arrow in Exhibit 5) migrate to the proper depth and reach the appropriate concentration in the silicon wafer.

- Ion implantation is a process that allows for greater control of the location and concentration of dopants added to the wafer. Metal dopants are ionized and accelerated to a high speed. As shown in Exhibit 5, the ions penetrate the silicon surface and leave a distribution of the dopant.

Exhibit 5
Doping Processes



Source: Based on 1990 Microchip Fabrication: A Practical Guide to Semiconductor Processing.

Either doping process can be used in semiconductor manufacturing. Antimony, arsenic, phosphorus, and boron compounds are the dopant materials most commonly used for silicon-based semiconductors. Other dopants include aluminum, gallium, gold, beryllium, germanium, magnesium, silicon, tin, and tellurium. Wastes including antimony, arsenic, phosphorus, and boron may be generated in the wastewater as a result of ion implantation or diffusion. Excess dopant gases, contaminated carrier gases, and outgassed dopant gases from semiconductor materials may also be generated.

Most semiconductor manufacturers obtain single crystal silicon ingots from other firms. Ingots are sliced into round wafers approximately 0.76 mm (0.03 inches) thick and then **rinsed**. The wafers are further prepared by mechanical or chemical means. A wafer's surface may be **mechanically ground**, **smoothed**, and **polished**, as well as **chemically etched** so that the surface is smooth and free of oxides and contaminants. Chemical etching removes organic contaminants using cleaning solvents and removes damaged surfaces using acid solutions. Chemical etching is usually followed by a **deionized water rinse** and **drying** with compressed air or nitrogen. In some cases, bare silicon wafers are cleaned using ultrasound techniques, which involve potassium chromate or other mildly alkaline solutions.

Etching is a method of cutting into, or imprinting on, the surface of a material. Several etching processes can be used on semiconductors, as well as integrated circuits and printed wiring boards. Wet etching uses acid solutions to cut patterns into the metal. Dry etching involves reactive gases and is rapidly becoming the method of choice for high resolution. Dry etching processes use various halogenated or nonhalogenated gaseous compounds.

In the semiconductor industry, dry plasma etching, reactive ion etching, and ion milling processes are being developed to overcome the limitations of wet chemical etching. Dry plasma etching, the most advanced technique, allows for etching of fine lines and features without the loss of definition. This process forms a plasma above the surface to be etched by combining large amounts of energy with low pressure gases. The gases usually contain halogens.

Materials used during the wet etching process may include acids (sulfuric, phosphoric, hydrogen peroxide, nitric, hydrofluoric, and hydrochloric), ethylene glycol, hydroxide solutions, and solutions of ammonium, ferric, or potassium compounds. Materials used during the dry etching process may include chlorine, hydrogen bromide, carbon tetrafluoride, sulfur hexafluoride, trifluoromethane, fluorine, fluorocarbons, carbon tetrachloride, boron trichloride, hydrogen, oxygen, helium, and argon. Typical solvents and cleaning agents include acetone, deionized water, xylene, glycol ethers, and isopropyl alcohol. The most commonly used cleaning solution in semiconductor manufacturing includes a combination of hydrogen peroxide and sulfuric acid.

Acid fumes and organic solvent vapors may be released during cleaning, etching, resist drying, developing, and resist stripping operations. Hydrogen chloride vapors may also be released during the etching process.

Step Three: Wafer Fabrication

Wafers are usually fabricated in batches of 25 to 40. Wafer preparation begins with an **oxidation** step.

- Oxidation is a process in which a film of silicon dioxide is formed on the exterior surface of the silicon wafer. Thermal oxidation takes place in a tube furnace with controlled, high temperatures and a controlled atmosphere. Oxidation is a reaction between the silicon wafer surface and an oxidant gas such as oxygen or steam. This process may be needed as a preliminary step before diffusion or ion implantation (doping). This layer protects the wafer during further processing. Following oxidation, the wafer surface is thoroughly cleaned and dried.

Materials used during oxidation, include silicon dioxide, acids (hydrofluoric), and solvents. Materials such as oxygen, hydrogen chloride, nitrogen, trichloroethane, and trichloroethylene may also be used. Wastes that may be generated from this process include: organic solvent vapors from cleaning gases; rinsewaters with organic solvents from cleaning operations; spent solvents (including F003); and spent acids and solvents in the wastewater.

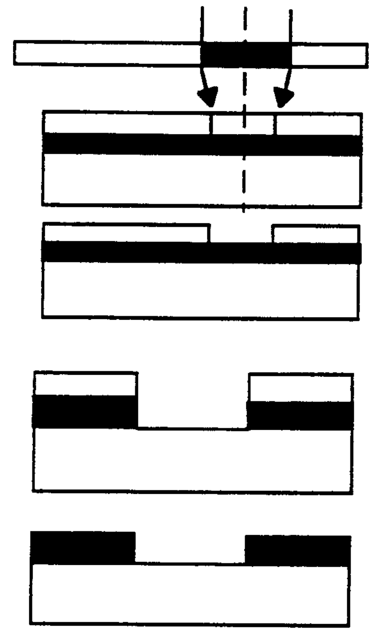
Next, patterns are imprinted onto the substrate using **photolithography** (also referred to as lithography) and **etching** processes. Photolithography is the most crucial step in semiconductor manufacturing because it sets a device's dimensions; incorrect patterns affect the electrical functions of the semiconductor.

- Photolithography is a process similar to photoprocessing techniques and other etching processes in that a pattern is imprinted. The silicon wafer is coated uniformly with a thin film of resist. A glass plate or mask is created with the circuit pattern, and the pattern is imprinted in one of several ways. One type of optical photolithography is the projection of x-rays through a special mask close to the silicon slice. Another type of optical photolithography, one that does not need a mask, is electron-beam direct patterning, which uses a controllable electron beam and an electron sensitive resist. Once the pattern is developed, some areas of the wafer are clear and the rest are covered with resist (See Exhibit 6).

Exhibit 6
Photolithography Process

Process Step	Purpose
1. Alignment and exposure	Precise alignment of mask to wafer and exposure to U.V. light. Negative resist is polymerized.
2. Development	Removal of unpolymerized resist.
3. Etch	Selective removal of top surface layer.
4. Photoresist Removal	Cleaning of photoresist from the wafer's surface.
5. Final Inspection	Inspection of wafer for correctness of image transfer from photoresist to top layer.

Cross Section



Source: Based on 1990 Microchip Fabrication: A Practical Guide to Semiconductor Processing.

Two types of photoresists can be used during semiconductor production:

- Positive photoresists are chemicals that are made more soluble, with regard to a solvent (i.e., developer), after exposure to radiation. During development, the developer removes the resist that was exposed to radiation.

- Negative photoresists are chemicals that polymerize and stabilize upon exposure to radiation. During development, the developer removes the resist that was protected from radiation.

After photolithography, chemical **developers** are used to remove unnecessary coatings or resist material that remains on the substrate. Development can be conducted by liquid methods (dip, manual immersion, or spray coating) or dry methods (plasma). The wafer is then **etched** in an acid solution to remove selected portions of the oxide layer to create depressions or patterns. The patterns are areas in which dopants will be applied. The wafer is **rinsed**, typically by immersing in a stripping solution to remove unwanted photoresist, and then dried. See Exhibit 7 for a list of materials used during the photolithography process.

Exhibit 7
Chemicals Used in Photolithography for Semiconductors

Photoresists	Developer	Solvents and Cleaning Agents
Positive:	**Positive:**	Deionized water
Ortho-diazoketone	Sodium hydroxide	Detergent
Polymethacrylate	Potassium hydroxide	Isopropyl alcohol
Polyfluoroalkylmethacrylate	Silicates	Acetone
Polyalkylaldehyde	Ethylene glycol	Ethanol
Polycyanoethylacrylate	Ethanolamine	Hydrofluoric acid
Polymethylmethacrylate	Isopropyl alcohol	Sulfuric acid
Poly (hexafluorobutylmeth-acrylate)	Phosphates	Hydrogen peroxide
	Tetramethyl-ammonium hydroxide	Hydrochloric acid
Negative:		Nitric acid
Isoprene	Alkyl amine	Chromic acid
Ethyl acrylate	Ethyl acetate	Ammonium hydroxide
Glycidylmetharcylate	Methyl isobutyl ketone	Hexamethyldisilazane
Copolymer-ethylacrylate		Xylene
	Negative:	Cellosolve acetate
	Xylene	n-Butyl acetate
	Aliphatic Hydrocarbons	Ethylbenzene
	N-Butyl acetate	Chlorofluorocarbons
	Cellosolve acetate	Chlorotoluene
	Isopropyl alcohol	Glycol ethers
	Stoddard solvent	
	Glycol ethers

During the next step, **dopants** are applied to the patterned wafer surface typically using diffusion or ion implantation. See Step two for a list of materials used and wastes generated during the doping process.

Additional layers of silicon may also be applied to the wafer using **deposition** techniques, typically epitaxial growth or chemical vapor deposition.

- Epitaxyl allows the growth of another layer of silicon on top of the wafer. A silicon layer is grown using high temperatures and dopant compounds. This top layer of

R0074969

silicon is where the final device will be formed. Not all semiconductors need this layer.

- Chemical vapor deposition deposits a thin coating on materials by a chemical process. Vapor deposition is a low pressure process that combines appropriate gases in a reactant chamber at elevated temperatures to produce a uniform film thickness.

Materials that may be used during deposition include silane, silicon tetrachloride, ammonia, nitrous oxide, tungsten hexafluoride, arsine, phosphine, diborane, nitrogen, and hydrogen.

Wastes that may be generated from these processes include: acid fumes from etching operations; organic solvent vapors from cleaning resist drying, developing, and resist stripping; hydrogen chloride vapors from etching; rinsewaters containing acids and organic solvents from cleaning, developing, etching, and resist stripping processes; rinsewaters from aqueous developing systems; spent etchant solutions; spent solvents (including F003) and spent acid baths.

Many products require that steps two through three be repeated several times in order to create the specified structure.

Step Four: Final Layering and Cleaning

Once the wafer is patterned, the wafer surface is coated with thin layers of metal by a process called **metallization**. These metal layers perform circuit functions within the finished semiconductor. External connections to the silicon wafer are provided by evaporation of thin metal films onto areas of the semiconductor chip surface in a vacuum. Almost every metal can be used to make this electrical connection to the silicon; aluminum, platinum, titanium, nickel/chromium, silver, copper, tungsten, gold, germanium, and tantalum are most common. Argon gas is also used in some operations. **Sputtering** and **high vacuum evaporation** are two types of metallization.

- Sputtering (also called partial vacuum evaporation) is a physical, rather than chemical process. This process occurs in a vacuum chamber which contains a target (solid slab of the film material) and the wafers. Argon gas is introduced in the chamber and ionized to a positive charge. The positively charged argon atoms accelerate toward and strike the target, dislodging the target atoms. The dislodged atoms are deposited onto the wafer surface. A uniform thickness of the coating is produced over the silicon slice.

- High vacuum evaporation is a process that uses an electron beam, a ceramic bar heated by thermal resistance, or a wire heated by electrical resistance. This method coats the surface of the wafer with metal.

Photolithography and etching are also used to remove any unnecessary metal using chlorinated solvents or acid solutions. Wastes generated include: acid fumes and organic solvent vapors from cleaning, etching, resist drying, developing, and resist stripping; liquid organic waste; aqueous metals; and wastewaters contaminated with spent cleaning solutions.

In the next step, **passivation** is used to apply a final layer of oxide over the wafer surface to provide a protective seal over the circuit. This coating protects the semiconductor from exterior influences and may range in thickness from a single layer of silicon dioxide to a relatively thick deposit of special glass. It also insulates the chip from unwanted contact with other external metal contacts. Materials used to form the passivation layer are silicon dioxide or silicon nitride.

After all layers have been applied to the wafer, the wafer is typically **rinsed** in deionized water. The back of the wafer is then mechanically ground (also called **lapping** or **backgrinding**) to remove unnecessary material. A film of gold may be applied to the back of the wafer by an evaporation process to aid the connection of leads to the bonding pads during a later process step.

Testing with alcohol compounds is conducted to ensure that each chip is performing the operation for which it was designed. Chips that do not meet specifications are marked with an ink droplet for discard during assembly operations. The wafer is cleaned again after testing, using solvents such as deionized water, isopropyl alcohol, acetone, and methanol.

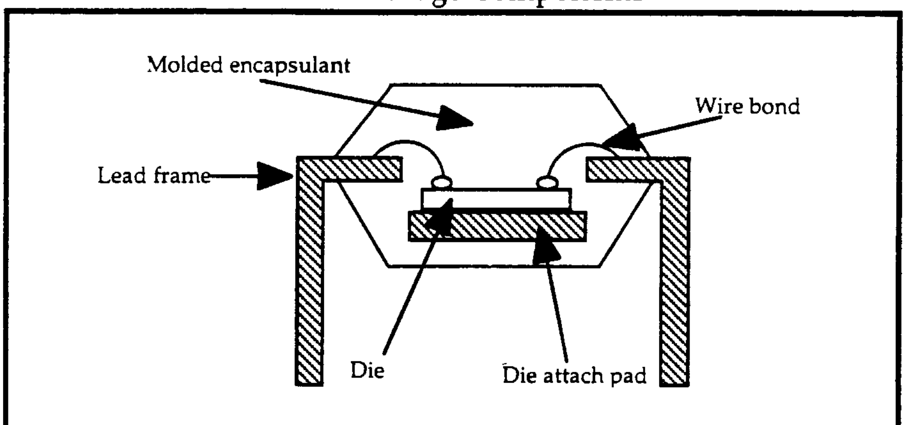
Wastes generated from these processes include: spent solvents and acids in the wastewater and rinsewater from cleaning, developing, etching, resist stripping, and rinsing processes; acid fumes and organic solvent vapors from cleaning, rinsing, resist drying, developing, and resist stripping; spent silicon dioxide or nitride; hydrogen chloride vapors from etching; rinsewaters from aqueous developing systems; spent etchant solutions; spent acid baths; and spent solvents.

Step Five: Assembly

Semiconductors are assembled by mounting chips onto a metal frame, connecting the chips to metal strips (leads), and enclosing the device to protect against mechanical shock and the external environment. There are many types of packaging; such as plastic or ceramic. Plastic packages comprised more than 90 percent of the market in 1990.

Each package contains five parts: the die (e.g., chip), the lead frame of the package, the die-attach pad, the wire bond, and the molded encapsulant (i.e., plastic housing) (See Exhibit 8). This section describes how plastic packages are assembled. All semiconductor packages whether plastic or ceramic share the same basic parts and are assembled using the same general processes.

Exhibit 8
Plastic Package Components



Source: Based on 1993 Environmental Consciousness: A Strategic Competitiveness Issue for the Electronics Industry.

The lead frame consists of a rectangular-shaped metal frame connected to metal strips or leads. The leads connect the chip to the electronic product. Plastic package lead frames are fabricated from sheets of metal, either copper or alloy 42, that is either **punched** or **etched**. The lead frame and leads provide the connections for the electronic components.

- The punching process consists of an array of small mechanical punches that remove sections of the metal sheet until the lead frame is complete. The leads are cleaned with water-based cleaning systems. In the past, manufacturers used chlorinated fluorocarbons (CFCs) or other solvents to remove cutting fluids. The lead frame is coated with a layer

R0074972

of photoresist, exposed, and developed. The manufacturer etches the lead frame, removes the photoresist, and cleans the lead frame again with water based cleaning systems.

- If the lead frames are etched, the process is similar to that used during PWB manufacturing. Acids or metal chlorides are usually used during etching. Sometimes ammonia is used to stabilize the metal chloride. The photoresist contains solvents (such as trichloroethylene or TCE) that are baked out and generate VOC emissions. Developers that are typically used include either an amine or metal hydroxide. Once the photoresist is removed, it is cleaned with solvents such as a mild hydrochloric acid (HCL) solution or with a brightener that contains sulfuric acid.

Wastes generated during punching or etching may include: spent organic vapors generated from cleaning, resist drying, developing, and resist stripping; spent cleaning solutions; rinsewaters contaminated with organic solvents; and spent aqueous developing solutions. Scrap copper or alloy 42 may be recycled during the punching process.

The chip is then **attached** to an "attach pad," with a substance such as an epoxy material (thermoset plastic). Once mounted, the chips are inspected. The chip parts are bonded to the leads of the package with tiny gold or aluminum wires. A package may have between 2 and 48 wire bonds. The assembly is cleaned and inspected again. The combined components are then placed into a **molding press**, which encases the chip, wire bonds, and portions of the leads in plastic. The plastic-molding compound used in the press contains primarily fused silica. After the molding compound cures and cools around the package, the package is heated again to ensure that the plastic is completely cured. Excess material is removed using a chemical or mechanical **deflash** process. M-Pyrol is one organic solvent used during the deflash process. The final steps in package fabrication include **trimming** and **forming** the leads.

Waste generated during these steps includes excess epoxy/thermoset plastic; antimony trioxide (from the molding process); and spent organic solvents. Excess gold or aluminum from trimming processes can be reclaimed and reused.

Final computer tests are conducted to evaluate whether the product meets specifications. Even though the chips are produced using the same process, some may work better (e.g., faster) than others. As a result, packages are separated into low- and high-quality circuits. Often, low-quality circuits can still be sold. Final process steps include marking the circuits with a product brand. The finished product is then packaged, labeled, and shipped according to customer specifications.

III.A.2. Printed Wiring Board Manufacturing

Printed wiring boards (PWBs) are the physical structures on which electronic components such as semiconductors and capacitors are mounted. The combination of PWBs and electronic components is an electronic assembly or printed wiring assembly (PWA). According to Microelectronics and Computer Technology Corporation's (MCC) *Environmental Consciousness: A Strategic Competitiveness Issue for the Electronics and Computer Industry,* PWB manufacturing is the most chemical intensive process in the building of a computer workstation.

PWBs are subdivided into single-sided, double-sided, multilayer, and flexible boards. Multilayer boards are manufactured similarly to single and double-sided boards, except that conducting circuits are etched on both the external and internal layers. Multilayer boards allow for increased complexity and density. PWBs are produced using three methods: additive, subtractive, or semi-additive technology. The subtractive process accounts for a significant majority, perhaps 80 percent, of PWB manufacturing.

The conventional subtractive manufacturing process begins with a board, consisting of epoxy resin and fiberglass, onto which patterns are imaged. In most operations, conducting material, usually copper, is bonded onto the substrate surface to form copper-clad laminate. After drilling holes through the laminate and making those holes conductive, unwanted copper is etched off, leaving copper patterns. The patterns on the board form the electric circuits that conduct electricity. Multilayer boards typically use metals such as platinum, palladium, and copper to form electric circuits. Specialized PWBs may use nickel, silver, or gold.

Additive technology is used less often than substractive technology because it is a more difficult and costly production process. This capital-intensive technology is used primarily for small interconnection components used in multi-chip devices. The production process begins with a base plate upon which a dielectric material is deposited. An interconnecting layer of copper is plated onto the dielectric layer which connects the layers of dielectric material and copper. Copper posts are plated-up and another layer of dielectric material is deposited exposing the posts. The next interconnect layer is plated and makes contact with the posts. Layers of dielectric material, copper, and copper posts are added to complete the interconnect. A lithographic process, similar to the one used in semiconductor manufacturing, diminishes the spaces and widths of the PWB.

This section provides a simplified discussion of the steps commonly performed during conventional subtractive manufacturing. The actual steps and materials used by a PWB manufacturer vary depending on customer requirements and the product being manufactured. The information provided in this section comes from various sources, including documents developed by MCC, IPC, EPA's Center for Environmental Research Information, EPA's DfE Program, California Department of Toxic Substances, EPA's CSI, and EPA's Office of Research and Development. PWB manufacturing can be grouped into five steps:

- Board preparation
- Application of conductive coatings (plating)
- Soldering
- Fabrication
- Assembly.

Step One: Board Preparation

Board preparation begins with a **lamination** process. Two-side etched copper dielectric boards (consisting usually of fiberglass and epoxy resin) are separated by an insulating layer and laminated or bonded together, usually by heat and pressure. Photographic tools are used to transfer the circuit pattern to the PWB, and computer control programs are used to control the drilling, routing, and testing equipment. Preparing the copper-clad board involves **drilling** holes to establish an electrical path between the layers and to mount components. The boards are then mechanically **cleaned** to remove drilling wastes (i.e., fine particulate contaminants, such as copper). Vapor degreasing, abrasive cleaning, chemical cleaning with alkaline solutions, acid dips, and water rinses are techniques used to clean the boards and prepare them for the next process, **electroless plating**. See Exhibit 9 for a list of materials used during lamination, drilling, and cleaning processes.

Exhibit 9
Chemicals Used in Lamination, Drilling, and Cleaning

Lamination	Drilling	Cleaning
Epoxies	Sulfuric Acid Potassium Permanganate Ammonium bifluoride Oxygen Fluorocarbon gas	Acetone 1,1,1-Trichloroethane Silica (and other abrasives) Sulfuric acid Ammonium hydroxide Hydrochloric acid

Source: Based on EPA DfE 1993: Industry Profile and Description of Chemical Use for the Printed Wiring Board Industry: Preliminary Draft.

Wastes generated include: airborne particulates, acid fumes, and organic vapors from cleaning, surface preparation, and drilling; spent acid and alkaline solutions; spent developing solutions, spent etchants, and waste rinsewaters in the wastewater; and scrap board materials and sludges from wastewater treatment. Drilling and routing dust (copper, aluminum, and gold) are collected and recycled.

Step Two: Electroless Plating

The first process in this step is to prepare the surfaces of the drilled holes. The holes are prepared by an etchback process to remove smeared epoxy resin and other contaminants using one of the following: sulfuric or hydrochloric acid; potassium permanganate; or carbon tetrafluoride, oxygen and nitrogen. The holes are then coated with a material such as copper or graphite carbon, by a chemical process called **electroless plating.**

Electroless plating coats a uniform conducting layer of copper or other material on the entire surface including the barrels of the holes of the prepared board without outside power sources. According to *Printed Circuit Board Basics*, this coating of copper is not thick enough to carry an electrical current, but provides a base upon which additional copper can be deposited electrolytically. According to DfE, copper is the industry standard, but many are switching to direct metallization processes. Chemical deposition is the technique used to coat the board. After the electroless plating, the boards are dried to prevent the board from oxidation (e.g., rusting). The board may also be cleaned to prepare for a following electroplating processing. See Exhibit 12 for a list of materials used. Waste generated include: spent electroless copper baths; spent catalyst solutions; spent acid solutions; waste rinsewaters; and sludges from wastewater treatment.

Step Three: Imaging

During imaging, circuit patterns are transferred onto the boards through **photolithography** or a **stencil printing** process. Photoresist (i.e., a light sensitive chemical) is applied to the board in areas where the circuit pattern will not be set. The board is exposed to a radiation source and **developed** to remove the unwanted areas of the resist layer. Stencil printing uses a printing process, such as silk screening, to apply a protective film that forms the circuit pattern.

After photolithography, the boards are subjected to a light **etching** process, typically using ammoniacal etchants, to remove rust inhibitor (applied by the company that produced the material from which the board is made) or other metals (usually copper). After the stencil printing process, the protective film is dried, and the exposed copper is etched away. Sulfuric acid and hydrogen peroxide are common etchants used during imaging. After plating or etching, the photoresist is removed with an photoresist stripper.

See Exhibits 10 and 11 for a list of materials used during photolithography and etching processes. Wastes generated during the cleaning and etching processes include: RCRA listed F001, F002, F003, F004, and F005 depending on the concentration of the spent solvents and the mixture of spent halogenated and non-halogenated solvents; spent resist material; and wastewater containing metals (copper). Other wastes generated include organic vapors and acid fumes, spent developing solutions, spent resist material, spent etchant, spend acid solutions, and sludges from waste water treatment.

Source: Based on EPA DfE 1993: Industry Profile and Description of Chemical Use for the Printed Wiring Board Industry: Preliminary Draft.

Step Four: Electroplating

Electroplating is a process in which a metal is deposited on a substrate through electrochemical reactions. Electroplating is required to build up the thickness and strength of the conducting layers to provide reliable electrical conductivity between inner layers or from one side of the PWB to the other. Electroplating can also protect against corrosion, wear, or erosion. This process involves immersing the article to be coated/plated into a bath containing acids, bases, or salts. The industry standard for this process is copper, although many are switching to direct metallization techniques according to DfE.

The **electroplating** process for PWBs usually begins with the copper laminate which is coated with a plating resist (**photolithography**), by stenciling, leaving the area exposed to form the circuit pattern. The resist prevents the conductive material from adhering to other areas of the board and forms the circuit pattern.

The PWB plating process typically uses as copper and tin-lead as plating materials, although silver, nickel, or gold can be used. Copper in a plating bath solution is deposited to a sufficient thickness, and a solvent or aqueous solution is applied to remove the plating resist. The copper coating forms interconnections between the layers and provides electrical contact for electronic parts mounted or assembled on the PWB surface. PWB manufacturers then typically electroplate a tin or tin-lead solder on the board to protect the circuit pattern during the following etching or stripping processes. An acid etch solution (ammoniacal, peroxide solutions, sodium persulfate, cupric chloride, or ferric chloride) removes the exposed copper foil, leaving the thicker copper plating to form the circuit pattern. Ammoniacal and cupric chloride are the primary etchants used by PWB manufacturers. Fluoroboric acid is used in the tin-lead plating process to keep the metals dissolved in the solution and to ensure a consistent deposition of the tin-lead alloy onto the circuit board.

After the plating bath, the board is **rinsed** with water, scrubbed, and then dried to remove the copper, spray etch solutions, and other materials. Rinsing ends the chemical reactions during plating and prevents contamination or dragout from being released in the next bath or rinse water (dragout is the plating solution that sticks to parts after taken out of the plating bath). Dragout can occur in any bath step, not just in one plating bath. The tin-lead layer is generally removed and the panel is electrically tested for discontinuities in the electrical pathway and shorts. See Exhibit 12 for a list of materials used during the electroplating process.

Exhibit 12
Materials Used in Copper and Tin-Lead Electro- and Electroless Plating Processes

Type of Plating	Electroplating Chemicals	Electroless Chemicals
Copper	Copper pyrophosphate Orthophosphate Pyrophosphate Nitrates Ammonia Acid copper Copper sulfate Sulfuric acid	Hydrochloric acid Palladium chloride Stannous chloride Metallic tin pellets Sodium hydroxide Copper sulfate Formaldehyde
Tin-Lead	Tin-Lead Fluoroboric acid Boric acid Peptone	Tin chloride Sodium hypophosphite Sodium citrate

Source: Based on EPA DfE 1993: Industry Profile and Description of Chemical Use for the Printed Wiring Board Industry: Preliminary Draft.

The primary RCRA hazardous wastes generated during plating include: photoresist skins, F006 sludge from plating wastewater treatment, D008, F007, and F008 from plating and etching; spent acid solutions, waste rinsewaters, spent developing solutions, spent etchant, and spent plating baths in the wastewater; organic vapors from spent developing solution and spent resist removal solution; and acid and ammonia fumes. According to IPC, photoresist skins or the stripped resist material are exempt from categorical F006 classification if the skins stripping is separate from electroplating and if the boards are rinsed and dried.

Step Five: Soldering Coating

Solder coating is used to add solder to PWB copper component before component assembly. Fabricators use several methods of solder coating, but all of them involve dipping the panel into molten solder. The solder, an alloy consisting of 60 percent tin and 40 percent lead, coats the pads and holes not covered by solder mask. The excess solder is removed with a blast of hot oil or hot air. However, the hot oil or hot air does not remove the solder that has formed a chemical (intermetallic) bond with the copper. The removal of the excess solder is called "solder leveling." The most common process is hot-air leveling. According to *Printed Circuit Board Basics: Quick and Easy Guide*, final solder coating thicknesses of 50 to 1,200 microinches can be achieved with most solder-leveling processes. Solder is only applied to desired areas so there is no metal or "objectionable fluid" discharged to the wastestream, according to MCC. MCC considers it to be the most environmental friendly solder application method.

Step Six: Electrical and Mechanical Testing

A cross section is cut from a sample panel from each lot using a grinding process called **routing,** and the plated holes are examined with a photomicrograph. Individual circuit boards are cut out of panels that pass quality control. Routing generates dust which may contain copper, lead, or other metals plated to the panel, but the dust is recycled. Electrical tests, dimensional and visual inspections, and quality audits are performed to ensure compliance with customer requirements. Finally, the finished PWBs are packaged, labeled, and shipped to the customer which in most cases is the original equipment manufacturer (OEM) or contract electronic assembly company.

Step Seven: Printed Wiring Board Assembly and Soldering

After the PWBs are manufactured, the electrical components are attached during **assembly**. Adhesives are applied to the boards, and then the components are attached and soldered to the boards. Components are attached to the PWB by a process called **soldering**. There are several different kinds of soldering processes, including wave, dip, and drag. In wave soldering, the PWA is passed over the crest of a wave of molten solder, thereby permanently attaching the components to the board. A type of chemical known as "flux" is used before soldering to facilitate the production of the solder connection. Not only does flux clean the surface and remove oxidized material, it prevents oxidation from occurring during the solder process. After the solder has been applied, flux residue may be removed from the board. According to a leading PWB manufacturer, deionized water instead of CFCs (such as Freon 113) and trichloroethane (TCA), are now used to remove flux. Although the residue may not affect the PWB's performance, it may lower the board's cosmetic quality. After soldering, the board may be cleaned and dried. Many assemblies, however, are looking at no-clean soldering operations.

The wastes generated during assembly include: solder dross, post-solder scrap boards, filters, gloves, rags, and spent gaseous or semi-gaseous solvents from cleaning processes. The wastes that may be generated during soldering, flux application, and cleaning include: organic vapors and CFCs (although CFC usage will be eliminated by 1996); copper, lead, spent solvents, and spent deionized water into the wastewater; solder dross; and wastewater treatment sludge. Solder dross is primarily oxidized solder skin that forms on any molten solder exposed to oxygen and can be recycled off-site.

III.A.3. Cathode Ray Tube Manufacturing

Cathode Ray Tubes (CRTs) have four major components: the glass panel (faceplate), shadow mask (aperture), electron gun (mount), and glass funnel. The glass funnel protects the electron gun and forms the back end of the CRT. In response to electrical signals, the electron gun emits electrons that excite the screen. The shadow mask forms a pattern on the screen. The shadow mask itself is a steel panel with a mask pattern applied through one of several kinds of photolithography.

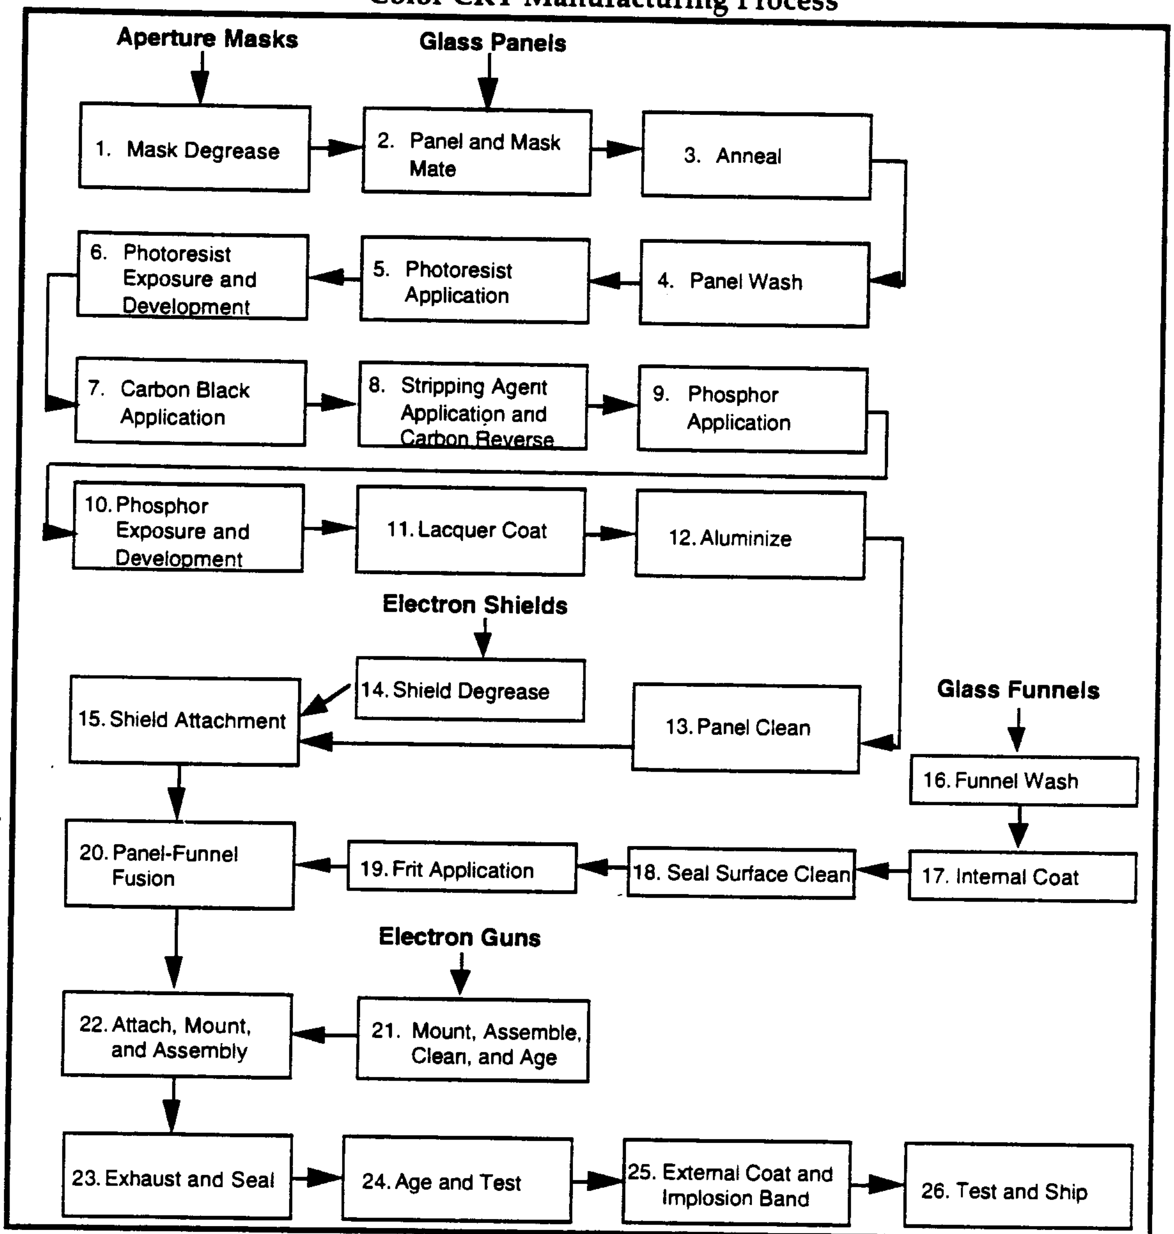
This section summarizes the manufacturing process for color CRTs. Information used to describe CRT manufacturing comes from a variety of sources such as MCC, EPA's Common Sense Initiative (CSI), Corporate Environmental Engineering, and EPA's Effluent Guideline Division. For this discussion, the process is grouped into six steps:

- Preparation of the glass panel and shadow mask
- Application of the coating to the glass panel interior
- Installation of the electron shield
- Preparation of the funnel and joining to the glass panel/shadow mask assembly
- Installation of the electron gun
- Finishing.

Color CRTs

Exhibit 13 presents the steps for manufacturing a color CRT. The names of the operations may vary by manufacturer, but the basic processing sequence is identical in all color CRT manufacturing facilities. Lead in CRT display components and end-of-life concerns have been the most significant environmental issues in CRT manufacturing.

Exhibit 13
Color CRT Manufacturing Process



Source: *Based on 1995 EPA Common Sense Initiative (CSI) documents.*

R0074983

Step One: Preparation of the Panel and Shadow Mask

The shadow mask is constructed from a thin layer of aluminum steel (referred to as a flat mask) which is etched with many small slits or holes, and a metal frame that supports the flat mask. The shadow mask serves as a template for preparing a pattern on the glass panel surface. Shadow masks are commonly manufactured overseas and shipped to CRT manufacturers in the United States. The shadow mask is then **molded** to match the contour of the glass panel's interior surface and "blackened" in an oven to provide corrosion resistance. Finally, the shadow mask is **welded** to a blackened metal frame, usually steel, that provides support. Degreasing solvents and caustics are frequently used for **cleaning** the shadow mask assembly and production equipment. Oils are used for lubricating the press and other production equipment.

The front end glass panel is purchased from a glass manufacturer and shipped to the CRT manufacturer. Metal "pins," provided as part of the glass panel, are attached to the inside of the glass to serve as connection points for the shadow mask.

The shadow mask is carefully positioned inside the glass panel. Steel springs are then placed over the pins in the glass panel and attached to "hook-plates" or "clips" located on the mask assembly frame. With the glass panel and shadow mask assembly positions fixed in relation to each other, the springs are **welded** to the hook-plates. The glass panel and mask must remain as a matched pair through the remaining processes. The glass panel and shadow mask preparation operation frequently uses organic solvents or caustic cleaners for degreasing, oil for equipment maintenance, and oxidizers, such as hydrogen peroxide, for cleaning reclaimed masks.

Wastes generated during this step include spent solvents in the wastewater, vapors from solvent degreasing tanks, and waste glass from breakage.

Step Two: Application of Coating to Panel Interior

For the panel-mask to create images, a special coating is applied to the interior surface through a process called screening. Screening, the most complex part of the manufacturing process, is comparable to a photographic development process.

The screening operation begins with a **panel wash**. The mask is removed and the glass panel is washed to remove dust, oil, grease, and other contamination. The glass panel wash commonly uses

R0074984

acids and caustics followed by deionized water rinses for cleaning the glass.

The glass panel undergoes the **carbon stripe** process, which uses organic photoresist, chromate, deionized water, dilute acids and oxidizers, carbon slurry with binding agents, and surfactants to produce the black and clear striped pattern called the "black matrix." The clear areas will eventually be filled with color-producing phosphors. The glass panels are coated with a photoresist, which contains chromate (a toxic heavy metal compound) as a catalyzer. The panel is spun to even out the photoresist and then dried.

The shadow mask is re-inserted in the glass panel and a series of exposures are made on the panel surface using ultraviolet (UV) light in a **photolithography** process. The light passes through the mask openings to imprint the mask pattern on the photoresist. The mask also shadows the areas of the photoresist that will not be exposed. When UV light contacts the photoresist, polymerization occurs, and the exposed areas become less soluble in water than the non-exposed areas.

After the exposure, the shadow mask is removed and the glass panel is sprayed with water to remove the non-polymerized material. The imprinted pattern of exposed photoresist remains on the glass panel. The glass panel is then coated and developed again. The resulting image is essentially a "negative image" of the original photoresist exposure pattern.

During the **phosphor stripe** process, three phosphor colors (green, blue, and red) are used to make a color CRT and are applied using the same steps as the carbon stripe process. The phosphor stripe process uses various chemicals, including phosphor slurries containing metals (such as zinc compounds) and organic photoresists, chromate, deionized water, dilute oxidizers, and surfactants. The phosphor materials that are spun off the panels and removed in the developers are recovered and reclaimed either onsite or by a phosphor vendor. The reclaiming process involves the use of acids and caustics, chelating agents, and surfactants.

Two **coatings** are then added to the glass panel, which now has the black matrix and the three phosphor colors on it: lacquer (a wax-like layer) to smooth and seal the inside surface of the screen, and aluminum to enhance brightness. The panel is then ready to be joined to the back end of the CRT, known as the funnel. In preparation for joining, the panel edges must be **cleaned** to remove all traces of contaminants. A clean edge is critical to ensuring a good panel-to-seal connection in the finished CRT. The shadow mask and glass panel are reattached. Chemicals used in these processes include organic solvents and alcohol, caustics, silica-based coatings, aluminum, acids, ammonia, and deionized water. The material removed in the cleaning process is sent to a smelter to recover metals and sulfites.

Wastes generated during this step include: vapors from the lacquer area; wastewater containing deionized water, acids, oxidizers, carbon slurry, surfactants, chromate, phosphor solutions, chelating agents, caustics, organic solvents, alcohol, silica-based coatings, ammonia, zinc, and aluminum; process cooling waters, liquid wastes from precipitation, washing, filtration, and scrubber blowdown; lacquer wastes from spun off and over-sprayed lacquer; and lacquer remaining in lacquer containers.

Step Three: Installation of the Electron Shield

Most CRT manufacturers employ an internal **electron shield** to prevent stray electrons from reaching outside the screen area. Computer monitor CRTs often use external shielding, which is installed on the outside of the CRT's glass bulb. Before installation, the shields are cleaned with degreasing solvents or caustic cleaners. The internal-type electron shield is made of thin aluminum and is typically **welded** to the shadow mask assembly before the panel and shadow mask are connected with the funnel. Metal (steel) springs are also **welded** to the mask frame at this time. The springs provide an electrical connection between the mask and the funnel interior surface. Wastes generated from these processes include electron shield degrease wastewaters and metals from the welding.

Step Four: Preparation of the Funnel and Joining to Panel-Mask Assembly

The back end of the CRT (funnel) is purchased from a glass vendor and washed prior to use. The funnel is made of high lead content glass and the resulting wash water contains elevated lead levels. After the funnel is **washed**, the interior surface is **coated** with a black graphite coating which is a good electrical conductor and a non-reflective coating. The seal edge of the funnel is **cleaned** to facilitate bonding with the panel, and **frit** or **solder** glass is applied in a bead along the entire surface of the seal edge. The frit, approximately 70 percent lead, has the consistency of toothpaste or caulking. The viscosity of the frit is controlled by the addition of organic solvents. The frit serves as an adhesive to join the panel-mask assembly to the funnel.

After the frit is applied, the panel-mask assembly is connected to the funnel, and the whole glass package is placed in a positioning clamp to hold the two parts in place. The connected panel-mask and funnel assembly is then exposed to high temperatures in an oven to fuse the frit joint between the panel and funnel at the seal edges. The frit forms a strong bond between the two pieces of glass. During the **frit-seal fusion** process, the organic chemicals from the screening operation and in the frit are "burned out" of the CRT. The organic materials must "burn" cleanly to minimize any remaining residue. Wastes generated include wastewaters contaminated with spent black graphic, lead, and chemicals associated with the funnel wash, frit application, and seal surface cleaning. Wastes generated include frit contaminated clothing, instruments and utensil used to prepare the frit, unusable frit glass, and waste glass from breakage.

Step Five: Installation of the Electron Gun

Each CRT contains three guns: one dedicated to each of the phosphor colors used in the screen (red, green, and blue). To produce an electron gun, several metal components are **assembled** and loaded onto spindles to align the various elements. Glass parts are placed into fixture blocks and **heated**. When the glass reaches the proper temperature, the metal parts are embedded in the glass. The combination of metal parts and glass make up the gun. The guns are **cleaned** with organic solvents or caustic cleaners before they are mounted in the neck of the CRT funnel. Materials commonly found in the gun assemblies include metals, high lead glass stem (for electrical connection feed-through and exhaust purposes), ribbon connectors, and other manufacturer-specific parts.

The gun assembly is then inserted in the neck of the CRT funnel. The gun is aligned and the CRT funnel neck is **fused** to the gun by rotating the parts in front of open flame burners. An additional component is **welded** to the gun assembly to allow for removal of gases from the electron gun in subsequent steps. Wastes generated from this step include waste glass from breakage and wastewaters contaminated with spent organic solvents and caustic cleaners from mount cleaning.

Step Six: Finishing

The CRT "bulb" is still open to the atmosphere after the gun mount is sealed in the neck of the funnel. To complete the tube, the gases are removed by applying a vacuum to the bulb. Organic solvents are used to clean and maintain the vacuum pumps.

The bulb is "aged" by an electronic treatment applied to the gun or mount. The CRT is then coated with an external carbon black paint, and a metal band is placed around the outside of the panel with adhesives for implosion protection and safety. The band also provides mounting brackets for installing the CRT. The finished tube is tested in a high voltage testing station, and the CRT tested thoroughly to ensure that it meets all specifications before shipment. Each tube is packaged prior to shipment to the customer. Wastes generated from finishing processes include spent solvents and VOC emissions.

In some cases where the bulb face needs a special application, such as reference lines for an oscilloscope, a separate panel and funnel are used. A photoresist and mask are used to apply the reference lines on the panel. The single phosphor is applied in the same way as for a one-piece bulb, using a settling solution that contains potassium silicate and, usually, an electrolyte.

Tube Salvage

Cathode ray tubes may or may not be salvaged. Picture tube salvage operations reclaim spent or rejected picture tubes and return them to production. Salvage operation processes include a panel-funnel acid defrit, acid cleaning of panels and funnels (i.e., nitric acid), and cleaning of the shadow mask. These reclaimed components are returned to the process for reuse or are returned to the glass manufacturer for recycling. A product with knocks, scratches, chips, etc., is repaired. New necks are spliced onto funnels. Electron guns are usually discarded. Glass that cannot be used because of serious defects is recycled back to a glass plant directly or is sent off-site for cleaning and segregation before going to a glass plant.

CRT technology is a mature and efficient process; however, the use of a new technology called Flat Panel Displays (FPD) is becoming more common. FPDs offer certain environmental advantages over CRTs because of the tenfold reduction in glass used and substantial power savings. Existing performance deficiencies, such as poorer screen brightness and substantially higher prices, are limiting the widespread incorporation of FPDs into electronics products.

III.B. Raw Materials Inputs and Pollution Outputs

Outputs from the electronics and computer industry manufacturing processes affect the land, air, and water. Exhibits 14-16 describe the wastes generated during each manufacturing process.

Exhibit 14
Semiconductor Pollution Outputs

Process	Air Emissions	Process Wastes (Liquids/Waste Waters)	Other Wastes (Solids/RCRA)
Crystal Preparation	Acid fumes, VOCs, dopant gases	Spent deionized water, spent solvents, spent alkaline cleaning solutions, spent acids, spent resist material	Silicon,
Wafer Fabrication	VOCs and dopant gases	Spent solvents, spent acids, aqueous metals, spent etchant solution, and spent aqueous developing solutions.	F003
Final Layering and Cleaning	Acid fumes and VOCs	Spent deionized water, spent solvents, spent acids, spent etchants, spent aqueous developing solutions, spent cleaning solutions, aqueous metals, and D007 (chromium).	Spent solvents
Assembly	VOCs	Spent cleaning solutions, spent solvents, aqueous developing solutions, and P & U wastes.	Spent epoxy material and spent solvents

Exhibit 15
Printed Wiring Board Pollution Outputs

Process	Air Emissions	Process Wastes (Liquids/Waste Waters)	Other Wastes (Solids/RCRA)
Board Preparation	Particulates, acid fumes, and VOCs	Spent acids and spent alkaline solutions	Sludge and scrap board material
Electroless Plating		Spent electroless copper baths, spent catalyst solutions, spent acid solutions	Waste rinse water and sludges from waste water treatment
Imaging	Organic vapors and acid fumes	Spent developing solutions, spent resist material, spent etchants, spent acid solutions, and aqueous metals	F001-5, depending on concentration and mixture of solvents. Sludges from waste water treatment
Electroplating	Acid fumes, ammonia fumes, and VOCs	D008 (lead), D002, D003, spent etchants, spent acid solutions, spent developing solutions, spent plating baths	F006, F007, and F008

Exhibit 15 (cont'd)

Process	Air Emissions	Process Wastes (Liquids/Waste Water)	Other Wastes (Solids/RCRA)
Solder Coating	VOCs and CFCs		
PWB Assembly And Soldering	VOCs and CFCs	Metals (nickel, silver, and copper), D008 (lead), flux residue, spent deionized water, spent solvents	Solder dross, scrap boards, filters, gloves, rags, waste water treatment sludge

Exhibit 16
Cathode Ray Tubes Pollution Outputs

Process	Air Emissions	Process Wastes (Liquid/Waste Waters)	Other Wastes (Solids/RCRA)
Preparation of the Panel and Shadow Mask	Solvent vapors	Spent solvents	Glass (lead) from breakage
Application of Coating to Panel Interior	Vapors from lacquer area	Spent photoresists, deionized water, acids, oxidizers, carbon slurry, surfactants, chromate, phosphor solutions, chelating agents, caustics, solvents, alcohol, coatings, ammonia, aluminum, and process cooling waters	Lacquer wastes
Installation of Electron Shield		Electron shield degrease and metals	
Preparation of Funnel and Joining to Panel-Mask Assembly		Funnel wash, seal surface cleaning, and frit application wastewaters	Frit contaminated clothing, instruments, utensils, unusable frit glass (lead), glass (lead) from break-age
Installation of Electron Gun		Spent solvents and caustic cleaners	Glass from breakage
Finishing	VOCs	Spent solvents	

R0074990

III.C. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (EPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and are meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The EPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 17 shows that the electronics/computer industry managed about 122 million pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, 44 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 81 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E and F, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production-related wastes (6.7 percent), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

R0074992

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act (EPCRA), TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7 percent between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount, and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

R0074994

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) - encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of waste to on-site landfills, waste that is land treated or incorporated into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Electronics/Computer Industry

The follow section provides TRI data for the semiconductor, printed wiring board (PWB) and cathode ray tube (CRT) industries. The manufacture of these products results in the release of similar substances, including solvents, acids, and heavy metals. The commonly released solvents include acetone, xylene, and methanol. Commonly released acids include sulfuric, hydrochloric, and nitric. A significant amount of ammonia is also released by the electronics/computer industry.

IV.A.1. TRI Data for Semiconductor Industry

The following exhibits present TRI data pertaining to semiconductor manufacturing. Exhibit 18 presents the top ten facilities in terms of TRI releases. Many of these companies are also among the top companies in terms of sales. Exhibit 19 presents the top TRI releasing facilities for all of electronics and other electric facilities. Exhibit 20 displays the number of TRI-reporting semiconductor manufacturing facilities per State. As expected, California and Texas contain the largest number of semiconductor manufacturing facilities.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported <u>only</u> the SIC codes covered under this notebook appear on the first list. The second list contains additional facilities that have reported the SIC code covered within this report, <u>and</u> one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations — some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibits 21 and 22 show the chemical releases and transfers for the semiconductor industry. Sulfuric acid and hydrochloric acid, two of the most commonly-released chemicals, are used during etching and cleaning processes. Solvents such as acetone, glycol ethers, xylene, and Freon 113 are used during photolithography and cleaning processes. 1,1,1-trichloroethane is used during oxidation and ammonia is used during photolithography and cleaning. A significant amount of methyl ethyl ketone is released during the degreasing and cleaning processes. Most of these solvents are released into the air. Facilities with zero releases of certain chemicals are reported here because transfers of the chemical may have been reported.

IV.A.2. TRI Data for Printed Wiring Board Industry

The following exhibits present TRI data pertaining to PWB manufacturing. Exhibit 23 presents the top ten TRI-reporting PWB manufacturing facilities in terms of TRI releases. IBM is one of these companies which is also among the top ten electronics sales generating companies. Exhibit 24 displays the number of TRI-reporting facilities per State. California has the largest number of PWB manufacturing facilities.

R0075001

As seen in Exhibits 25 and 26, the top releases of acids from PWB facilities include sulfuric acid, hydrochloric acid, and nitric acid, all of which are used during cleaning, electroless plating and electroplating operations. Hydrochloric acid is also used during etching. The acids are primarily released to the air or recycled. Glycol ethers are released during image application and cleaning; most of the releases are emitted into the air. Freon 113 is used primarily for flux removal and is released into the air. Nearly all Freon 113 transfers are recycled. Acetone, a solvent used to clean the board before imaging, is released primarily into the air. Ammonium sulfate solution is used during electroplating, imaging, and etching processes and is released to the water or transferred to POTWs. Metals such as lead and copper are commonly used during electroplating, etching, and soldering (i.e., lead) processes. These metals and their compounds are primarily recycled.

IV.A.3. TRI Data for Cathode Ray Tube Industry

Exhibits 27 present the top ten TRI-reporting CRT manufacturers in terms of releases, and Exhibit 28 presents the number of TRI reporting CRT manufacturing facilities by State. It is not surprising that few facilities are reported in TRI because most manufacturing occurs outside the United States. Exhibits 29 and 30 show TRI releases and transfers per chemical. As expected, a significant amount of lead (used during the frit sealing process) is released, much of which is transferred off-site for disposal and recycling. Zinc compounds are used during the phosphor stripe process and are transferred for recycling. Nitric acid, which is used during tube salvaging, is released into the air. Freon 113 is used as a cleaning agent during panel shadow mask preparation and is also released into the air. Solvents (i.e., acetone, methyl ethyl ketone, toluene, and methanol) are used for cleaning and degreasing and are released primarily into the air or transferred for recycling.

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

R0075007

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET[2]. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB.

The following chemicals are those released in the greatest quantity by the electronics/computer manufacturing industry:

Acetone
Ammonia
Dichloromethane
Freon 113
Glycol Ethers
Methanol
Methyl Ethyl Ketone
Sulfuric Acid
Toluene
Trichloroethylene
Xylene

[2] TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

Acetone

Toxicity. Acetone is irritating to the eyes, nose, and throat. Symptoms of exposure to large quantities of acetone may include headache, unsteadiness, confusion, lassitude, drowsiness, vomiting, and respiratory depression.

Reactions of acetone (see environmental fate) in the lower atmosphere contribute to the formation of ground-level ozone. Ozone (a major component of urban smog) can affect the respiratory system, especially in sensitive individuals such as asthmatics or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released into water, acetone will be degraded by microorganisms or will evaporate into the atmosphere. Degradation by microorganisms will be the primary removal mechanism.

Acetone is highly volatile, and once it reaches the troposphere (lower atmosphere), it will react with other gases, contributing to the formation of ground-level ozone and other air pollutants. EPA is reevaluating acetone's reactivity in the lower atmosphere to determine whether this contribution is significant.

Physical Properties. Acetone is a volatile and flammable organic chemical.

Note: Acetone was removed from the list of TRI chemicals on June 16, 1995 (60 FR 31643) and will not be reported for 1994 or subsequent years.

Freon 113 (Trichlorotrifluoroethane)

Toxicity. No adverse human health effects are expected from ambient exposure to Freon 113. Inhalation of high concentrations of Freon 113 causes some deterioration of psychomotor performance (loss of ability to concentrate and a mild lethargy), and an irregular heartbeat. Chronic exposure to Freon 113 caused reversible weakness, pain, and tingling in the legs of one occupationally-exposed woman. There is some evidence of a higher incidence of coronary heart disease among hospital personnel and refrigerant mechanics exposed to fluorocarbons. Exposure to high concentrations of Freon 113 may cause eye and throat irritation.

Fluorocarbons are, however, considerably less toxic than the process materials used in their manufacture (e.g., chlorine). In addition, under certain conditions, fluorocarbon vapors may decompose on contact with flames or hot surfaces, creating the potential hazard of inhalation of toxic decomposition products.

Populations at increased risk from exposure to Freon 113 include people with existing skin disorders, and people with a history of cardiac arrhythmias.

The most significant toxic effect associated with Freon 113 is its role as a potent ozone-depleter. Stratospheric ozone depletion causes an increase in the levels of ultraviolet solar radiation reaching the earth's surface, which in turn is linked to increased incidence of skin cancers, immune system suppression, cataracts, and disruptions in terrestrial and aquatic ecosystems. In addition, increased UV-B radiation is expected to increase photochemical smog, aggravating related health problems in urban and industrialized areas.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. All of the Freon 113 produced is eventually lost as air emissions and builds up in the atmosphere. If released on land, Freon 113 will leach into the ground and volatilize from the soil surface. No degradative processes are known to occur in the soil. Freon 113 is not very water soluble and is removed rapidly from water via volatilization. Chemical hydrolysis, bioaccumulation and adsorption to sediments are not significant fate processes in water.

Freon 113 is extremely stable in the lower atmosphere and will disperse over the globe and diffuse slowly into the stratosphere where it will be lost by photolysis. In this process, chlorine atoms are released that attack ozone.

Glycol Ethers

Due to data limitations, data on diethylene glycol (glycol ether) are used to represent all glycol ethers.

Toxicity. Diethylene glycol is only a hazard to human health if concentrated vapors are generated through heating or vigorous agitation or if appreciable skin contact or ingestion occurs over an extended period of time. Under normal occupational and ambient exposures, diethylene glycol is low in oral toxicity, is not irritating to the eyes or skin, is not readily absorbed through the skin, and has a low vapor pressure so that toxic concentrations of the vapor can not occur in the air at room temperatures.

At high levels of exposure, diethylene glycol causes central nervous depression and liver and kidney damage. Symptoms of moderate 0 diethylene glycol poisoning include nausea, vomiting, headache, diarrhea, abdominal pain, and damage to the pulmonary and cardiovascular systems. Sulfanilamide in diethylene glycol was once used therapeutically against bacterial infection; it was withdrawn from the market after causing over 100 deaths from acute kidney failure.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Diethylene glycol is a water-soluble, volatile organic chemical. It may enter the environment in liquid form via petrochemical plant effluents or as an unburned gas from combustion sources. Diethylene glycol typically does not occur in sufficient concentrations to pose a hazard to human health.

Methanol

Toxicity. Methanol is readily absorbed from the gastrointestinal tract and the respiratory tract, and is toxic to humans in moderate to high doses. In the body, methanol is converted into formaldehyde and formic acid. Methanol is excreted as formic acid. Observed toxic effects at high dose levels generally include central nervous system damage and blindness. Long-term exposure to high levels of methanol via inhalation cause liver and blood damage in animals.

Ecologically, methanol is expected to have low toxicity to aquatic organisms. Concentrations lethal to half the organisms of a test population are expected to exceed 1 mg methanol per liter water. Methanol is not likely to persist in water or to bioaccumulate in aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Liquid methanol is likely to evaporate when left exposed. Methanol reacts in air to produce formaldehyde which contributes to the formation of air pollutants. In the atmosphere it can react with other atmospheric chemicals or be washed out by rain. Methanol is readily degraded by microorganisms in soils and surface waters.

Physical Properties. Methanol is highly flammable.

Methylene Chloride (Dichloromethane)

Toxicity. Short-term exposure to dichloromethane (DCM) is associated with central nervous system effects, including headache, giddiness, stupor, irritability, and numbness and tingling in the limbs. More severe neurological effects are reported from longer-term exposure, apparently due to increased carbon monoxide in the blood from the break down of DCM. Contact with DCM causes irritation of the eyes, skin, and respiratory tract.

Occupational exposure to DCM has also been linked to increased incidence of spontaneous abortions in women. Acute damage to the eyes and upper respiratory tract, unconsciousness, and death were reported in workers exposed to high concentrations of DCM. Phosgene (a degradation product of DCM) poisoning has been reported to occur in several cases where DCM was used in the presence of an open fire.

Populations at special risk from exposure to DCM include obese people (due to accumulation of DCM in fat), and people with impaired cardiovascular systems.

Carcinogenicity. DCM is a probable human carcinogen via both oral and inhalation exposure, based on inadequate human data and sufficient evidence in animals.

Environmental Fate. When spilled on land, DCM is rapidly lost from the soil surface through volatilization. The remainder leaches through the subsoil into the groundwater.

Biodegradation is possible in natural waters but will probably be very slow compared with evaporation. Little is known about bioconcentration in aquatic organisms or adsorption to sediments but these are not likely to be significant processes. Hydrolysis is not an important process under normal environmental conditions.

DCM released into the atmosphere degrades via contact with other gases with a half-life of several months. A small fraction of the chemical diffuses to the stratosphere where it rapidly degrades through exposure to ultraviolet radiation and contact with chlorine ions. Being a moderately soluble chemical, DCM is expected to partially return to earth in rain.

Methyl Ethyl Ketone

Toxicity. Breathing moderate amounts of methyl ethyl ketone (MEK) for short periods of time can cause adverse effects on the nervous system ranging from headaches, dizziness, nausea, and numbness in the fingers and toes to unconsciousness. Its vapors are irritating to the skin, eyes, nose, and throat and can damage the eyes. Repeated exposure to moderate to high amounts may cause liver and kidney effects.

Carcinogenicity. No agreement exists over the carcinogenicity of MEK. One source believes MEK is a possible carcinogen in humans based on limited animal evidence. Other sources believe that there is insufficient evidence to make any statements about possible carcinogenicity.

Environmental Fate. Most of the MEK released to the environment will end up in the atmosphere. MEK can contribute to the formation of air pollutants in the lower atmosphere. It can be degraded by microorganisms living in water and soil.

Physical Properties. Methyl ethyl ketone is a flammable liquid.

Sulfuric Acid

Toxicity. Concentrated sulfuric acid is corrosive. In its aerosol form, sulfuric acid has been implicated in causing and exacerbating a variety of respiratory ailments.

Ecologically, accidental releases of solution forms of sulfuric acid may adversely affect aquatic life by inducing a transient lowering of the pH (i.e., increasing the acidity) of surface waters. In addition, sulfuric acid in its aerosol form is also a component of acid rain. Acid rain can cause serious damage to crops and forests.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of sulfuric acid to surface waters and soils will be neutralized to an extent due to the buffering capacities of both systems. The extent of these reactions will depend on the characteristics of the specific environment.

In the atmosphere, aerosol forms of sulfuric acid contribute to acid rain. These aerosol forms can travel large distances from the point of release before the acid is deposited on land and surface waters in the form of rain.

Toluene

Toxicity. Inhalation or ingestion of toluene can cause headaches, confusion, weakness, and memory loss. Toluene may also affect the way the kidneys and liver function.

Reactions of toluene (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Some studies have shown that unborn animals were harmed when high levels of toluene were inhaled by their mothers, although the same effects were not seen when the mothers were fed large quantities of toluene. Note that these results may reflect similar difficulties in humans.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases of toluene to land and water will evaporate. Toluene may also be degraded by microorganisms. Once volatilized, toluene in the lower atmosphere will react with other atmospheric components contributing to the formation of ground-level ozone and other air pollutants.

Physical Properties. Toluene is a volatile organic chemical.

Trichloroethylene

Toxicity. Trichloroethylene was once used as an anesthetic, though its use caused several fatalities due to liver failure. Short term inhalation exposure to high levels of trichloroethylene may cause rapid coma followed by eventual death from liver, kidney, or heart failure. Short-term exposure to lower concentrations of trichloroethylene causes eye, skin, and respiratory tract irritation. Ingestion causes a burning sensation in the mouth, nausea, vomiting and abdominal pain. Delayed effects from short-term trichloroethylene poisoning include liver and kidney lesions, reversible nerve degeneration, and psychic disturbances. Long-term exposure can produce headache, dizziness, weight loss, nerve damage, heart damage, nausea, fatigue, insomnia, visual impairment, mood perturbation, sexual problems, dermatitis, and rarely jaundice. Degradation products of trichloroethylene (particularly phosgene) may cause rapid death due to respiratory collapse.

Carcinogenicity. Trichloroethylene is a probable human carcinogen via both oral and inhalation exposure, based on limited human evidence and sufficient animal evidence.

Environmental Fate. Trichloroethylene breaks down slowly in water in the presence of sunlight and bioconcentrates moderately in aquatic organisms. The main removal of trichloroethylene from water is via rapid evaporation.

Trichloroethylene does not photodegrade in the atmosphere, though it breaks down quickly under smog conditions, forming other pollutants such as phosgene, dichloroacetyl chloride, and formyl chloride. In addition, trichloroethylene vapors may be decomposed to toxic levels of phosgene in the presence of an intense heat source such as an open arc welder.

When spilled on the land, trichloroethylene rapidly volatilizes from surface soils. The remaining chemical leaches through the soil to groundwater.

Xylene (Mixed Isomers)

Toxicity. Xylenes are rapidly absorbed into the body after inhalation, ingestion, or skin contact. Short-term exposure of humans to high levels of xylenes can cause irritation of the skin, eyes, nose, and throat, difficulty in breathing, impaired lung function, impaired memory, and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations can cause effects such as headaches, dizziness, confusion, and lack of muscle coordination. Reactions of xylenes (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases to land and water will quickly evaporate, although some degradation by microorganisms will occur.

Xylenes are moderately mobile in soils and may leach into groundwater, where they may persist for several years.

Xylenes are volatile organic chemicals. As such, xylenes in the lower atmosphere will react with other atmospheric components, contributing to the formation of ground-level ozone and other air pollutants.

IV.C. Other Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 31 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 31

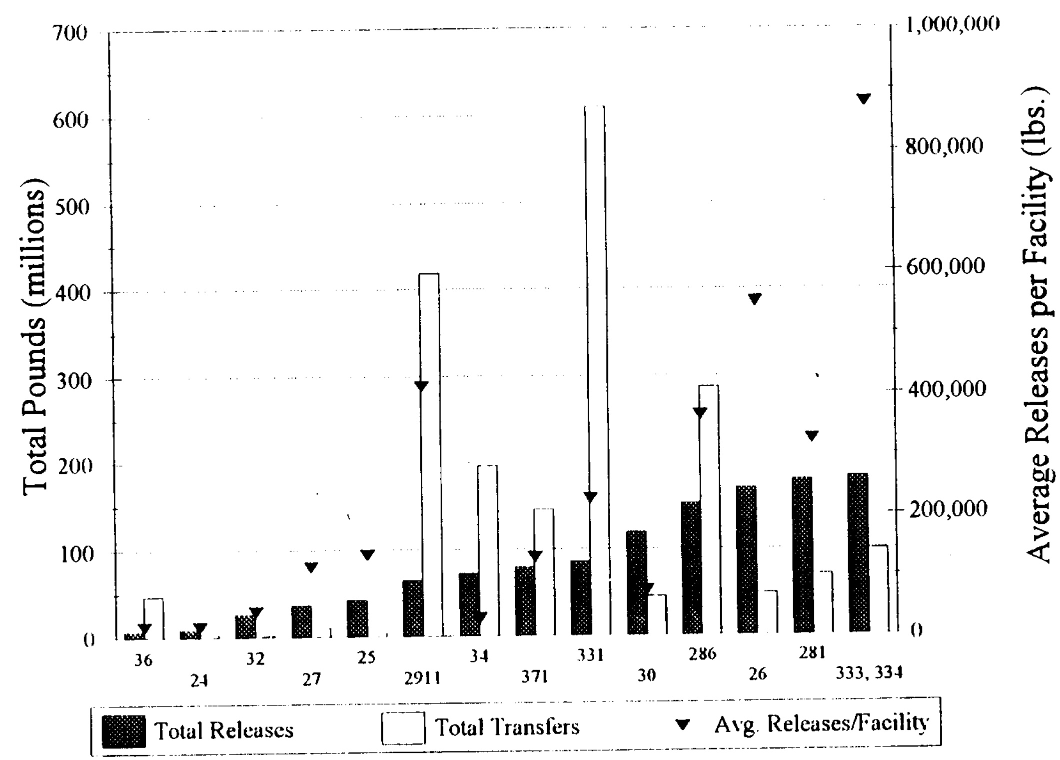
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following table does not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release book.

Exhibit 32 is a graphical representation of a summary of the 1993 TRI data for the electronics/computer industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 33 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of electronics/computer industry, the 1993 TRI data presented here covers 406 facilities. These facilities listed SIC 36 Electronics/Computer Industry as a primary SIC code.

Exhibit 32: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg.

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the electronics/computer industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

Pollution prevention (sometimes referred to as source reduction) is the use of materials, processes, or practices that reduce or eliminate the creation of pollutants or wastes at the source. Pollution prevention includes practices that reduce the use of hazardous materials, energy, water or other resources, and practices that protect natural resources through conservation or more efficient use.

EPA is promoting pollution prevention because it is often the most cost-effective option to reduce pollution and the environmental and health risks associated with pollution. Pollution prevention is often cost effective because it may reduce raw material losses; reduce reliance on expensive "end-of-pipe" treatment technologies and disposal practices; conserve energy, water, chemicals, and other inputs; and reduce the potential liability associated with waste generation. Pollution prevention is environmentally desirable for these very same reasons: pollution itself is reduced at the source while resources are conserved.

V.A. Identification of Pollution Prevention Activities in Use

The electronics and computer industries have participated in many pollution prevention projects and have been the focus of many case studies. Pollution prevention techniques and processes used by these industries can be grouped into four general categories:

- Process or equipment modification
- Raw material substitution or elimination
- Waste segregation/separation/preparation
- Recycling.

Each of these categories is briefly discussed below. Refer to Section V.B. for a list of specific pollution prevention techniques and associated costs, savings, and other information.

Process or equipment modification is used to reduce the amount of waste generated. For example, manufacturers can change equipment or processes to: enhance water conservation by installation of countercurrent rinsing systems; reduce alkaline and acid concentration in tanks by installing a pH controller; and reduce drag-out by decreasing the withdrawal rate of parts from plating tanks.

Raw material substitution or elimination is the replacement of existing raw materials with other materials that produce less waste, or a non-toxic waste. Examples include substituting non-cyanide solution for a sodium cyanide solution in copper plating baths and replacing hexavalent chromium with trivalent chrome plating system.

Waste segregation/separation/preparation involves avoiding the mixture of different types of wastes and avoiding the mixture of hazardous wastes with non-hazardous wastes. This makes the recovery of hazardous wastes easier by minimizing the number of different hazardous constituents in a given waste stream. Also, it prevents the contamination of non-hazardous wastes. A specific example is segregation of wastewater sludge by metal contaminants.

Recycling is the use or reuse of a waste as an ingredient or feedstock in the production process on-site. Examples of recycling include: recovering copper during the etching processes, recovering lead and tin from printed wiring boards, and installing a closed-loop recycling system to reuse freon (which is being phased-out) and reduce/reuse water consumption.

V.B. Pollution Prevention Techniques for the Electronics/Computer Industry

This section provides examples of pollution prevention techniques used in the electronics/computer industry. Much of the information provided in this section is from the following EPA offices/programs: the Common Sense Initiative (CSI), EPA's DfE Program, the Pollution Prevention Information Center, the Office of Environmental Engineering and Technology Demonstration, the Office of Pollution Prevention, and Office of Research and Development. Other sources include the Oregon Department of Environmental Quality and the California Department of Toxic Substances and Control. Where available, cost information is provided. However, source documents did not always provide cost information.

V.B.1. Examples of Source Reduction and Recycling Options for Electroplating Operations

Technique - Process or Equipment Modification

Option 1 - Modify rinsing methods to control drag-out by:

- Increasing bath temperature
- Decreasing withdrawal rate of parts from plating bath
- Increasing drip time over solution tanks; racking parts to avoid cupping solution within part cavities
- Shaking, vibrating, or passing the parts through an air knife, angling drain boards between tanks
- Using wetting agents to decrease surface tension in tank.

Contact: Braun Intertec Environmental, Inc., and MN Office of Waste Management (612) 649-5750.

Option 2 - Utilize water conservation methods including:

- Flow restrictors on flowing rinses
- Counter current rinsing systems
- Fog or spray rinsing
- Reactive rinsing
- Purified or softened water
- Dead rinses
- Conductivity controllers
- Agitation to assure adequate rinsing and homogeneity in rinse tank
- Flow control valves.

Contact: Braun Intertec Environmental, Inc., and MN Office of Waste Management (612) 649-5750.

Option 3 - Implement counter flow rinsing and cascade rinsing systems to conserve consumption of water. **Costs and Savings:** Costs: $75,000 to upgrade existing equipment and purchasing new and used equipment. Waste Savings/Reduction: reduce water use and wastewater treatment costs. **Contact:** Eastside Plating and OR Department of Environmental Quality (800) 452-4011.

Option 4 - Use drip bars to reduce drag-out. **Costs and Savings:** Capital Investment: $100/tank. Savings: $600/year. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 5 - Use drain boards between tanks to reduce generations of drag-out. **Costs and Savings:** Capital Investment: $25/tank. Savings: $450/year . **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 6 - Install racking to reduce generations of drag-out. **Costs and Savings:** Capital Investment: zero dollars. Operating Costs: minimal. Savings: $600/year. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 7 - Employ drag out recovery tanks to reduce generations of drag-out. **Costs and Savings:** Capital Investment: $500/tank. Savings: $4,700/year. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 8 - Install counter-current rinsing operation to reduce water consumption. **Costs and Savings:** Capital Investment: $1,800-2,300. No direct costs. Savings: $1,350/year. Waste Savings/Reductions: reduce water use by 90-99%. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 9 - Redesign rinse tank to reduce water conservation. **Costs and Savings:** Capital Investment: $100. No direct costs. Savings: $750/year. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 10 - Increase parts drainage time to reduce drag-out. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 11 - Regenerate plating bath by activated carbon filtration to remove built up organic contaminants. **Costs and Savings:** Capital Investment: $9,192. Costs: $7,973/year. Savings: $122,420/year. Waste Savings/Reduction: 10,800 gallons/year. Reduce volume of plating baths disposed and requirements for virgin chemicals. **Contact:** EPA Hazardous Waste Engineering Research Laboratory, Cincinnati, OH, Harry Freeman.

Option 12 - Install pH controller to reduce the alkaline and acid concentrations in tanks. **Contact:** Securus, Inc., DBA Hubbard Enterprises.

Option 13 - Install atmospheric evaporator to reduce metal concentrations. **Contact:** Securus, Inc., DBA Hubbard Enterprises.

Option 14 - Install process (e.g., CALFRAN) to reduce pressure to vaporize water at cooler temperatures and recycle water by condensing the vapors in another container, thus concentrating and precipitating solutes out. **Costs and Savings:** Waste Savings/Reduction: reduce volume and quantity of aqueous waste solutions by recovering pure water. **Contact:** CALFRAN International, Inc., (413) 525-4957.

Option 15- Use reactive rinsing and multiple drag-out baths. **Costs and Savings:** Savings: Reduce cost of treating spent process baths and rinsewaters. Waste Savings/Reduction: increase lifetime of process baths and reduce the quantity or rinsewater requiring treatment. **Contact:** SAIC, Edward R. Saltzberg.

Option 16 - Improve control of water level in rinse tanks, improve sludge separation, and enhance recycling of supernatant to the process by aerating the sludge. **Costs and Savings:** Savings: $2,000/year. Waste Savings/Reduction: reduce sludge generation by 32%. **Contact:** NJ Hazardous Waste Facilities Siting Commission, Hazardous Waste Source Reduction and Recycling Task Force.

Option 17 - Install system (e.g., Low Solids Fluxer) that applies flux to printed wiring boards, leaving little residue and eliminates the need for cleaning CFCs. **Costs and Savings:** Waste Savings/Reduction: reduce CFC emissions over 50%. **Contact:** AT&T Bell Laboratories, Princeton, NJ.

Option 18 - Install ion exchange system to reduce generation of drag-out. **Costs and Savings:** Savings: $1,900/year. Capital Investment: $78,000. Operating Costs: $3,200/year. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 19 - Employ reverse osmosis system to reduce generation of drag-out. **Costs and Savings:** Savings: $40,000/year. Capital Investment: $62,000. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 20 - Use electrolytic metal recovery to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $1,000. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 21- Utilize electrodialysis to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $50,000. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 22 - Implement evaporative recovery to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $2,500. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 23- Implement the electrodialysis reversal process for metal salts in wastewater. **Costs and Savings**: Savings: $40,100/year in operating costs. **Contact:** Ionics, Inc., Separations Technology Division.

Technique - Raw Material Substitution

Option 1 - Substitute cyanide plating solutions with alkaline zinc, acid zinc, acid sulfate copper, pyrophosphate copper, alkaline copper, copper fluoborate, electroless nickel, ammonium silver, halide silver, methanesulfonate-potassium iodide silver, amino or thio complex silver, no free cyanide silver, cadmium chloride, cadmium sulfate, cadmium fluoborate, cadmium perchlorate, gold sulfite, and cobalt harden gold. **Contact:** Braun Intertec Environmental, Inc. and MN Office of Waste Management (612) 649-5750.

Option 2 - Substitute sodium bisulfite and sulfuric acid for ferrous sulfate in order to oxidize chromic acid wastes, and substitute gaseous chlorine for liquid chlorine in order to reduce cyanide reduction. **Costs and Savings:** Savings: $300,000/year. Waste Savings/Reduction: reduces feedstock by 50%. **Contact:** Eastside Plating and OR Department of Environmental Quality (800) 452-4011.

Option 3 - Replace hexavalent chromium with trivalent chromium plating systems. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 4 - Replace cyanide with non-cyanide baths. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 5 - Replace conventional chelating agents such as tartarates, phosphates, EDTA, and ammonia with sodium sulfides and iron sulfates in removing metal from rinse water which reduces the amount of waste generated from precipitation of metals from aqueous wastestreams. **Costs and Savings:** Costs: $178,830/year. Savings: $382,995/year. Waste Savings/Reduction: 496 tons of sludge/year. **Contact:** Tyndall Air Force Base, FL, Charles Carpenter (904) 283-2942; EG & G, Dan Sucia, Penny Wilcoff, & John Beller (208) 526-1149.

Option 6 - Replace methylene chloride, 1,1,1-trichloroethane, and perchloroethylene (solvent-based photochemical coatings) with aqueous base coating of 1% sodium carbonate. **Costs and Savings:** Waste Savings/Reduction: reduce solvent use by 60 tons/year. **Contact:** American Etching and Manufacturing, Pacoima, CA.

Option 7 - Replace methanol with nonflammable alkaline cleaners. **Costs and Savings:** Waste Savings/Reduction: eliminate 32 tons/year of flammable methyl alcohol. **Contact:** American Etching and Manufacturing, Pacoima, CA.

Option 8 - Substitute a non-cyanide for a sodium cyanide solution used in copper plating baths. **Costs and Savings:** Waste Savings/Reduction: reduce 7,630 pounds/year. **Contact:** Highland Plating Company, Los Angeles, CA.

Technique - Recycling

Option 1 - Send drag-out waste to another company for waste exchange. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 2 - Reuse rinse water. **Costs and Savings:** Savings: $1,500/year. Capital Investment: $340/tank. No direct costs. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 3- Reuse drag-out waste back into process tank. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 4- Recover process chemicals with fog rinsing parts over plating bath. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 5 - Evaporate and concentrate rinse baths for recycling. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 6 - Use ion exchange and electrowinning, reverse osmosis, and thermal bonding when possible. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 7 - Use sludge slagging techniques to extract and recycle metals. **Costs and Savings:** Capital Investment: $80,000 for 80 tons/year and $400,000 for 1,000 tons/year. Operating Costs: $18,000 per year for an 80 ton facility. Waste Savings/Reduction: reduces volume of waste by 94%. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 8 - Use hydrometallurgical processes to extract metals from sludge. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 9- Convert sludge to smelter feed. **Contact:** City of Los Angeles Hazardous and Toxic Material Project; Board of Public Works (213) 237-1209.

Option 10 - Remove and recover lead and tin from boards by electrolysis or chemical precipitation. **Contact:** Control Data Corporation and MN Office of Waste Management (612) 649-5750.

Option 11 - Install a closed loop batch treatment system for rinsewater to reduce water use and waste volume. **Costs and Savings:** Savings: $58,460/year. Capital Investment: $210,000. Waste Savings/Reduction: 40,000 gallons/year (40%). **Contact:** Pioneer Metal Finishing, Inc., Harry Desoi (609) 694-0400.

Option 12 - Install an electrolytic cell which recovers 92 percent of dissolved copper in drag-out rinses and atmospheric evaporator to recover 95 percent of chromatic acid drag-out, and recycle it into chromic acid etch line. **Contact:** Digital Equipment Corporation and Lancy International Consulting Firm, William McLay (412) 452-9360.

Option 13- Oxidize cyanide and remove metallic copper to reduce metal concentrations. **Contact:** Securus, Inc., DBA Hubbard Enterprises.

V.B.2. Examples of Source Reduction and Recycling Options for Etching Operations

Technique - Raw Material Substitution

Option 1 - Substitute sodium persulfate etchant (acid etch solution) with hydrogen peroxide/ sulfuric acid. **Contact:** ADC Products and MnTAP (612) 625-4949.

Technique - Recycling

Option 1 - Recover copper by electrolytic processes. **Contact:** ADC Products and MnTAP (612) 625-4949.

V.B.3. Examples of Source Reduction and Recycling Options for Semiconductor Manufacturing

Technique - Process or Equipment Modification

Option 1 - Install a system (e.g., the CALFRAN process) to reduce pressure to vaporize water at cooler temperatures, recycle water by condensing the vapors in another container, and concentrate and precipitate solutes. **Costs and Savings**: Waste Savings/Reduction: reduce volume and quantity of aqueous waste solutions by recovering pure water. **Contact**: CALFRAN International, Inc. Springfield, MA 01101, Val Partyka (413) 525-4957.

Option 2 - Reduce chrome waste generation by :

- Installing a rain cover over on outdoor tanks to reduce chrome waste
- Treating on-site with caustics and sodium bisulfite to reduce chrome VI liquid to chrome III sludge
- Repairing water leaks in process rinse tank to reduce chrome waste.

Costs and Savings: Capital Investment: $30,000 for the rain cover, pipe repairs, and on-site treatment system. Waste Savings/Reduction: Savings: $15,000/year in disposal costs, and reduce 95% of chrome wastes from 6,000 gallons to two or three drums generated per quarter. **Contact**: Wacker Siltronic Corporation and University of MN (612) 625-4949.

Technique - Raw Material Substitution

Option 1 - Replace chlorinated solvent baths with a non-hazardous product to reduce, and later, eliminate use of chlorinated solvents. **Costs and Savings**: Waste Savings/Reduction: reduce chlorinated solvent use by 93%, and then completely eliminate the use of the chemical. **Contact**: Wacker Siltronic Corporation and University of MN (612) 625-4949.

Technique - Recycling

Option 1 - Convert an open-top still into a closed loop system to recycle Freon 113. **Costs and Savings**: Costs: $20,000. Waste Savings/Reduction: $57,000/year in disposal and feedstock costs, and reduce waste volume by 85%. **Contact**: Wacker Siltronic Corporation and University of MN (612) 625-4949.

Option 2 - Use Athens system to reprocess sulfuric acid generated during wafer fabrication operations. The acid is heated to boil off water and other impurities, purified through distillation, and pumped back into wet stations to continue wafer processing. Costs and savings: Annual savings/Reductions: $2.9 million from not purchasing sulfuric acid and 28% reduction in sulfuric acid generated in 1993. Contact: Intel or Alameda Instruments, Inc. and Athens Corporation (manufacturers of this type of equipment).

V.B.4. Examples of Source Reduction and Recycling Options for Printed Wiring Board Manufacturing

V.B.4.a. General Operations

Technique - Process or Equipment Modification

Option 1 - Modify sludge pretreatment processes by:

- Adding flow control valves
- Installing metal recovery equipment
- Adding of deionization system

Costs and Savings: Costs: lower chemical treatment costs. Waste Savings/Reduction: $90,000 in disposal costs. **Contact**: Unisys Corporation and MnTAP (612) 625-4949.

Option 2 - Redesign board during board assembly. **Contact:** Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Option 3 - Install a system (e.g., CALFRAN process) to reduce pressure to vaporize water at cooler temperatures, recycle water by condensing the vapors in another container, concentrate and precipitate solutes. **Costs and Savings**: Waste Savings/Reduction: reduce volume and quantity of aqueous waste solutions by recovering pure water. **Contact:** CALFRAN International, Inc. Springfield, MA 01101, Val Partyka (413) 525-4957.

Option 4 - Alternatives to wet chemical processes include:
- Mechanical cleaning as an alternative to chemical methods;
- Process efficiency improvements for applying photopolymers, printing, and developing;
- Alternative processes for connecting the PWB layers together; and
- Alternatives to lead-based soldering involving the use of lasers, reactive gases, or ultrasonics.

Contact: EPA CSI.

Technique - Raw Material Substitution

Option 1 - Substitute semiaqueous or aqueous photoresist for TCA and methylene chloride during board manufacturing. **Contact**: Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Option 2 - Substitute no-clean fluxes for CFC 113 and TCA during board assembly. **Contact**: Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Option 3 - Substitute aqueous clean fluxes for CFC 113 and TCA during board assembly. **Contact**: Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Option 4 - Substitute semi-aqueous cleaning materials for CFC 113 and TCA during board assembly. **Contact:** Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Option 5 - Substitute other solvents for CFC 113 and TCA during board assembly. **Contact**: Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

Technique - Waste Segregation/Separation/Preparation

Option 1 - Segregate wastewater sludge to prepare for metal recovery. **Contact**: Unisys Corporation and MnTAP (612) 625-4949.

Technique - Recycling

Option 1 - Remove and recover lead and tin from boards by electrolysis-chemical precipitation. **Contact**: Control Data Corporation and MN Office of Waste Management (612) 649-5750.

V.B.4.b. Cleaning Operations

Technique - Process or Equipment Modification

Option 1 - Install a system (e.g., Low Solids Fluxer (LSF)) which applies flux to printed wiring boards, leaves little residue, and eliminates the need for cleaning with CFCs. **Costs and Savings**: Waste Savings/Reduction: reduce CFC emissions over 50%. **Contact**: AT&T Bell Laboratories, Princeton, NJ.

Technique - Raw Material Substitution

Option 1 - Substitute for CFC 113 used in defluxing with:
- Fully aqueous system using water soluble fluxes
- Aqueous system using saponifiers to remove rosin based fluxes
- Semi-aqueous system using terpenes as a solvent
- Hydrogenated CFCs with chlorinated solvents

Contact: Medtronic Inc. and MN Technical Assistance Program (MnTAP) (612) 627-4848 Maria Scheller.

Option 2 - Substitute CFC 113 used in hand cleaning boards with:
- Blend of HCFC and methanol dispensed from a trigger-grip device that limits the amount of solvent lost to the atmosphere

Contact: Medtronic Inc. and MN Technical Assistance Program (MnTAP) (612) 627-4848 Maria Scheller.

V.B.4.c. Electroplating Operations

Technique - Raw Material Substitution

Option 1 - During tin-lead electroplating process, substitute fluoboric acid with:
- Organic sulfonic acid (OSA) plating
- Acid tin sulfate plating which eliminates lead use
- Hot air leveling
- Conductive, solderable polymer solutions

Contact: Capsule Environmental Engineering Inc. and MN Office of Waste Management (612) 649-5750.

V.B.5. Examples of Source Reduction and Recycling Options for Cathode Ray Tube Manufacturing

Technique - Process or Equipment Modification

Option 1- Reduce building of contamination in bath solutions by increasing process efficiency (e.g., implement ion exchange technology). **Contact:** EPA CSI.

R0075030

Technique - Raw Material Substitution

Option 1 - Replace lacquer in panel preparation with a wax-like material similar to floor wax. It provides the necessary coating without a high VOC content. One potential drawback, however, is the use of ammonia. **Contact:** EPA CSI.

Option 2 - Replace Freon as a cleaning agent for removing particulate contaminants from panel mask frames with air blow cleaning and an aqueous wash (nearly all CRT manufacturers have implemented this change). **Contact:** EPA CSI.

Option 3 - Identify less hazardous cleaning chemicals, such as isopropyl alcohol, as alternatives to acetone or chlorinated solvents in maintenance and cleanup processes. **Contact:** EPA CSI.

Option 4 - Find substitutes for chromium-based photoresists. **Contact:** EPA CSI.

Option 5 - Identify alternatives to the lead-based frit used in sealing the funnel with the panel mask. **Contact:** EPA CSI.

Technique - Recycling

Option 1 - Regenerate acids for glass cleaning and frit removal in waste glass recovery operations using existing technologies and equipment. **Contact:** EPA CSI.

Option 2 - Reclaim and reuse photoresists from one of the panel preparation processes. **Contact:** EPA CSI.

Option 3 - Recover soluble lead generated during the waste glass recovery operation by ion exchange resins. Reuse in lead smelting operations. **Contact:** EPA CSI.

Option 4 - Improve phosphor solution recovery and recycling efficiencies to further reduce discharge of metals to the environment. **Contact:** EPA CSI.

Option 5- Reduce or recover the following:
- Chrome wastes
- Cleaning materials (hydrofluoric acids)
- EP effluent
- Furnaces slag
- Cullet dust
- Fugitive dust
- Refractory brick wastes
- Alcohols

Contact: EPA CSI.

V.C. Pollution Prevention Case Studies

The electronics/computer industry is actively involved in pollution prevention activities, especially for products such as semiconductors and printed wiring boards. Pollution prevention techniques are available and have been implemented successfully for processes such as cleaning, etching, electroplating, and wastewater treatment. California's *Assessment of the Semiconductor Industry Source Reduction Planning Efforts* provides additional information and case studies on pollution prevention techniques. Eastside Plating, Unisys Corporation, and Wacker Siltronic Corporation are examples of companies with successful pollution prevention programs. The pollution prevention activities employed in these three case studies provided each company with significant savings.

Eastside Plating, Portland, Oregon's oldest and largest electroplating facility, demonstrated that complying with environmental laws and implementing pollution prevention activities is cost effective. Eastside used three major pollution prevention techniques: water conservation, material substitution, and machinery automation and upgrade.

The first activity addressed the challenge of diminishing the use of water. Ninety percent of water required for electroplating is used during the rinsing process (to clean the wafer, end chemical reactions, and prevent contaminants from being released into the next bath). Eastside modified the rinsing process by installing two systems that conserve water: counter flow and cascade rinsing systems. Counter flow rinsing recycles and reuses water throughout a multiple tank system, reducing significantly the volume of water required. Fresh water is only introduced in the last tank of the system. Cascade rinsing also reduces the volume of water required. This system uses one tank with a center divider which allows the water to spill into the other side. During cascade rinsing, the tank is filled and drained slowly and continuously in order to reduce water consumption. Overflow from one tank can be used as the water supply for another compatible rinsing system.

Eastside also reduced chromium and cyanide wastes through material substitution. The reducing agent for chromic acid wastes was changed from ferrous sulfate to bisulfite and sulfuric acid, which reduced the volume of sludge produced. Cyanide wastes are reduced more efficiently with gaseous instead of liquid chlorine.

Finally, three major waste treatment components were upgraded or automated: the cyanide oxidation tank, chromium reduction tank, and the acid/alkali neutralization tank. The goal of automating and upgrading this equipment was to increase efficiency, separate tank flow, and eliminate contamination of acid/alkali neutralization tank. Automated metering equipment was installed and reduced the expensive caustic chemicals required to treat acid wastes by 50 percent. The cyanide and chromic acid oxidation tanks were redesigned as gravity flow systems to equalize flow rate and to eliminate the risks associated with plumbing failure. To prevent cross contamination of the tanks, the plumbing was segregated.

Other important steps taken by Eastside Plating to enhance pollution prevention included collaborating with suppliers on modifications to reaction and neutralization tanks, working with regulators to solve problems, and providing employee education.

The new rinsing systems, materials substitution, and upgrade/ automation of equipment cost Eastside $75,000. Overall, Eastside implemented changes to the operation which has saved the company more than $300,000 annually. In addition, pollution prevention and waste minimization has resulted in a cleaner facility, increased productivity, and a better product.

Unisys is a manufacturer of both large and small computers. In 1986, Unisys implemented pollution prevention/waste minimization techniques associated with the automated copper plating process in its printed circuit board manufacturing plant in Roseville, Minnesota. Unisys worked with Minnesota Technical Assistance Program (MnTAP) to reduce the two to three drums of wastewater treatment sludge produced each day.

MnTAP recommended several changes in the pretreatment process such as: segregation of the wastestreams; addition of flow control valves; installation of metal recovery equipment; and addition of a deionization system. Wastestream segregation involved changing the plumbing to separate the wastestreams containing metal contaminants. Another modification reduced overall water usage through the installation of flow control valves. Metal recovery techniques, such as ion exchange and electrolytic metal recovery, reclaim copper from metal-bearing wastestreams. The deionization systems allow the pretreatment process to operate more efficiently. Ion exchange and electrolytic recovery is enhanced by deionization by removing hard water ions in the process and rinse tanks. The modifications ensure environmental compliance, lower treatment chemical costs, and reduce sludge disposal costs by an estimated $90,000 per year. In addition, the pollution prevention and waste minimization changes have allowed Unisys to expand its plating line.

Wacker Siltronic Corporation, a semiconductor manufacturer, successfully implemented pollution prevention and waste minimization techniques similar to those employed by Unisys and Eastside. In order to maintain cleanliness in silicon wafer production, Wacker made extensive use of chloride solvent baths. Once the disposal of chlorinated solvent wastes at a Oregon hazardous waste facility was prohibited by Federal regulations, Wacker sought to recycle the solvents. However, the potential liability associated with transporting thousands of gallons of solvents to a recycling facility led Wacker to seek other alternatives. A six month pilot project was first implemented to decrease chlorinated solvent use which resulted in the elimination of 93 percent of Wacker's chlorinated solvent waste. Ultimately, Wacker eliminated completely the use of chlorinated solvents through replacement with non-hazardous cleaning products.

Wacker used to generate 2000 gallons of chrome VI waste each month, which needed to be sent off-site for disposal. Reduction of chrome waste to two to three drums each quarter involved three techniques: installation of a rain cover over the outdoor tanks; on-site treatment of chrome VI waste using caustics and sodium bisulfite; and repairing water leaks in the process rinse tank. The rain cover cost $7,000, but reduced the volume of waste shipments by 25 percent. The new treatment of the chrome VI liquid reduced it to a less hazardous chrome III sludge which can be dried and sent off-site for disposal. Repair of small leaks in the rinse tanks resulted in a 50 percent reduction of wastes. The cover, pipe repairs, and on-site treatment system cost $30,000 and led to a 95 percent reduction of chrome waste as well as annual savings of $15,000. The initial costs were recovered within three years.

A final pollution prevention waste minimization technique involved recycling Freon 113. An open-top still was converted into a closed-loop system at a cost of $20,000. The conversion reduced the volume of Freon waste by 85 percent and saves the company $57,000 each year. Overall, Wacker states that pollution prevention and waste minimization has resulted in annual savings of $300,000.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations (CFR) and other State or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.
- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.
- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the

designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and States can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about

R0075038

chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQS) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQS for a given pollutant are classified as attainment areas; those that do not meet NAAQS are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPS), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPS are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAP), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date, EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996.

provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Requirements

Clean Air Act (CAA)

Under the CAA, the National Ambient Air Quality Standards (NAAQS) have been established for six pollutants. The only one that significantly impacts the electronics/computer industry is the standard for ozone. While the electronics/computer industry is not a major source of ozone, it is a major source of volatile organic compounds (VOC). A source defined as "major" in ozone nonattainment areas must install Reasonable Available Control Technology (RACT) as prescribed in the applicable State Implementation Plan (SIP). A major source is both defined by the size of the source's emissions and the category of the nonattainment area. A determination of the necessary RACT requirements is made on the basis of a case by case review of each facility. In an attempt to issue uniform guidelines, EPA has begun to issue Control Technology Guidance (CTG) for each industrial category. The following CTGs may apply to the semiconductor industry:

- Miscellaneous Metal Parts and Products
- Plastic Parts
- Alternative Control Technology (ATG) for Solvent Cleaning.

Clean Water Act (CWA)

The National Pollution Discharge Elimination System (NPDES) permit program regulates the discharge of pollutants to the waters of the United States. A permit is required if a source discharges directly to surface waters. Facilities must provide the results of biological toxicity tests and any information on its "effluent characteristics." The electronics/computer industry must test for all 126 priority pollutants listed in 40 CFR 122, Appendix D. Facilities must provide quantifiable data only for discharges of priority pollutants which the applicant knows or has reason to believe will be greater than trace amounts. Priority pollutants likely to be discharged by facilities in the electronics/computer industry include

R0075047

copper, lead, lead compounds, silver, chromium, and trichloroethylene.

Quantitative testing is required for non-conventional pollutants if they are expected to be present in discharges. Examples of hazardous substances and non-conventional pollutants likely to be discharged by the electronics/computer industry include butyl acetate, xylene, formaldehyde, tin-total, nitrate/nitrites, titanium-total, and chlorine-total residual.

The electronics/computer industry must satisfy the following technology-based effluent limitation guidelines:

- 40 CFR Part 469 applies to discharges from all processes associated with semiconductor manufacturing except sputtering, vapor deposition, and electroplating.
- 40 CFR Part 433 applies to semiconductor manufacturing plants that perform any of six metal finishing operations - electroplating, electroless plating, anodizing, coating, chemical etching, milling, and printed wired board manufacturing.
- 40 CFR Part 433 applies to discharges associated with the manufacture of printed wiring boards (PWB), except indirect discharging job shops and independent PWB manufacturers who discharge to POTWs, which are covered by Part 413.
- 40 CFR Part 469, Subpart C applies to discharges from display manufacturing.
- 40 CFR Part 469, Subpart D applies to discharges from the manufacturing of luminescent materials which are used in coatings in fluorescent lamps and cathode ray tubes. Luminescent materials include, but are not limited to, calcium halophosphate, zinc sulfide, and zinc-cadmium.
- 40 CFR Part 413 applies to electroplating of common metals, chemical etching and milling, and electroless plating. Subpart A refers to discharges of pollutants from processes that involve ferrous or nonferrous material electroplated with (or any combination of) copper, nickel, chromium, zinc, tin, lead, cadmium, iron, or aluminum. Subpart F applies to process wastewaters from chemical milling or etching of ferrous or nonferrous materials. Subpart G applies to process wastewaters from the electroless plating of a metallic layer on a metallic or nonmetallic substrate.

Facilities that discharge to POTWs must comply with categorical and general pretreatment requirements:

- 40 CFR Part 413, Subpart B applies to electroplating of precious metals or to discharges from a process in which a ferrous or nonferrous material is plated with, or a combination of, gold, silver, iridium, palladium, platinum, rhodium, or ruthenium.

Resource Conservation and Recovery Act (RCRA)

Many wastes generated by the electronics/computer industry are considered RCRA toxicity characteristic (TC) hazardous wastes due to constituents such as silver, trichloroethylene, and lead. The greatest quantities of RCRA listed waste and characteristic hazardous waste present in the electronics/computer industry are identified in Exhibit 30. For more information on RCRA hazardous waste, refer to 40 CFR Part 261.

Exhibit 34
Hazardous Wastes Relevant to the Electronics/Computer Industry

EPA Hazardous Waste No.	Hazardous Waste
D006 (cadmium) D007 (chromium) D008 (lead) D011 (silver)	Wastes which are hazardous due to the characteristic of toxicity for each of the constituents.
F001	Halogenated solvents used in degreasing: tetrachloroethylene, methylene chloride, 1,1,1-trichloroethane, carbon tetrachloride, and chlorinated fluorocarbons; all spent solvent mixtures/blends used in degreasing containing, before use, a total of 10 percent or more (by volume) of one or more of the above halogenated solvents or those solvents listed in F002, F004, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F002	Spent halogenated solvents; tetrachloroethylene, methylene chloride, trichloroethylene, 1,1,1-trichloroethane chlorobenzene, 1,1,2-trichloro-1,2,2-trifluoroethane, ortho-dichlorobenzene, trichlorofluoromethane, and 1,1,2-trichloroethane; all spent solvent mixtures/blends containing, before use, one or more of the above halogenated solvents or those listed in F001, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F003	Spent non-halogenated solvents: xylene, acetone, ethyl acetate, ethyl benzene, ethyl ether, methyl isobutyl ketone, n-butyl alcohol, cyclohexanone, and methanol; all spent solvent mixtures/blends containing, before use, only the above spent non-halogenated solvents; and all spent solvent mixtures/blends containing, before use, one or more of the above non-halogenated solvents, and, a total of 10% or more (by volume) of one of those solvents listed in F001, F002, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F004	Spent non-halogenated solvents: cresols and cresylic acid, and nitrobenzene; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F005	Spent non-halogenated solvents: toluene, methyl ethyl ketone, carbon disulfide, isobutanol, pyridine, benzene, 2-ethoxyethanol, and 2-nitropropane; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, or F004; and still bottoms from the recovery of these spent solvents and spent solvents mixtures.
F006	Wastewater treatment sludges from electroplating operations except from the following processes: (1) sulfuric acid anodizing of aluminum; (2) tin plating on carbon steel; (3) zinc plating (segregated basis) on carbon steel; (4) aluminum or zinc-aluminum plating on carbon steel; (5) cleaning/stripping associated with tin, zinc, and aluminum plating on carbon steel; and (6) chemical etching and milling of aluminum.
F007	Spent cyanide plating bath solutions from electroplating operations.
F008	Plating bath residues from the bottom of plating baths from electroplating operations where cyanides are used in the process.
F009	Spent stripping and cleaning bath solutions from electroplating operations where cyanides are used in the process.

VI.B.1. Notable State Regulations

California's *Hazardous Waste Source Reduction and Management Review Act of 1988,* commonly referred to as SB14, requires generators that produce over 12,000 kilograms of hazardous waste or 12 kilograms of extremely hazardous waste to produce two documents every four years. The documents include a Source Reduction Plan and a Management Performance Report. The Act intends to promote hazardous waste reduction at the source and recycling. For more information on the compilation of these reports by the semiconductor industry, see the October 1994 *Assessment of the Semiconductor Industry Source Reduction Planning Efforts,* by the California Department of Toxic Substances Control.

According to Daryl Burn of the California Air Resources Board, the Board has promulgated Rule 830, Semiconductor Manufacturing Operations, which regulates VOC emissions from semiconductor manufacturing facilities. VOCs are released during wafer preparation, photolithography, and cleaning operations. Rule 830 was developed in 1988 for the Bay Area Air Quality Management District (San Francisco area) because a large concentration of semiconductor manufacturing facilities are located in South Bay and San Francisco. The Board does not provide assistance to facilities to help achieve compliance.

VI.C. Pending and Proposed Regulatory Requirements

SDWA/Underground Injection Control Wells (UIC)

New regulations are being developed for UIC which will amend 40 CFR 144 and 146. The regulations will establish minimum Federal requirements for the permitting, operating, monitoring, and closure of several types of shallow injection wells. Restrictions will be imposed on the operation of certain types of shallow disposal wells, especially those that inject industrial wastes. Computer manufacturing facilities located in areas without sewer systems that rely on shallow waste injection wells to dispose of industrial and non-sanitary wastes will be impacted by these regulations.

Resource Conservation and Recovery Act (RCRA)

RCRA prohibits the land disposal of most hazardous wastes until they meet a waste specific treatment standard. While most hazardous wastes have already been assigned treatment standards,

R0075051

EPA must still promulgate additional rule makings to address newly listed wastes and to make changes to the land disposal restrictions (LDR) program. Rules are required every time EPA lists a waste.

The Phase III LDR rulemaking proposes to establish treatment standards for some newly listed wastes and RCRA equivalent treatment standards for certain formerly characteristic hazardous wastes that are injected into UIC wells under the Safe Drinking Water Act (SDWA) or managed in Subtitle D surface impoundments prior to discharge pursuant to the Clean Water Act (CWA). By consent decree, EPA must promulgate the final rule for Phase III by January 1996.

Phase IV will similarly consider restrictions on other newly listed or identified wastes from land disposal and evaluate what, if any, treatment standards may be needed to mitigate the impact of sludges, leaks, and air emissions from surface impoundments that manage decharacterized wastes. In addition to considering restrictions on the land disposal of the previously exempt Bevill wastes and wastes from wood preserving, Phase IV will also consider adjustments to the treatment standards applicable to wastes that exhibit the toxicity characteristic for a metal constituent. Subject to the same consent decree, Phase IV has been assigned a judicial deadline of June 1996 for promulgation of a final rule.

Clean Air Act (CAA)

Lead NAAQS may impact the electronics/computer industry in the future. It is believed that emissions from the use of lead in soldering and other processes are not significant enough to subject facilities to air pollution control requirements. However, EPA has not yet studied the electronics/computer industry as a source of lead emissions.

Clean Air Act Amendments of 1990 (CAAA)

EPA promulgated a final NESHAP for chromium emissions from new and existing electroplating operations on January 25, 1995. The 1990 CAA Amendments (CAAA) list chromium compounds as a criteria air pollutant under §112. The purpose of the rule is to limit chromium emissions to the level of Maximum Achievable Control Technology (MACT) (60 FR 4948).

A NESHAP for halogenated solvent cleaning was issued December 2, 1994. The regulation applies to organic halogenated solvent cleaners (degreasers) using specified halogenated HAP solvents.

Several hazardous air pollutants (HAP) which are used in printed wired board manufacturing as well as semiconductor manufacturing and assembly are scheduled for MACT standards. According to IPC and EPA, these HAPs include: ethylene glycol; hydrochloric acid; hydrofluoric acid; lead compounds; and nickel compounds.

EPA is in the process of identifying industries that emit any substantial quantities of the 189 HAPs. Regulations that apply specifically to the semiconductor industry are expected in 1997.

Clean Water Act (CWA)

EPA is scheduled to propose effluent limitation guidelines and standards for metal products and machinery. These guidelines and standards will address facilities that generate wastewater while processing metal parts, products, and machinery. The proposal will also include facilities that generate wastewater during the following processes: manufacturing, assembly, repairing, rebuilding, and maintenance. Phase I of these guidelines and standards covers seven industries. The industries relevant to SIC code 36 and 35 are stationary industrial equipment (electrical equipment) and electronic equipment (including communication equipment). A notice of proposed rule making is expected to be published by November 1994, and final action on this proposed regulation is scheduled for May 1996.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[3] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

[3] EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Electronics/Computer Industry Compliance History

The exhibit below contains a Regional breakdown of the inspection and enforcement action over the last five years in the electronics/computer industry. As expected, the largest number of electronics/computer industry facilities is located in Region IX. However, other Regions (i.e., Regions I and II) inspected a greater number of electronics facilities than Region IX. Also, Regions IX and X have significantly higher enforcement to inspection ratios than the other Regions. In addition, 100 percent of Region VI and VII enforcement actions are led by the Federal government and 100 percent of Region VIII were enforcement actions were State-lead.

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 36 and 37 below present five and one year enforcement and compliance summaries for selected industries. The exhibits show that the number of inspections for the electronics/computer industry is low in comparison to other industries, and the average time between inspections is longer than other industries.

Exhibit 38 and 39 present five and one year inspection and enforcement summaries by statute. As expected, a significant percentage of inspections and enforcement actions involving electronics facilities are RCRA-related. This is in part due to the large amount of solvents used and sludges generated during various stages of the manufacturing process. The exhibit also shows a significantly lower percentage of Clean Air Act and Clean Water Act inspections and actions. This is somewhat surprising in light of the VOC emissions and the wastewaters and rinsewaters contaminated with spent solvents and acids generated by this industry.

VII.C. Review of Major Legal Actions

This section provides a listing of major legal cases and supplemental enforcement projects that pertain to the Electronics/Computer Industry. Information in this section is provided by EPA's *Enforcement Accomplishments Report, FY 1991, FY 1992, FY 1993* and the Office of Enforcement.

VII.C.1. Review of Major Cases

This section provides summary information about major cases that have affected this sector. As indicated in the EPA's *Enforcement Accomplishments Report, FY 1991, FY 1992, FY 1993* publications, 16 significant enforcement actions involving the electronics/computer industry were resolved between 1991 and 1993. CERCLA violations comprised nine of these cases, the most of any statute. Following CERCLA violations were five cases involving CWA violations, three involving RCRA violations, and one involving a TSCA violation. Two of the sites were Superfund sites. Several of the settlements required reimbursement of Superfund response costs or payment of the remedial costs. The companies against which the cases were brought are primarily manufacturers of electrical components such as printed wiring boards. The other companies performed electroplating operations and manufactured electrical equipment.

Four of the sixteen actions resulted in the assessment of a penalty. Penalties ranged from $25,000 to $300,000. The average penalty was approximately $178,125. In a case involving General Electric, the company was subject to a penalty and agreed to pay for removal and disposal of PWB electrical equipment over a period of three years at an estimated cost of one million dollars. In the case of U.S. v. Electrochemical Co., Inc., the court stated it would suspend $225,000 of a $250,000 fine if the company would clean up the contaminated area.

Although many cases involved civil penalties, four of the cases involved criminal convictions, resulting in penalties and/or jail sentences for the owners and operators of the facilities. All of these cases involved electroplating facilities and CWA violations. In one case, U.S. v. Robert H. Schmidt and Lawrence B. Schmidt, the owner was sentenced to 30 months in prison, followed by two years of probation. His son, the plant supervisor, was sentenced to 24 months of jail and two years of probation. Father and son were subject to penalties of $50,000 and $25,000 respectively.

VII.C.2. Supplemental Environmental Projects

Below is a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement and Compliance Assurance to provide information on the number and type of SEPs entered into by the Regions. Exhibit 40 contains a representative sample of the Regional responses addressing the electronics and computer industries. The information contained in the chart is not comprehensive and provides only a sample of the types of SEPs developed for the electronics and computer industries.

Exhibit 40
Supplemental Environmental Projects
Electronics/Computer Industry (SIC 36)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Lane Electronic Cooperative Eugene, OR	10	TSCA	Pollution Reduction	$ 9,775	Early disposal of PCBs or PCB contaminated electrical equipment.	$ 9,775	$ 4,888
Cirtech, Inc.	9	RCRA	Pollution Prevention	$ 9,900	Purcahse and install a device to eliminate copper from the waste stream and to reduce the hazardous waste stream. Will allow corrosive etch water to be reused.	$11,400	$ 7,630
Universal Circuits	9	EPCRA	Pollution Prevention		Implement a waste water recycling project which permanently reduces the consumption of water. Sponsor and conduct an outreach program		
Trojan Battery	9	EPCRA			Eliminate wastewater discharges. Operate a battery recycling center.		
G & W Electric Company Blue Island, IL	5	EPCRA	Pollution Prevention	$ 97,000	Implement process modifications designed to eliminate the use of 72,000 lbs/yr of 1,1,1,-trichloroethane.	$ 68,000	$ 7,825
Manu-Tronics Kenosha, WI	5	EPCRA	Pollution Prevention	$ 81,700	Modify the industrial processes eliminate the use and release of 25,000 lbs/yr of Freon 113.	$ 34,000	$ 3,400
Anchor Electric Co. Manchester, NH	1	EPCRA	Pollution Prevention	$40,000	Purchase, install, and operate an aqueous washer system in place of current vapor degreaser. Change will result in virtual elimination of the use of 1,1,1,-trichloroethane.	$51,000	$13,650

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Activities

VIII.A.1. Federal Activities

Common Sense Initiative (CSI)

The Common Sense Initiative (CSI), a partnership between EPA and private industry, aims to create environmental protection strategies that are cleaner for the environment and cheaper for industry and taxpayers. As part of CSI, representatives from Federal, State, and local governments; industry; community-based and national environmental organizations; environmental justice groups; and labor organizations, come together to examine the full range of environmental requirements affecting the following six selected industries: automobile manufacturing; computers and electronics, iron and steel, metal finishing, petroleum refining; and printing.

CSI participants are looking for solutions that:

- Focus on the industry as a whole rather than one pollutant
- Seek consensus-based solutions
- Focus on pollution prevention rather than end-of-pipe controls
- Are industry-specific.

The Common Sense Initiative Council (CSIC), chaired by EPA Administrator Browner, consists of a parent council and six subcommittees (one per industry sector). Each of the subcommittees have met and identified issues and project areas for emphasis, and workgroups have been established to analyze and make recommendations on these issues.

Design for the Environment (DfE)

DfE is an EPA program operated by the Office of Pollution Prevention and Toxics. DfE is a voluntary program which promotes the use of safer chemicals, processes, and technologies in the earliest product design stages. The DfE program assists industry in making informed, environmentally responsible design choices by providing standardized analytical tools for industry application and providing information on the comparative environmental and human health risk, cost, and performance of chemicals, processes, and technologies. DfE also helps small businesses by analyzing pollution prevention alternatives and disseminating the information to industry and the public. By helping to translate pollution prevention into meaningful terms, DfE contributes to building the institutional structure in corporations to support pollution prevention. DfE activities fall into two broad categories: (1) the industry-specific projects which encourage businesses to incorporate pollution prevention into their designs; and (2) long-term projects that translate pollution prevention into terms that make sense to professions such as chemistry, chemical engineering, marketing, accounting, and insurance.

DfE currently is working with the PWB industry because it is a critical component of the electronics, automotive, and defense industries. Also, MCC's lifecycle assessment of a computer work station study recognized that chemical processes such as those used in PWB fabrication are a significant source of hazardous waste and consume large amounts of water and energy. The potential for improvement in those areas led EPA's DfE Program to sponsor a project to assist the PWB industry in evaluating substitute materials and processes for making PWB holes conductive. DfE also plans to help the PWB industry identify multi-media environmental issues and the trade-offs of competing environmental objectives.

Industry/Government Partnerships

In 1993, the initial results of a six month lifecycle assessment of a computer workstation was released in a report called *Environmental Consciousness: A Strategic Competitiveness Issue for the Electronics and Computer Industry; Comprehensive Report: Analyses and Synthesis, Task Force Reports, and Appendices*. The study was conducted by Microelectronics and Computer Technology Corp. (MCC), SEMATECH (sponsored by the Semiconductor Industry Association), EPA, and the Department of Energy (DOE).

As a result of the assessment, the Department of Defense funded an industry led effort, the first phase of which involved development of the *Electronics Industry Environmental Roadmap*, which prioritizes the electronics and computer industries' environmental needs over the next ten years. The goal of the *Roadmap* is to assist U.S. companies to compete with foreign competitors who have established partnerships with their governments. MCC produced the *Electronics Industry Environmental Roadmap* in November 1993. MCC has received funding from the Department of Defense Advanced Research Projects Agency (ARPA) and EPA to continue to working with industry task groups to compile information, learn the needs of industry, and to suggest possible solutions to environmental/economic problems.

VIII.A.2. State Activities

Several States are actively involved in promoting pollution prevention by initiating partnerships with industry to develop and implement pollution prevention and waste minimization practices. Following is a description of some State pollution prevention initiatives related to the electronics/computer industry.

The **Minnesota Technical Assistance Program (MnTAP)** is supported by a grant to the University of Minnesota's School of Public Health. MnTAP staff and interns assists Minnesota businesses in the electronics and computer industries by identifying effective waste reduction opportunities. MnTAP researches treatment options, makes on-site visits to discuss recommendations, and coordinates documentation. MnTAP developed a checklist for businesses to evaluate their waste streams and identify waste reduction opportunities. MnTAP gathered vendor and technical information that may assist facilities in the industry in their evaluations in addition to a list of recycling vendors if the options on the checklists are not feasible to implement. Pollution prevention techniques for the electronics and computer industries that were recommended by MnTAP include material substitution, process modification, and recycling.

The **State of Minnesota's Office of Waste Management (OWM)** also has a Pollution Prevention Research Award Program. The program is part of Minnesota's efforts to promote pollution prevention. OWM contracts with private industry to investigate available pollution prevention alternatives in the electronics and computer industries. The process involves literature searches, telephone surveys, case study development, and working with trade associations and MnTAP. In July 1992, four cases studies were written as part of a report on alternatives to cyanide solutions in electroplating. OWM encourages implementation of pollution prevention techniques such as material substitution, recycling, process modification, wastewater treatment, electroplating, and the recycling of spent printed wiring boards.

The **North Carolina Department of Natural Resources and Community Development** has a Pollution Prevention Pays Program. The program provides technical, cost (operating and capital), economic benefit, and environmental benefit information to the public and facilities in the electronics and computer industries. The program recommends equipment modification, recycling, and process modification/pollution prevention techniques for the treatment of wastewater generated by electroplating processes.

The **City of Los Angeles' Board of Public Works** has a Hazardous and Toxic Materials Project (HTMP). HTMP provides fact sheets to the public and facilities in the electronics and computer industry describing different strategies to reduce the cost and quantity of waste generated. Pollution prevention techniques include material substitution, process modification, and recycling. HTMP also provides information on vendors who provide alternative waste management services.

The **City of Santa Monica's Department of General Services** provides fact sheets and information on pollution prevention to businesses. The City outlines pollution prevention techniques for printed circuit board manufacturing in fact sheets. The fact sheets rate waste reduction practices in terms of easiest, more difficult, and most difficult to implement. The fact sheets also provide contacts from the Department of Health Services, small business assistance loan programs, and California agencies with waste reduction programs.

Other pollution prevention initiatives that have targeted the electronics and computer industries include: the Hazardous Waste Reduction Program of the Oregon Department of Environmental Quality (DEQ); the New Jersey Hazardous Waste Facilities Siting Commission of the Hazardous Waste Source Reduction and Recycling Taskforce; and the San Diego County Department of Health Services.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of 17 chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given to participants who met their 1992 goals. The list of chemicals includes 17 high-use chemicals reported in the Toxics Release Inventory.

Thirty-four companies and 72 facilities listed under SIC 36 (the electronics/computer industry) are currently participating in the 33/50 program. They account for approximately 17 percent of the 406 companies under SIC 36, which is slightly higher than the average for all industries of 14 percent participation. (Contact: Mike Burns 202-260-6394 or the 33/50 Program 202-260-6907)

Exhibit 41 lists those companies participating in the 33/50 program that reported under SIC code 36 to TRI. Many of the participating companies listed multiple SIC codes (in no particular order), and are therefore likely to conduct operations in addition to electronics/computer industry. The table shows the number of facilities within each company that are participating in the 33/50 program; each company's total 1993 releases and transfers of 33/50 chemicals; and the percent reduction in these chemicals since 1988.

**** = use reduction goal only.**
***** = no numerical goal.**

R0075073

Energy Star Computer Program

The Energy Star Computer program is a voluntary partnership between the EPA and computer companies that manufacture energy-efficient computer equipment such as desktop computers, printers, and monitors. The companies that participate in this program comprise 70 percent of all U.S. sales of desktop computers and 90 percent of laser printers. In order for a computer to qualify and display the EPA Energy Star logo, it must operate on low power when inactive and can "sleep" or "power-down," and then awaken by touching the mouse or keyboard. The program requires that the central processing unit, printer, and monitor of the computer must enter a standby mode when not in use and use no more than 30 watts. Energy-efficient computers were available to the public and businesses as of June 1993.

Computer equipment is the fastest growing user of electricity in the commercial sector. Currently, computers account for five percent of commercial electricity consumption, and this is expected to grow to 10 percent by the year 2000. The Energy Star sleep feature can reduce electricity consumption by 50 to 75 percent. In addition, the efficient systems generate less heat while the computer sleeps, which reduces electricity needed to cool a building by five to ten percent. These computers are predicted to diminish electricity consumption by 25 billion kilowatts hours per year by the year 2000. The reduction of electricity use would eliminate the need for 10 coal-fired plants and reduce carbon-dioxide emissions by up to 20 million tons. An Executive Order, which was issued in April 1993 and took effect in October 1993, directed the U.S. government to purchase only Energy Star computer equipment where available and if performance needs are met. Implementation of the Executive Order is expected to save $40 million annually. (Contact: Maria Tikoff (202) 233-9178)

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director (202) 564-5081 or Robert Fentress (202) 564-7023)

Motorola ELP Project

Motorola is participating in a pilot phase of the Environmental Leadership Program with EPA and the State of Texas. Their Oak Hill facility located in Austin, Texas, will encompass two key projects, both in the pursuit of better environmental compliance. They are mentoring another facility and applying an environmental management system that aims to go beyond compliance status. (Contact: Steve Hoover (202) 564-7007)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Jon Kessler at (202) 260-4034)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at (202) 233-9065 or the Green Light/Energy Star Hotline at (202) 775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWiSe logo for promotional purposes. (Contact: Lynda Wynn (202) 260-0700 or the WasteWi$e Hotline at (800) 372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman (202) 260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office (303) 275-4729)

VIII.C. Trade Association Activity

Many trade associations have been involved in researching ways to reduce pollution associated with the manufacturing of semiconductors, printed wiring boards, and cathode ray tubes. Following is description of the trade association environmental programs or partnerships. A list of some of the major trade associations and contacts is also provided.

VIII.C.1. Environmental Programs

The Semiconductor Industry Association (SIA), in association with EPA and DOE, released a report in March 1993 called *Environmental Consciousness: A Strategic Competitiveness Issue for the Electronics and Computer Industry.* This report contains the initial results of a six month, lifecycle assessment of a computer workstation. The report indicates that the industry should pursue the development of pollution prevention and waste minimization techniques in the printed wired board (PWB) manufacturing industry. As a result of this study, EPA provided funding to the Institute for Interconnecting and Packaging Electronic Circuits (IPC) and Microelectronics and Computer Technology Corporation (MCC) to redesign PWB manufacturing processes in order to reduce the amount of chemicals used during production.

According to IPC, environmental research is also being conducted by the Interconnection Technology Research Institute (ITRI) and by many independent companies.

According to SIA, the Department of Defense has awarded SEMATECH $10 million to perform research into pollution prevention and environmentally friendly microchip manufacturing processes. As part of a separate initiative, SIA produced a report, *The National Technology Roadmap for Semiconductors*. The *Roadmap* acts as a guide for R&D investment decisions.

SIA's *Roadmap* calls for reducing the use of approximately 60 hazardous chemicals in various stages of the manufacturing process (e.g., mask making, photolithography, cleaning, leadframe plating, deflashing, and soldering). The chemicals include solvents, acids, toxics, alcohols, and other organic and inorganic substances. The goal of the *Roadmap* is to phase out ozone depleting substances and targeted ethylene glycol ethers during the next 15 years. The *Roadmap* identifies 46 projects for implementation in 1994 that involved process modifications. The majority of the process modifications center around alternatives to wet chemical processes and continued progress in development of alternative technologies for applying layers of silicon to the wafer. The development of water-based (or gas process) cleaners and resists is also a priority.

VIII.C.2. Trade Associations

Electronic Industries Association (EIA) 2500 Wilson Boulevard Arlington, VA 22201 Phone: (703) 907-7500 Fax: (703) 907-7501	Members: 1200 Staff: 150 Budget: $25,000,000 Contact: Peter McCloskey

EIA was founded in 1924, and represents manufacturers of electronic components, parts, systems, and equipment for communications, industrial, government, and consumer use. EIA publishes a free, semiannual *EIA Publications Index* that contains price, content, and ordering information for their publications. EIA works to develop sound environmental practices by promoting research, workshops, and tool development through a variety of industry committees.

American Electronics Association (AEA) 5201 Great American Parkway, Suite 520 Santa Clara, CA 95054 Phone: (408) 987-4200 Fax: (408) 970-8565	Members: 3500 Staff: 140 Budget: NA Contact: J. Richard Iverson

AEA was founded in 1943, and is a trade association that represents the U.S. electronics/computer industry. Formerly known as the West Coast Electronic Manufacturer Association (WEMA), AEA's programs and services include: public affairs, educational meetings conferences, and executive summits. AEA publishes an annual directory; a monthly association and trade news publication, *American Electronics Association,* which includes legislative briefs, industry statistics, and a calendar of events; a periodic California Legislative Bulletin; and handbooks, manuals, and surveys. In addition, AEA sponsors an annual Systems/USA trade show.

National Electronic Manufacturing Association (NEMA) 2101 L Street, NW, Suite 300 Washington, DC 20037 Phone: (202) 457-8400 Fax: (202) 457-8411	Members: 600 Staff: 100 Budget: $10,000,000 Contact: Malcolm O'Hagan

NEMA was established in 1926. NEMA represents companies that manufacture equipment used for the generation, transmission, distribution, control, and utilization of electric power. NEMA was formed by the merger of Associated Manufacturers of Electrical and Supplies and the Electronic Power Club. NEMA's areas of interest include: electrical machinery; motors; and industrial automation, construction, utility, medial diagnostic imaging, transportation, communication, and lighting equipment. NEMA's objectives are to maintain and enhance the quality and reliability of products, ensure safety standards in the manufacturing and use of products, and to organize and act upon members' interest in areas such as energy conservation, efficiency and foreign competition. NEMA conducts regulatory and legislative analysis on issues of concern to electronic manufacturers, and compiles periodic summaries of statistical data on sales and production. In addition, NEMA publishes a periodic directory; a free, semiannual catalog of its publications and materials; *Tech Alert* bimonthly; and manuals, guidebooks, and other material on wiring, equipment installation, lighting, and standards.

Semiconductor Equipment and Materials International (SEMI) 805 E. Middlefield Road Mountain View, CA 94043 Phone: (415) 964-5111 Fax: (415) 967-5375	Members: 1750 Staff: NA Budget: NA Contact: William H. Reeds

SEMI was founded in 1970, and represents firms, corporations, and individuals who participate in supplying fabrication equipment, materials, or services to the semiconductor industry. SEMI operates an industry data collection program, conducts SEMI Technical Education Programs, and provides an annual Information Services Seminar (ISS) forecast. SEMI is the former Semiconductor Equipment and Materials Institute. SEMI publishes an annual *Book of SEMI Standards*, the annual *Business Outlook for the Semiconductor Equipment and Materials Industry*; a bimonthly newsletter providing general industry news; a quarterly newsletter, *SEMI Outlook*, that provides information on industry trends, analyses, and opinions; and the SEMICON Technical Proceedings which contains the proceedings and paper topics from the Institute's technical symposia.

Institute for Interconnecting and Packaging Electronic Circuits (IPC) 2215 Sanders Road, Suite 200 South Northbrook, IL 60062 Phone: (708) 677-2850 Fax: (708) 677-9570	Members: 1900 Staff: 42 Budget: NA Contact: Thomas Dammrich

Founded in 1957, IPC represents companies that produce and use electronic interconnections for electronic equipment. IPC's primary members are independent PWB manufacturers and contract assembly companies that mount components onto bare PWBs to produce printed wiring assemblies (PWAs) or electronic assemblies. IPC also represents original equipment manufacturers (OEMs), suppliers, academia, and technical members of the industry. IPC has over 100 committees, that cover all aspects of the industry including: technical standards; specifications and guidelines; education and training; technology research and development; market research and publications; management practices; environmental and safety programs; and government regulations.

Semiconductor Industry Association (SIA) 4300 Stevens Creek Boulevard Suite 271 San Jose, CA 95129 Phone: (408) 246-2711 Fax: (408) 246-2830	Members: 40 Staff: 14 Budget: $2,000,000 Contact: Andrew Procassini

SIA represents companies that produce semiconductor products including discrete components, integrated circuits, and microprocessors. This association compiles industry trade statistics and maintains a private library and sponsors the Semiconductor Research Corporation and SEMATECH. SIA's publications include the following: *Circuit*, a free, quarterly newsletter; Semiconductor Yearbook and Directory, which contains a review of programs sponsored by the association, key industry statistics, analyses by industry experts, public policy discussions, and sales volume; and essays, research reports, and proceedings.

Computer and Communications Industry Association (CCIA) 666 11th Street, NW Washington, DC 20001 Phone: (202) 783-0070 Fax: (202) 783-0534	Members: 60 Staff: 10 Budget: $1,000,000 Contact: A.G.W. Biddle

Comprised of computer manufacturers, CCIA provides information processing and telecommunication-related products and services. CCIA represents the interests of its members before Congress, Federal agencies, and the courts in the areas of domestic and foreign trade, tax policy, Federal procurement policy, and telecommunication policy. It hosts policy briefings on legislative and regulatory matters to keep members aware of policy, political, technological, and market and economic developments and trends. CCIA publishes *CEO Report* semimonthly and *Federal Procurement Policy Report*, *International Trade Report*, and *Telecommunication Report* on a monthly basis.

IX. BIBLIOGRAPHY/OTHER MATERIALS AVAILABLE

For further information on selected topics within the electronic and computer industries, a list of publications are provided below:

INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies: environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROSEN$E WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

FOSSIL FUEL ELECTRIC POWER GENERATION INDUSTRY (SIC 4911, 493)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Integrated environmental policies based upon comprehensive analysis of air, water, and land pollution are a logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (i.e., air, water, and land) affect each other and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the U.S. Environmental Protection Agency (EPA) Office of Compliance led to the creation of this document.

The Sector Notebook Project was originally initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for 18 specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded to its current form. The ability to design comprehensive, common sense environmental protection measures for specific industries depends on knowledge of several interrelated topics. For the purposes of this project, the key elements chosen for inclusion are general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, however, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue and references where more in-depth information is available. Text within each profile was researched from a variety of sources and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. To check the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those who participated in this process who enabled the development of more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

The OECA Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project (2223-A), 401 M Street, SW, Washington, DC 20460. Comments can also be uploaded to the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing this system. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or repackage the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks for sectors not covered in the original 18, please contact the Office of Compliance at (202) 564-2395.

II. INTRODUCTION TO THE FOSSIL FUEL ELECTRIC POWER GENERATION INDUSTRY

This Sector Notebook addresses the fossil fuel electric power generation industry, which comprises the majority of the total electric power generation industry. This subset of the industry includes only facilities that use either coal, petroleum, or gas as the energy source to generate electricity and does not include facilities that use nuclear or renewable (e.g., wood, solar) energy sources exclusively. However, this subset would include power generation activities at facilities that use both fossil fuels and another energy source. In addition, the scope of this profile is further limited to address only those facilities that generate electricity either as a primary activity or as an ancillary activity. The profile does not include facilities and activities associated with the transmission and distribution of electricity.

II.A Introduction, Background, and Scope of the Notebook

Fossil fuel electric power generation facilities are classified under Standard Industrial Classification (SIC) code 49, which includes establishments engaged in electric, gas, and sanitary services. These facilities can be further classified under the following three- and four-digit SIC codes from the *Standard Industrial Classification (SIC) Manual* of the Office of Management and Budget.

- **SIC 4911 - Electric Services**: Establishments that are engaged in the generation, transmission, and/or distribution of electric energy for sale.
- **SIC 493 - Combination Electric and Gas, and Other Utility Services**: Establishments providing electric or gas services in combination with other services. Establishments are classified here only if one service does not constitute at least 95 percent of revenues.

It should be noted that these SIC codes do not make the necessary distinctions between fuels used and generation versus transmission and distribution activities. Data available to characterize the fossil fuel electric power generation industry that use these SIC codes also may not distinguish between these categories of facilities. Where these categories of facilities and/or activities cannot be distinguished in the available data, it will be so noted within the profile.

Fossil fuel electric power generation facilities are also classified under a new system called the North American Industry Classification System (NAICS), which replaced the existing SIC codes in January 1997. The NAICS classification code for fossil fuel electric power generation is 221112.

Power generation facilities and activities exist in association with both traditional utilities or nonutility power producers. Traditional utilities are the regulated industry that produces and provides electricity for public use. Prior to 1980, nonutilities consisted of industrial manufacturers that produced electricity for their own use. Currently, nonutilities not only consist of industrial manufacturers, but also other industrial groups that provide electricity and other services for their own use and/or for sale to others. These categories are discussed further below.

This section provides background information on the size, geographic distribution, electricity production, sales, and economic condition of the fossil fuel electric power generation industry. The type of facilities described within the document are also described in terms of their SIC codes. Additionally, this section lists the largest companies in terms of sales.

II.B Characterization of the Fossil Fuel Electric Power Generation Industry

The U.S. Department of Energy's (DOE) Energy Information Administration (EIA) collects, evaluates, and disseminates information on the fossil fuel electric power generation industry. This information is published annually. In addition, industry trade associations collect information.

Available statistics on the fossil fuel electric power generation industry typically characterize the industry in terms of capacity, generating capability, net generation, and revenues. These terms are defined as follows:

- **Capacity** is the amount of electric power delivered or required for which a generator, turbine, or system has been rated by the manufacturer.
- **Capability** is the maximum load that a generating unit can be expected to carry under specified conditions for a given period of time without exceeding approved limits of temperature or stress. The net capability of a generating unit is always less than the rated capacity.
- **Net generation** is the total amount of electricity generated minus the electricity used by the facility itself.
- **Revenue** is the total amount of money received by a firm from sales of its products and/or services, gains from the sales or exchange assets, interest and dividends earned on investments, and other increases in the owner's equity except those arising from capital adjustments.

The following sections briefly summarize information available to characterize the industry.

II.B.1 Product Characterization

The product in fossil fuel electric power generation is electricity. Ancillary activities associated with the generation of electricity may generate other products, however. For example, cogeneration systems produce electricity, as well as another form of usable energy (i.e., steam or heat). In addition, utilities with SIC code 493 may produce other products, such as gas. These other products are beyond the scope of this profile.

II.B.2 Industry Size and Geographic Distribution of the Fossil Fuel Electric Power Generation Industry

In general, the power generation industry comprises both traditional and nontraditional electric-producing companies. They are called "utility" and "nonutility" power producers, respectively. A key difference between utilities and nonutilities is that utilities own generation, transmission, and distribution functions. Thus, utilities are "vertically" oriented. Nonutilities, on the other hand, generally own only generation capabilities. Often, the nonutilities must rely on utilities to sell the electricity they produce.

A utility power producer is generally defined as any person, corporation, municipality, State political subdivision or agency, irrigation project, Federal power administration, or other legal entity that is primarily engaged in the retail or wholesale sale, exchange, and/or transmission of electric energy. In 1995, there were 3,199 utilities in the United States; however, only 700 of these utilities generated electric power. The remainder were electric utilities that purchased wholesale power from others for the purpose of distribution over their lines to the ultimate consumer. The 700 utilities that generated power had a total of 3,094 power plants or stations.[1]

A nonutility power producer is defined as any person, corporation, municipality, State political subdivision or agency, Federal agency, or other legal entity that either (1) produces electric energy at a qualifying facility (QF)[a] as defined under the Public Utility Regulatory Policies Act (PURPA) or (2) produces electric energy but is primarily engaged in business activities other than the sale of electricity. In 1995, there were 4,190 nonutility power-generating facilities. Generation by nonutility power producers accounted for approximately 12 percent of the total U.S. electric generation. Fifty-six percent of the electricity generated by nonutilities was sold to electric utilities.[2]

---

[a] To receive status as a QF under PURPA, a facility must meet certain ownership, thermal output size, and efficiency criteria established by the Federal Energy Regulatory Commission (FERC). QFs are guaranteed that electric utilities will purchase their output at a reasonable price.

Table 1 provides electric power generation statistics for the year 1995 that allows comparison between electric power generation by both utilities and nonutilities based on the fuels used.

Table 1: Comparison of Utility and Nonutility Electric Power Generation (1995)

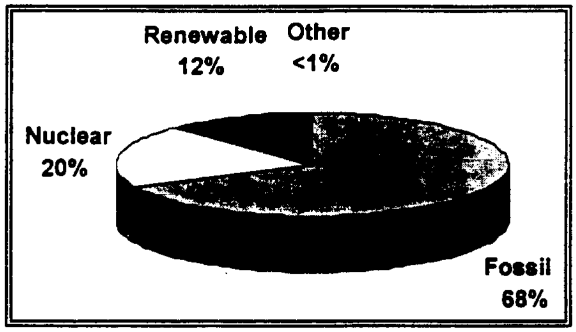
Energy Source	Utility Generation (thousand megawatthours)	Nonutility Generation (thousand megawatthours)***	Total U.S. Generation (thousand megawatthours)***
Fossil	2,021,064	287,696	2,308,760
Nuclear	673,402	—(†)	673,402
Hydroelectric*	293,653	14,515	308,168
Renewable and other**	6,409	98,295	104,704
Total	**2,994,528**	**400,505**	**3,395,033**

* Includes hydroelectric, conventional, and pumped storage.
** Includes geothermal, solar, waste, wind, photovoltaic, and biomass; projects for which there were two primary energy sources; and projects that did not identify the primary energy source. Nonutility data includes nuclear.
*** Totals may not equal sum of components because of independent rounding.
† Nonutility facilities using nuclear are including under "Renewable and other."

Sources: (a) *Electric Power Annual, 1995, Volume 1.* U.S. Department of Energy, Energy Information Administration, Washington, DC. July 1996. DOE/EIA-0348(95/1); and (b) *1995 Capacity and Generation of Non-Utility Sources of Energy.* Prepared by the Edison Electric Institute, Washington, DC. November 1996.

Based on these numbers and as shown in Figure 1, fossil fuel electric power generation represented 68 percent of the total U.S. electric power generation industry's total production of electricity in that year (both utility and nonutility combined). Nuclear energy represented 20 percent, renewable energy sources represented about 12 percent, and other energy sources represented less than 1 percent of the electricity production.

Figure 1: Total Utility and Nonutility Electric Power Net Generation Based on Fuels (1995)



In general, statistics on utility and nonutility electric power production are not aggregated. The following sections provide a more in-depth discussion of the information available to characterize the utility and nonutility electric power generators.

II.B.3 Industry Size and Geographic Distribution of Traditional Utilities

Ownership Categories and Revenues

Electric utilities are divided into four ownership categories: investor-owned, publicly owned, cooperative-owned, and Federally owned. These categories are described as follows:

- **Investor-owned utilities** produce a return for investors. They either distribute profits to stockholders as dividends or reinvest the profits. Investor-owned utilities are regulated entities that are granted a service monopoly in certain geographic areas and are obliged to serve all consumers and charge reasonable prices.

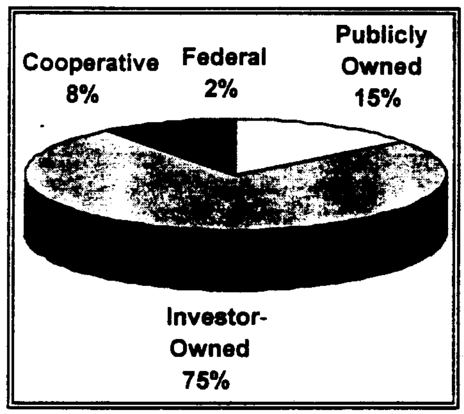
- **Publicly-owned utilities** are non-profit local government agencies (e.g., municipalities, counties, States, and public utility districts) that serve communities and nearby consumers at cost, returning excess funds to the consumer in the form of community contributions, economic and efficient facilities, and lower rates.

- **Cooperative utilities** are owned by their members and are established to provide electricity to those members. Cooperatives typically provide electric service to small rural communities of 1,500 or less.

- **Federal electrical utilities** do not generate power for profit. The Federal government is primarily a producer and wholesaler of electricity, and preference in the purchase of the electricity is given to publicly owned and cooperative electric utilities.

In 1995, there were 244 investor-owned, 2,014 publicly owned, 10 Federal, and 931 cooperative utilities. Figure 2 shows the percentage of 1995 U.S. electricity sales to ultimate consumers based on ownership type. Total sales were 1,013 billion kilowatthours. Only a portion of these utilities own and/or operate fossil fuel electric power generation capacity.

Figure 2: Total Utility Electricity Sales to Ultimate Consumers [3]



Among the ownership classes, investor-owned utilities account for more than 75 percent of all retail sales and revenues. In 1995, revenues from major utility generators totaled 208 billion dollars. Table 2 provides the revenues from major utility generators based on ownership category. Tables 3 and 4 list the 1995 top ten investor-owned and publicly owned utilities based on revenues from sales and megawatts sales to ultimate consumers, respectively. It should be noted that these data are for all electric utility activities, not just those that generate electricity.

Table 2: Revenues From Major Utility Generators (1995)

Ownership Category	Revenue (billion $)
Investor-Owned	164
Publicly Owned	26
Cooperative	17
Federal	1
Total	**208**

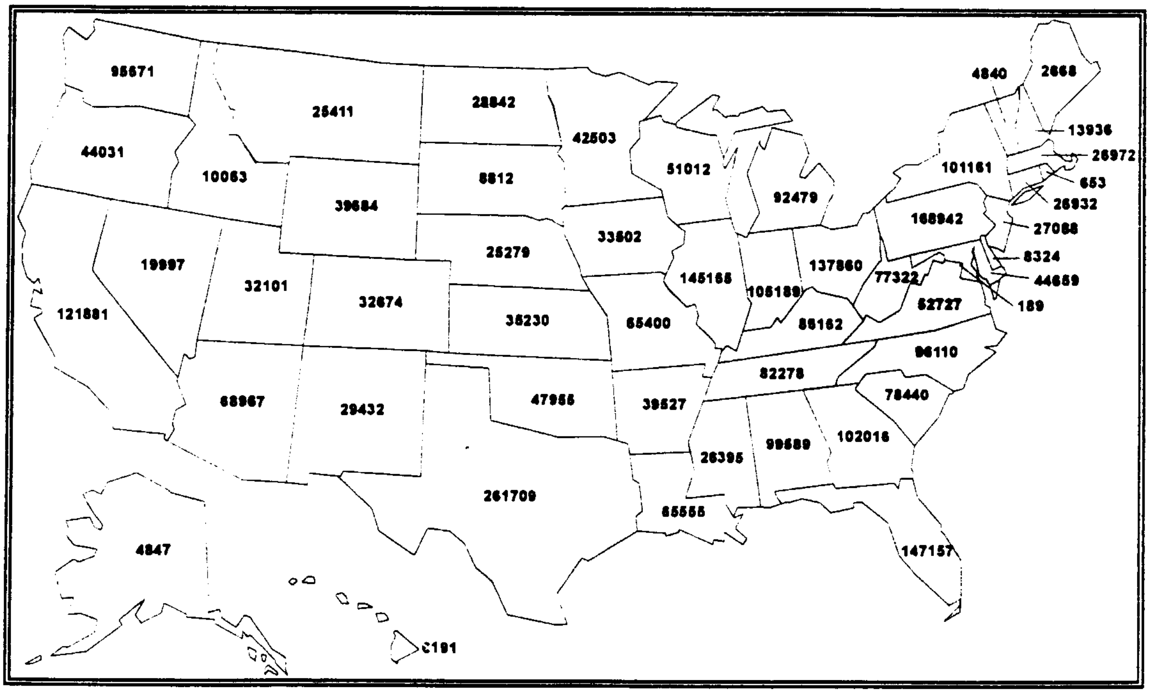
Geographic Distribution of Utilities

Fossil fuel electric power generation by utilities occurs across the United States. Figure 3 provides the total electric power net generation for each State. Higher values for net generation from utilities generally mirror higher population densities and industrial centers. The States with the highest utility net generation included were California, Texas, Illinois, Ohio, Pennsylvania, and Florida. The amount and geographical distribution of capacity by energy source are a function of availability and price of fuels and/or regulations. Energy sources used by utilities generally show a geographical pattern, such as significant coal and petroleum-fired capacity in the East and gas-fired capacity in the Coastal South.[4]

Figure 3: Geographic Distribution of U.S. Utility Electric Power Net Generation



Source: *Electric Power Annual, 1995, Volume I and II.* U.S. Department of Energy, Energy Information Administration, Washington, DC. July 1996. DOE/EIA-0348(95)/1&2.

Existing Utility Capacity and Electricity Generation

In general, electric power generation utilities use several technologies to generate electric power. These technologies, known as prime movers, are steam turbines, gas turbines, internal combustion engines, combined-cycle, hydraulic turbines, and others (e.g., geothermal, solar, and wind). Combined-cycle facilities use a technology in which electricity is produced from otherwise lost heat exiting from one or more gas (combustion) turbines. The exiting heat is routed to a conventional boiler or to a heat recovery steam generator for utilization by a steam turbine in the production of electricity. This process increases the efficiency of the generating unit. Table 5 shows the 1995 existing capacity that employs these technologies and the percent of total U.S. utility capacity. Steam turbines are associated with 77 percent of the total U.S. utility capacity.

Table 5: Existing Capacity of All U.S. Utilities by Prime Mover (fossil fuels, renewable fuels, and other fuels) (1995)		
Prime Mover	**Generating Capacity (megawatts)****	**Percent of Total U.S. Capacity**
Steam Turbines*	579,647	77
Gas Turbines	58,329	7
Internal Combustion	4,985	>1
Combined-Cycle (gas and steam)	14,578	2
Hydraulic Turbines (hydroelectric)	91,114	12
Others	1,888	>1
Total	**750,542**	**100**

* Includes nuclear generators.
** Total may not equal sum of components because of independent rounding.

Source: *Inventory of Power Plants in the United States, as of January 1, 1996.* U.S. Department of Energy, Energy Information Administration, Washington, DC. December 1996. DOE/EIA-0095(95).

Not all of the existing capacity uses fossil fuels. Only a subsection of steam turbine, gas turbine, internal combustion, and combined-cycle capacity (657,539 megawatts) uses fossil fuels. More than 75 percent of the total existing capacity is fossil-fueled. Table 6 presents the 1995 capacity that used fossil fuels for each prime mover. In 1995, approximately 86 percent of the fossil-fueled electric power generation capacity was from steam turbine systems.

Table 6: Fossil-Fueled Utility Capacity by Prime Mover (1995)*		
Prime Mover	**Generating Capacity (megawatts)**	**% of Fossil-Fueled Capacity**
Steam Turbine	475,860	86
Gas Turbine/Internal Combustion	73,166	14
Total	**549,026**	**100**

* Includes combined-cycle capacity.

Source: *Inventory of Power Plants in the United States, As of January 1, 1996.* U.S. Department of Energy, Energy Information Administration, Washington, DC. December 1996. DOE/EIA-0095(95).

Fossil fuel-fired steam electric utilities had the capability to produce 445,627 megawatts of electricity, or more than 50 percent of the net generating capability at U.S. electric utilities. Gas turbine and internal combustion facilities combined had the capability to produce 61,424 megawatts of electricity, or 11.5 percent of generating capability at U.S. electric utilities in 1995.

In 1995, coal was used as the energy source to generate the most electricity in the utility industry, accounting for net generation of 1,652,914 thousand megawatthours of electricity, consuming 829,007 thousand short tons of coal. Gas-fired generators generated 307,306 thousand megawatthours, consuming 3,196,507 million cubic feet of gas, and petroleum-fired generators generated 60,844 thousand megawatthours of electricity, consuming 102,150 thousand barrels of petroleum (not including petroleum coke). Many utility generators have the flexibility to switch fuel sources in response to market conditions. Table 7 provides the 1995 U.S. utility generating capacity and net generation for each fossil fuel energy source.

Table 7: Utility Generating Capability and Net Generation by Energy Source (1995)

Energy Source	Generating Capability (megawatts)	Net Generation (thousand megawatthours)
Coal	301,484	1,652,914
Gas	135,749	307,306
Petroleum	70,043	60,844
Total	**507,276**	**2,020,822**

Source: *Electric Power Annual, 1995, Volume 1.* U.S. Department of Energy, Energy Information Administration, Washington, DC. July 1996. DOE/EIA-0348(95/1).

II.B.4 Industry Size and Geographic Distribution of Nonutilities

Nonutility Classifications

There are three categories of nonutilities:

- **Cogeneration** is the major technology used among nonutility power producers. This technology, which is discussed in greater detail in Section III, is the combined production of electric power and another form of useful energy (e.g., heat or steam). To receive QF status under PURPA, a cogeneration facility must meet certain operating criteria to "produce electrical energy and another form of useful thermal energy through the sequential use of energy." Depending upon the technology used, a facility may also be required to meet specific efficiency criteria. QFs are guaranteed that electric utilities will purchase their output at the incremental cost that an electric utility would incur to produce or purchase an amount of power equivalent to that purchased from QFs.

QFs are also guaranteed that electric utilities will provide backup service at prevailing (non-discriminatory) rates.

Fossil-fueled steam turbine systems are used in most industrial applications of cogenerating processes, while gas turbine systems are used in most other processes (e.g., commercial). Diesel engine systems are limited in their application to cogeneration because they provide less useable process heat per unit of electric power input.

- **Small Power Producers** are designated under PURPA regulations based on fuel consumption of a renewable energy source greater than 75 percent. This means that most nonutility fossil fuel electric power generators are not likely to carry this designation. In limited cases however, a facility may use fossil fuel in conjunction with a renewable energy source.

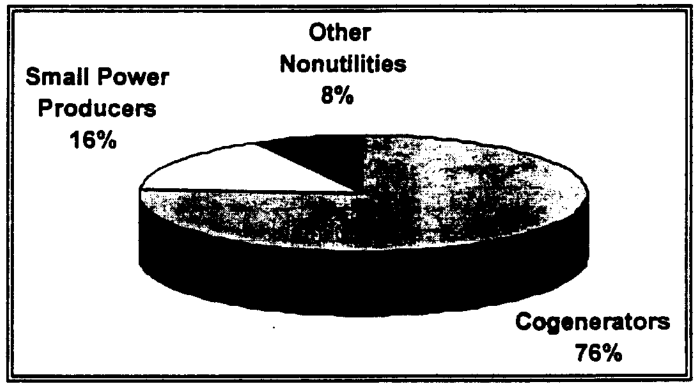
- **Other Nonutility Generators** are facilities not classified in the previous categories that produce electric power for their own use and for sale to electric utilities. These facilities include:

  - Independent power producers (IPPs)
  - Nonqualifying cogenerators
  - Exempt wholesale generators (EWGs)
  - Other commercial and industrial establishments.

FERC defines IPPs as producers of electric power other than QFs that are unaffiliated with franchised utilities in the IPP's market area and that for other reasons lack significant market power. The IPPs may lack market power due to siting or access to transmission. The EWGs are engaged exclusively in the business of wholesale electric generation and are exempt from corporate organizational restrictions under the Public Utility Holding Company Act of 1935.

In 1995, the makeup of the nonutility industry, based on capacity, included 76.2 percent cogenerators, 15.8 percent small power producers, and 8 percent other nonutility producers. Figure 4 illustrates the percent capacity of the different classes of nonutility power producers.[5]

Figure 4: Nonutility Capacity by Type of Producer



Qualified facilities comprised 78 percent of the total nonutility capacity in 1995. Non-qualified facilities were 12.9 percent of the capacity.

Nonutility power generation facilities and activities may be found in association with commercial and industrial facilities. Table 8 lists SIC codes and industries where power generation facilities and activities may be found.

In 1995, nonutility generation capacity within the chemical industry (SIC Code 28) accounted for 21 percent of the nonutility capacity and 23 percent of the total nonutility generation. The paper industry (SIC Code 26) accounted for 17 percent of the nonutility capacity and 18 percent of the generation. The coal, oil, and gas mining and refining industries (SIC Codes 12, 13, and 29) accounted for 12 percent of the total nonutility capacity and 13 percent of the generation.[6]

Table 8: Major SIC Codes and Industrial Categories Where Nonutility Power Generation Activities Are Found

Major SIC Code	Industrial Category
01, 02	Agricultural Production - Crops, Livestock, and Animals
07	Agricultural Services
10	Metal Mining
12	Coal Mining
13	Oil and Gas Extraction
20	Food and Kindred Products
21	Tobacco Products
22	Textile Mill Products
23	Apparel & Other Finished Fabric Products
24	Lumber and Wood Products (Except Furniture)
25	Furniture and Fixtures
26	Paper and Allied Products
27	Printing, Publishing, and Allied Industries
28	Chemicals and Allied Products
29	Petroleum Refining and Related Industries
30	Rubber and Miscellaneous Plastics Products
31	Leather and Leather Products
32	Stone, Clay, Glass, and Concrete Products
33	Primary Metal Industries

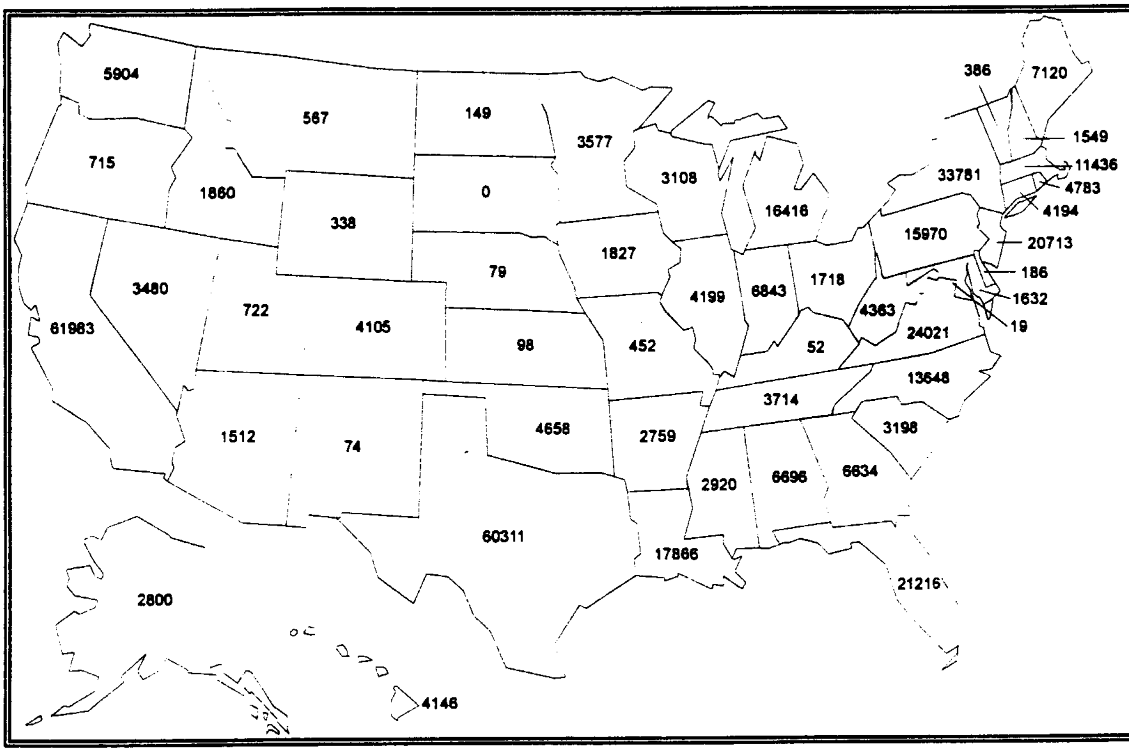
Geographic Distribution of Nonutilities

Fossil fuel electric power generation by nonutilities occurs all across the United States. Figure 5 provides the total nonutility electric power net generation for each State. As with the utilities, higher values for net generation for nonutilities generally mirror higher population densities and industrial centers. The States with the highest nonutility net generation included were California, Texas, Virginia, New York, Florida, and New Jersey.

Figure 5: Geographic Distribution of U.S. Nonutility Electric Power Net Generation



Source: *Electric Power Annual Volume I and II.* July 1995. U.S. Department of Energy, Energy Information Administration, Washington, DC. DOE/EIA-0348(95)/1&2.

Existing Nonutility Capacity and Electricity Generation

As in the traditional utilities, nonutilities use steam turbines, gas turbines, internal combustion engines, hydraulic turbines, and combined-cycle systems to generate electricity. Steam turbines accounted for 42 percent of all the capacity and combined-cycle generating systems accounted for 27 percent. Table 9 provides existing 1995 nonutility generating capacity by prime mover technology.

The majority (more than 68 percent) of existing 1995 nonutility capacity is attributed to fossil-fueled electricity production.[7] Many facilities are able to switch from one fossil fuel to another if the fuel supply is interrupted or the economics warrant it. Some facilities are even able to switch from fossil fuels to renewable energy sources, while still others can use combustors that can burn two or more different fuels simultaneously, in varying combinations, to generate a desired heat output. Thus, the nonutility industry can be very adaptable, depending upon the type of equipment at a facility and based on economic conditions. Table 10 provides the 1995 nonutility capacity associated with each fossil fuel energy source.

Table 9 : Existing Capacity of Nonutilities by Prime Mover (1995)

Prime Mover	Generating Capacity (megawatts)	Percent of Total U.S. Capacity
Steam Turbines	28,192	42
Combined-Cycle	17,417	27
Gas Turbines	12,081	18
Internal Combustion	2,018	3
Hydraulic Turbines	3,410	5
Others*	3,297	5
Total	**66,415**	**100**

* Includes nuclear generators.

Table 10: Nonutility Capacity by Fossil Fuel Energy Source (1995)

Fossil Fuel	Generating Capacity (megawatts)	Percent of Total Fossil Fuel Nonutility Capacity
Gas	33,221	73
Coal	10,324	23
Petroleum	1,657	4
Total	**45,202**	**100**

Source: *1995 Capacity and Generation of Nonutility Sources of Energy.* Edison Electric Institute, Washington. DC. November 1996.

The majority of the nonutility power producers use fossil fuels to generate electricity. Fossil fuels accounted for more than 287 million megawatthours, which was 72 percent of the total electricity produced by nonutilities in 1995.[8]

Gas was the fossil fuel used to generate the most electricity in the nonutility industry, providing a total of 213 million megawatthours of electricity in 1995. Coal was used to produce 70 million megawatthours of electricity, and petroleum was used to produce 4 million megawatthours of electricity. Table 11 provides 1995 nonutility generation by power producer class and energy source.

Table 11: 1995 Nonutility Net Generation by Primary Fossil Fuel Energy Source and Type of Producer (thousand megawatthours)

Energy Source	Cogenerators	Small Power Producers	Other Nonutility Power Producers	Total U.S. Nonutility Generation
Gas	200,080	0	13,357	213,437
Coal	63,440	0	6,740	70,180
Petroleum	3,957	0	121	4,079
Total	**267,477**	**0**	**20,218**	**287,696**

II.B.5 Economic Trends

Change in Structure of the Utility Electric Power Industry

Utility electric power generation is one of the largest industries that remains regulated in the United States. Change is rapidly occurring in this industry due to the issuance by the FERC of Orders 888 and 889 (dated April 24, 1996), which encourage wholesale competition. Order 888 deals with issues of open access to transmission networks and stranded costs; Order 889 requires utilities to establish systems to share information on the availability of transmission capacity. To date, many States have initiated activities related to retail competition, and legislative proposals have been introduced into the U.S. Congress on restructuring the electric power industry.

With a competitive industry structure eminent, investor-owned utilities have been downsizing staff and reorganizing their company structures to lower costs. They have lowered costs by taking advantage of lower fuel prices and modifying fuel acquisition procedures. This has resulted in lower operation and maintenance costs. Some large investor-owned utilities have begun to expand their business investments into such areas as energy service companies; oil and gas exploration, development, and production; foreign ventures; and telecommunications. Numerous utilities are planning to improve their position in a competitive market through mergers and acquisitions. In 1995, 13 investor-owned utilities merged or had mergers pending.[9]

Publicly owned and cooperative utilities are expected to be affected by the posturing of the investor-owned companies. Although they can sell electricity at a competitive price, increased competition from investor-owned utilities and electricity marketing companies may require them to lower costs.

Many have already begun to reduce staff and engage in other cost-cutting measures. Mergers are also expected to occur among public utilities, however, not at the same rate as the investor-owned.

Stranded costs are a major concern for this industry as they move to a competitive market. Stranded costs are costs that have been incurred by the utilities to serve their consumers but cannot be recovered if the consumers choose other electricity suppliers. Estimates of stranded costs have been from $10 to $500 billion. Currently, utilities are looking for ways to mitigate stranded costs, and regulators are looking at alternatives for recovering these costs.[10]

The structure of the electric power industry is undergoing other changes. In the past, the electric power industry has been dominated by utilities, especially regulated investor-owned utilities. It is expected that utility generators will continue to dominate capacity in the United States, increasing from 703 gigawatts in 1995 to 724.4 gigawatts in 2015. In addition, nonutilities will continue to increase their role in the industry. Recent legislation has had an effect. For example, PURPA in 1978 has allowed QF status, and the Energy Policy Act of 1992 (EPACT) has removed constraints on utility ownership of significant shares of nonutility producers. In 10 years (1985-1995), the nonutility role in U.S. electric power industry has grown from 4 percent to 11 percent of the total generation.[11]

With the advent of a more competitive market, a new type of firm called "power marketers" has arisen in the electric power generation industry. Power marketers buy electric energy and transmission and other services from utilities, or other suppliers, and resell the products for profit. This practice started in the late 1980s, and growth in this market has increased competition in the wholesale market. Nine wholesale marketers existed in 1992; 180 existed by the end of 1995. The growth and success of power marketers signal a potential for fundamental change in the wholesale electricity business.

Projected Growth in the Power Generation Industry

Demands for electricity have slowed in recent years due to several factors. These factors include market saturation of electric appliances, improvements in equipment efficiency, utility investments in demand-side management programs, and legislation establishing more stringent equipment efficiency standards. In the 1960s, electricity demand grew by more than 7 percent a year. By the 1980s, this growth had slowed to only 1 percent per year. A further decline in growth is expected into the next century.[12]

Despite the slower demand growth, 319 gigawatts of new generating capacity are expected to be needed by 2015. This need is both a result of the demand and because of the amount of capacity that is expected to be retired. In particular, approximately 38 percent of the existing nuclear capacity is expected to be retired, in addition to 16 percent of the existing fossil-fueled steam turbine capacity. Of the new capacity needed, 81 percent is projected to be combined-cycle or combustion turbine technology expected to be fueled with natural gas or both oil and gas. Both of these technologies supply peak and intermediate capacity, but combined-cycle units can also be used to meet baseload requirements.

Before building new capacity, many utilities are exploring other alternatives to meet the growth demand. Some of these alternatives are life extension and repowering, power imports, demand-side management programs, and purchase from cogenerators. Even with these alternatives, a projected 1,063 new plants (assuming approximately 300 megawatts capacity per plant) will be needed by 2015 to meet the growing demand and to offset the retirements.[13]

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the fossil fuel electric power generation industry, including the materials and equipment used and the processes employed. The section is designed for those interested in gaining a general understanding of the industry and for those interested in the interrelationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Section IX lists available resource materials and contacts.

This section describes commonly used production processes, associated raw materials, the by-products produced or released, and the materials either recycled or transferred offsite. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A Industrial Processes in the Fossil Fuel Electric Generation Industry

The majority of the electricity generated in the United States today is produced by facilities that employ steam turbine systems.[14] Other fossil fuel prime movers commonly used include gas turbines and internal combustion engines. Still other power generation systems employ a combination of the above, such as combined-cycle and cogeneration systems. The numbers of these systems being built are increasing as a result of the demands placed on the industry to provide economic and efficient systems.

The type of system employed at a facility is chosen based on the loads, the availability of fuels, and the energy requirements of the electric power generation facility. At facilities employing these systems, other ancillary processes must be performed to support the generation of electricity. These ancillary processes may include such supporting operations as coal processing and pollution control, for example. The following subsections describe each system and then discuss ancillary processes at the facility.

III.A.1 Steam Turbine Generation

The process of generating electricity from steam comprises four parts: a heating subsystem (fuel to produce the steam), a steam subsystem (boiler and steam delivery system), a steam turbine, and a condenser (for condensation of used steam). Heat for the system is usually provided by the combustion of coal, natural gas, or oil. The fuel is pumped into the boiler's furnace. The boilers generate steam in the pressurized vessel in small boilers or in the water-wall tube system in modern utility and industrial boilers. Additional elements within or associated with the boiler, such as the superheater, reheater, economizer and air heaters, improve the boiler's efficiency.

Wastes from the combustion process include exhaust gases and, when coal or oil is used as the boiler fuel, ash. These wastes are typically controlled to reduce the levels of pollutants exiting the exhaust stack. Bottom ash, another byproduct of combustion, also is discharged from the furnace.

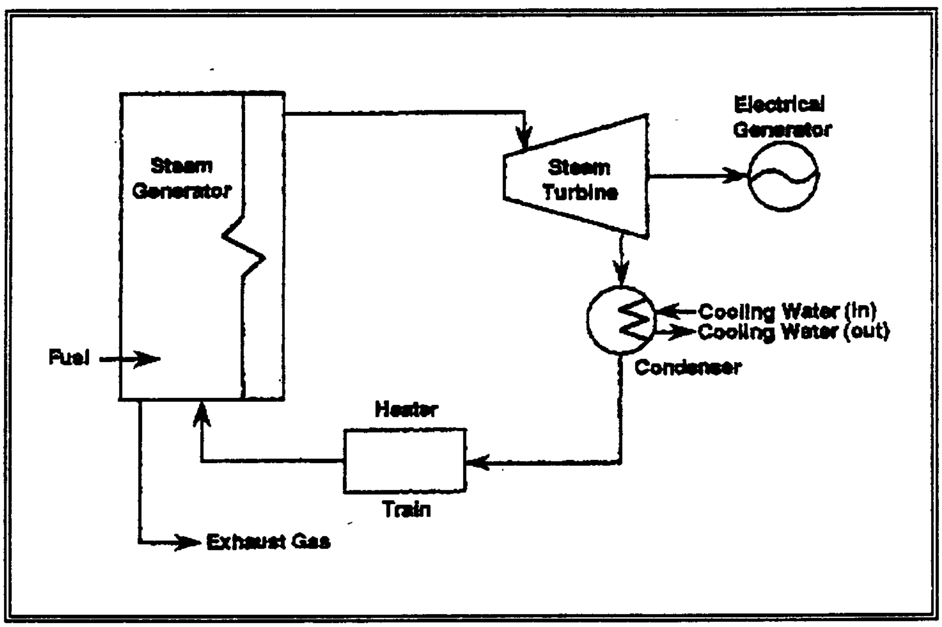
High temperature, high pressure steam is generated in the boiler and then enters the steam turbine. At the other end of the steam turbine is the condenser, which is maintained at a low temperature and pressure. Steam rushing from the high pressure boiler to the low pressure condenser drives the turbine blades, which powers the electric generator. Steam expands as it works; hence, the turbine is wider at the exit end of the steam. The theoretical thermal efficiency of the unit is dependent on the high pressure and temperature in the boiler and the low temperature and pressure in condenser. Steam turbines typically have a thermal efficiency of about 35 percent, meaning that 35 percent of the heat of combustion is transformed into electricity. The remaining 65 percent of the heat either goes up the stack (typically 10 percent) or is discharged with the condenser cooling water (typically 55 percent).

Low pressure steam exiting the turbine enters the condenser shell and is condensed on the condenser tubes. The condenser tubes are maintained at a low temperature by the flow of cooling water. The condenser is necessary for efficient operation by providing a low pressure sink for the exhausted steam. As the steam is cooled to condensate, the condensate is transported by the boiler feedwater system back to the boiler, where it is used again. Being a low-volume incompressible liquid, the condensate water can be efficiently pumped back into the high pressure boiler.

A constant flow of low-temperature cooling water in the condenser tubes is required to keep the condenser shell (steam side) at proper pressure and to ensure efficient electricity generation. Through the condensing process, the cooling water is warmed. If the cooling system is an open or a once-through system, this warm water is released back to the source water body. In a closed system, the warm water is cooled by recirculation through cooling towers, lakes, or ponds, where the heat is released into the air through evaporation and/or sensible heat transfer. If a recirculating cooling system is used, only a small amount of make-up water is required to offset the cooling tower blowdown which must be discharged periodically to control the build-up of solids. Compared to a once-through system, a recirculated system uses about one twentieth the water.[15] Figure 6 presents a typical steam generation process.

There are several types of coal-fired steam generators. A description of each follows. The classification of these generators is based on the characteristics of the coal fed to the burners and the mode of burning the coal. Coal-fired steam generation systems are designed to use pulverized coal or crushed coal. Before the coal is introduced to the burners, it must be processed, as discussed in Section III.A.6.

Figure 6: Steam Turbine Generation



Stoker-Fired Furnace

Stoker-fired furnaces are designed to feed coal to the combustion zone on a traveling grate. Stokers can be divided into three general groups, depending on how the coal reaches the grate of the stoker for burning. The three general types of stokers are (1) underfeed, (2) overfeed, and (3) spreader configurations. Table 12 presents the general characteristics of these three general types of stokers. Figure 7 presents a schematic of a stoker coal feeder.

Table 12: Characteristics of Various Types of Stokers

Stoker Type and Subclass	Burning Rate * (BTU/hr/ft²)	Characteristics
Spreader		
Stationary	450,000	Capable of burning a wide range of coals, best in handling fluctuating loads, high fly ash carry over, low load smoke.
Traveling grate	750,000	
Vibrating grate	400,000	
Overfeed		
Chain grate and traveling grate	600,000	Low maintenance but difficult in burning caking coals.
Vibrating grate	400,000	Low maintenance but difficult in burning weakly caking coals, smokeless operation.
Underfeed		
Single or double retort	400,000	Capable of burning caking coals and a wide range of coals, high maintenance, low fly ash carry over, suitable for continuous load operation.
Multiple retort		

* Maximum amount of British thermal units per hour per square foot of grate in the stoker.

In a cyclone-fired furnace, fuel is fired under intense heat and air is injected tangentially to create a swirling motion as shown in Figure 8. The resulting hot gases exit through the cyclone bore into the cyclone in the furnace. Ash becomes a molten slag that is collected below the furnace. Coal is the primary cyclone fuel, but oil and gas are used as startup, auxiliary, and main fuels.

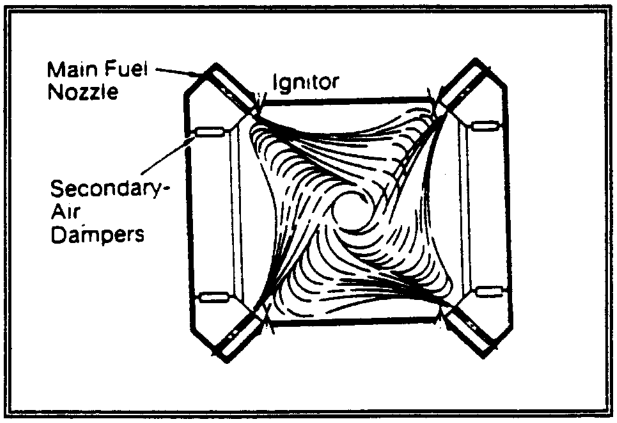
Tangential-Fired Furnace

In a tangential-fired furnace, both air and fuel are projected from the corners of the furnace along lines tangent to a vertical cylinder at the center. A rotating motion is created, allowing a high degree of mixing. This system provides great flexibility for multiple fuel firing (see Figure 9).[16]

Figure 9: Tangential Firing Pattern



Source: *Standard Handbook of Power Plant Engineering*. Elliot, Thomas C. ed. McGraw-Hill, Inc. New York, NY. 1989. Reproduced with permission of the McGraw-Hill Companies.

Horizontal or Wall-Fired Furnace

In horizontal or wall-fired systems, pulverized coal and primary air are introduced tangentially to the coal nozzle. The degree of air swirl and the contour of the burner throat establish a recirculation pattern extending several throat diameters into the furnace. The hot products of combustion are directed back toward the nozzle to provide the ignition energy necessary for stable combustion. In this system, burners are located in rows on the front wall (see Figure 10) or both front and rear walls.[17]

Arch-Fired Systems

Vertical-fired systems are used to fire solid fuels that are difficult to ignite, such as coals with moisture and ash-free volatile matter of less than 13 percent. In this system, the pulverized coal is discharged through a nozzle surrounded by heated combustion air. High-pressure jets are used to prevent fuel-air streams from short circuiting. The firing system produces a looping flame with hot gases discharging at the center (see Figure 11).[18]

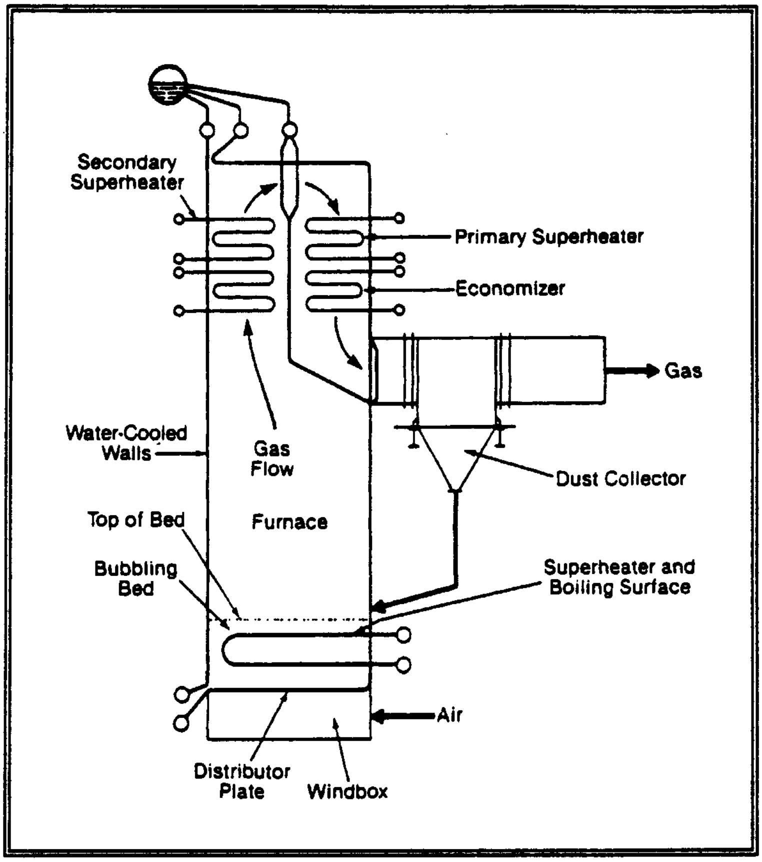
Fluidized-Bed Combustors

In fluidized-bed combustors, fuel materials are forced by gas into a state of buoyancy. The gas cushion between the solids allows the particles to move freely, thus flowing like a liquid. By using this technology, SO_2 and NO_X emissions are reduced because an SO_2 sorbent, such as limestone, can be used efficiently. Also, because the operating temperature is low, the amount of NO_X gases formed is lower than those produced using conventional technology.

Fluidized-bed combustors are divided into two categories: circulating fluidized-beds and bubbling fluidized-beds (see Figure 12). Fluidized-bed combustors can operate at atmospheric pressure or in a pressurized chamber. In the pressurized chamber, operating pressures can be 10 to 20 times the atmospheric pressure. Pressurized fluidized-bed furnaces provide significant gain in overall thermal efficiency over atmospheric fluidized-bed furnances. [19]

Figure 12: Typical Bubbling Fluidized-Bed Boiler



Source: Adapted from *Steam, Its Generation and Use*; 40th Edition. Stultz and Kitto, eds. Babcock and Wilcox, Barbeton, OH. 1992. Reproduced with permission from the Babcock and Will Cox. Co.

Fluidized-bed combustion allows for the use of high sulfur coals, high fouling and slagging fuels, and low British Thermal Unit (BTU) fuels. High ash coals burned in fluidized-beds require less preparation than in pulverized coal combustors. Additionally, fluidized-bed combustors require less maintenance than pulverized coal combustors.

III.A.2 Internal Combustion Generation

Internal combustion generating units, also known as diesel engines, have one or more cylinders in which fuel combustion occurs. Internal combustion generating units convert the chemical energy of fuels into mechanical energy in a design similar to an automobile engine. Attached to the shaft of the generator, the engine provides the mechanical energy to drive the generator to produce electricity. Internal combustion generating units for power plants are typically designed to operate on either four- or two-stroke cycles.

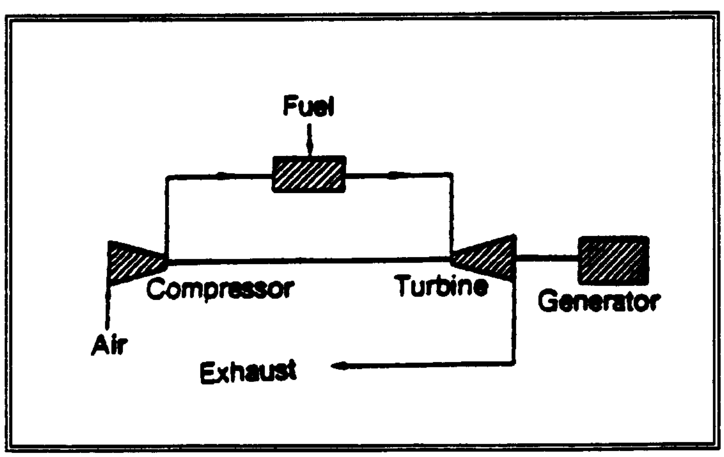
Internal combustion generators are small and range in capacity from 2 to 6 megawatts. They are more efficient than gas turbines.[20] In addition, capital costs are low, they are easily transported, and they can generate electricity almost immediately upon startup. For this reason, internal combustion generators are often used for small loads and for emergency power.[21]

III.A.3 Gas Turbine Generation

Gas turbine systems operate in a manner similar to steam turbine systems except that combustion gases are used to turn the turbine blades instead of steam. In addition to the electric generator, the turbine also drives a rotating compressor to pressurize the air, which is then mixed with either gas or liquid fuel in a combustion chamber. The greater the compression, the higher the temperature and the efficiency that can be achieved in a gas turbine. Exhaust gases are emitted to the atmosphere from the turbine. Unlike a steam turbine system, gas turbine systems do not have boilers or a steam supply, condensers, or a waste heat disposal system. Therefore, capital costs are much lower for a gas turbine system than for a steam system.

In electrical power applications, gas turbines are typically used for peaking duty, where rapid startup and short runs are needed. Most installed simple gas turbines with no controls have only a 20- to 30-percent efficiency. Figure 13 presents a schematic of a simple gas turbine system.

Figure 13: Simple Gas Turbine Cycle



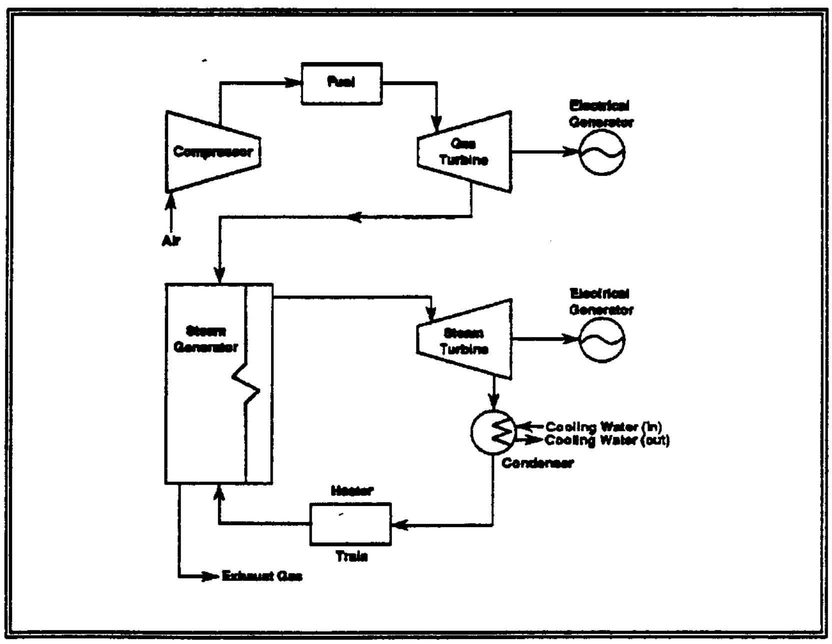
Source: *Standard Handbook of Power Plant Engineering.* Elliot, Thomas C. ed. McGraw-Hill, Inc. New York, N.Y. 1989.

R0075138

III.A.4 Combined-Cycle Generation

Combined-cycle generation is a configuration using both gas turbines and steam generators. In a combined-cycle gas turbine (CCGT), the hot exhaust gases of a gas turbine are used to provide all, or a portion of, the heat source for the boiler, which produces steam for the steam generator turbine. This combination increases the thermal efficiency over a coal- or oil- fueled steam generator. The system has an efficiency of about 54 percent, and the fuel consumption is approximately 25 percent lower. Combined-cycle systems may have multiple gas turbines driving one steam turbine (see Figure 14).[22]

Figure 14: Combined Cycle with Heat Recovery



There are four major classifications of combined-cycle facilities:

- **Gas Turbine Plus Unfired Steam Generator**: A steam generator is installed at the discharge of a gas turbine to recover the heat in the gas turbine exhaust so as to create steam in the steam generator. The fuel is fired only in the gas turbine.

- **Gas Turbine Plus Supplementary-Fired Steam Generator**: A portion of the oxygen in the gas turbine exhaust is used to support further combustion in a supplementary firing system in the connecting duct between the gas turbine and the steam generator.

- **Gas Turbine Plus Furnace-Fired Steam Generator**: This generator is the same as the gas turbine plus supplementary-fired steam generator, except that essentially all of the oxygen from the gas turbine exhaust is used to support further combustion.

- **Supercharged Furnace-Fired Steam Generator Plus Gas Turbine**: A steam generator is placed between the air compressor and the gas turbine. The air compressor is used to pressurize the boiler where the fuel is fired. The products of combustion that have been cooled within the boiler are then discharged through a gas turbine.

In addition, integrated coal gasification combined-cycle (IGCC) units are combined systems that are in the demonstration stage, but are expected be in commercial operation by the year 2000. In an IGCC system, coal gas is manufactured and cleaned in a "gasifier" under pressure, thereby reducing emissions and particulates. The coal gas then is combusted in a CCGT generation system.

III.A.5 Cogeneration

Cogeneration is the merging of a system designed to produce electric power and a system used for producing industrial heat and steam. Cogeneration accounted for 75 percent of all nonutility power generation in 1995.[23] This system is a more efficient way of using energy inputs and allows the recovery of otherwise wasted thermal energy for use in an industrial process. Cogeneration technologies are classified as "topping cycle" and "bottoming cycle" systems, depending on whether electrical (topping cycle) or thermal (bottoming cycle) energy is derived first.

Most cogeneration systems use a topping cycle. This is shown as a steam turbine topping system in Figure 15. The process steam shown in Figure 15 is condensed as it delivers heat to an industrial process, and the resulting return condensate is returned back to the boiler as shown.

Facilities that cogenerate may be eligible for QF status under PURPA. To qualify, the facility must produce electric energy and "another form of useful thermal energy through sequential use of energy," and meet certain ownership, operating, and efficiency criteria established by FERC (See 18 CFR Part 292). In a topping cycle system, the fuel is used to generate power with a steam boiler or gas turbine cycle combustor. The waste heat from the power generation process is then used in an industrial process.[24]

III.A.6 Supporting Operations

Many operations associated with fossil fuel electric power generation facilities are not directly involved in the production of electricity but serve in a supporting role. This section discusses some of the major supporting processes.

Coal Processing

Fifty-seven percent of coal used in power plants is transported from mines by rail.[25] Coal is also transported by truck and barge. Once coal arrives at the plant, it is unloaded to live storage, dead storage, or directly to the stoker or hopper. Live storage is an enclosed silo or bunker next to conveyors leading to the pulverizer. Dead storage is exposed outdoors and is the backup supply. Coal unloading devices depend on the size and type of plant. Coal arriving by rail may be unloaded directly into the storage area or to conveyors leading directly to generation units. Coal arriving by barge is unloaded by buckets, which are part of coal towers or unloading bridges.[26] Coal shipped by truck generally needs little equipment for unloading.

Precautions must be taken in the transportation and storage of coal. In transporting coal during warmer months and in dry climates, dust suppression may be necessary. Dust suppression is typically accomplished through the use of water, oil, or calcium chloride ($CaCl_2$). In winter months, antifreeze chemicals are applied to the coal. Because coal oxidizes easily in open air, it should be stored in layered piles to minimize air flow. Hot areas should be removed from the pile to prevent fire; water should not be added to reduce the heat, since the water increases the air flow and, therefore, would increase the oxidation of the coal.

Coal may be cleaned and prepared before being either crushed or pulverized. Impurities in coal, such as ash, metals, silica, and sulfur, can cause boiler fouling and slagging. Coal cleaning can be used to reduce sulfur in the coal to meet sulfur dioxide (SO_2) emissions regulations. Cleaning the coal is a costly process that increases its fuel efficiency, yet reduces the size of the particles. Coal cleaning is typically performed at the mine by using gravity concentration, flotation, or dewatering methods. Some smaller stoker plants purchase pre-cleaned, pre-crushed coal.[27]

Coal is transported from the coal bunker or silo to be crushed, ground, and dried further before it is fired in the burner or combustion system. Many mechanisms can be used to grind the coal and prepare it for firing. Pulverizers, cyclones, and stokers are all used to grind and dry the coal. Increasing the coal's particle surface area and decreasing its moisture content greatly increases its heating capacity. Once prepared, the coal is transported within the system to the combustion system, or boiler. Devices at the bottom of the boilers catch ash and/or slag.

Air Pollution Control Processes

Air pollution control devices found in fossil fuel-fired systems (particularly steam electric power facilities) include particulate removal equipment, sulfur oxide (SO_X) removal equipment, and nitrogen oxide (NO_X) removal equipment. Particulate removal equipment includes electrostatic precipitators, fabric filters, or mechanical particulate collectors, such as cyclones. SO_X removal equipment includes sorbent injection technologies and wet and dry scrubbers. Both types of scrubbers result in the formation of calcium sulfate and sulfite as waste products. NO_X emission control systems include low NO_X burners and selective catalytic or non-catalytic reduction technologies. The selective catalytic and non-catalytic reduction technologies convert oxides of nitrogen into nitrogen gas and water.

Other Processes to Mitigate Environmental Impacts

Control technologies are used at many utility electric power generation facilities to mitigate the environmental impacts of cooling water intake structures. These technologies may include intake screening systems, passive intake system (physical exclusion devices), or fish diversion and avoidance systems. Technologies used to mitigate thermal pollution include cooling towers, cooling ponds or lakes, and sprinklers. Other control technologies may include recycling and reuse equipment for metals recovery; evaporators; and physical, chemical, and biological wastewater treatment.

III.B Raw Material Inputs and Pollution Outputs

The primary raw material used in fossil fuel electric power generation is the fossil fuel needed as the energy source to drive the prime mover (i.e., turbine). Fossil fuels employed in the United States predominantly include coal, petroleum, and gas. Other inputs include water (for cooling and steam generation) and chemicals used for equipment cleaning and maintenance. Pollution outputs include solid waste pollution, wastewater pollution, air pollution, and thermal pollution. The following subsection discusses the major sources of raw materials and the sources of emissions associated with the power generation industry.

III.B.1 Fossil Fuels and Other Raw Material Inputs

The major types of fossil fuels used for electricity generation in the United States are coal, petroleum, gas. Other fossil fuels used include petroleum coke, refinery gas, coke oven gas, blast furnace gas, and liquefied petroleum gas. These latter fuels are used much less frequently and, therefore, will not be discussed in this notebook.

Coal

Coal is the most abundant fossil fuel in the United States and the most frequently used energy source for U.S. electricity generation. More than one-half of all electricity generated by utilities comes from coal-fired facilities.[28] Although the use of coal has decreased since the 1970s, some areas of the country use coal almost exclusively.

Coals used for electric power generation are very heterogeneous and vary in content, depending on the location of the mine. The major chemical makeup, which includes carbon, hydrogen, and oxygen, also contains impurities, such as minerals and sulfur. These impurities are a major concern because they contribute to the pollutants produced during combustion of the coal.

Of all the fossil fuel used for electricity generation, coal requires the most extensive processing, handling, storage, and loading and unloading facilities. Coal firing requires the use of crushers, pulverizers, ash handling equipment, dust control, emissions control equipment, and soot blowers.

Petroleum

Petroleum, or crude oil, is the source of various fuel oils used as the energy source for power generation. As an energy source, petroleum accounts for less than five percent of all electricity receipts in the United States. However, numerous utilities in the New England States, New York, Florida, and Hawaii still rely on petroleum as an energy source.[29]

Most petroleum used for power generation is refined prior to use. Typical fuel oils include fuel oil numbers 4, 5, and 6 (heavy oil) and constitute the majority of all petroleum receipts at electric utilities. Smaller amounts of fuel oil number 2 (light oil) are used typically for startup and flame stabilization of the boilers.[30] Other less frequently used sources include topped crude, kerosene, and jet fuel.

Fuel oils used for electricity generation require special handling, storage, and loading and unloading facilities. Oil requires ash handling equipment, dust control, emissions control equipment, soot blowers, and, in some instances, warming and heating facilities.

Gas

Gas is used less than coal as a primary fuel source at power generation utilities. Gas is widely used for industrial electric power generation, however. Gas is used in those areas of the United States where it is readily accessible or in States in which environmental laws for air emissions are stringent (e.g., California). Many of the facilities that use gas also use petroleum in dual-fired generating units. The use of one fuel over the other is based on economics.

Natural gas must be treated to produce commercial fuel. Natural gas comprises primarily methane and ethane. Natural gas suitable for use as a fuel in power generation facilities must be at least 70-percent methane, 60-percent propane, or 25-percent hydrogen. The fuel may come in either a gaseous or liquid form.[31]

Gas has one advantage over other fuels in that it is a cleaner burning fuel. Therefore, some electric utilities use gas in order to comply with environmental regulations. Gas used for generating electricity requires relatively little special handling (piping) and may or may not require storage facilities.

Other Inputs

In addition to fossil fuels, electric power generation requires other material inputs. These inputs include (1) water for steam condensation and equipment cooling, (2) lime or limestone, as a sorbent for pollution control equipment, (3) chlorine and/or biocides to prevent biofouling of steam condensers and cooling towers, (4) chemical solvents, oils, and lubricants for equipment cleaning and maintenance.

III.B.2 Pollutant Outputs

Pollutants are generated as byproducts from the burning of fossil fuels to generate electricity. The combustion process releases highly regulated pollutants, such as NO_X, carbon monoxide (CO), particulate matter (PM), SO_2, volatile organic compounds (VOCs), organic hydrocarbons, and trace metals, into the air. Combustion waste, the majority of which is ash waste, is created during combustion processes using coal or oil for fuel. Non-combustion wastes, such as cooling, process, and storm waters, that are discharged from fossil fuel electric power generation facilities have the potential to release pollutants (e.g., chlorine, heavy metals, and thermal pollution) into surface waters. The following discussion highlights each of the waste streams created during the generation of fossil fuel electric power.

Air Emissions

Air emissions from the stack gases from coal- and oil-fired boilers include four of six criteria pollutants regulated through the National Ambient Air Quality Standards (NAAQS) under the Clean Air Act (CAA) as amended: NO_X, CO, SO_2, and PM. Amounts of SO_2 emitted depend largely on the amount of sulfur present in the coal or oil and the method used to generate steam.

Other emissions regulated by the CAA commonly contained in emission gases are total organic carbon (TOC) as methane, non-methane hydrocarbons (NMHC), and VOCs. Traces of lead, another criteria pollutant, and other metals and minerals are also found. These metals are present in the coal and oil. Sulfur is also found in these fuels (more in coal than in oil), and fly ash is the product of sulfur and other mineral materials that do not combust.

Fugitive dust from coal piles and fuel handling equipment is another source of particulates. In addition, fugitive emissions of VOCs can arise from coal

R0075145

piles during low temperature devolatilization. Thermal rise plumes are also discharged from cooling towers. These plumes contain such pollutants as heat and some trace materials in the water vapor.

Compared to a fossil-fueled steam turbine generating system with no air pollution controls, a gas-fired power generation system with no controls emits less tonnage of NO_X and SO_2 and trace amounts of TOC, particulate matter, and CO.

Combined-cycle gas turbines have virtually no SO_2 emissions because of the purity of natural gas. Because oil and coal are not used, solid waste is eliminated, and CO_2, NO_X, and thermal pollution are cut by 60 percent.

Cogeneration is considered a pollution prevention technology. Other benefits of cogeneration are reduced fuel consumption and lower air emissions. Because of their smaller size, however, cogeneration systems in the United States tend to have lower stack heights. Therefore, air emissions to the immediate atmosphere contribute to increased local pollution.

Combustion Wastes

Two principal wastes are associated with the combustion of fossil fuels: ash waste and flue gas desulfurization (FGD) wastes. The quantities of these wastes generated depend upon the fossil fuel burned.

Ash waste -Two types of ash are generated during combustion of fossil fuels: bottom ash and fly ash. Ash that collects at the bottom of the boiler is called bottom ash and/or slag. Fly ash is a finer ash material that is borne by the flue gas from the furnace to the end of the boiler. Bottom ashes are collected and discharged from the boiler, economizer, air heaters, electrostatic precipitator, and fabric filters. Fly ash is collected in the economizer and air heaters or is collected by the particulate control equipment. Coal-fired facilities generate the largest quantity of ash; gas facilities generate so little that separate ash management facilities are not necessary. Fly and bottom ash may be managed separately or together in landfills or in wet surface impoundments.

Ashes differ in characteristics depending upon the content of the fuel burned. For coal, the chemical composition of ash is a function of the type of coal that is burned, the extent to which the coal is prepared before it is burned, and the operating conditions of the boiler. These factors are very plant- and coal-specific. Generally, however, more than 95 percent of ash is made up of silicon, aluminum, iron, and calcium in their oxide forms, with magnesium, potassium, sodium, and titanium representing the remaining major constituents. Ash may also contain a wide range of trace constituents in highly variable concentrations. Potential trace constituents include antimony, arsenic, barium, cadmium, chromium, lead, mercury, selenium, strontium, zinc, and other metals.

Flue gas desulfurization waste - If coal or oil is the fuel source, the FGD control technologies result in the generation of solid wastes. Wet lime/limestone scrubbers produce a slurry of ash, unreacted lime, calcium sulfate, and calcium sulfite. Dry scrubber systems produce a mixture of unreacted sorbent (e.g., lime, limestone, sodium carbonates, calcium carbonates), sulfur salts, and fly ash. Sludges are typically stabilized with fly ash. Sludges produced in a wet scrubber may be disposed of in impoundments or below-grade landfills, or they may be stabilized and disposed of in landfills. Dry scrubber sludges may be managed dry or wet.

Non-Combustion Wastes

Non-combustion wastes can be categorized into contact and noncontact wastes. Contact wastes come in contact with combustion wastes and, therefore, contain the same constituents as the combustion wastes. In many cases, these contact wastes are managed with the combustion wastes. Non-contact wastes do not come in contact with ashes or FGD wastes and may be managed separately. Table 13 summarizes the typical waste streams, potential pollutants, and ways of managing these pollutants. Figure 16 shows where the waste streams are generated at a typical steam electric power plant.

Table 13: Summary of Typical Waste Streams and Pollutants Generated at Fossil Fuel Electric Power Generation Facilities Based on Fuel Type

Fuel Type	Wastes/Pollutant	Air Emissions	Combustion Wastes	Non-Combustion Wastes
Coal	Process wastes	Flue gas and heat - thermal rise plume.	Bottom ash, fly ash, and FGD wastes desulfurization, and fly ash.	*Contact*†: ash transport, gas-side boiler cleaning,* FGD blowdown, coal pile runoff, pyrite waste, floor drains. *Noncontact:* once-through cooling water,* cooling system blowdown,* boiler blowdown,* water-side boiler cleaning,* demineralizer regenerent.*
	Pollutants	SO_2, NO_X, CO_2, CO (more from small boilers), VOCs, TOC, PM, metals, sulfur.	Heavy metals, ferrous sulfate, sulfuric acid, sulfate, $CaSO_3$, and CaO.	Chlorine, organic chemicals, metals, pH, TSS, TDSS, ferrous sulfate, sulfuric acid, metals, pyrite.
Oil	Process wastes	Flue gas and heat - thermal rise plume.	Bottom ash and fly ash.	*Contact*†: ash transport, gas-side boiler cleaning,* FGD blowdown, floor drains. *Noncontact:* once-through cooling water,* cooling system blowdown,* boiler blowdown,* water-side boiler cleaning,* demineralizer regenerent.*
	Pollutants	Low SO_2, NO_X (as NO_X particulate), CO_2, sulfur, and PM compared to coal. Metals and TOC.	VOCs and heavy metals.	Chlorine, organic chemicals, metals, pH, TSS, TDSS, ferrous sulfate, sulfuric acid, metals.
Gas	Process wastes	Flue gas.	None.	*Contact*†: infrequent gas-side boiler cleaning,* floor drains. *Noncontact:* once-through cooling water,* cooling system blowdown,* boiler blowdown,* water-side boiler cleaning,* demineralizer regenerent.*
	Pollutants	Low No_X, and SO_2 compared to oil and coal. Thermal pollution is 60% less than coal.	None.	Chlorine, organic chemicals, metals, pH, TSS, TDSS, metals.

Contact, Non-Combustion Wastes

Metal and boiler cleaning waste (gas-side) - Gas-side metal and boiler cleaning wastes are produced during maintenance of the gas-side of the boiler, including the air preheater, economizer, superheater, stack, and ancillary equipment. Residues from coal combustion (soot and fly ash) build up on the surfaces of the equipment and must be removed periodically. This buildup is typically removed with plain, pressurized water containing no chemical additives. Wastewaters are sometimes neutralized and metals precipitated. At coal plants, the wastewater is most often put into the ash ponds without treatment.

Ash transport wastewater - Ash produced from the combustion of coal or oil is typically collected in a sluice water that is then sent to settling ponds for disposal. The ash settling pond discharge may contain dissolved and suspended solids, heavy metals (nickel, iron, vanadium), organometalic compounds, and magnesium compounds when magnesium oxides are used for corrosion control.

Flue gas desulfurization blowdown - Blowdown from FGD systems is discharged when the recycled liquor begins to build up chlorine. The discharge contains calcium sulfate, calcium chloride, and sodium chloride. Depending upon fly ash carryover, the wastewater may contain metal ions.

Coal pile runoff - Open storage of coal allows contact with rain and/or other precipitation. These storm waters react with the minerals in the coal to produce a leachate contaminated with ferrous sulfate and sulfuric acid. The low pH of the leachate reacts with the coal, thereby accelerating dissolution of metals in the coal.

Pyrite waste - Coal mills or pulverizers reduce the size of the feed coal going into the boiler. During this process, various impurities, such as hard coal, rocks, and pyrites (an iron-based mineral), are mechanically separated from the feed stream. This solid waste is typically collected and fed into the bottom ash transport system and eventually co-disposed with the ash in either a landfill or an impoundment.

Floor drains - Floor and yard drains collect rainfall, seepage, leakage wastewaters from small equipment cleaning operations, process spills, and leaks. As a result, the pollutants found in the wastewaters are variable. The waste streams may contain coal dust, oil, and detergents.

Noncontact, Non-combustion Wastes

Once-through cooling water - When a steam turbine is used to drive the electric generator the process is called "steam electric." Steam electric units require large amounts of cooling water for steam condensation and efficient thermal operation. The cooling water flow rate through the condenser is by far the largest process water flow, normally equating to about 98 percent of the total process water flow for the entire unit. In a once-through cooling water system, water is usually taken into the plant from surface waters, but sometimes ground waters or municipal supplies are used. The water is passed through the condenser where it absorbs heat and is then discharged to a receiving water. Chlorine, which is added intermittently to the cooling water to control biofouling, is a pollutant of concern in cooling water discharge. Heat is also a concern.

Cooling tower blowdown - Cooling water is recirculated when the water supply is inadequate to sustain a once-through system or when thermal discharges are regulated or undesirable. In a system that recirculates cooling water, heat from the water is transferred to the atmosphere via cooling towers, cooling ponds, or spray facilities. The recirculated water eventually builds up dissolved solids and suspended matter. Cooling tower blowdown (a percentage of the recirculated water) is discharged regularly and additional fresh makeup water is treated and added into the recirculating system to relieve this buildup of solids. Pollutants of concern in cooling tower blowdown discharges include chlorine, organic chemicals, and trace metals from biofouling and corrosion control.

Boiler blowdown - Water to make steam may be recirculated and eventually build up impurities in the boiler. This water is periodically purged from the system. Boiler blowdown is typically alkaline, is low in total dissolved solids, and contains chemical additives used to control scale and corrosion. Blowdown also contains trace amounts of copper, iron, and nickel.

Metal and boiler cleaning waste (water-side) - Metal cleaning wastes are produced during cleaning of the boiler tubes, superheater, and condenser located on the water-side or steam-side of the boiler. Scale and corrosion products build up in the boiler and must be removed with chemical cleaning using an acid or alkaline solution. The composition of the waste solvents depends on the construction material of the feedwater system, but largely consists of iron with lesser amounts of copper, nickel, zinc, chromium, calcium, and magnesium. Spent solvents may be treated in numerous ways: (1) neutralization and then discharge, (2) evaporation in other operating boilers onsite, (3) dedicated holding ponds, (4) mixing with rinsate and sending to ash impoundments, or (5) disposal offsite.

Demineralizer Regenerant - Boiler systems may require treatment of boiler makeup water prior to use. Ion exchange resins used in the treatment of the water accumulate cations and anions removed from the raw water. These resins are regenerated using a strong acid, such as sulfuric acid, or a strong base, such as sodium hydroxide. Regenerant wastes contain dissolved ions removed from the raw wastewater and excess acid or base. Often, the waste is directed into the ash impoundment for disposal or to a settling pond with other liquid wastes prior to discharge.

IV. WASTE RELEASE PROFILE

This section provides estimates and reported quantities of wastes released from the fossil fuel electric power generation industry. Currently, this information is not available from the Toxics Release Inventory (TRI) under the Emergency Planning and Community Right-to-Know Act (EPCRA). However, regulations promulgated on May 1, 1997, would require facilities that combust coal and/or oil for the purpose of generating power for distribution in commerce to begin reporting in 1999 (for the period from January 1 to December 31, 1998). Because TRI reporting is not currently required, other sources of waste release data have been identified for this profile.

This section comprises three subsections. The first section provides available data on releases of solid wastes from fossil fuel electric power generation facilities. The second section provides available data on releases to surface waters. A third section provides available data on releases of criteria pollutants and hazardous pollutants to the air.

IV.A Available Solid Waste Release Data for the Fossil Fuel Electric Power Generation Industry

As described previously, the primary solid waste releases from coal- and oil-fired steam electric facilities are fly ash and bottom ash produced during the combustion process. An increasing number of facilities must condition flue gases to remove sulfur compounds, which results in the generation of another solid waste typically referred to as FGD sludge. The following tables present aggregated ash and FGD sludge generation estimates for utility and nonutility steam electric facilities.

Table 14 presents the estimated quantity of fly and bottom ash (combined) for utility boilers in 1994. Coal ash figures have been derived from 1994 DOE, EIA Form EIA-767 utility survey responses. These responses are compiled by the Edison Electric Institute (EEI) in their *Power Statistics Database*.[32] The oil ash figures were developed by the Electric Power Research Institute (EPRI) based on utility-provided estimates, as well as extrapolations based on oil consumption and particulate collection efficiencies for individual plants. Gas-fired facilities are not presented in the table because gas combustion does not generate measurable quantities of particulate ash. In general, coal-fired utilities produce ash at approximately 10 percent of the fuel consumption rate. This high rate of production confirms that ash management can represent an important operational consideration at coal plants. In contrast, oil-fired utilities produce much less than 0.1 percent of the total ash produced by the coal-fired facilities. This figure reflects the low ash content of oil compared with coal, the typically lower requirements for particulate collection devices at coal-fired facilities, the small average particle size of oil ash, and the small contribution that oil currently makes to total U.S. electricity generation.

Table 14: Generation and Disposition of Utility Fly and Bottom Ash, 1994 (thousand short tons)

Fuel Type	Number of Plants	Quantity Sold	Quantity Removed by Contractor	Quantity Landfilled	Quantity Ponded	Quantity Used Onsite, Given Away, or Disposed of in Other Ways	Total Quantity Collected for the Record Year (1994)
Coal*	404	12,122	8,762	24,849	19,929	4,014	69,676

Totals	**540**	**13,600**	**9,750**	**25,833**	**20,558**	**4,306**	**74,070**

* Coal ash values provided in EEI *Power Statistics Database (1994 Data).* Prepared by Utility Data Institute, McGraw-Hill, Washington, DC. 1995. Plants include only those reporting coal as primary or secondary fuel. Includes 88 facilities reporting zero waste generation: 26 facilities reported zero fuel consumption and 62 facilities did not exceed the capacity and/or ash generation reporting thresholds for the DOE EIA 767 Survey.

** Oil ash values are for 1995. Source: *Oil Combustion By-Products -- Chemical Characteristics and Management Practices: Draft Report.* Electric Power Research Institute, Palo Alto, California. March 1997.

Table 14 also indicates the range of management options employed by utilities in managing coal ash. While the figure varies considerable between operators and sites, roughly one-third of all U.S. utility coal ash finds its way to some type of beneficial use project. Of the material remaining in traditional disposal environments, the majority is managed in onsite impoundments or landfills. These units vary in size, design, and environmental controls, depending on the age, the State, and the operator.

Table 15 presents similar findings for utility FGD sludge generation and management. Again, the data reflect utility responses to the Form EIA-767, as compiled by EEI in the *Power Statistics Database*. Note that there are no oil-fired utility boilers equipped with FGD scrubbers. The quantity of FGD

R0075153

sludge generated at a given plant is a function of the sulfur content of the coal consumed, the total quantity of coal consumed, the type of scrubber

Table 15: Generation and Disposition of Utility FGD Sludge, 1994 (thousand short tons)

Fuel Type	Number of Plants	Quantity Sold	Quantity Removed by Contractor	Quantity Landfilled	Quantity Ponded	Quantity used onsite, given away, or disposed of in other ways	Total Quantity Collected for the record year (1994)
Coal	71	118	759	8,286	4,082	708	13,953

employed, the efficiency of reaction of the scrubber, and other factors. The majority of FGD sludge is managed in onsite landfills or impoundments.

Table 16 presents an estimate of the 1990 coal ash generation by nonutility fossil fuel combustors, broken out by major industrial category. Based on EPA Office of Air and Radiation's 1990 *Particulate Inventory Database (Version 3)*, the ash figures are derived from the estimated 1990 coal consumption and coal ash content for the boiler population. The table includes all coal combustors permitted as major sources of criteria pollutants under the CAA and, therefore, includes many combustors that do not produce electricity. The electric generators, however, may be expected to represent the largest of the nonutility combustors and the greatest portion of the fuel usage by that population, such that the estimates shown provide at least a fair picture of the ability of the population to generate ash.

Compared with the utility coal ash estimates presented above, the nonutility universe represents only roughly 5 percent of the total U.S. ash generation. This fact reflects the generally small boiler size and the small aggregate coal consumption represented by nonutility combustors. Two industry categories, paper and chemicals manufacturing, represent 50 percent of all nonutility coal consumption, with only five industry categories accounting for more than 80 percent of all nonutility coal consumption.

Table 16: Estimated Nonutility Generation of Coal Ash, 1990

Standard Industrial Classification	Number of Facilities	Number of Boilers	Total Capacity (MMBTU)	Estimated Ash Generation (1,000 tons)
2600-2699, Paper and Allied Products	139	243	61,348	1,189

Source: *Nonutility Fossil Fuel Combustion: Sources and Volumes - Revised Draft Report.* Prepared for U.S.EPA, Office of Solid Waste by Science Applications International Corporation, McLean, VA. December 1996.

As discussed previously, steam electric facilities may generate a variety of other solid wastes. These may include boiler and cooling water treatment wastes, coal mill rejects, boiler cleaning wastes, and a variety of smaller waste streams incidental to power generation of ancillary activities. At coal plants, these waste streams typically are small compared with ash and sludge generation. At oil- and gas-fired plants, they may represent the largest solid wastes present at the site. Unfortunately, available data sources do not provide credible estimates of the total quantity of these materials generated at utility and nonutility steam electric sites.

IV.B Available Water Release Information for the Fossil Fuel Electric Power Generation Industry

The EPA Office of Water, Office of Science and Technology, Engineering and Analysis Division, has collected water release data in evaluating the need for revisions to the 1982 Effluent Limitations Guidelines and Standards for the Steam Electric Point Source Category. The EPA has identified 53 chemicals (29 priority and 24 nonconventional) as pollutants of interest in wastewaters discharged from steam electric power generation facilities. These pollutants were identified in the EPA Permit Compliance System (PCS) database. The PCS is a computerized information management system maintained by the EPA Office of Enforcement. The PCS contains data on permit conditions, monitoring, compliance, and enforcement data for facilities regulated by the National Pollutant Discharge Elimination System (NPDES) Program. The information contained in the database is generally limited to only those facilities that have been classified as "major" by EPA based on factors such as effluent design flow and physical, chemical, and locational characteristics of the discharge. Information on facilities designated as "minor" is not required to be entered into the PCS database.

The data collected included 1992 records of pollutant releases from facilities with primary SIC codes 4911 and 4931. Approximately 512 facilities were identified in PCS as "major" steam electric facilities. Please note that facilities that use nuclear energy to drive steam turbines are also covered in the universe evaluated under this study. An option in the PCS system called Effluent Data Statistics (EDS) was used to generate the annual loading values. For the purposes of the effluent guideline study, the EDS-derived data were subjected to numerous refinements in an attempt to overcome limitations in the database. These refinements included review of the data by monitored facilities, as arranged by the Utility Water Act Group (UWAG) and the EEI. The industry still contends, however, that the loadings of pollutants in these data are over estimated.[33] Therefore actual loadings cannot be provided in this Sector Notebook.

Table 17 provides a list of the pollutants found in the 1992 PCS data for steam electric effluents.

Table 17: List of Pollutants Reported in 1992 PCS Data from Steam Electric Facilities*

Priority Pollutant	Pollutant	Priority Pollutant	Pollutant
	Iron	X	Trichloromethane
	Chlorine	X	Beryllium
	Aluminum		Ethylene glycol
	Boron		Nitrosomorpholine, N-
	Fluoride	X	Mercury
	Boric Acid	X	Pentachlorophenol
X	Zinc	X	Silver
	Barium	X	Thallium
	Magnesium	X	Antimony
X	Copper		Molybdenum
	Ammonia		Benzonitrile
	Iron Sulfate		Titanium
	Manganese		Polychlorinated biphenyls, NOS
X	Chromium, trivalent	X	Dichloromethane
X	Nickel	X	Tetrachloroethane
X	Lead		Dibenzofuran
X	Arsenic	X	Toluene
X	Chromium		Xylene
X	Selenium		Lithium
	Bromine	X	Benzene
	Hydrogen Sulfide	X	Ethylbenzene
X	Chromium, hexavalent	X	Phenanthrene

IV.C Available Air Emissions Data for the Fossil Fuel Electric Power Generation Industry

Three existing sources of data for estimating the releases to the air from the fossil fuel electric power generation industry were identified. The following sections discuss the available data and associated limitations.

IV.C.1 Annual Emissions Estimated by the Department of Energy, Energy Information Administration

Emissions data for traditional utility steam electric facilities that generate 10 or more megawatts electricity using fossil fuels are derived or obtained directly from information collected in an annual survey by the DOE EIA. This survey (Form EIA-767) is a restricted-universe census used to collect boiler-specific data from almost 900 electric utility power plants. The emissions are calculated based on fuel consumption data and using emission factors from the EPA report AP-42, *Compilation of Air Pollutant Emission Factors* and reduction factors for control equipment, where applicable. The CO_2 emissions are estimated using additional information about fuel quality. Table 18 provides the estimated 1995 emissions for utility fossil fuel steam electric generating units that generate 10 or more megawatts electricity.

Table 18: Estimated 1995 Emissions From Fossil Fuel Steam Electric Generating Units at Electric Utilities by Fuel Type (thousand short tons)

Fuel	Net Generation (thousand megawatts)	SO_2	NO_X	CO_2
Coal	1,652,914	11,248	6,508	1,752,527
Gas	307,306	1	533	161,969
Petroleum	60,844	321	92	50,878

Source: *Electric Power Annual 1995, Volume 2.* Energy Information Administration, Department of Energy, Washington, DC. DOE/EIA-0348(95)/2. December 1996.

As indicated in the table, the majority of the emissions from utility fossil fuel steam electric generating units come from coal-burning facilities. This is due in part because there is more coal-fired capacity than other fossil-fueled capacity in use. SO_2 emissions are higher in coal-burning facilities due to the higher sulfur content in coals than in other fuels. The average sulfur content in coals ranges from 0.3 percent in the West to approximately 2.5 percent in the East. Petroleum burned at utility power plants ranges from almost no sulfur to about 3.5 percent. The amount of sulfur contained in natural gas is relatively small.

The Form EIA-767 does not collect data for facilities employing internal combustion engines, gas turbines, or combined-cycle systems or steam electric plants generating less than 10 megawatts electricity. The EIA conducted a study in 1991 to estimate air emissions from these generating units, using a methodology similar to that used on the larger steam electric facilities. The study indicated that emissions of SO_2, NO_X, and CO_2 are less than 0.1, 1.2, and 1.1 percent, respectively, of total utility air emissions.[34]

The EIA collects similar fuel consumption and quality information for nonutility power producers. However, EIA provides only aggregate statistics on estimated emissions for all fuels (fossil and renewable energy sources) and does not separate out emissions for fossil-fueled facilities. These statistics are not provided in this document since the capacity of nonutility generation using nonrenewable energy sources is large.

IV.C.2 AIRS Database Annual Estimated Releases for the Electric Power Generation Industry

The Aerometric Information Retrieval System (AIRS) is an air pollution data delivery system managed by the Technical Support Division in EPA's Office of Air Quality Planning and Standards (OAQPS), located in Research Triangle Park, North Carolina. The AIRS is a national repository of data related to air pollution monitoring and control. It contains a wide range of information related to stationary sources of air pollution, including the emission of a number of air pollutants that may be of concern within a particular industry. States are the primary suppliers of data to AIRS. Data are used to support monitoring, planning, tracking, and enforcement related to implementation by EPA staff, the scientific community, other countries, and the general public. The following criteria pollutant emissions and estimated TRI pollutant release data for the fossil fuel electric power generation industry were extracted from this database.

AIRS Estimated Criteria Pollutant Emissions

The AIRS database contains data on criteria pollutants: CO, NO_X, particulate matter (PM) of 10 microns or less (PM10), total particulate emissions (PT), SO_2, and VOCs. Criteria pollutant releases for the fossil fuel electric power generation industry were accessed using SIC codes 4911 and 4931. It should be noted that accessing the data using SIC codes does not allow the segregation of emissions for facilities that use fossil fuels from facilities that use nuclear, renewable, or a combination of fuels. Therefore, the annual emissions taken from the AIRS database will overestimate the emissions from the fossil fuel subsector of the power generation industry. Table 19 presents the criteria pollutant data available for this industry. Pollutant releases for other industries are also included in the table.

Table 19: Annual Air Pollutant Releases (tons/year)

Industry Sector	CO	NO_2	PM_{10}	PT	SO_2	VOC
Metal Mining	4,670	39,849	63,541	173,566	17,690	915

Source: U.S. EPA Office of Air and Radiation, AIRS Database, 1997.

AIRS Estimated TRI Pollutant Emissions

Data were collected from the AIRS database by the EPA Office of Pollution Prevention and Toxics, Environmental Assistance Division, Toxics Release Inventory Branch in support of the TRI expansion project discussed previously. The data set that was downloaded included the most recent data available for each facility up to and including 1995 data. The data presented in Table 20 are estimates of TRI releases based on air releases reported in the AIRS Facility Subsystem (AFS) from facilities within SIC codes 4911 and 4931. The data contain quantities of directly reported TRI chemicals, as well as quantities of additional TRI chemicals extrapolated from reported releases of PM and VOCs. The PM and VOC releases were matched with chemical profiles contained in the SPECIATE database (Version 1.5). The SPECIATE is a computerized format of the EPA Air Emissions Species Manual and is available for download from the Clearing House of Inventory and Emissions Factors (CHIEFs). The data presented are based only on apportionment of "original" species profiles in the SPECIATE database -- those species profiles that were developed specifically for the source of the release where it has been applied. Despite the use of only the highest quality profiles in the SPECIATE database, these data should only be used as a preliminary indication of potential releases and not as actual air releases. These data have been provided for illustrative purposes only and should not be used in comparisons with other release data.

IV.C.3 Hazardous Air Pollutant Emissions Estimates for Fossil Fuel Electric Utility Steam Generating Units

Estimates of hazardous air pollutant (HAP) emissions from fossil fuel electric utility steam generating units have been developed by OAQPS and are reported in a report entitled, *Study of Hazardous Air Pollutant Emissions from Electric Utility Steam Generating Units - Interim Final Report* (Volumes 1-3).[35] These estimates are based on emissions test data from 52 units obtained from extensive emission tests by the EPRI, DOE, the Northern States Power Company, and EPA. The testing program covered a wide range of facility types with a variety of control scenarios. Therefore, the data are considered to be generally representative of fossil fuel utility steam electric generating units as a whole. This study estimated the average annual emissions for each of 684 power plants. A total of 67 HAPs were identified in the emission testing program as potentially being emitted from these facilities.

It should be noted that the report states that because of the small sample sizes for specific boiler types and control scenarios, there are uncertainties in the data. Therefore, the data for individual plants may either underestimate or overestimate the actual emissions. According to the report, the average annual emissions estimates will be roughly within a factor of plus or minus three of the actual annual emissions. However, it is recognized that the analysis had numerous limitations, such as not including data on potential upsets or unusual operating conditions, and it is possible that the range of uncertainty is greater. Tables 21, 22, and 23 present data on estimated inorganic HAPs from coal-fired, oil-fired, and gas-fired utility steam electric facilities. Tables 24, 25, and 26 present data on estimated organic HAPs from coal-fired, oil-fired, and gas-fired utility steam electric facilities.

Table 20: Estimated Releases of TRI Chemicals *		
CAS NO.	Chemical Name	Total Releases (pounds per year)
71556	1,1,1-Trichloroethane (Methyl chloroform)	52,923,638
79005	1,1,2-Trichloroethane	422,954
95636	1,2,4-Trimethylbenzene	264,682
106934	1,2-Dibromoethane (Ethylene dibromide)	1,820,797
95501	1,2-Dichlorobenzene	22,292
107062	1,2-Dichloroethane (Ethylene dichloride)	35,222,942
106990	1,3-Butadiene	7,443,883
541731	1,3-Dichlorobenzene	672
106467	1,4-Dichlorobenzene	378,018
112345	2-(2-Butoxyethoxy)ethanol	103,100
124174	2-(2-Butoxyethoxy)ethanol acetate	0
111900	2-(2-Ethoxyethoxy)ethanol	885,978
111773	2-(2-Methoxyethoxy)ethanol	0
111762	2-Butoxyethanol	21,929,191
110805	2-Ethoxyethanol	998,125
111159	2-Ethoxyethyl acetate	111,202
109864	2-Methoxyethanol	60
90437	2-Phenylphenol	8,507
101779	4,4'-Methylenedianiline	43
75070	Acetaldehyde	2,010,699

Selenium	19	62	9	8	190	230

* Compounds are listed in the following sequence: inorganic, organic, and dioxin/furan/polycyclic aromatic hydrocarbons (PAHs). Median emission factors were determined from organic HAP concentrations at the stack, control device outlet, or boiler outlet when at least one of typically three measured flue gas concentrations was detected.
** Stack factors for inorganic HAPs were taken from test reports when at least one of typically three measured flue gas concentrations was detected. These factors were not used to develop the estimated emissions.
*** Since the inorganic emissions were not directly estimated from stack factors, total emissions of inorganic HAPs projected with the computer program and from median stack factors will vary.
† Nationwide hydrogen cyanide emissions were detected from stack emission factors and not from emission median factors.
†† Nationwide phosphorous emissions were detected from stack emission factors and not from emission median factors.

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways, such as reducing material inputs, re-engineering processes to reuse byproducts, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasibly. In the waste management hierarchy, if source reduction is not feasible the next alternative is recycling of wastes, followed by energy recovery, and waste treatment as a last alternative.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the fossil fuel electric power generation industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be used effectively. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

Coal is considered the primary energy source for power generation now and in the future. Coal is relatively abundant and inexpensive. However, environmental impacts associated with coal combustion, most notably, acid rain, represent a cost to the environment and human health. This section emphasizes technologies for coal-fired electric power generation plants, but includes pollution prevention practices that apply to other fossil fuel electric plants as well. Many of the technologies and practices may be employed in existing plants, in the repowering of existing plants, and in the design and construction of new plants.

V.A Pollution Prevention Technologies in the DOE Clean Coal Technology Demonstration Program

The DOE is charged with protecting the Nation's energy interests. In recognition of the vital role of coal as a sustainable energy source, DOE vigorously researches and promotes ways to reduce the environmental impacts associated with coal combustion under the Clean Coal Technology Demonstration (CCT) Program. Specific goals of the CCT Program include (1) increasing the efficiency of electricity production and (2) enhancing the efficient and cost effective use of U.S. coal reserves, while ensuring achievement of national and environmental goals.

One way in which the CCT Program progresses towards these goals is by building a portfolio of advanced, coal-based technology demonstration projects. Included in the portfolio are technologies that result in improved efficiency with fewer environmental consequences. The technologies demonstrated under the CCT Program include commercially viable processes, as well as projects whose commercial viability is still being explored. These technologies may be categorized as (1) power systems, (2) environmental control devices, and (3) clean coal processing. Pollution prevention technologies being demonstrated under the CCT Program are included under the categories labeled "power systems" and "clean coal processing." Technologies categorized as "environmental control devices" may not be considered pollution prevention technologies; however, they may enable the recovery of pollutants for subsequent reuse/resale in products.

A brief discussion of emerging power systems and coal processing technologies being demonstrated under the CCT Program is provided below. DOE's *Clean Coal Technology Demonstration Program, Program Update 1995* (April 1996) provides a more detailed discussion.

V.A.1 Emerging Technologies

Pollution prevention opportunities in advanced coal-fired power systems are realized by the increase in overall efficiency of the combustion (electricity produced per amount of fuel) resulting in the reduction of environmental pollutants released. Efficiency of a technology is determined by the portion of energy in fuel that is converted into electricity. Thus, the process of combustion and heat transfers are critical variables. In considering advanced technologies, one must consider the environmental transfer of wastes from one media to another. Unless the transfer represents a more manageable form of the waste, there may be little or no environmental gain.

A brief description of power system technologies is provided below. While none of the technologies described are currently commercially viable, they may be in the future. Table 27 summarizes demonstration projects for power system technologies funded by DOE and participating companies.

Table 27: Summaries of Clean Coal Technologies Under DOE's Clean Coal Technology Demonstration Program

Demonstration: Pressurized Fluidized-Bed Combustion Combined-cycle, Tidd Project-The Ohio Power Company

Status: *Completed on the 70 MW scale, future testing on 340 MW scale planned.*
Size: *55 MW steam turbine, 15 MW gas turbine*
Efficiency: *Combustion efficiency of 99.6%. Heat rate efficiency of 33.2 percent*
Environmental Benefits: *SO_2 removal of up to 95%. Resulting NO_X emissions of 0.15-0.33lb/million Btu.*

Demonstration: Integrated Gasification Combined-cycle Repowering Project

Status: *Currently still in design stage.*
Size: *65 MW*
Projected Efficiency: *Heat efficiency of approximately 43%.*
Environmental Benefits: *Expected CO_2 reduction, improved efficiency over coal-fired plant with flue gas desulfurization.*

Demonstration: Indirect Fired Cycle-Repowering, Pennsylvania Electric Co. Warren Station, Unit No. 2

Status: *Currently still in design stage.*
Size: *62.4 MW*
Projected Heat Rate: *9,650 BTU/KWh (31.3% improvement over existing).*
Environmental Benefits: *Eliminates the need for hot gas cleanup systems.*

Demonstration: Coal Diesel Combined-Cycle Project, Arthur D. Little, Inc.

Status: *Currently in design stage.*
Size: *14 MW*
Projected Efficiency: *Heat efficiency of approximately 48%.*
Environmental Benefits: *Emissions reductions to levels of 50%-70% below NSPS.*

Demonstration: Slagging Combustor, Heavy Clean Coal Project, Alaska Industrial Development and Export Authority, Golden Valley Electric Association

Status: *Currently in construction stage.*
Size: *50 MW*
Projected Efficiency: *Projected SO_2 removal of 90%, NO_X emissions/million BTU emissions of less than 0.015 lb/million BTU, particulates of 0.0015 lb/million BTU.*
Environmental Benefits: *SO_2, NO_X, particulates emissions reductions.*

Fluidized-Bed Combustion

Fluidized bed combustion (FBC) technology includes three designs: atmospheric, pressurized, and two-stage bubbling bed. Although FBC technology is not yet widespread in the industry, it allows any kind of fuel to be burned while controlling the emission of SO_2 without the use of a flue gas scrubbing device. In the FBC process, a sorbent, such as crushed limestone, is introduced with pulverized coal in the combustion chamber. Air forced into the combustion chamber suspends the coal-limestone mixture. Sulfur, released from the coal, combines with the sorbent to form a solid waste that is relatively easy to handle and dispose of. The advantage of FBC technology is that it creates a turbulent environment conducive to a high rate of combustion and a high rate of sulfur capture and allows for lower operating temperatures than conventional boilers. Because operating temperatures are below the threshold of thermally induced NO_X formation, NO_X emissions are reduced. In addition, the operating temperature tends to be below the ash fusion range for coal, resulting in less wastes present in fireside wash waters and less frequent cleaning requirements.

Integrated Gasification Combined-cycle

In the IGCC, coal is converted into a gaseous fuel, purified, and combusted in a gas turbine generator to produce electricity. The constituents react to produce a fuel gas. Heat from the exhaust gas is recovered and used to generate steam, which produces additional electricity. Gasification is a process in which coal is introduced to a reducing atmosphere with oxygen or air and steam. In some systems, a limestone sorbent is added to the gasifier for sulfur removal. The environmental advantages of IGCC include:

- High efficiency
- Removal of nitrogen, sulfur, and particulates prior to the addition of combustion air, thereby lowering the volume of gas requiring treatment
- Sulfur in the gas is in the form of hydrogen sulfide, which is removable to a greater extent than SO_2
- NO_X removal of more than 90 percent
- Reduced CO_2 emissions compared to traditional coal-fired boilers.

Currently, gas cleanup in IGCC requires the gas to be cooled; however, hot gas cleanup systems are being developed that will remove 99.9 percent of the sulfur and result in a saleable sulfur product. The IGCC system is well suited for repowering because it can use the existing steam turbine, electrical generator, and coal-handling facilities in most cases.

Indirect-Fired Cycle

An indirect-fired cycle operates such that coal or biomass combustion products do not come in direct contact with gas turbine components. Instead, heated gases pass on the shell side of an air heater. On the tube side of the air heater, compressed gas is heated and passes through a gas turbine. The environmental advantage is that this eliminates the need for hot gas cleanup since the corrosive and abrasive fuel products do not come into direct contact with the turbines. Heat is recovered from air heater exhaust and is used to produce steam, which powers a steam turbine. In addition, corrosive gas products do not come into direct contact with the turbine, thereby eliminating the need for hot gas cleanup. Although the technology is still in the design stage, the efficiency is expected to be 20 percent greater than that of a pulverized coal plant. Furthermore, SO_2 reductions of 90 percent, as well as reduced NO_X and particulate emissions, are expected.

Integrated Gasification Fuel Cell

An integrated gasification fuel cell system consists of a coal gasifier with a gas cleanup system, a fuel cell, an inverter, and a heat recovery system. Coal gas, made through the reaction of steam, oxygen, and limestone, is introduced to a fuel cell composed of an anode and a cathode and separated by an electrolytic layer. The fuel cell converts the chemical energy of the gas to direct current electrical energy and generates heat, and an inverter converts direct current to alternating current. A heat recovery system delivers heat to a bottoming steam cycle for further generation of electricity. Pollution prevention is realized by improved emissions reduction associated with the gas cleanup system and solid-waste reduction.

Coal-Fired Diesel

Diesel generators are modified to accept a coal/water slurry as a fuel source. Environmental control systems are typically installed to remove NO_X, SO_2, and particulates. The advantage of a coal-fired diesel system is that it is well suited to small generators (below 50 megawatts). In addition, it is estimated to result in emissions reduction of 50 percent below New Source Performance Standards. Similarly, coal-oil mixture technology can replace up to 50 percent of fuel oil with pulverized coal for burning in conventional oil or gas burners.

Slagging Combustor

In a slagging combustor, coal is burned at very high combustion temperatures outside the furnace cavity, and combustion gasses pass into the boiler, where heat exchange takes place. In a conventional boiler, the ash enters the boiler and collects on boiler tubes, thus decreasing the efficiency of heat exchange. Alternatively, the high temperature of the slagging combustor causes ash to form slag, which is collected in cyclones. The advantage of the slagging combustor is that it prevents a loss in heat exchange efficiency that would occur from ash accumulation on boiler tubes.

V.A.2 Coal Processing for Clean Fuels

Pollution prevention entails removal of the pollutants from coal in the precombustion stage. This is accomplished through coal cleaning, whereby pollutants are removed without altering the solid state of the coal, or by conversions (gasification or liquefaction), which represent transformations in the state of the coal.

Coal Cleaning

Most coal cleaning occurs at the mouth of the mine. The cleaning method depends on the size of the coal pieces. Typically, coal is cleaned by pulsing currents of water through a bed of coal in a jig to separate the impurities from the coal. Coal cleaning can be achieved through physical, biological, or chemical means. Physical cleaning is the most common method and involves the separation of coals to obtain coals with lower ash content. A lower ash content helps in meeting particulate emissions standards and results in lower operating and maintenance costs associated with ash handling. Coal cleaning can also reduce the trace metal content, thus reducing trace metal content in ashes. Furthermore, cleaning is effective in removing sulfur from coal. This is sulfur that may otherwise end up as SO_2 emissions. There is a tradeoff between sulfur reduction and energy recovery.[36] It should be noted, however, that a reduction in energy recovery is associated with sulfur removal.

A study cited in a report written by the Virginia Department of Environmental Quality compared two FBC conceptual plant designs using mine-run coal versus washed coal. The washed coal facility reduced SO_2 emissions by more than 50 percent on the basis of equivalent heat input and sulfur removal. The NO_X emissions from the washed coal are about one-third lower in comparison to mine-run coal based on equivalent heat input. In addition, the washed coal facility was physically smaller, had lower installation costs, required less storage area for limestone and ash, used less water, and generated less high-volume wastes.

Coal Gasification

Gasification is the process of converting coal to a gaseous fuel—coal gas—followed by chemical cleaning. Coal gas has the benefit of burning as cleanly as natural gas. The process entails coal gas reacted with steam and an oxidant in a reducing atmosphere. If air is the oxidant, a low-BTU gas results; if oxygen is the oxidant, a medium-BTU gas results.

Mild Gasification

In mild gasification, coal is heated in a oxygen-free reactor, which produces gaseous, solid, and liquid products. The environment in the reactor drives off the condensed, volatile hydrocarbons and leaves behind carbon. The benefit of mild gasification is that it produces multiple fuels and feedstocks using medium temperature treatment of coal.

Coal Liquefaction

Hydrogen added to coal increases the fuel's ratio of hydrogen to carbon to a level similar to that of petroleum-based fuels. Coprocessing is a liquefaction process, whereby heavy petroleum residue combined with coal produces a liquid fuel. The liquids can be cleaned of sulfur and ash prior to use as a fuel and have higher thermal efficiencies (60-70 percent range), high product yield, and potentially marketable byproducts, such as gasoline.

V.B Other Pollution Prevention Technologies

Cogeneration

Cogeneration is the production of electricity and heat from a single power plant unit. Because of the heat recovery aspect, cogeneration itself is a pollution prevention strategy. In cogeneration, heat that would otherwise be released from a steam turbine, gas turbine, or diesel engine is recaptured and used to heat buildings or other industrial processes or to generate additional electricity. In fact, whereas the typical efficiency at a fossil fuel electric plant is around 33 to 38 percent, cogenerators can obtain up to 80-percent efficiency because of the heat recaptured. The heat recovered comes mainly from the flue gases.[37]

Cogeneration plants were originally industrial applications. They are still used primarily to provide power for industries, hotels, universities, etc., yet they are increasingly being designed for larger capacities and are competing with utilities for power production. Cogeneration plants may be owned by an industrial company, supplying its own power, or they may be owned by small entrepreneurial companies. Besides size requirements, factors such as type of fuel to burn, methods of recapturing heat, and control of emissions, should be considered when evaluating cogeneration as a power source.

DOE's Office of Industrial Technology (OIT) has several projects underway to promote cogeneration, which is a commercially available technology. For example, OIT teamed up with Riegel Textile Corporation to design and test an innovative 4.3 MW high-back-pressure steam cogeneration system using a modified coal-fired boiler. The turbine exhaust (225 psig at 570 degrees Fahrenheit) is hot enough to be used for process heating and can also be used to drive an existing low-pressure turbine to generate additional electricity. In 1994, 17 such systems were in operation.[38]

Repowering

Repowering is a way in which power generation facilities can improve and increase both the production and efficiency of standard thermal generating facilities. Repowering options include expanding a unit's size or changing the type or quality of the fuel used. In most cases, it involves partial or complete replacement of the steam supply system and usually a more or less complete retention, refurbishment, and reuse of the turbine/generator. Many of the technologies listed above are appropriate for repowering.

Fuel Cells

Natural gas fuel cell (NGFC) energy systems improve gas utilization and efficiency. Like batteries, fuel cells are based on the principles of electrochemistry, except that they consume fuel to maintain the chemical reaction. The most common electrochemical reaction in a fuel cell is that of hydrogen with oxygen. The oxygen is usually derived from the air, and the hydrogen is usually obtained by steam-reforming fossil fuel. Natural gas is the most common fuel; however, other fuels can be used: peaked-shaved gas, air-stabilized gas from local production such as landfills, propane, or other fuels with high methane content. Fuel Cells, being electrochemical, are more efficient than combustion systems. In addition, emissions are reduced from typical gas systems because there is no combustion of fossil fuel. Although many fuel cells are being researched, developed, and demonstrated around the world, only one system is commercially available at this time. It is a 200 kW phosphoric acid fuel cell system.[39]

Because emissions are reduced, State and local air quality regulating agencies have begun to grant and/or consider exemptions from air quality permitting requirements. For example, after extensive emissions testing, the South Coast Air Quality Management District has granted NGFC's exemption in the Los Angeles area. Exemptions have also been granted by the Santa Barbara Air Quality Management District, the Bay Area Air Quality Management District, and the State of Massachusetts. These exemptions may create economic incentives to install NGFC systems to avoid permitting fees and violation fines, or to take advantage of emissions credits. A Federal incentive program is being managed by the DOE Morgantown Energy Technology Center to reduce the cost of the fuel cell by $1,000 per kW.[40]

Additional information on this technology may be obtained from the North American Fuel Cell Owner Group (NAFCOG), an independent users group comprised of owners and operators of NGFCs.

V.C Other Pollution Prevention and Waste Minimization Opportunities

In addition to the technologies discussed previously, several other pollution prevention methods can be employed. Some of the methods are common solutions applicable to a wide range of facilities; others are more tailored to site-specific situations. Some of the methods are relatively simple, whereas others require more technological modifications. This section includes not only physical tasks, but management and training steps that foster pollution prevention.

V.C.1 Process or Equipment Modification Options

Fuel Sources

As discussed under the CCT Program, the initial fuel source may be examined as a potential pollution prevention opportunity. Clean coal technologies remove the pollutants prior to the major processes of electrical generation. But on a case-by-case basis, one can also consider the option of using fuels that are naturally lower in pollutants. Low-sulfur coals produce less SO_2 emissions, and there is less pollution associated with coal pile runoff. However, a tradeoff exists in that most low-sulfur coal in the United States is "low rank" (i.e., it has a higher ash and moisture content). Several operational difficulties stem from switching from high-rank to low-rank coal. Nonetheless, processing techniques to improve the BTU and remove sulfur from low-rank coals are being developed. For example, SynCoal (Western Energy Company) is a technology that produces a fuel with a 0.5 percent sulfur content, a moisture content of greater than 5 percent, a heating value of 11,800 Btu per pound, and ash content of approximately 9 percent.

Another related technology that has been researched extensively is co-firing using refuse derived fuel (RDF) pellets and coal in power plants. In 1992, DOE's OIT, in cooperation with several organizations, operated a power plant with a mixture of coal and up to 25 percent RDF pellets. The project found that the mixture resulted in reduced acid gas emissions. The CAA amendments of 1990 allow the combustion of up to 30 percent municipal solid waste in coal plants. The results of this project are facilitating commercialization of the co-combustion technology.

Cooling Water

Cooling water is used in steam turbine electric power plants and is circulated through the condenser to condense the steam left after the generation of electricity. The resulting condensate can then be pumped back into the high-pressure boiler. Cooling systems may be once-through, where cooling water is discharged into a receiving water body after use, or recirculating, which involves the use of cooling towers, lakes, or ponds. Scaling of heat exchange equipment and piping occurs from cooling water contact and reduces the efficiency of the equipment. To prevent scaling, chemical additives, such as polyphosphates, polyester, phosphates, and polyacrylates, are added to cooling water. In the past, cooling tower treatment chemicals contained hexavalent chromium. Recent regulations have restricted the use of chrome-based treatment to reduce the associated public health and environmental impacts. As a result, industry has switched to non-chrome treatment chemicals.

Corrosion, fostered through aeration of cooling water in cooling towers, is another problem. A number of different chemicals such as zinc, molybdate, silicate, polyphosphate, aromatic azole, carboxylate, and sometimes chromate are added to cooling water for corrosion control. Fouling and biological growth are commonly controlled through the addition of polyester, phosphates, polyacrylates, non-oxidizing biocides, chlorine, and bromine.

Pollution prevention opportunities for cooling water address minimizing chemical additives and conserving water. Table 28 presents a few general pollution prevention recommendations for reducing cooling tower emissions.

First and foremost, a facility can determine the optimum chemicals for the prevention of biologic growth and corrosion. In general, chlorinated biocides are less toxic than brominated biocides, and polyphosphate and organo-phosphate inhibitors are less toxic than chromate corrosion inhibitors. Another possible means to reduce the need for chemical additives for control of scaling is magnetic water conditioning.

Widespread attention has focused on ozone treatment in lieu of common biocide use. Ozone acts to rupture bacterial cells through oxidation. Reductions in scaling, biofouling, and overall toxics may be realized from ozone. It has been successful mainly in once-through cooling water systems for power plants. Drawbacks in the use of ozone treatment include (1) the potential for corrosion in cooling towers, unless careful dosing is practiced to maintain the oxidation-reduction potential rate and (2) ozone treatments have been shown to exhibit rapid fouling on high temperature surfaces such as would be found in recirculating systems. In addition, health and safety issues associated with worker exposure to ozone must be considered.

Table 28: Pollution Prevention Opportunities for Reducing Cooling Tower Emissions
Pretreat makeup water: Pretreating the makeup water to cooling towers reduces the chemical treatment requirements for scale and corrosion control and can increase the number of times cooling water may be recycled before blowdown.
Use inert construction materials: Polyethylene, titanium, and stainless steel are relatively nonreactive compared to carbon steel and require lesser quantities of scale and corrosion inhibitors.
Install automatic bleed/feed controllers and bypass feeders: By installing this equipment on the cooling towers, facilities have reduced volumes of cooling tower chemicals, as well as energy costs, labor, and water.
Recirculate the cooling water: When possible, cooling tower water should be recirculated instead of cycling once-through the system.
Use chlorinated biocides: Facilities can use chlorinated biocides instead of brominated biocides to reduce the toxicity of biocides.

Fireside Washes

In the combustion of fossil fuels, products of incomplete combustion will rise with gas and collect on boiler tubes and heat transfer units. Fireside wastes consist primarily of bottom ash and damaged refractory brick, which may be contaminated with heavy metals from the ash. As the buildup increases, the heat exchange efficiency decreases. Periodically, the buildup is removed by applying a large volume of water to the boiler surfaces. The wash water contains trace metals (nickel, chromium, iron, vanadium, and zinc), calcium, sodium, chlorides, nitrates, sulfates, and organics contained in suspended soot. The resulting waste is a wet ash sludge. This sludge may be co-managed for disposal with large volume combustion waste (fly ash, bottom ash, FGD sludge) or managed separately with other low-volume wastes and treated through physical or chemical precipitation, as well as pond evaporation.

Soot blowers use steam, air, or water to clean fireside fouled heat transfer surfaces. The removed soot and ash deposits are either reintroduced into the combustion process, redeposited for easier removal, or captured by particulate control equipment. Sonic horns generate sound waves that cause the heat transfer surface to vibrate and dislodge soot and ash. Manual cleaning includes brushing, sweeping, and vacuuming.

Abrasive cleaning methods remove contaminants by blasting a compound at the substrate. Typical blasting compounds are sand, walnut shells, or carbon dioxide pellets. The abrasive cleaning technology field is changing rapidly. New materials that may remove soot and ash without damaging the boiler tubes and refractory include plastic beads, sodium bicarbonate, and, potentially, liquid CO_2.

Table 29 provides some examples of pollution prevention opportunities for fireside washes.

Table 29: Pollution Prevention Options for Fireside Washes

Options	Comments
Use cleaner fuels	Natural gas is the cleanest burning fossil fuel, but availability limits widespread use. Cleaner burning fuel oils and coals are available but may be cost-prohibitive.
Use alternative cleaning methods	Soot blowers and sonic horns may be used to reduce the need for washing. Dry ash has higher potential for reuse. Abrasives may be used but add to waste created.
Recycle or reuse fireside wastes	Lime sludge from treatment may be sold to copper smelters. Vanadium recovery from fuel oil ash may be feasible. Coal ash can be used as a substitute for cement in concrete or as structural fill.

Boiler Chemical Cleaning Wastes

The purpose of boiler cleaning is to remove scale from the inside (water side) of boiler tubes. The waste generated contains spent cleaning solution and the scaling components: copper, iron, zinc, nickel, magnesium, and chromium. Certain cleaning agents target certain types of boilers and deposits. Boiler cleaning wastewaters may be difficult to treat and, in some cases, fall under the jurisdiction of the Resource Conservation and Recovery Act (RCRA) as a hazardous waste.

One way to minimize the volume of boiler cleaning wastes is to optimize the cleaning frequency. Specific practices that help to optimize cleaning frequency include:

- Maintaining records of operations
- Conducting biweekly chemical analysis to define normal cycle chemistry
- Sampling tubes annually
- Determining the location and/or type of deposits through ultrasonic imaging, thermocouples, removable test strips, and fiberscopic inspections.

Controlling the chemistry of the boiler feed water is a significant way to control the rate of scaling. Generally, boiler water is treated through fine filtration, chemical treatment, reverse osmosis, and/or ion exchange to remove minerals. Other constituents in the boiler water targeted for removal may include oxygen and carbon dioxide.

While most utilities use hydrazine and morpholine in the chemical treatment of boiler feed water, an elevated oxygen treatment process has been demonstrated that results in the accumulation of a finer-grained, more unified, magnetite layer that necessitates less frequent cleaning. To create this condition, oxygen or hydrogen peroxide is added to condensate at a pH of 7 to 7.5, oxygen and ammonia are added at a pH of 8 to 8.5, and ammonia is added at a pH of 9 or greater, until ammonia concentrations of 250 parts per billion are reached.

The boiler cleaning frequency may be decreased by reducing the amount of oxygen entering the boiler due to leaks in the system. Leaks can be corrected through inspection and replacement of seals on steam cycle components. Maintenance schedules and monitoring techniques are effective practices in preventing leaks. Furthermore, maintaining high quality performance of the oxygen deaerators will also help to prevent oxygen ingress.

Another effective pollution prevention technique is determining the optimum frequency of boiler cleanouts. Utilities should clean the boilers based on the actual deposit thickness instead of according to a predetermined schedule. According to a survey performed by EPRI, one California utility monitors both scale thickness and composition by means of small, retrievable test strips placed inside the boiler. Base unit boilers are now cleaned about once every 72 months, and cycling units are cleaned once every 48 months. Other California utilities report cleaning schedules as often as once every 24 months.[41]

On-line cleaning involves boiler cleaning while the boiler remains in operation. This can be done by injection of a sodium poly-acrylate additive into the boiler feedwater to a concentration of 400 mg/L. The most critical outer layer of magnetite is removed, but an inner layer remains. This method requires less cleaning time than traditional boiler cleaning, uses less hazardous chemicals, and results in a more easily handled waste. The drawbacks of on-line cleaning include the risk of contaminating the steam turbine, less deposits removed, and potentially poor copper removal. Cost savings associated with the use of this technology at a 300-MW unit have been estimated to be $25,000 to $30,000 per year.[42]

Sodium bicarbonate-based blast media can be used in association with specifically designed delivery systems to meet a wide range of cleaning needs, including general facility maintenance (e.g., floor cleaning, paint stripping and boiler tube cleaning). Sodium bicarbonate blasting is becoming increasingly common in the electric utility industry.[43]

In areas where water costs are high, utilities may choose to reuse their boiler chemical cleaning wastewater as makeup for cooling towers, fly ash scrubbers, or flue gas desulfurization systems.[44] Also, depending on the composition of the chemical cleaning sludge, it may be economically feasible to recycle the sludge for its metal content. Arizona Electric Power Cooperative (AEPCO), Incorporated, for example, uses this cleaning material, rather than face potentially expensive disposal costs. The EPA, the Arizona Department of Environmental Quality, the California Department of Toxic Substances Control, and the Occupational Safety and Health Administration approved the use of by products from chemical cleaning from AEPCO's boilers. AEPCO sells the by-product to Pacific Gas & Electric Company for hydrogen sulfide gas abatement at its Geysers Power Plant, a geothermal power generation facility.[45]

Table 30 lists pollution prevention opportunities for boiler cleaning wastes.

Fly Ash

Fly ash is typically collected in the flue of the combustion unit and transported to a centralized containment area for treatment and storage. Both wet ash transport and dry collection are commonly practiced. Some facilities use wet ash, creating a slurry as the mechanism for transport. The disadvantage of wet ash transport is that it increases the volume of the ash waste and it must eventually be separated out and treated. In contrast, a dry process control electrostatic precipitator avoids the added volume due to water and allows the collection of a dry product for recycling and/or beneficial reuse.

Chemical Substitutions

Several process modifications described previously have required material substitution (e.g., switching fuels). However, material substitutions are not

Table 30: Pollution Prevention Options for Boiler Cleaning Wastes

Options	Comments
Improve boiler water supply	Regenerate ion exchange resins promptly. Install reverse osmosis equipment ahead of ion exchange systems to reduce mineral loading and reduce regeneration frequency.
Control boiler water chemistry	Use hydrazine to control dissolved oxygen and morpholine to control carbon dioxide.
Reduce contaminant ingress	Improve equipment seals to prevent air and cooling water leaks into the boiler.
Base cleaning on fouling	Use coupons to measure scale buildup and schedule cleaning accordingly.
Use on-line cleaning	Sodium polyacrylate injection may be used to remove deposits without having to shut down boiler. Further research required.
Reuse wastewater	Wastewater may be used for cooling tower makeup or as feedwater to ash scrubbers and flue gas desulfurization units. Some pretreatment and/or segregation may be required.
Reuse lime sludge	Sludges from lime treatment of chemical cleaning wastes may be sold to copper smelters for reuse.
Control H_2S	Ethylenediamine-tetraacetic acid (EDTA)-based cleaning processes can produce Fe-EDTA, which is an effective chelating agent for H_2S control.

Source: Adapted from *Industrial Pollution Prevention Handbook.* Freeman, Harry M., ed. McGraw Hill, Inc. 1995.

limited to major processes. Sometimes, toxic chemicals are used unnecessarily on a wide-scale basis for a variety of operations and maintenance activities (e.g., cleaning, lubrication). By substituting less toxic chemicals, a facility can avoid unnecessary risks associated with worker exposure and the potential for release into the environment. The first step in determining the viability of material substitutions is to inventory the chemicals used at the site. The chemical can be evaluated as to its hazard potential, its necessity, and possible alternatives. For example, San Diego Gas and Electric Company determined several different solvents onsite could be replaced by just a few different solvents. By eliminating the wide array of solvents, the company is now able to install a solvent recovery unit, which will reduce the amount of solvent waste.

V.C.2 Inventory Management and Preventative Maintenance for Waste Minimization

Fossil fuel electric power generation facilities, like many industrial facilities, use solvents and other chemicals for everyday operations. Everyday

R0075190

operations include parts washing, lubricating, general cleaning, and degreasing application during plant and equipment maintenance activities. Often, chemical wastes generated by these operations are made up of out-of-date, necessary, off-specification, and spilled or damaged chemical products. Actual costs for materials used include not only the cost of the original product, but also the costs of disposal. Inventory management and preventative maintenance are ways these facilities can decrease the amounts of chemical wastes generated in a cost-effective manner.

There are two categories of inventory management including inventory control and material control. Inventory control includes techniques to reduce inventory size, reduce toxic and/or hazardous chemical use, and increase current inventory turnover. Material control includes the proper storage and safer transfer of materials. Proper material control will ensure that materials are used efficiently to reduce waste and preserve the ability to recycle the wastes.

Corrective and preventative maintenance can reduce waste generation. A well run preventative maintenance program will serve to identify the potential for releases and correct problems before material is lost and/or considered a waste. New or updated equipment can use process materials more efficiently, producing less waste. Table 31 provides examples of inventory management and preventative maintenance waste minimization techniques that can be used at fossil fuel electric power generation facilities.

V.C.3 Potential Waste Segregation and Separation Options

Fossil fuel electric power generation facilities can reduce their waste disposal costs by carefully segregating their waste streams. In particular, facilities should segregate RCRA nonhazardous wastes from hazardous wastes to reduce the quantity of waste that must be disposed of as a hazardous waste. For example, facilities should segregate used oil from degreasing solvents because uncontaminated used oil can be recycled or fed into the boiler as a supplemental fuel. Oil contaminated with polychlorinated biphenyls (PCBs) should be segregated from other used oils. Absorbent material that is not fully saturated with oils, etc., should be stored separately from saturated material so that it can be reused. Recycling companies typically offer a higher price for segregated recyclables (e.g., clean office paper, scrap metal) than mixed waste streams.

Table 31: Inventory Management and Preventative Maintenance Waste Minimization Opportunities
Inventory Management
Inventory Control
• Purchase only the quantity of material needed for the job or a set period of time • Evaluate set expiration date on materials, especially for stable compounds, to determine if they could be extended. • Search the inventory at other company sites for available stock before ordering additional material • Purchase material in the proper quantity and the proper container size. If large quantities are needed, purchase in bulk. If the material has a short shelf-life or small quantities are needed, purchase in small containers • If surplus inventories exist, use excess material before new material are ordered • Contact supplier to determine if surplus materials can be returned. If not, identify other potential users or markets • Evaluate whether alternative, non-hazardous substitutes prior to purchase and checked for acceptance at the facility.
Material Control
• Reduce material loss through improved process operation, increased maintenance and employee training to identify sources of loss • Handle and manage wastes to allow recycling.
Maintenance Programs
Operational and Maintenance Procedures
• Reduce raw material and product loss due to leaks, spills, and off-specification products • Develop employee training procedures on waste reduction • Evaluation the need for operational steps and eliminate practices that are unnecessary • Collect spilled or leaked material for re-use whenever possible • Consolidate like chemicals and segregate wastes to reduce the number of different waste streams and increase recoverability.
Preventive Maintenance Programs
• Perform maintenance cost tracking • Perform scheduled preventive maintenance and monitoring • Monitor closely "Problem" equipment or processes that are known to generate hazardous waste (e.g., past spills).
Source: Adapted from "ComEd Operation and Maintenance Manual" and "Pollution Prevention Success" Fact Sheets. Received From Edison Electric Institute. July 1997.

V.C.4 Recycling Options

With the exception of cooling water and used oil, fly ash represents the greatest waste component at fossil fuel plants. For this reason, recycling options for fly ash present a significant opportunity for pollution prevention. Typical uses include incorporating fly ash into construction materials, such as asphalt or cement. However, new uses are being found every day. Table 32 lists existing and potential marketable uses for fly ash. More information about the production and use of fly ash and other coal combustion materials can be obtained from the American Coal Ash Association.[46]

R0075192

Table 32: Current and Potential Uses for Fly Ash
Current Uses for Fly Ash
Flowable fill Soil stabilization Lightweight aggregate building material Roofing materials Roofing granules Plastics, paint Filter cloth precoat for sludge dewatering Pipe bedding Structural fills Concrete and block Portland cement Mine reclamation Agricultural enhancement Road paving: as a sub-base or fill material under a paved road
Potential Uses for Fly Ash
Ingredient of golf ball coverings Flue gas reactants An additive to sewage sludge for use as a soil conditioner An alkali reactivity minimizer in concrete aggregate The footprint of a structure, a paved parking lot, sidewalk, walkway, or similar structure

The Carolina Power and Light (CP&L) is successful in selling 80 to 100 percent of the fly ash generated at three coal-fired power plants. The CP&L estimates capital costs to be $1 to $2/ton of fly ash and operation and maintenance costs to be $3 to $4/ton of fly ash. The ash sales revenues have resulted in reduced disposal costs. Duke Power has experienced similar success. Duke Power has sold more than 230,000 tons of fly ash and 65,400 tons of bottom ash for use in concrete production. Other markets for the fly ash included plastic manufacturing and asphalt production. In addition, Duke Power donated 30,000 tons of bottom ash to the State of North Carolina to use as a base in road construction.

It should be noted that uses for fly ash vary greatly according to market conditions and transportation costs. In addition, for most uses, the ash must have a low carbon content. However, available commercial technologies can separate the ash into carbon-rich and carbon-poor fractions.

Pollution prevention associated with boiler blowdown was discussed previously; however, boiler blowdown water may potentially be recycled and used as makeup to cooling tower waters and flashing blowdown to generate additional steam. This is accomplished through the regeneration of demineralizer waters.

Sulfur is produced through the cleaning of fuels and ores and the use of clean scrubbers. Recycling options include the following:

- Substituting sulfur for Portland cement and water to act as a binding agent to produce a durable, acid-resistant concrete
- Using sulfur in protective coatings to improve the resistance of conventional building materials to chemical and other stresses; fabric can be impregnated with sulfur and additive materials to produce flexible or rigid lining materials
- Using sulfur as an asphalt extender or as an asphalt replacement to totally eliminate the need for asphalt.

The FGD units can produce sulfur, sulfuric acid, gypsum, or some non-saleable sludge material. Select FGD units can produce saleable materials, as indicated in the following examples:

- Gypsum can be processed into a quality gypsum grade for resale to wall board producers or sold for use in cement manufacturing.
- Sodium sulfate and sulfuric acid can be produced for resale.
- An electron beam scrubbing system can be used to produce ammonium sulfate and ammonium nitrate for sale as a fertilizer supplement.
- A pozzolanic stabilization reaction process can be implemented where lime-based reagent is added to scrubber sludge and fly ash to create a mineral product suitable for roadway base course. (Pozzolans are siliceous or siliceous/aluminous materials that, when mixed with lime and water, form cementitious compounds.)

V.C.5 Facility Maintenance Wastes

In addition to the wastes associated with the power production operations, fossil fuel electric power generation facilities also generate wastes from support operations, such as facility and equipment maintenance, storage areas, transportation, and offices. Pollution prevention techniques can greatly reduce many of these waste streams for relatively little cost.

Table 33 highlights several basic pollution prevention options for equipment and facility maintenance. All of the options involve the use of commercially available equipment that is already in widespread use. In addition to the options described in Table 33, common pollution prevention options include:

- Establishing preventive maintenance programs for equipment
- Testing fluids prior to changing them
- Purchasing equipment to enable recycling of antifreeze, solvents, and oil/water mixtures

- Purchasing longer lasting/reusable absorbent materials and rags
- Laundering rags offsite instead of disposing of them
- Using steam cleaning equipment or sodium bicarbonate blast systems for general facility cleaning
- Purchasing electric-powered vehicles for onsite use
- Upgrading bulk storage equipment and spill prevention practices
- Improving spill containment equipment and equipment for transferring fluids
- Using low- or no-VOC paints for facility maintenance and restricting color choices
- Recycling office paper, cardboard, plastics, scrap metals, wood products, etc.
- Purchasing products with recycled content
- Finding alternatives to replace ozone depleting substances (e.g., refrigerants, fire suppression, degreasers)
- Practicing integrated pest management to reduce the use of pesticides in grounds maintenance operations
- Using less toxic products for custodial operations.

Table 33: Pollution Prevention Opportunities For Facility Maintenance Wastes	
Options	**Comments**
Rotating Equipment Maintenance	
Use high quality fluids	While costing more initially, high quality fluids may last twice as long in service.
Routinely monitor fluid condition	Waste fluid generation can be reduced by switching to a replacement schedule based on fluid condition. Low-cost testing services can provide detailed information.
Use nonleak equipment	Use dry disconnect hose couplings, self sealing lock nuts, and elastomeric flange gaskets to reduce oil leakage. Canned or magnetically driven pumps, bellow valves, and bellow flanges are also effective.
Clean and recycle dirty fluids	Dirty fluids may be cleaned for extended use by small filtration devices. More complex systems may use centrifugation or vacuum distillation.
Use waste oils as boiler fuel	This depends on boiler size, PCB content, and halogen content of the waste oil. Would not apply to synthetic hydraulic fluids.
Facility Maintenance	
Eliminate use of hazardous materials	Major accomplishments have been made in this area, including eliminating the use of PCBs, asbestos insulation, chromium-based cooling water treatment chemicals, and leaded paints.
Replace tricarboxylic acid (TCA) and chlorofluorocarbons (CFCs) with non-ODS cleaners	Petroleum distillate and D-limonene blends are effective cleaners for electrical equipment. Detergents are good for general purpose cleaning but must be kept out of yard drains and oil water separators.
Use high transfer efficiency painting equipment	Brushes, rollers, and hand mitts are very efficient but labor-intensive. Airless spray is common for field use since a source of clean, dry air is not required.
Use an enclosed cleaning station	Several air districts mandate the use of enclosed gun cleaners and prohibit the spraying of cleanup solvent into the air.
Avoid the removal of leaded paint	Removal of lead-based paint should only be performed when the paint fails to provide adequate protection. Use wet blasting or vacuum collective devices to prevent the generation of leaded paint dust.
Source: *Industrial Pollution Prevention Handbook*. Freeman, Harry M., ed. McGraw-Hill, Inc. 1995.	

V.C.6 Storm Water Management Practices

An important pollution prevention consideration at fossil fuel electric power generation plants is the management of runoff. Coal pile runoff is perhaps the most significant. Coal pile runoff results from precipitation coming into contact with coal storage piles. The most effective way to eliminate coal pile runoff is to store coal indoors. In many instances, this is not feasible, at which point, pollution prevention turns to managing runoff. A facility's storm water pollution prevention plan should address storm water controls (e.g., dikes, levies) and the potential for reuse of storm water. Coal-handling areas also represent potential for coal pollutants to contaminate storm water. Table 34 lists practices that can prevent pollutants in coal from contaminating storm water.

Table 34: Common Pollution Prevention Practices for Managing Runoff at Coal Storage and Handling Areas [47]
• Consider rail transport of coal over barge transport, because the potential impacts to water are lessened. • Cover coal off-loading areas, crushers, screens, and conveyors to reduce dust emissions. • Cover coal storage piles or store in silos to prevent contact with precipitation and to minimize dust. • Spray coal piles with anionic detergents. This will reduce the acidic content of the pile by reducing bacterial oxidation of sulfide minerals. • Configure a storm water collection system based on slopes, collection ditches, diversions and storage, and treatment ponds. • If settling ponds exist, consider recycling the dredgings.

Some of the practices listed in the table are applicable to fly ash storage and handling areas, as well as coal pile runoff. For example, if dry ash transport is employed, covers will prevent dust and contact with precipitation. Other areas of concern with respect to storm water pollution prevention include fuel and chemical handling and storage areas where there is potential for spills. Table 35 provides some recommended practices that apply to these areas. Ideally, these practices should be addressed in a facility's storm water pollution prevention plan.

Table 35: Storm Water Pollution Prevention Opportunities at Fossil Fuel Electric Power Generation Facilities

Areas of Concern	Storm Water Pollution Prevention Opportunities
Fuel Oil Unloading Areas	• Use containment curbs to contain spills • Station personnel familiar with spill prevention and response procedures at areas during deliveries to ensure quick response for leaks or spills • Use spill and overflow protection technologies
Chemical Unloading/Loading Areas	• Use containment curbs to contain spills • Cover area • Station personnel familiar with spill prevention and response procedures at areas during deliveries to ensure quick response for leaks or spills
Miscellaneous Loading/Unloading Areas	• Use grading, berming, and curbing to minimize runon • Locate equipment and vehicles so leaks can be controlled in existing containment and flow diversion system • Cover area
Liquid Storage Tanks	• Use dry cleanup methods • Use containment curbs to contain spills • Use spill and overflow protection technologies
Large Bulk Fuel Storage Tanks	• Use containment curbs to contain spills
Oil-Bearing Equipment Storage Areas	• Use level grades and gravel surfaces to retard flow and limit spread of spills • Collect storm water in perimeter ditches
Ash-Loading Areas	• Establish procedures to reduce or control tracking of ash or residue from ash loading areas • Clear ash from building floor and immediately adjacent roadways of spillage, debris, and excess water before each loaded vehicle departs
Areas Adjacent to Disposal Ponds	• Reduce ash residue, which can be tracked onto access roads traveled by residue trucks or residue handling vehicles • Reduce ash residue on exit roads leading into and out of residue-handling areas
Material Storage Areas	• Use level grades • Collect runoff in graded swales or ditches • Implement erosion protection measures at steep outfall sites • Provide cover for material

R0075198

V.C.7 Training and Supervision Options

While the major pollution prevention gains are achieved through process controls and reuse/recycling, many day-to-day common sense practices are relatively easy and inexpensive to incorporate. Through training, these practices can become effective means of pollution prevention. Examples of proactive employee behavior includes training for careful use and disposal of cleaners and detergents to prevent them from entering floor and yard drains. If these substances do enter the drains, they may interfere with oil/water separators. Good housekeeping will ensure optimum performance of these treatment units.

V.C.8 Demand-Side Management Programs

In the past, electric utilities have implemented demand-side management (DSM) programs to achieve two basic objectives: energy efficiency and load management. Through these demand-side programs, the utilities have successfully reduced toxic air emissions and achieved cost effectiveness for both the utility and the consumer, mainly by deferring the need to build new power plants.[48] The energy efficiency goal has been achieved primarily by reducing the overall consumption of electricity from specific end-use devices and systems by promoting high-efficiency equipment and building design.

With the advent of deregulation and restructuring in the utility power generation industry, DSM programs appear to be diminishing. The industry is reducing DSM spending and experiencing a reduction in the rate of growth on energy savings. Among other factors, the potential for restructuring could affect the utilities interest in energy savings or may create new types of DSM activities.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe, the applicable Federal requirements, as well as to provide citations for more detailed information. This sections includes:

- Section VI.A, a general overview of major statutes
- Section VI.B, a list of regulations specific to this industry
- Section VI.C, a list of pending and proposed regulations.

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. This section also provides EPA hotline contacts for each major statute.

VI.A General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act of 1976, which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (listed wastes). Listed wastes are designated with a specific code. Hazardous wastes designated with the code "P" or "U" are commercial chemical products including technical grades, pure forms, off-specification products, sole-active-ingredient products, or spill or container residues of these products. "P" wastes are considered acutely hazardous and are subject to more stringent requirements. Hazardous wastes from specific industries/sources are designated with the code "K" and hazardous wastes from non-specific sources are designated with the code "F." Materials that exhibit a hazardous waste characteristic (i.e., ignitability, corrosivity, reactivity, or toxicity) are designated with the code "D."

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities generally must obtain a permit either from EPA or from a State agency that EPA has authorized to implement the permitting program if they store hazardous wastes for more than 90 days before treatment or disposal. Facilities may treat hazardous wastes stored in less-than-ninety-day tanks or containers without a permit. Subtitle C permits contain general facility standards, such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.101) for conducting corrective actions that govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA treatment, storage, and disposal facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated authority to implement various provisions of RCRA to 47 of the 50 States and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. The following list highlights important RCRA regulatory requirements:

- **Identification of solid and hazardous wastes** (40 CFR Part 261) lays out the procedure every generator must follow to determine whether the material in question is considered a hazardous waste or a solid waste or is exempted from regulation.

- **Standards for generators of hazardous waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and fulfilling record keeping and reporting requirements. Providing they meet additional requirements described in 40 CFR Part 262.34, generators may accumulate hazardous waste for up to 90 days (or 180 or 270 days depending on the amount of waste generated and the distance the waste will be transported) without obtaining a Subtitle C permit.

- **Land disposal restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet LDR treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated treatment, storage, and disposal (TSD) facility to ensure proper treatment prior to disposal.

- **Used oil management standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (i.e., one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including tanks and containers. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities that store such waste, including large quantity generators accumulating waste prior to shipment off-site.

- **Underground storage tanks** containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that must be met by December 22, 1998.

- **Boilers and industrial furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. The BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

The EPA RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m. ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law known commonly as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. In addition, CERCLA enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs (including remediation costs) incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act.

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance that equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA or by one or more Federal or State emergency response authorities.

The EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as removals. The EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1,300 sites. Both EPA and states can act at sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

The EPA RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund Program. The CERCLA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m. ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act of 1986 created EPCRA, a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. The EPCRA required the establishment of State emergency response commissions (SERCs), which are responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

The EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities that store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and LEPC in the event of a release equaling or exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** applies to facilities covered in SIC major groups 10 (except 1011, 1081, and 1094), 12 (except 1241), or 20 through 39; SIC codes 4911, 1193, and 4939 (limited to facilities that combust coal and/or oil for the purposes of generating power for distribution in commerce); or 4935 (limited to facilities regulated under RCRA, Subtitle C), or 5169, or 5171, and 7389 (limited to facilities primarily engaged in solvent recovery services on a contract or fee basis). These facilities must also have 10 or more employees and manufacture, process, or use specified chemicals in amounts greater than threshold quantities. Facilities that meet these criteria must submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media and allows EPA to compile the national TRI database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

The EPA RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and distributes guidance regarding the EPCRA regulations. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m. ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the Nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "nonconventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The NPDES Program (CWA §502) controls direct discharges into waters of the U.S. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized 42 States to administer the NPDES Program), contain industry-specific, technology-based limits and may also include additional water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the Nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set the conditions and effluent limitations on the facility discharges.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines, which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987, the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated the NPDES storm water permit application regulations. These regulations require facilities with the following storm water discharges to apply for a NPDES permit: (1) a discharge associated with industrial activity, (2) a discharge from a large or medium municipal storm sewer system, or (3) a discharge that EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" is a storm water discharge from 1 of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes, while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified in the following list:

- **Category I**: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

- **Category ii**: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC code 26-paper and allied products (except paperboard containers and products); SIC code 28-chemicals and allied products (except drugs and paints); SIC code 291-petroleum refining; and SIC code 311-leather tanning and finishing; SIC code 32 (except 323)-stone, clay, glass, and concrete, 33-primary metals, 3441-fabricated structural metal, and 373-ship and boat building and repairing.

- **Category iii**: Facilities classified as SIC code 10-metal mining; SIC code 12-coal mining; SIC code 13-oil and gas extraction; and SIC code 14-nonmetallic mineral mining.

- **Category iv**: Hazardous waste treatment, storage, or disposal facilities.

- **Category v**: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

- **Category vi**: Facilities classified as SIC code 5015-used motor vehicle parts; and SIC code 5093-automotive scrap and waste material recycling facilities.

- **Category vii**: Steam electric power generating facilities.

- **Category viii**: Facilities classified as SIC code 40-railroad transportation; SIC code 41-local passenger transportation; SIC code 42-trucking and warehousing (except public warehousing and storage); SIC code 43-U.S. Postal Service; SIC code 44-water transportation; SIC code 45-transportation by air; and SIC code 5171-petroleum bulk storage stations and terminals.

- **Category ix**: Sewage treatment works.

- **Category x**: Construction activities except operations that result in the disturbance of less than five acres of total land area.

- **Category xi**: Facilities classified as SIC code 20-food and kindred products; SIC code 21-tobacco products; SIC code 22-textile mill products; SIC code 23-apparel related products; SIC code 2434-wood kitchen cabinets manufacturing; SIC code 25-furniture and fixtures; SIC code 265-paperboard containers and boxes; SIC code 267-converted paper and paperboard products; SIC code 27-printing, publishing, and allied industries; SIC code 283-drugs; SIC code 285-paints, varnishes, lacquer, enamels, and allied products; SIC code 30-rubber and plastics; SIC code 31-leather and leather products (except leather and tanning and finishing); SIC code 323-glass products; SIC code 34-fabricated metal products (except fabricated structural metal); SIC code 35-industrial and commercial machinery and computer equipment; SIC code 36-electronic and other electrical equipment and components; SIC code 37-transportation equipment (except ship and boat building and repairing); SIC code 38-measuring, analyzing, and controlling instruments; SIC code 39-miscellaneous manufacturing industries; and SIC code 4221-4225-public warehousing and storage.

To determine whether a particular facility falls within one of these categories. consult the regulation.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national pretreatment program (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

The EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention, Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities that could reasonably be expected to discharge oil in harmful quantities prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR §112.20) and for PCB transformers and PCB-containing items were revised and finalized in 1995.

EPA's Office of Water, at (202) 260-5700, will direct callers that questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water Resource Center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water by controlling underground injection of liquid wastes.

The EPA has developed primary and secondary drinking water standards under its SDWA authority. The EPA and authorized States enforce the primary drinking water standards, which are contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable, health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) Program (40 CFR Parts 144-148) is a permit program that protects underground sources of drinking water by regulating five classes of injection wells. The UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit and must meet applicable

RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented sole source aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented wellhead protection program which is designed to protect drinking water wells and drinking water recharge areas.

The EPA Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m. ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks that may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

The TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. The EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce of, limit the use of, require labeling for, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, CFCs, and PCBs.

The EPA TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to TSCA standards. The Service operates from 8:30 a.m. through 4:30 p.m. ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as titles, that direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. The CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established NAAQS to limit levels of criteria pollutants, including carbon monoxide (CO), lead (Pb), NO_2, PM, ozone, SO_2, and volatile organic compounds (VOCs). Geographic areas that meet NAAQS for a given pollutant are classified as attainment areas; those that do not meet NAAQS are classified as non-attainment areas. Under section 110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards. Revised NAAQS for particulates and ozone were proposed in 1996 and may go into effect as early as late 1997.

Title I also authorizes EPA to establish new source performance standards (NSPS), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPS are based on the pollution control technology available to that category of industrial source.

Under Title I, EPA establishes and enforces national emission standards for hazardous air pollutants (NESHAPs), which are nationally uniform standards oriented towards controlling particular HAPs. Title I, section 112(c) of the CAA further directed EPA to develop a list of sources that emit any of 188 HAPs and to develop regulations for these categories of sources. To date, EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on maximum achievable control technology (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV of the CAA establishes a SO_2 and NO_2 emissions control program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of SO_2 sulfur dioxide releases. Reduction of nitrogen will be obtained by required reduction of nitrogen oxides from power plants and new cars.

Title V of the CAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once EPA approves a State program that state will issue and monitor permits.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of CFCs and chloroform, were phased out (except for essential uses) in 1996.

The EPA Clean Air Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and the EPA EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities (http://www.epa.gov/ttn then select Directory and then CATC).

VI.B Industry Specific Requirements

Since the 1960s, there has been an increased public awareness that industrial growth, as well as its inherent need for energy produced using fossil fuels, is accompanied by the release of potentially harmful pollutants into the environment. Hence, the fossil fuel electric power generation industry has become one of the most highly regulated industries. In addressing environmental issues, the industry has moved from providing not only the lowest cost energy, to providing the lowest cost energy with an acceptable impact on the environment. Air pollution control has been of most concern, with a significant percentage of the cost of a power plant going towards the purchase of air pollution control equipment. However, control of hazardous effluent discharges and proper management and disposal of solid wastes have also been key concerns. This section summarizes the current major Federal regulations affecting the fossil fuel electric power generation industry.

National Environmental Policy Act

The National Environmental Policy Act of 1969 (NEPA) applies to all Federal agencies and to Federal actions that may significantly impact the environment. The NEPA requires that all Federal agencies prepare detailed statements assessing the environmental impact of, and alternatives to, major Federal actions that may significantly affect the quality of the human environment. Implementing regulations are issued by the Council on Environmental Quality (CEQ) at 40 CFR Parts 1500-1508. NEPA implementing regulations that are most applicable to the fossil fuel electric power generation industry can be found at 40 CFR Part 6 (EPA) and 10 CFR Part 1021 (DOE). Each government agency has issued its own implementing regulations under NEPA. The types of Federal activities associated with fossil fuel electric power generating facilities that may be subject to NEPA requirements include siting, construction, and operations of federally owned facilities, federally issued NPDES, RCRA, and air permits, and federally issued operation licenses.

Each Federal activity subject to NEPA must follow certain environmental review procedures. If there is enough information to determine at the outset that the Federal action will cause a significant effect on the environment, then an environmental impact statement (EIS) must be prepared. If there is insufficient information available, an environmental assessment (EA) must be prepared to assist the agency in determining if the impacts are significant enough to require an EIS. If the assessment shows the impacts not to be significant, the agency must prepare a finding of no significant impact (FONSI). Further stages of the Federal activity may then be excluded from the NEPA requirements.

Clean Air Act

Numerous existing standards and programs under the Clean Air Act may affect the fossil fuel electric power generation industry. These regulations and programs include Title I New Source Performance Standards, Title III National Emissions Standards for Hazardous Air Pollutants, Title IV Acid Rain Program, and Title V Operating Permits Program. The NAAQS under Title I may affect the industry indirectly through permits.

National Ambient Air Quality Standards

Regulations for NAAQS do not directly affect the fossil fuel electric power generation industry because they are not applied to sources. Rather, these standards are applied to the ambient air in a particular area. Fossil fuel electric power generators may be indirectly affected by these standards if they are located in or near an area with nonattainment status. In meeting NAAQS, States develop and implement SIPs that prescribe use of reasonably available control technologies (RACTs) for major sources. In addition, as fossil fuel electric power generation facilities are typically one of the largest emitters of criteria pollutants, they may be targeted for more stringent controls implemented through operating permits.

The NAAQS currently exist for the following criteria pollutants (40 CFR Part 50): PM_{10}, SO_2, CO, Pb, ozone, and NO_X.

On July 16, 1997, new and/or revised standards for particulate matter and ozone were promulgated. The regulations revise the current primary standard by adding a new annual $PM_{2.5}$ (or PM "fine") standard set at 15 micrograms per cubic meter ($\mu g/m^3$) and a new 24-hour $PM_{2.5}$ standard set at 65 $\mu g/m^3$. These regulations revise the current 1-hour primary standard for ground level ozone by adding an 8-hour standard set at 0.08 ppm (the 1-hour standard will eventually be phased out).

Among the tools proposed for implementing these new ambient standards is a trading plan for emissions from utilities. The new standards will require local controls in 2004 for ozone and 2005 for particulate matter, with compliance by 2007 and 2008, respectively.

A group called the Ozone Transport Assessment Group (OTAG) was formed between EPA, the Environmental Council of States, and various industry and environmental groups. The primary objective of OTAG is the collective assessment of the ozone transport problem and the development of a strategy for reducing ozone pollution on a regional scale.

New Source Review and New Source Performance Standards

New source review (NSR) requirements in 40 CFR §52.21(b)(1)(I)(a)-(b) apply to all new facilities and may apply to expansions of existing facilities or process modifications. The NSRs are typically conducted by State agencies in accordance with their SIP. SIPs are the primary tool for meeting NAAQS and are administered through State and local agencies.

Prevention of significant deterioration (PSD) reviews are performed for areas meeting NAAQS. Nonattainment reviews are performed for areas violating the NAAQS. In nonattainment areas, permits may be issued to require new sources to meet lowest achievable emission rate (LAER) standards. Operators of the new sources must procure reductions in emission of the same pollutants from other sources in the nonattainment area in equal or greater amounts to the emissions from the new source. These "emission offsets" may be banked and traded through the State agencies. In PSD areas, permits require the best available control technology (BACT), and the operator must conduct continuous air monitoring for one year prior to the startup of the new source to determine the effects that the new emissions may have on air quality.

Under NSPS, given at 40 CFR Part 60, EPA sets standards for LAER and BACT for the following subcategories of the fossil fuel electric power generation industry:

- Subpart D: Standards of Performance for Fossil-Fuel-Fired Steam Generators for Which Construction Is Commenced After August 17, 1971
- Subpart Da: Standards of Performance for Fossil-Fuel-Fired Steam Generators for Which Construction Is Commenced After September 18, 1978
- Subpart Db: Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units
- Subpart Dc: Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units
- Subpart GG: Standards of Performance for Stationary Gas Turbines.

The standards in each subcategory apply to units of a specified size and age. Table 36 provides the NSPS.

Table 36: New Source Performance Standards

Emission	Standards
SO_2	General standard for various levels of ng/J (lb/mm Btu) heat input and % reduction, depending on fuel type and sulfur content (see 40 CFR Subparts D, Da, Db, and Dc). For gas turbines, no gases in excess of 0.015% by volume (at 15% O_2 by volume) or with sulfur contents in excess of 0.8% by weight shall be burned.
NO_X	Between 0.2 and 0.8 lb/mm BTU, depending on category of combustion. For gas turbines, NO_X standards specified in equation in 60.332(a)(1) or (2) as directed in 60.332(b), (c), and (d).
PM	Between 0.05 and 0.20 lb/mm BTU, unless a low nitrogen fuel is used, in which case compliance is based on results of performance tests.
Opacity	20%.

R0075214

National Emission Standards for Hazardous Air Pollutants

Current regulations at 40 CFR Part 61 provide standards for eight substances identified as air toxics: vinyl chloride, mercury, beryllium, radon, radionuclides, benzene, asbestos, and arsenic. Under Title III of the CAA, EPA is required to identify source categories of 188 HAPs or toxic air pollutants and then issue (at 40 CFR Part 63) MACT standards for each source category according to a prescribed schedule. The standards are to be based on best demonstrated control technologies or practices within the regulated industry. Eight years after a MACT is installed on a source, EPA is required to evaluate the risk levels remaining at the facilities and determine whether additional controls are needed to reduce the risk to acceptable levels.

The EPA has issued an initial list of categories of major and area sources that will be subject to regulation under Section 112 (57 FR 31576). The list contains numerous sources from the fossil fuel electric power generation industry, and standards are currently being developed under the Industrial Combustion Coordinated Rulemaking (see Section VI.C.).

Acid Rain Program

The 1990 amendments to the CAA added a new provision (Title IV) to control acid deposition. Title IV of the CAAA sets primary goals to reduce annual emissions of both SO_2 and NO_2.

Upwards of 20 million tons of SO_2 are emitted annually in the United States. Most of this amount is from the burning of fossil fuels by electric utilities. Because acid rain is a problem, Title IV requires EPA to reduce SO_2 emissions to 10 million tons below the 1980 level. Reduction in SO_2 will be attained in two phases by a marketable emission allowance program (40 CFR Part 73). Phase I, which became effective in January 1995, required 110 power plants to reduce their emissions to a level equivalent to the product of an emissions rate of 2.5 pounds (lbs) of SO_2/mmBtu times an average of their 1985-1987 fuel use. Plants that use certain control technologies to meet the Phase I reduction requirements received a 2-year extension of compliance until 1997. The new law also allows for special allocation of 200,000 annual allowances per year, in each of the 5 years of Phase I, to power plants in Illinois, Indiana, and Ohio.

Under the new requirements, utilities may trade allowances within their systems and/or buy or sell allowances to and from other affected sources. Phase I facilities were allocated allowances based on historic fuel consumption and a specific emission rate. One allowance equals the right to emit one ton of SO_2. Affected facilities are required to turn into the EPA one

R0075215

allowance for each ton emitted in a calendar year. Unused allowances may be sold, traded, or banked by the facilities. Power plants that do not have sufficient allowances to cover annual emissions are subject to fees and requirements to offset the excess emissions the following year.

Power plants that emit less than 1.2 lbs of SO_2/mmBtu are allowed to increase emissions by 20 percent until the year 2000.
