Phase II of the CAAA SO_2 reduction requirement becomes effective January 1, 2000, and affects all utilities generating at least 25 MW of electricity. These requirements require approximately 2,128 electric power utilities to reduce emissions to a level equivalent to the product of an emissions rate of 1.2 lbs of SO_2/mmBtu times the average of their 1985-1987 fuel use. SO_2 emissions from electric utilities will be capped at 8.95 million tons per year.

Title IV of the CAAA requires a 2 million ton reduction in NO_X emissions from 1980 levels. The EPA has developed regulations to help reduce NO_X emissions that may affect the fossil fuel electric power generation industry. As in the SO_2 reduction program, the NO_X Emission Reduction Program is being implemented in two phases for two categories of coal-fired electric utility boilers. The NO_X program differs from the SO_2 program in that it neither "caps" the NO_X emissions, nor utilizes an allowance trading system.

Phase I of the program for "Group I" boilers was effective on January 1, 1996, and affected dry-bottom wall fired boilers and tangentially fired boilers that are required to meet NO_X performance standards (40 CFR Part 76). Regulations for Phase II of the NO_X reduction program were promulgated in December 1996. These rules become effective in the year 2000. These regulations set lower emission limits for Group 1 boilers. In addition, the regulation establishes initial NO_X emission limitations for Group 2 boilers. Group 2 boilers include boilers applying cell burner technology, cyclone boilers, wet bottom boilers, and other types of coal-fired boilers.

Facilities covered by the Acid Rain Program must apply for an Acid Rain Permit. Most utilities must apply for permits in either Phase I or Phase II of the program. Two categories of utility units may be eligible for exemption: small new units burning clean fuels and retired units. Some cogeneration units are not covered under the program.

To support the mandated reductions in SO_2 and NO_X, the 1990 CAAA also required EPA to issue regulations requiring facilities to install continuous emissions monitoring systems (40 CFR Part 75). Fossil fuel electric power generation units over 25 megawatts and new units under 25 megawatts that use fuel with a sulfur content greater than .05 percent by weight are required to measure and report emissions under the Acid Rain Program.

Federal/State Operating Permits Programs

Title V of the CAAA requires the development of a comprehensive permitting program to control air emissions from major stationary sources. Major sources include those that emit 100 tons/year or more of VOCs or criteria pollutants, 10 tons/year or more of any single toxic air pollutant, or 25 tons/year or more of a combination of toxic air pollutants. This program is modeled after the NPDES program under the CWA and serves to bring together all of the requirements concerning air emissions that apply to affected sources. Like the NPDES program, administration of the operating permit program is also delegated to States with approved programs.

This program requires all significant sources of air emissions to obtain permits. In general, utility fossil fuel steam electric power plants are all considered major sources, so they will most likely be required to obtain permits. Other types of fossil fuel electric power generation facilities, such as those employing small gas turbines, may not be considered a major source and may not be required to apply for a permit. Any operational change that increases emissions above specified limits will most likely necessitate permit modifications. Permit terms are determined by State regulations for delegated programs but may not exceed 5 years.

Clean Water Act

Wastewater discharges from fossil fuel electric power generation facilities released to waters of the United States are covered under the CWA. Any point source discharge is required to apply for, and obtain, an NPDES permit (40 CFR Part 122). Permits may be issued by EPA or a State, depending upon whether the State has a delegated program. The NPDES permits serve to regulate point source discharges by establishing pollutant limitations and other special conditions. Facilities discharging to a POTW may be required to obtain a permit from a POTW that has an approved pretreatment program.

Current technology-based effluent limitations guidelines and pretreatment standards for discharges from the steam electric generating point source category were promulgated in 1982 (40 CFR Part 423). The waste streams covered and parameters limited are summarized in Table 37 below.

Table 37: Waste Streams and Pollutants Regulated Under National Effluent Limitation Guidelines for the Steam Electric Generating Point Source Category

Type of Waste Stream	BAT Effluent Limitations Guidelines
All discharges	pH , PCBs
Bottom ash transport waters and low volume waste sources	TSS, oil and grease
Chemical boiler metal cleaning wastes	TSS, oil and grease, iron, and copper
Non-chemical metal cleaning wastes	Reserved (low volume wastewater limits apply)
Fly ash transport water (including economizer ash)	No discharge allowed (based on the availability of dry disposal methods and the potential for reuse of fly ash transport water)
Once-through cooling water	Total residual chlorine (TRC) or free available chlorine (FAC), depending on facility's generating capacity
Cooling tower blowdown	FAC, chromium, zinc, other 126 priority pollutants where they are found in chemicals used for cooling tower maintenance
Coal pile runoff	TSS

In general, steam electric facilities built after 1982 are considered new sources and must comply with the 1982 effluent limitations. Less stringent guidelines may apply for facilities constructed between 1974 and 1982 (see 1974 guidelines and standards). Steam electric generating facilities that have been repowered are considered new sources.

Steam electric facilities that discharge to a POTW may be required to meet pretreatment standards for existing sources (PSES) or for new sources (PSNS). General pretreatment standards applying to most industries discharging to a POTW are described in 40 CFR Part 403. Pretreatment standards applying specifically to the steam electric generating point source category are listed in 40 CFR §§423.16 and 17.

Beyond the applicable technology-based effluent limitations described above, permits may also establish technology-based limits for other pollutants based on the application of best professional judgement (BPJ). Permit limits and special conditions may also be established based on water quality considerations. Thermal limitations are often placed in permits for steam electric power plants based on Section 316(a) of the CWA and water quality considerations. Additionally, permits may require the performance of a demonstration study and implementation of control technologies to minimize adverse environmental impacts from cooling water intake structures.

Storm water discharges associated with any industrial activity onsite at a fossil fuel electric power generation facility are covered under the National

Storm Water Program. Steam electric power generating activities are listed as one of the categories of industrial activities subject to the storm water permit application requirements (category vii). The regulations at 40 CFR Part 122.26 require facilities discharging storm water from 1 of the 11 categories of industrial activities to apply for a storm water permit if the storm water discharges to waters of the United States. In most permits, facilities are required to develop and implement a storm water pollution prevention plan. However, limitations and other special conditions may be included on a case-by-case basis. Some permits may include the numeric effluent limitation guideline for coal pile runoff. Storm water discharges associated with other industrial activities at fossil fuel electric power generation facilities are typically not subject to numeric limits, however.

Resource Conservation and Recovery Act

The 1980 Solid Waste Disposal Act Amendments conditionally exempted from regulation under Subtitle C large volume wastes, including fly ash waste, bottom ash waste, boiler slag waste, and flue gas emission control waste generated primarily from the combustion of coal or other fossil fuels (RCRA §3001). Section 8002(n) of RCRA directed EPA to study these wastes.

In 1993, EPA issued a regulatory determination addressing large volume wastes (fly ash, bottom ash, boiler ash, boiler slag, and flue gas emission control wastes) generated by coal-fired utility power plants, including independent power producers not engaged in any other industrial activity. The regulatory determination stated that these wastes should not be regulated as Subtitle C wastes when they are managed separately from other wastes. A similar determination for other large volume fossil fuel combustion wastes and co-managed wastes was deferred pending additional studies.

Wastes exempt from hazardous waste regulation (currently all wastes from fossil fuel combustion) are addressed by Subtitle D of RCRA (for nonhazardous solid wastes). There are currently no Federal nonhazardous waste regulations. As a result, fossil fuel electric power generation waste management is addressed solely by the States, either through their general industrial solid waste programs or through specific programs for fossil fuel combustion wastes. These State programs vary considerably.

Subtitle I of RCRA has stringent requirements for underground petroleum and hazardous substances storage tank (UST) systems with 110-gallon or greater capacity. Any storage of fuels in USTs onsite at a fossil fuel electric power generation facility would be covered under these regulations at 40 CFR Part 280.

Subtitle C of RCRA provides for a comprehensive cradle to grave system of management for hazardous waste and includes rules governing waste disposal on land; recycling and generators; and treatment, storage, or disposal facilities (TSDFs). Low volume fossil fuel combustion wastes not co-managed with ash, slag, or flue gas desulfurization wastes and other wastes that are not directly associated with the combustion process are not exempted from hazardous waste regulation. As such, they are hazardous wastes if they are listed as hazardous wastes from non-specific sources (e.g., spent solvents) or if they exhibit one or more of the RCRA hazardous waste characteristics of toxicity, corrosivity, reactivity, and ignitability. The identification of specific listed wastes and the definitions of the hazardous waste characteristics are listed in 40 CFR Part 261.

Fossil fuel electric power generating plants do not typically generate large quantities of hazardous waste. Furthermore, the requirements and costs of operating an onsite hazardous waste TSDF are extensive. Therefore, most electric power generating facilities send any generated hazardous waste to offsite RCRA-permitted commercial TSDFs for permanent disposal.

Some steam electric power generating plants co-fire their boilers with hazardous wastes (e.g., spent solvents), along with their primary fossil fuel source. Such facilities are subject to RCRA regulation under the BIF Rule (40 CFR Part 266, Subpart H). The BIF Rule includes operating condition requirements, as well as testing requirements, for air emissions and residuals to ensure adequate destruction of toxic constituents.

Emergency Planning and Community Right-to-Know Act

In a recent rulemaking (62 FR 23834, May 1, 1997), EPA expanded the list of industry groups subject to reporting requirements under Section 313 of EPCRA (61 FR 33587). The expanded list of industry groups includes electric utilities classified in the following SIC codes: 4911 Electric Services, 4931 Electric and Other Services Combined, and 4939 Combination Utilities, Not Elsewhere Classified. EPCRA Section 313 now requires electric generating facilities that combust coal and/or oil for the purpose of generating electricity for distribution in commerce to evaluate their chemical use and management activities to determine potential reporting responsibilities. Section 313 establishes annual requirements for amounts released and otherwise managed of "section 313 chemicals" (a list of more than 650 chemicals and chemical categories).

For each Section 313 chemical or chemical category, covered facilities must report total routine and accidental amounts entering each environmental media, as well as onsite waste management via, and offsite transfers for.

disposal, waste treatment, energy recovery and recycling, and onsite source reduction activities. This information is submitted on the TRI reporting form called Form R if the facility has met or exceeded certain thresholds. The first period of reporting for this industry will be on or before July 1, 1999, for the period from January 1 to December 31, 1998. Reporting will be required annually thereafter. For additional information on these new TRI reporting requirements, contact the Emergency Planning and Right-to-Know Hotline at (800) 535-0202 (in Virginia and Alaska (703) 412-9877; TDD (800) 553-7672).

VI.C Pending and Proposed Regulatory Requirements

Clean Air Act Amendments of 1990

Hazardous Air Pollutants

In response to requirements under Section 112 of the CAA as well as Section 129, EPA is developing a unified set of Federal air emission regulations for industrial combustion sources. This rulemaking effort is being called the Industrial Combustion Coordinated Rulemaking (ICCR).

The ICCR will cover sources from industrial/institutional/commercial boiler, process heaters, industrial/commercial and other solid waste (not including hazardous, medical, or large municipal) incinerators, stationary gas turbines, and stationary internal combustion engines. These sources are not limited to use of fossil fuels and have the potential to emit both HAPs and criteria pollutants. This rulemaking effort will produce approximately seven separate regulations, six of which are expected to be finalized by November 2000. For additional information on the ICCR, contact Fred Porter, U.S. EPA Office of Air and Radiation, at (919) 541-5251.

Section 112(n) requires that EPA perform studies to evaluate the health risks associated with emissions of toxic air pollutants from electric utility steam generating units. Electric utility steam generating units are defined as any fossil fuel-fired combustion unit of more than 25 MW electric that serves a generator that produces electricity for sale. Cogenerators that supply more than one-third of their potential electric output capacity and more than 25 MW output to any utility power distribution system for sale will also be covered. A preliminary study has been completed and was issued as an interim final in October 1996. Additional studies will be performed, as well as an in-depth study of potential public health concerns due to mercury emissions from utilities. These findings will be published in a report to Congress at a later date and will include costs and technologies available to control these emissions and recommendations as to whether regulations are needed for air toxics emissions from this industry. For additional information on this study, contact Bill Maxwell, U.S. EPA Office of Air and Radiation, at (919) 541-5430.

Clean Water Act

Effluent Limitations Guidelines and Standards and Pretreatment Standards for the Steam Electric Point Source Category

The existing 1982 effluent limitations guidelines and standards and pretreatment standards for wastewater discharges from the Steam Electric Point Source Category are currently being reviewed by the Office of Water. A preliminary study has been completed by the Office of Water to evaluate the guidelines and standards based on current technical feasibility, environmental factors, economic impacts, and utility to permit writers. The study was performed because the steam electric power generating industrial category is considered as a candidate for possible regulatory revisions in the future. For additional information, contact Joe Daly, U.S. EPA Office of Water, at (202) 260-7186.

Cooling Water Intake Structure Regulations

Section 316(b) of the Clean Water Act requires that "...any standard established pursuant to Section 301 or 306... and applicable to a point source shall require that the location, design construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." Since fossil fuel electric power generators with steam turbines withdraw by far the greatest quantity of cooling water of any single industrial sector, it is expected that this industry will be the most affected by this requirement. Although some EPA regions and States have developed programs to minimize impacts from cooling water structures, no uniform national standards or implementing regulations are currently in force. As set forth in a consent decree *(Cronin v. Browner)*, EPA has initiated the information collection activities needed to develop proposed regulations to address impacts from the intake of cooling water by 1999. Final EPA action is scheduled for the year 2001. For additional information on the Section 316(b) rulemaking effort, contact Deborah Nagle, U.S. EPA Office of Water, at (202) 260-2656.

Resource Conservation and Recovery Act

A regulatory determination on whether large volume wastes at utility oil-fired, nonutility coal- and oil-fired, and fluidized bed combustion power plants and co-managed large volume wastes at all utility and nonutility coal- and oil-fired electric generation facilities should be considered hazardous wastes under Subtitle C is expected to be finalized in 1998, pending additional data collection. For additional information, contact Dennis Ruddy, U.S. EPA Office of Solid Waste, at (703) 308-8430.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the EPA to track compliance with CAA, RCRA, CWA, and other environmental statutes. Within the last several years, the EPA has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's IDEA system. The IDEA has the capacity to "read into" EPA's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match air, water, waste, toxics/pesticides/EPCRA, TRI, and enforcement docket records for a given facility and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are being developed.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consist of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census. For the fossil fuel electric power generation industry, statistics about the industry are collected by the DOE EIA (see Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries: one for the past five calendar years (April 1, 1992, to March 31, 1997) and the other for the most recent 12-month period (April 1, 1996, to March 31, 1997). The 5-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or led by EPA. However, the table breaking down the universe of violations does give a crude measurement of EPA's and States' efforts within each media program. The presented data illustrate the variations across EPA regions for certain sectors.[a] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

Facility Indexing System - This system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis - This data integration system can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of records for that facility. Some of the data systems accessible through IDEA are: AIRS (Office of Air and Radiation), PCS (Office of Water), RCRIS (Resource

[a] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in Sections IV and VII of this notebook were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with three enforcement actions counts as one facility.

Total Enforcement Actions describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times, e.g., a facility with three enforcement actions counts as three.

State Lead Actions shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the CWA, CAA, and RCRA. Inspections and actions from the TSCA/FIFRA/ EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA air, water, waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A Fossil Fuel Electric Power Generation Industry Compliance History

This section examines the historical enforcement and compliance data on the fossil fuel electric power generation sector. As noted earlier, these data were obtained from EPA's IDEA system. The five exhibits within this section provide both a 5-year and a 1-year review of the data from the sector and also provide data from other sectors for comparison purposes. It should be noted that the data are accessed in the IDEA database system through SIC codes. Therefore, only those facilities whose primary SIC codes indicate the potential for power generation activities can be accessed (see Section II). This means that the data retrieved from IDEA may be more inclusive (e.g., include transmission and distribution facilities). Other industry facilities that have associated power generation activities cannot be identified because their primary SIC codes do not indicate power generation.

Table 38 provides an overview of the reported compliance and enforcement data for the fossil fuel electric power generations sector over the past 5 years (April 1992 to April 1997). These data are also broken out by EPA Regions thereby permitting geographical comparisons. A few points evident from the data are listed below. As shown, 3,270 facilities were identified through IDEA with SIC codes that indicate power generation may be occurring (see discussion above). Of those, approximately 66 percent (2,166) were inspected in the last 5 years. Other points of interest include:

- 14,210 inspections were conducted over the last 5 years. Of the 3,166 facilities inspected, on average, each received over 6 inspections in the past 5-year period.

- The 14,210 inspections resulted in 403 facilities having enforcement actions taken against them. At those 403 facilities, there were a total of 789 enforcement actions; therefore, each facility averaged nearly 2 enforcement actions over the 5-year period.

- The average enforcement to inspection rate is 0.06, with the rate across the regions ranging from 0.02 to 0.13. There appears to be no correlation between State versus Federal lead on the inspections and the enforcement to inspection rate.

Table 38: Five-Year Enforcement and Compliance Summary for the Fossil Fuel Electric Power Industry

A	B	C	D	E	F	G	H	I	J
Region	Facilities in Search	Facilities Inspected	Number of Inspections	Average Months Between Inspections	Facilities with 1 or More Enforcement Actions	Total Enforcement Actions	Percent State Lead Actions	Percent Federal Lead Actions	Enforcement to Inspection Rate
I	250	140	664	23	36	55	84%	16%	0.08
II	269	199	1,455	11	75	187	84%	16%	0.13
III	305	221	1,997	9	57	130	87%	13%	0.07
IV	559	353	3,039	11	45	84	82%	18%	0.03
V	552	344	2,287	14	76	134	69%	31%	0.06
VI	315	222	1,079	18	30	61	54%	46%	0.06

VIII	134	91	643	13	15	35	60%	40%	0.05
IX	273	251	1622	10	38	57	84%	16%	0.04
X	204	86	254	48	9	18	61%	39%	0.07
TOTAL	3,270	2,166	14,210	14	403	789	76%	24%	0.06

VII.B Comparison of Enforcement Activity Between Selected Industries

Tables 39 and 40 allow the compliance history of the fossil fuel electric power generation sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Tables 39 and 40 permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering the last 5 years (April 1992 to April 1997) to that of the past year (April 1996 to April 1997). As shown in the data, the 3,270 fossil fuel electric power generation facilities is the sixth largest number of facilities identified through IDEA, with ground transportation having the most facilities with 7,786. However, while approximately 66 percent of the fossil fuel electric power generation facilities have been inspected in the past 5 years, only 41 percent of the ground transportation facilities have been inspected. Other points of interest from the 5-year summary include:

- The number of inspections over the past 5 years for fossil fuel electric power generation facilities (14,210) is more than 3 times the amount conducted in most other sectors.
- The enforcement to inspection rate of 0.06 over the past 5 years is one of the lower rates of the listed sectors.

Points of interest from the 1-year summary include:

- The 1,318 fossil fuel electric power generation facilities inspected in the past year places this sector among the top four sectors for number of facilities inspected.
- The total number of inspections in this sector is 2,430 which compares with the number of inspections performed in the ground transportation and non-metallic mining sectors, but is 1.5 to 17 times more than the other sectors which range from 1,436 down to 141.
- The enforcement to inspection rate of 0.06 is about average among all the sectors, with the lowest being 0.01 (dry cleaning) and the highest being 0.23 (petroleum refining). This is relatively constant with the 5-year average for the fossil fuel electric power generation sector.

Tables 41 and 42 provide a more in-depth comparison between the fossil fuel electric power generation sector and others by organizing inspection and enforcement data by environmental statute. As in the previous Tables (Tables 39 and 40), the data cover the last 5 years (Table 41) and the last

R0075230

Table 39: Five-Year Enforcement and Compliance Summary for Selected Industries									
A	B	C	D	E	F	G	H	I	J
Industry Sector	Facilities in Search	Facilities Inspected	Number of Inspections	Average Months Between Inspections	Facilities with 1 or More Enforcement Actions	Total Enforcement Actions	Percent State Lead Actions	Percent Federal Lead Actions	Enforcement to Inspection Rate

R0075234

one year (Table 42) to facilitate the identification of recent trends. Points of interest from the 5-year summary include:

- Compared to other sectors, the fossil fuel electric power generation sector has one of the higher percentages of CAA inspections (57%) and one of the lower percentages of RCRA inspections (11%), when measured against the total number of inspections conducted. As a result, it has one of the higher percentages of CAA enforcement actions (59%) and one of the lowest percentages of RCRA enforcement actions (10%), when measured against total enforcement actions.

The 1-year inspection and enforcement summary reflects similar numbers to those from the past 5 years. No notable exceptions are apparent.

VII.C Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VII.C.1 Review of Major Cases

As shown in the previous tables, the number of enforcement actions taken over the past 5 years, when compared to the number of inspections conducted, is minimal. Even though there have been 871 total enforcement actions, major cases involving fossil fuel electric power generation facilities are rare. Since 1992, however, there have been at least 13 actions against such facilities.

The 13 cases were broken out as follows:

- 6 cases under the CAA (asbestos NESHAPs, NO_X monitoring violations, and SO_2 violations)
- 2 cases under the CWA (NPDES permit violation, wetlands)
- 2 cases under TSCA (PCBs)
- 2 cases under EPCRA (release in excess of reportable quantities)
- 1 multimedia case (CWA, EPCRA, and TSCA).

The average penalty associated with these cases was just more than $150,000. In addition, two SEPs were associated with the 13 cases. Those are discussed in more detail in the following section.

The two most significant cases against fossil fuel electric power generation facilities included CWA violations by Potomac Electric Power Company (PEPCO) and CAA violations by Public Service Electric & Gas (PSE&G). In the PEPCO case, the violations occurred from 1988 to 1993, during which time a site supervisor either pumped or oversaw the pumping of polluted water from holding ponds into an adjacent swamp. PEPCO discovered the illegal discharge and informed EPA. The consent decree provides for a penalty of $975,000. Because the violation was self-disclosed, no criminal charges were brought against the company or its officers.

In *United States v. Public Service Electric & Gas*, PSE&G was charged with violating the CAA, specifically the asbestos NESHAP. While commuting home from work, an off-duty EPA inspector noticed a pile of old pipes laying in a yard. A subsequent inspection of the old gas-cracking operation revealed the NESHAP violations. The PSE&G was required to pay a civil penalty of $230,000 and complete an extensive worker training and notification program.

VII.C.2 Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the internet at EPA's Enviroene website: http://es.inel.gov/sep.

As mentioned above, there were two SEPs at fossil fuel electric power generation facilities. The SEPs were negotiated with IES Utilities, Incorporated, of Cedar Rapids, Iowa, and Consumers Power Company of West Olive, Michigan.

The case against IES Utilities, Incorporated, was the first acid rain administrative penalty action in the country. The complaint alleged IES failed to complete timely certification testing of the acid rain continuous emission monitors required for SO_2, NO_X, CO_2, and volumetric flow at several of its generating stations. As part of the settlement, IES agreed to a SEP involving the purchase and permanent surrender by the utility to EPA of 589 SO_2 allowances. Each allowance constitutes an authorization to emit during or after a specified calendar year one ton of SO_2. The value of the allowances permanently removed from the market was $76,570 at the time of the settlement. IES was also required to pay a penalty of $25,630 to settle the claims.

R0075236

In the Consumers Power Company case, the company agreed to carry out three SEPs at a total estimated cost of $247,742. The projects include (1) converting heat exchangers from ethylene glycol to propylene glycol, which is 300 times less toxic, (2) sending information on EPCRA requirements to an estimated 3,000 facilities in Michigan, and (3) conducting an outreach program on the EPCRA Section 302 notification requirement to rural communities. The company must also certify its compliance with EPCRA. In its complaint, EPA alleged that the company failed to notify authorities about an accidental release of 1,400 pounds of sodium hypochlorite.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

Clean Air Power Initiative

The goal of the Clean Air Power Initiative (CAPI) is to improve air pollution control efforts within the electric power generating industry by developing an integrated regulatory strategy for three major pollutants emitted by electric power generators: SO_2, NO_X, and air toxics (specifically, mercury). The project was initiated in 1995 by EPA's Assistant Administrator for Air and Radiation. Through the Initiative, EPA hopes to provide the electric power industry with greater regulatory flexibility and cost savings while achieving environmental goals for ozone, fine particles, regional haze, and toxics. The Initiative will use existing CAA authority where possible, although ultimately new congressional authority may be required. The EPA believes focusing on regional reductions of the pollutants and implementing a "cap and trade" approach for some pollutants, such as NO_X, SO_2, and mercury, would be most effective. The EPA is meeting with representatives of the power industry, State and local officials, environmental groups, and pollution control vendors to obtain their views and input for the regulatory framework for the Initiative. (Contact: Linda Reidt Critchfield, at (202) 233-9087. Website: http://www.epa.gov/capi).

EPA Regional Compliance And Enforcement Activities

The EPA Region VIII has focused on enforcement and compliance activities for coal-fired power plants. This industrial sector was targeted by Region VIII because they have 38 significant operating plants (i.e., generate greater than 25 MW electricity). The region has experienced ongoing compliance issues related to the new Acid Rain Program, impacts from plants in PSD Class I areas, and impacts in nonattainment areas. The goal of this EPA regional compliance and enforcement initiative is to comprehensively evaluate the compliance status of the facilities. The region is also evaluating any environmental justice issues due to the location of the facilities. States in Region VIII are participating in the sector initiative by performing annual air program and NPDES permit inspections on a yearly basis. South Dakota has conducted multimedia inspections at two coal-fired power plants.

Department of Energy Environmental Research Programs

The DOE maintains numerous laboratories and field facilities that perform research and development type activities. The following facilities are of interest to the fossil fuel electric power generation industry and environmental compliance:

- **Argonne National Laboratory:** The Argonne National Laboratory (ANL) conducts applied research and engineering development in energy and environmental technologies, high performance computing, and scientific research in physical and life sciences. The Energy Systems Division of ANL focuses its expertise on controlling environmental impacts of industrial energy use. The division is committed to a revitalized competitiveness in the national economy. (Website: http:\\www.anl.gov).

- **Oak Ridge National Laboratory:** The Oak Ridge National Laboratory performs research on a broad range of energy-related problems and provides technical information and assistance on energy research for State and local governments and the private sector. Areas of research include waste management, fossil, fuel power generation technology, nuclear power generation technologies, fusion technology, conservation, and environment. (Website: http:\\www.ornl.gov).

- **Federal Energy Technology Center:** The Federal Energy Technology Center (FETC), one of the government's principal fossil fuel energy research centers, is responsible for research and development programs in the technical and administration management of fossil energy. The FETC is part of the Bruceton Research Center, which is the Nation's largest governmental lab devoted to coal research and development. The center's program responsibilities include clean coal technology, coal preparation, combustion technology, alternative fuels utilization, flue gas cleanup, coal liquefaction, advanced research and technology development in direct utilization and liquefaction, and solids transport. (Website: http:\\www.fetc.doe.gov).

VIII.B EPA Voluntary Programs

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative developed by EPA that focuses on improving environmental performance, encouraging voluntary compliance, and building working relationships with stakeholders. EPA initiated a one year pilot program in 1995 by selecting 12 projects at industrial facilities and federal installations that demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, pollution prevention, community involvement, and mentor programs. In return for participating, pilot participants received public recognition and were given a period of time to correct any violations discovered during these experimental projects. Four fossil fuel electric power generation facilities proposals were accepted and are listed in Table 43. Progress reports and fact sheets from these pilot programs are now available from EPA or off the web.

Table 43: List of Power Plants That Participated in the Environmental Leadership Program For 1995 and 1996
1. Arizona Public Service, Deer Valley Facility (Phoenix, AZ)
2. Duke Power Riverbend Steam Station (Mt. Holly, NC)
3. Ocean State Power (Burrillville, RI)
4. Salt River Project (Phoenix, AZ)

EPA is making plans to launch its full-scale Environmental Leadership Program in 1997. The full-scale program will be facility-based with a 6-year participation cycle. Facilities that meet certain requirements will be eligible to participate, such as having a community outreach/employee involvement programs and an environmental management system (EMS) in place for 2 years. (Contact: Debby Thomas, ELP Deputy Director, (202)564-5041. Website: http://es.inel.gov/elp).

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information

R0075240

regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline 202-260-8590, or Christopher Knopes at EPA's Office of Policy, Planning and Evaluation (202)260-9298. Website: Web: http://www.epa.gov/ProjectXL)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and DOE. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Program participants are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, (202)260-4407. Website: http://www.oit.doe.gov/Access/climate).

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program saves money for businesses and organizations and creates a cleaner environment by reducing pollutants released into the atmosphere. The program has over 2,345 participants which include major corporations, small and medium sized businesses, federal, state and local governments, non-profit groups, schools, universities, and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. As of March 1997, participants had lowered their electric bills by $289 million annually. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and an information hotline. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Green Light/Energy Star Hotline at 1-888-STARYES or Maria Tikoff Vargar, EPA Program Director, at (202)233-9178. Website: http://www.epa.gov/greenlights.html).

R0075241

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1997, the program had about 500 companies as members, one third of whom are Fortune 1000 corporations. Members agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports. To member companies, EPA, in turn, provides technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne Oxley, EPA Program Manager, (703)308-0199. Website: http://www.epa.gov /epaoswer/non-hw/reduce/wstewise/ index.html)

NICE[3]

The U.S. Department of Energy is administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE[3]). By providing grants of up to 45 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, and demonstrate new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the forest products, chemicals, petroleum refining, steel, aluminum, metal casting and glass manufacturing sectors. (Contact: Chris Sifri, DOE, (303)275-4723 or Eric Hass, DOE, (303)275-4728. Website: http//www.oit.doe.gov/access/ nice3).

VIII.C Trade Association/Industry Sponsored Activity

Trade associations, in conjunction with their industry members, sponsor activities that serve to further regulatory compliance initiatives. This section describes a major environmental compliance assistance program being sponsored by the utilities in the fossil fuel electric power generation industry, as well as some of the major trade associations serving the fossil fuel electric power generation industry.

VIII.C.1 Environmental Programs

Climate Challenge Program

The Climate Challenge Program is a joint initiative of DOE and the electric utility industry to reduce greenhouse gas emissions. Electric utilities voluntarily commit to undertake actions to reduce, avoid, or sequester more than 47 million metric tons of carbon equivalent by the year 2000. These commitments are formalized in individual utility participation accords for large utilities, and letters of participation for utilities with less than 50,000 customers. Utilities report greenhouse gas emissions data and submit annual reports, which describe their achievements, to DOE. The Climate Challenge Options Workbook describe more than 50 options for utilities to implement to meet their participation commitments. The workbook was jointly developed by the electric power industry and DOE. (Contact: Larry Mansueti, Program Director, Office of Utility Technologies, EE-10, U.S. DOE, 1000 Independence Avenue SW, Washington, DC 20585. Website: http://bejing. dis.anl.gov/ ee-cgi-bin/ccap.pl)

The utility industry has also developed a set of initiatives to help utilities meet their commitments. These include:

- **EnviroTech Investment Fund**, which fund invests in companies focusing on regenerating energy technologies that are more energy efficient than those currently in use.
- **International Utility Efficiency Projects** that support energy development in a way that is environmentally beneficial.
- **Utility Forest Carbon Management Program**, which comprises domestic and international forestry projects to manage CO_2 emissions.

VIII.C.2 Summary of Trade Associations

Trade associations and professional organizations that serve the fossil fuel electric power generation industry are numerous and varied in their focus. They range from serving a relatively small portion of the industry (e.g., independent power producers) to serving the industry as a whole. This section briefly describes some major trade and professional organizations for this industry.

American Coal Ash Association (ACAA) 2760 Eisenhower Avenue, Suite 304 Alexandria, VA 22314 Phone: (703) 317-2400 Fax: (703) 317-2409 Website: http://www.acaa-usa.org	Members: 110 Staff: 5 Contact: Samuel S. Tyson

Founded in 1968, ACAA's mission is to advance the management and use of Coal Combustion Products (CCPs) in ways that are technically sound, commercially competitive, and environmentally safe.

American Public Power Association (APPA) 2301 M Street, NW Washington, DC 20037 Phone: (202) 467-2900 Fax: (202) 467-2910 Website: http://www.appa.org/	Members: 2,000 Staff: 60 Contact: Alan H. Richards

Founded in 1940, APPA's members include public utility systems, State- and county-owned electric systems, and rural cooperatives. The APPA maintains a library on the electric power industry and publishes a bimonthly magazine. The APPA also conducts research programs, compiles statistics, and offers utility education courses in electric power. The association holds an annual conference and workshops.

Association of Energy Engineers (AEE) 4025 Pleasantville Road., Suite 420 Atlanta, GA 30340 Phone: (770) 447-5083 Fax: (770) 446-3969 Website: http://www.aeecenter.org/	Members: 8,500 Staff: 9 Contact: Ruth M. Bennett

Founded in 1977, the members of the AEE are engineers, architects, and other professionals interested in energy management and cogeneration. The AEE promotes advancement of the profession and contributes to the professional development of its membership. The AEE provides scholarships for students in energy engineering, supports the National Energy Policy Council, and sponsors the Cogeneration and Competitive Power Institute, a research organization. The AEE publishes journals and newsletters and sponsors several technical and managerial congresses each year.

Edison Electric Institute (EEI) 701 Pennsylvania Avenue, NW Washington, DC 20004-2696 Phone: (202) 508-5000 Fax: (202) 508-5360 Website: http://www.eei.org/	Members: 202 Staff: 262 Contact: Thomas Kuhn, President

Founded in 1933, EEI members are investor-owned electric utility companies operating in the United States. Some affiliated members are from Canada, Mexico, and Central and South America. The EEI acts as a representative for the shareholder-owned electric power industry on subjects of public interest and provides a medium for the exchange of ideas and information within the electric power industry. The institute maintains a library and database and compiles statistics. The EEI provides educational programs and publishes surveys, which provide statistical and factual information about operation, rates, regulation, and environmental practices.

Electric Power Research Institute (EPRI) 3412 Hillview Road Palo Alto, CA 94303 Phone: (415) 855-2000 Fax: (415) 855-2041 Website: http://www.epri.com/	Members: 700 Staff: 500 Contact: Kurt Yeager, Exec. Officer

The EPRI was founded in 1972 and serves all sectors of the electric utility industry. The EPRI mission is to conduct a broad economically and environmentally acceptable program of research and development in technologies for electric power production, distribution, transmission, and utilization. The EPRI primary research areas are advanced power systems, coal combustion systems, electrical systems, energy analysis, and environment and energy management and utilization. The institute maintains a library and a database of current and completed research in the electric power industry. The institute also publishes a guide and a journal.

Electric Power Supply Association (EPSA) 1401 H Street NW, Suite 760 Washington, DC 20005 Phone: (202) 789-7200 Fax: (202) 789-7201	Members: 90 Staff: 12

The EPSA was formed by a merger of two former trade associations: the Electric Generating Association and the National Independent Energy Producers (NIEP). (The Electric Generation Association was formed by the merger of the Independent Power Producers Working Group and the

R0075245

Cogeneration and Independent Power Coalition of America.) The EPSA mission is to advance the interests of its members: competitive generators, power marketers, and other suppliers. The EPSA advocates domestic and international policies that will result in a fully competitive electric power supply marketplace. The EPSA supports the development of a market in which existing commitments, such as independent power contracts, are honored and in which all customers have a choice of electric suppliers by a certain date.

National Rural Electric Cooperative Association (NRECA) 4301 Wilson Boulevard Arlington, VA 22203 Phone: (703) 907-5500 Fax: (703) 907-5521 Website: http://www.nreca.org/	Members: 1000 Staff: 600 Contact: Glenn English

The NRECA, founded in 1942, represents rural electric cooperatives, public power districts, and public utility districts in 46 States. The NRECA is an advocate for energy and operational issues, as well as rural electric development. The association maintains a library of 20,000 volumes, holds professional conferences, and publishes a magazine and newsletter. Other activities include legislative representation; energy, regulatory, and legal expertise; industry public relations; management institutes; training and energy research and development consulting services; insurance and safety programs; wage and salary surveys; and an international program.

North American Electric Reliability Council (NERC) Princeton Forrestal Village 116-390 Village Boulevard Princeton, NJ 08540-5731 Phone: (609) 452-9550 Fax:(609) 452-7669 Website: http://www.nerc.com/	Members: 9 Regional Councils Contact: Michehl R. Gent

The NERC is a nonprofit company owned by nine regional councils. The members of the regional councils and one affiliate are individual utilities representing all ownership categories of the electric utility industry, including investor-owned, municipal, rural electric cooperatives, Federal, independent power producers, power marketers, and power brokers. The principal purpose of NERC is to coordinate, promote, and communicate the reliability of North American electric utilities. The organization annually reviews the reliability and adequacy of the bulk electricity systems in North America and maintains several databases. In addition, the organization facilitates

R0075246

development of reliability-related planning and operating criteria and standards, and publishes reports and reference documents.

Utility Air Regulatory Group (UARG) c\o Hunton & Williams 1900 K Street NW Washington, DC 20460 Phone: (202) 955-1500 Fax: (202) 778-2201	Members: 74

The UARG is a voluntary, nonprofit, unincorporated, ad hoc group of 74 electric utilities, the EEI, the NRECA, and the APPA. The UARG's purpose is to participate on behalf of its members collectively in Federal air pollution control regulatory activities and in related litigation.

Utility Solid Waste Activities Group (USWAG) c\o EEI 701 Pennsylvania Ave. NW Washington, DC 20004 Phone: (202) 508-5645 Fax: (202) 508-5150	Members: 83 Contact: Jim Roewer

The USWAG is an informal consortium of the EEI, the APPA, the NRECA and approximately 80 electric utility companies. Together, USWAG members represent more than 85 percent of the total electric generating capacity of the United States and service more than 95 percent of the Nation's consumers of electricity. The mission of USWAG is to help member companies manage all utility wastes and byproducts in a manner that is protective of human health and the environment and is of reasonable cost.

Utility Water Act Group (UWAG) c\o Hunton & Williams 1900 K Street NW Washington, DC 20460 Phone: (202) 955-1500 Fax: (202) 778-2201	Members: 78 Contact: John (Jack) F. Mackenzie, Chair Pacific Gas and Electric Co. Phone: (415) 973-6901 Fax: (415) 973-9201

The UWAG is an association of 75 individual utilities and three national trade associations of electric utilities--the EEI, the NRECA, and the APPA. The UWAG purpose is to participate on behalf of its members in EPA's rulemakings under the CWA and in litigation arising from those rulemakings.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS

For further information on selected topics within the fossil fuel electric power generation industry a list of contacts and publications are provided below.

Contacts

Name	Organization	Telephone	Subject
Rafael Sanchez	EPA/OECA/METD	(202) 564-7028	Compliance assistance
Chris Oh	EPA/OECA/METD	(202) 564-7004	Compliance assistance
Joe Daly	EPA/OST/EAD	(202) 260-7186	Steam Electric Effluent Guidelines

Acknowledgments

The contacts listed below have provided valuable background information and comments during the development of this document. EPA appreciates this support and acknowledges that the individuals listed do not necessarily endorse all statements made within this sector notebook.

Joseph Daly - EPA/Office of Water (EPA/OW)
Rafael Sanchez - EPA/Office of Enforcement and Compliance Assurance (EPA/OECA)
Bill Maxwell - EPA/Office of Air Quality Standards and Planning (EPA/OAQSP)
Samuel S. Tyson - American Coal Ash Association (ACAA)
Bill Wemhoff - American Public Power Association (APPA)
Kara M. Downey - Arizona Electric Power Cooperative, Inc.(AEPC)
Ruth M. Bennett - Association of Energy Engineers (AEE)
Alice Meyer - Edison Electric Institute (EEI)
Richard W. Sternberg - National Rural Electric Cooperative Association (NRECA)
Anthony Riai - EPA/Office of Enforcement and Compliance Assurance (EPA/OECA)

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.epa.gov/comply/sector/index.html

or use

www.epa.gov/oeca - then select the button labeled Industry and Gov't Sectors and select the appropriate sector from the menu. The Notebook will be listed.

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

hazardous waste. Nevertheless, RCRA issues at trucking facilities include several non-transportation activities.

Some fluids used in truck maintenance are considered hazardous waste, requiring specific storage treatment, and disposal. Waste accumulated or generated during trucking maintenance may cause facilities to be considered small or large quantity generators depending on the volume waste. The primary RCRA issues for maintenance facilities are used oil, lead-acid motor vehicle batteries, vehicle maintenance fluids, and scrap tire disposal.

EPCRA

Most trucking companies do not store listed chemicals for use in their facilities. The only exception is diesel fuel or gasoline, which when stored at facilities in quantities slightly over 10,000 pounds,* requires reporting to Local Emergency Response Commissions (LERCs) and State Emergency Response Commissions (SERCs). Chemicals in transition are exempt from inventory reporting under EPCRA. This includes all hazardous materials shipments in packages or bulk quantities.

* The previous version incorrectly stated the quantity in gallons.

OPA

OPA imposes contingency planning and readiness requirements on certain facilities defined to include rolling stock and motor vehicles. These requirements may affect some trucking establishments.

VII.B.3. Pipelines

Almost all of the petroleum feed stock and products used in the U.S. are, at some point, transported through a Federally-regulated pipeline. The Office of Pipeline Safety (OPS), part of the DOT's Research and Special Programs Administration, regulate essentially all of the approximately 155,000 miles of hazardous liquid pipelines in the U.S., as well as the approximately 255,000 miles of gas transmission lines.

RCRA

Natural gas pipelines do not generate significant quantities of listed hazardous waste. Typical pipeline wastes include condensate, cleaning solvents, and used oil. Each gas pipeline compressor station typically produces an average of 20,000 gallons of used oil each year. This figure depends on the amount of maintenance performed on engines, how often the engines are running, and how much oil is drained from the engines. Under RCRA, used oil is not necessarily a hazardous waste and most gas pipeline companies sell it to refiners.

May 1999 | ERRATA SHEET | EPA/ 310-R-97-002ES

Document Title: Profile Of The Ground Transportation Industry – Trucking, Railroad And Pipeline

EPA 310-R-97-002
September 1997

Correction on page 84 under EPCRA :

Note that the unit of measure in which a trucking facility is required to report to Local Emergency Response Commissions (LERCs) and State Emergency Response Commissions (SERCs) when storing diesel fuel or gasoline is 10,000 pounds. This was incorrectly expressed in gallons in the previous version.

The corrected page appears on the reverse side of this sheet.

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, and local governments, and the media from EPA's National Center for Environmental Publications and Information at (800) 490-9198. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

TRANSPORTATION INDUSTRY (SIC 40, 42, 46, AND 49)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Integrated environmental policies based upon comprehensive analysis of air, water and land pollution are a logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was originally initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded to its current form. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process who enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project (2223-A), 401 M St., SW, Washington, DC 20460. Comments can also be uploaded to the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing this system. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks for sectors not already covered, please contact the Office of Compliance at 202-564-2395.

II. Introduction to the Ground Transportation Industry

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the ground transportation industry. Facilities described within this document are described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

This notebook pertains to the transportation industry as classified by the Office of Management and Budget (OMB) under Standard Industrial Classification (SIC) codes 40 (Rail Transportation); 42 (Trucking); and 46, 4922-4924 (Pipelines). Where possible, data are specific to sub-divisions of these SIC codes. In many cases, information about the industries (i.e., rail, trucking, and pipeline) does not directly correlate to SIC distinctions. This is due to various factors, including different reporting requirements and classifications within each industry that are not consistent with SIC delineations. This limitation is discussed throughout the notebook, as appropriate. OMB is in the process of changing the SIC code system to a system based on similar production processes called the North American Industrial Classification System (NAICS). In the NAICS system, Rail Transportation is classified as NAIC 482, Trucking is NAIC 484 and 492, and Pipelines are NAIC 486.

The transportation industry includes other modes of transport such as water and air. Although these are not addressed in this document, they make up an important portion of overall transportation activity in the United States.

The transportation industry affects nearly every American. Either through the necessity of traveling from one place to another, shipping goods and services around the country, or working in a transportation-related job. transportation's share of the national economy is significant. According to the Eno Transportation Foundation, for all transportation-related industries, total transportation expenditures in the U.S. accounted for 16.1 percent of the gross national product in 1993.

II.B. Industry Sectors Analyzed

II.B.1. Rail Transportation

The rail transportation industry includes establishments furnishing transportation by line-haul railroad, and switching and terminal establishments. These terms refer to the distance the particular railroad operation covers — line-haul operations cover longer distances, often connecting two cities, while switching and terminal railroads generally travel through a single city. For the purpose of this notebook, rail transportation does not include passenger railways serving a single municipality, contiguous municipalities, or a municipality and its suburban areas; these economic units are classified in SIC 41. Other services related to railroad transportation are classified in SIC 47; lessors of railroad property are classified in SIC 6517. The rail SIC sectors covered in this notebook are shown in the following table.

SIC 40 - RAILROAD TRANSPORTATION	
4011	Railroads, Line-Haul Operations
4013	Railroad Switching and Terminal Establishments

II.B.2. Trucking

The trucking industry includes establishments engaged in motor freight transportation and warehousing. This includes local and long-distance trucking or transfer services, and establishments engaged in the storage of farm products, furniture, and other household goods, or commercial goods of any kind. For the purpose of this notebook, the trucking industry also includes the operation of terminal facilities for handling freight, both those with and without maintenance facilities. The trucking SIC sectors covered in this notebook are shown in the following table.

SIC 42 - MOTOR FREIGHT TRANSPORTATION & WAREHOUSING	
4212	Local Trucking Without Storage
4213	Trucking, Except Local
4214	Local Trucking With Storage
4215	Courier Services, Except by Air
4221	Farm Product Warehousing & Storage
4222	Refrigerated Warehousing & Storage
4225	General Warehousing & Storage
4226	Special Warehousing & Storage, NEC*
4231	Terminal & Joint Terminal Maintenance Facilities for Motor Freight Transportation

* NEC = Not Elsewhere Classified

R0075275

II.B.3. Pipelines

The pipeline industry includes establishments primarily engaged in the pipeline transportation of petroleum and other commodities. Pipelines are classified within two SIC categories, Major Group 46 (Pipelines, except Natural Gas) and Major Group 49 (Electric, Gas, and Sanitary Services). This notebook will integrate the relevant operations from the two groups whenever possible. Occasionally, due to surveys that focus only on one of the groupings, data is segregated. The pipeline SIC sectors covered in this notebook are shown in the following table.

SIC 46 - PIPELINES, EXCEPT NATURAL GAS	
4612	Crude Petroleum Pipelines
4613	Refined Petroleum Pipelines
4619	Pipelines, NEC*
SIC 49 - ELECTRIC, GAS, AND SANITARY SERVICES	
4922	Natural Gas Transmission
4923	Natural Gas Transmission and Distribution
4924	Natural Gas Distribution
4925	Mixed, Manufactured, or Liquefied Petroleum Gas Production and/or Distribution

* NEC = Not Elsewhere Classified

Page 6 intentionally left blank.

III. RAIL TRANSPORTATION

III.A. Characterization of the Rail Transportation Industry

III.A.1. Industry Characterization

On February 28, 1827, the State of Maryland chartered the Baltimore & Ohio (B&O) Railroad, inaugurating America's first common-carrier railroad. The B&O marked the beginning of the nation's rail system. By 1850, rail trackage extended over 9,000 miles, mostly in the Northeast. Mirroring the movement of people to the American West, the first transcontinental rail link opened in 1869. By 1916, railroad tracks stretched across 254,000 miles. During the mid-twentieth century, railroads suffered from strict regulation and increased competition from trucks, buses, barges, and planes. By the late 1970s, nearly a quarter of the nation's rail mileage was operated in bankruptcy.

Railroads began to recover economically in 1980 with the passage of the Staggers Rail Act. This legislation partially deregulated the shipment rates charged by railroads, but continued to allow the Interstate Commerce Commission (ICC) to protect shippers from market abuse. The economic balance struck by the Staggers Act renewed the rail industry: by 1990, the rates charged to ship goods by rail had fallen 28.8 percent (adjusted for inflation). Ton-miles of freight moved by rail (reflecting the number of tons hauled and the miles traveled) per employee more than doubled from 1980 levels.

By 1993, the biggest railroads moved a record 1.1 trillion ton-miles of freight with 57 percent fewer employees, 30 percent fewer miles of track, 36 percent fewer locomotives, and 48 percent fewer freight cars than in 1980 (*Association of American Railroads Information Handbook*, 1994).

From an environmental standpoint, it is important to recognize that other industries have grown up around the rail industry. For example, railroads do not generally clean rail tank cars. This is usually performed by service companies on a fee-for-service basis. In addition, rail cars and tank cars are often owned and loaded by the shipper at its facility. Some of the operations described in this section are performed by these types of entities.

III.A.2. Industry Size and Geographic Distribution

Industry Size

Variations in facility counts occur across data sources due to many factors, including reporting and definition differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

The Interstate Commerce Commission (ICC) was the Federal agency that regulated many economic aspects of the rail industry. The ICC was abolished by an act of Congress in December 1995, with remaining essential functions transferred to a newly created Surface Transportation Board (STB) within the Department of Transportation. ICC statistics reported prior to the ICC's abolishment are referenced in this document. The ICC classified railroads based on their level of operating revenue. The levels are adjusted annually to reflect inflation. For 1994, the revenue threshold for Class I railroads was $255.9 million or more; Class II railroads had revenues of between $20.5 million and $255.8 million; and Class III railroads had revenues of less than $20.5 million. Since 1979, the ICC required reporting on financial and operating information from Class I railroads only. Class I railroad systems make up approximately two percent of the number of American railroads, but account for 73 percent of the mileage operated, 89 percent of the employees, and 90 percent of freight revenue in the industry. To fill the gap in information left by the ICC's decreased reporting requirements, the Association of American Railroads (AAR) annually surveys non-Class I railroads.

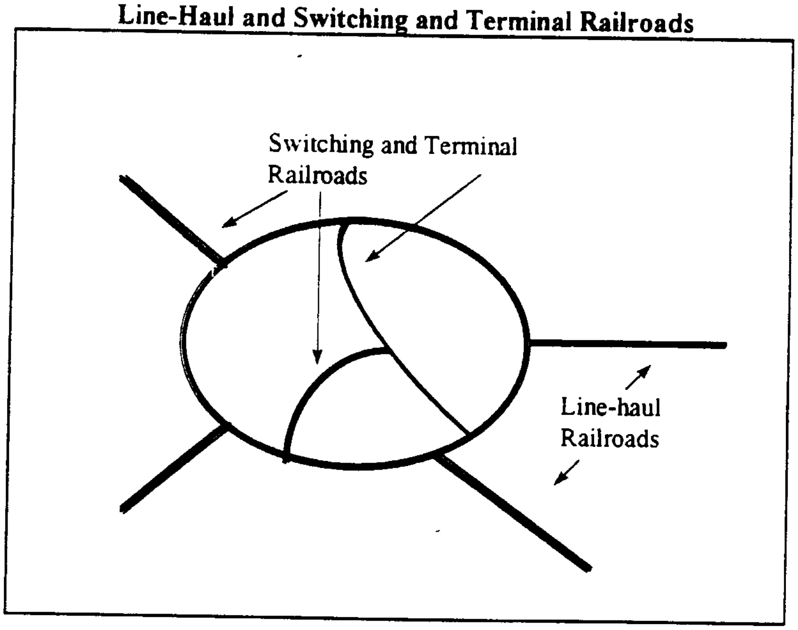
The AAR defines non-Class I railroads as being either regional or local (in contrast to the ICC definitions, which were based strictly on revenue). In 1994, regional railroads were defined as line-haul railroads operating at least 350 miles of road and/or earning revenue between $40 million and $255.9 million. Local railroads included those line-haul operations not meeting the regional criteria, plus switching and terminal railroads. Exhibit 1 summarizes the operating information for Class I, regional, and local railroads. Exhibit 2 depicts the relationship between line-haul railroads and switching and terminal railroads.

Exhibit 1
Facility Size Distribution of Rail Industry

Railroad	Number	Miles Operated	Year-End Employees	Freight Revenue
Class I	12	123335	189,240	$29,930,893
Regional	32	19842	10,701	$1,744,893
Local	487	25599	13,070	$1,422,285
Total	531	168776	213,011	$33,098,071

Source: Compiled from Railroad Facts (Association of American Railroads, 1995).

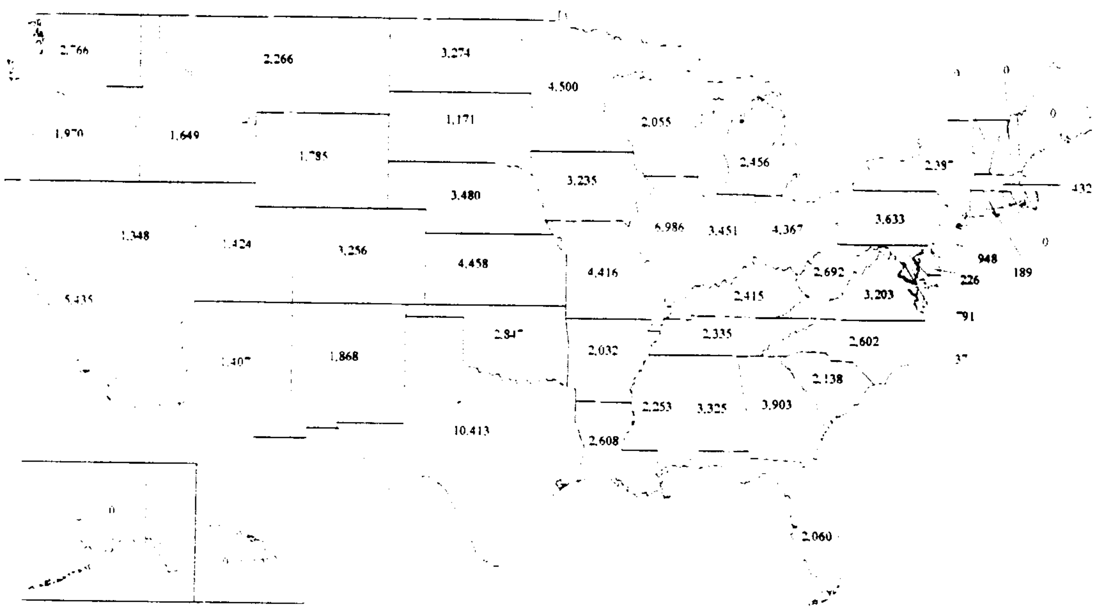
Exhibit 2
Line-Haul and Switching and Terminal Railroads



Geographic Distribution

Reflecting the national importance of railroad transportation, the rail industry is widely dispersed, and the rail system passes through every State in the country. Due to the nature of its operations, however, the rail industry is not characterized on a State-by-State basis, but rather by dividing the country into two halves, separated by the Mississippi River. Freight train-miles measure the movement of a train the distance of one mile, and are based on the distance between terminals and/or stations. Of the 440,896,000 total freight-train miles in the U.S. in 1994, 281,347,000 (64 percent) are West of the Mississippi and 159,549,000 (36 percent) are East of the Mississippi. Exhibit 3 illustrates the miles of track associated with major rail routes in the United States.

Exhibit 3
Geographic Distribution of Railroads in the United States: Mileage of Class I Railroads*



III.A.3. Economic Trends

The rail industry began to recover from a period of nearly 25 years of steady economic decline in 1980, with the passage of the Staggers Act. This legislation allowed railroad managers to restructure internal operations and meet competitive pressures. The Staggers Act authorized railroads to offer contract rate volume discounts for guaranteed shipments. The railroad is assured minimum volumes, which assists in capital budgeting and operations planning.

The railroad industry rebounded from the effects of widespread flooding in 1993 to post improved financial and operational results in 1994. Class I railroad traffic in 1994 increased 8.2 percent from 1993 to 1.201 trillion revenue ton-miles, reflecting increases in tons originated and longer average hauls. American railroads accounted for 39.2 percent of total inter-city revenue freight ton-miles.

Operating revenue rose 6.9 percent in 1994 to $30.8 billion, while operating expenses rose at a less rapid rate of 4.1 percent to $25.5 billion. Net railway operating income (defined as operating revenue minus the sum of operating expenses, current and deferred taxes, and rents for equipment and joint facilities) was $3.4 billion, an increase of 34.7 percent over 1993 figures.

Traditionally, the largest segment of railroad freight has been coal. In 1994, coal accounted for 39.1 percent of total tonnage and 21.7 percent of freight revenue. Other major rail commodities in 1994 included chemicals and allied products, motor vehicles and equipment, food and kindred products, and farm products. Exhibit 4 summarizes the tons originated and revenue associated with the shipment of commodities by Class I railroads in 1994.

Exhibit 4
Tons Originated and Revenue by Commodity — 1994*

	TONS ORIGINATED		REVENUE	
Commodity Group	Tons (thousands)	Percent of Total	$(millions)	Percent of Total
Coal	574,213	39.1	7,021	21.7
Chemicals & Allied Products	142,931	9.7	4,559	14.1
Farm Products	130,992	8.9	2,407	7.4
Non-metallic Minerals	106,404	7.2	862	2.7

**Information is for Class I railroads only.*
Source: Railroad Facts (Association of American Railroads, 1995).

The 1990's saw an increase in the efficiency of railroads, the transport of different materials such as waste and scrap materials, and a shift from boxcar to the faster intermodal container transport. Intermodal is a term used to describe containerization of freight for easy transloading to different modes of transportation. For example, the same container may be transferred from a truck to a train, with both modes of transportation equipped with locks or other mechanisms to hold the container in place. In rail transport, there is a growing use of truck containers and trailers.

III.B. Operations in the Rail Transportation Industry

This section provides an overview of commonly employed operations in the railroad industry. This discussion is not exhaustive; the operations discussed are intended to represent the major sources of environmental hazards from railroad transportation practices. These operations are grouped into three categories: rail car refurbishing and maintenance; locomotive maintenance; and transportation operations. Rail car refurbishing and maintenance operations consist of cleaning the interiors and exteriors of the rail cars, striping and painting the rail cars, and maintaining/repairing rail car parts. Locomotive maintenance operations include the cleaning, repair, and maintenance of the engine and locomotive car. Transportation operations include all activities associated with the movement of locomotives and cars over a section of track, including the loading and unloading of freight.

III.B.1. Rail Car Refurbishing and Maintenance

Rail car refurbishing and maintenance consists of cleaning the interiors and exteriors of rail cars, refurbishing operations (i.e., striping and painting rail cars), and other maintenance operations (i.e., brake and wheel set repair).

The initial cleaning of rail cars involves two steps: a mechanical cleaning and a water wash. Mechanical cleaning is the physical shaking and vibrating of the rail cars to loosen dirt and other debris. Typically, dirt and debris fall through a steel grate in the floor of the maintenance facility and are intermittently collected for disposal. The wash step usually consists of a high pressure water cleaning, collection of wastewater, and wastewater treatment at an on-site treatment facility.

Refurbishing operations are not employed at all rail facilities. Many railroad establishments contract out refurbishing work. Refurbishing operations usually start with paint removal using a steel grit blast system or other method. Paint chips and grit are collected through a steel grate in the floor and the mixture is conveyed to a cyclone and filter system for separation of reusable grit and paint. Once the original paint has been removed from the rail cars, new paint is applied to the clean rail car surface.

Rail cars have brakes and wheel sets that must be maintained and sometimes repaired or replaced. Brake and wheel set maintenance and repair operations consist of disassembly, cleaning, and repair; or disassembly and replacement of damaged parts. When wheel sets and air brakes are to be replaced or rebuilt, the cars must first be disassembled. Axles that can be reused are washed in a caustic solution to remove grease and dirt. External debris is removed from the air brakes or wheels using a grit or bead blast system or other method. Parts cleaning may also include the removal of paint and cleaning with solvents or caustics. Repaired brakes or wheel set may require repainting with spray guns.

III.B.2. Locomotive Maintenance

Locomotive maintenance includes, but is not limited to, the following operations: brake repair; large scale equipment cleaning operations (e.g., locomotive car); small scale cleaning operations (e.g., engine parts); hydraulic system repair, locomotive coolant disposal, metal machining, oil filter replacement and used oil management, painting and metal finishing, paint stripping, and spent battery management.

Locomotive maintenance operations usually take place at facility that is owned and maintained by the railroad. Most used oil is recycled or reused in energy recovery. Most locomotive batteries are recycled.

III.B.3. Transportation

Transportation operations include all activities associated with the movement of locomotives and cars over a section of track. These activities include fueling and hazardous material transport.

III.C. Raw Material Inputs and Pollution Outputs

III.C.1. Rail Car Refurbishing and Maintenance

Pollutant outputs from rail car refurbishing and maintenance are generally in the form of wastewater from preliminary cleaning of interiors and exteriors, and hazardous wastes generated from painting, paint removal, and the cleaning of parts. Exhibit 5 shows typical hazardous wastes generated including: spent solvents and solvent sludges; spent caustics and caustic sludges; paint chips; and paint sludges. Volatile organic compound (VOC) air emissions are also generated during the use of solvents and paints. Wastewater from preliminary cleaning of the rail cars and spent caustic solution is often treated in an on-site wastewater treatment system and then discharged to a publicly owned treatment works (POTW). Hazardous wastes are typically drummed and shipped off site as RCRA hazardous waste. Spent solvents, however, can be sent off site for reclamation. Brake and wheel set repair is not a significant environmental hazard, but discarded brake shoes may be regulated under the Resource Conservation and Recovery Act (RCRA) in some States.

Exhibit 5
Rail Car Refurbishing and Maintenance Process Material Input/Pollutant Output

Process	Material Input	Waste
Oil and Grease Removal	Degreasers, engine cleaners, aerosol, solvents, acids/alkalies	Ignitable wastes, spent solvents, combustible solids, waste acid/alkaline solutions, used oil
Car and Equipment Cleaning	Degreasers, solvents, acids/alkalies, cleaning fluids	Ignitable wastes, spent solvents, combustible solids, waste acid/alkaline solutions, rags
Rust Removal	Strong acids, strong alkalies	Waste acids, waste alkalies
Paint Preparation	Paint thinners, enamel reducers, white spirits	Spent solvents, ignitable wastes, ignitable paint wastes, paint wastes with heavy metals, rags
Painting	Enamels, lacquers, epoxies, alkyds, acrylics, primers	Ignitable paint wastes, spent solvents, paint wastes with heavy metals, ignitable wastes, rags
Spray Booth, Spray Guns, and Brush Cleaning	Paint thinners, enamel reducers, solvents, white spirits	Ignitable paint wastes, heavy metal paint wastes, spent solvents
Paint Removal	Solvents, paint thinners, enamel reducers, white spirits	Ignitable paint wastes, heavy metal paint wastes, spent solvents, rags

Source: U.S. EPA Office of Solid Waste, 1993.

III.C.2. Locomotive Maintenance

Each of the locomotive maintenance operations listed above is a potential source of pollution outputs. Following are brief discussions of the wastes that can be generated by these locomotive maintenance operations.

Brake Repair

Brake repair does not pose a significant environmental hazard, but discarded brake shoes may be regulated under RCRA in some States. Some older brake shoes contain asbestos and may require special disposal.

Cleaning Operations

Sludges created as a result of cleaning operations may be characterized as hazardous. If so, hazardous waste regulations must be complied with prior to disposal. Waste waters from locomotive cleaning can contain elevated levels of oil, grease, suspended solids (a measure of particulate matter in water) and pH (acidity or alkalinity of water). These substances are regulated water pollutants, so wash waters must be processed in a way that is consistent with Clean Water Act (CWA) requirements. In most cases, the State has authority for enforcement of CWA provisions and permit administration. Treatment of wash waters may be required before release to a local sewer system or an outfall regulated by a National Pollutant Discharge Elimination

System (NPDES) permit. The type of cleaning solution used may also pose an environmental concern. If mineral sprits or other chemicals are used to clean equipment, a variety of environmental compliance issues may result. Mineral sprits are hazardous substances that have environmental compliance requirements for storage, handling, and disposal.

Hydraulic System Repair

Used hydraulic fluids are listed as used oils under RCRA. The major compliance issues associated with hydraulic system repair involve handling and disposing of the hydraulic fluid, spill containment, and storage. Environmental damage can occur from waste oil seepage into the soil, waste oil run-off into water bodies during storms, and other contamination methods.

Coolant Disposal

Locomotive cooling systems do not contain automotive type ethylene glycol-based antifreeze. Because of this, locomotive cooling systems may need to be drained when engines are shut down during road operation in cold weather. Failure to do so can result in serious engine damage due to freezing of the coolant. To protect the cooling system from corrosion, locomotive coolants contain a dilute additive package, which is basically a mixture of sodium borate and sodium nitrate. The additive package usually contains a dye, to help identify leaks and ensure the cooling system is protected. The compounds are diluted in the cooling system to approximately one to three percent. The concentrations of the individual corrosion inhibitors is a fraction of one percent. Used coolant must be disposed of properly.

Metal Machining

Metal machining and punching can generate regulated wastes that may contaminate the environment from direct release into water or from stormwater runoff. Pollutant-carrying stormwater runoff may violate the CWA. Coolants from metal multi-punch operations may be regulated substances under RCRA or local waste regulations and may require special handling.

Oil Filter Replacement and Used Oil Disposal

A variety of environmental issues need to be considered when performing any oil handling activities such as oil changes or oil filter replacement to locomotives. Oil can drip or spill during maintenance and repair operations, particularly during oil filter replacement operations. Oil releases to the environment from oil drippage can also occur during locomotive tie-up. Oil filter and used oil replacement are generally conducted indoors at locomotive maintenance facilities and locomotive idling is conducted, to the extent practical, over track pans, absorbent materials, or other collection devices. This makes it possible for most facilities to collect used oil and oil filters before they leak or spill oil into the environment. Some facilities have routed track pan drains to oil-water separation systems. Used oils are not typically categorized as hazardous wastes under RCRA, but used oils have strict disposal requirements in some States.

Painting

Painting operations can be significant sources of environmental harm. Air pollution from the evaporation of chemicals contained in the paint (e.g., solvents) can contribute to smog and worker health and safety problems. Solid and hazardous wastes from the painting process (e.g., paint-covered cloths) may contaminate water and soil if not disposed of properly. Whether hazardous wastes are generated during painting depends upon the type of paint applied. Typically, latex paints and related paint wastes are classified as non-hazardous. Ignitable or solvent-based paint or paint thinner wastes are classified as hazardous. Air pollution issues are typical concerns only for large-scale painting operations involving paint booths and associated air ducting.

Battery Storage and Disposal

Used battery storage and disposal can be a significant environmental liability for railroads since many spent signal batteries are classified as hazardous wastes under RCRA. Most locomotive batteries are lead acid and recycled as non-hazardous solid waste.

III.C.3. Transportation Operations

The three main transportation operations that pose potential environmental problems are fueling, hazardous material transport, and oil and coolant releases during transport.

Fueling Operations

Air pollution and fuel spillage are the major environmental concerns associated with fueling operations. While air emissions are a problem for volatile petroleum products such as gasoline, the railroad industry uses very little gasoline on site. Their largest fuel product is diesel fuel, which is less volatile. If gasoline is dispensed on site, it could contribute to local air quality problems, and may require permitting and control. Spilled fuel may contaminate soil, ground water, or water bodies. Some super tanker fueling systems deliver fuel at approximately four gallons per second, so even a small connection malfunction can result in a large spill event. Filling and maintenance of fuel storage may require air quality permitting in some States.

Hazardous Materials

The spilling/leaking of hazardous materials is a significant environmental concern for the rail industry. According to DOT statistics, approximately 16 percent of all hazardous material releases to the environment in 1988 were from rail transport. In addition to being harmful to the environment, hazardous material spills and releases are subject to a variety of environmental regulations and may result in costly cleanups or fines.

Valve leakage or safety valve releases can be sources of material spills on pressurized and general service tank cars or other hazardous material containers such as covered hoppers, intermodal trailers/containers, or portable tanks. These leaks can manifest themselves as odors or vapors clouds from tanker top valves; spraying or splashing from the tanker top valves; wetness on the side of the car; or drippage from the bottom outlet valve. In intermodal cars, spills/leaks can result from improper packing and resultant load shifting during transport. Intermodal container doors and other openings can be spill/release sources. Unloading and transfer facilities are high potential spill and release areas. It should be noted that it is the responsibility of the shipper to properly secure the transportation vehicles to prevent these types of occurrences. In the latest effort to identify the source of these leaks, in 1995 the Association of American Railroads (AAR) introduced the non-accident release (NAR) program. The purpose was to identify and report these releases so that corrective measures could be taken to reduce them.

If hazardous materials are transported, DOT requirements regulate car inspections, car placement, switching, and shipping papers (e.g., waybills, manifests). If hazardous materials pass through a facility, rail containers should be inspected for proper labeling, valve cover placement, any signs of leakage, proper car stenciling, and fulfillment of other DOT requirements. Placarding and/or labeling is required for all containers carrying hazardous materials.

Oil and Coolant Releases

Oil and coolant releases from the locomotive engine to the environment can occur during transport operations. Oils can contaminate surface water, ground water, and soil, and expose the rail facility to punitive fines from violations of a variety of environmental statutes. Coolants may be regulated substances under RCRA or local waste regulations.

IV. TRUCKING

IV.A. Characterization of the Trucking Industry

IV.A.1. Industry Characterization

Construction of the nation's first transcontinental highway, the Lincoln Highway (U.S. 30), started in 1912. It took 20 years to complete the 3385-mile road between New York City and San Francisco. In 1956, the Federal Aid Highway Act was signed into law, authorizing the 41,000-mile National System of interstate and defense highways to be completed by 1972 at a cost of $42 billion. In 1982, landmark legislation boosted Federal spending for highway construction and repair work. By 1986, more than 97 percent of the 42,500-mile interstate highway system was open to traffic as the program entered its 30th year. The system represented a total Federal and State investment of more than $120 billion. Currently, there are 44,700 miles of interstate highways with 132,000 miles of other arteries in the United States.

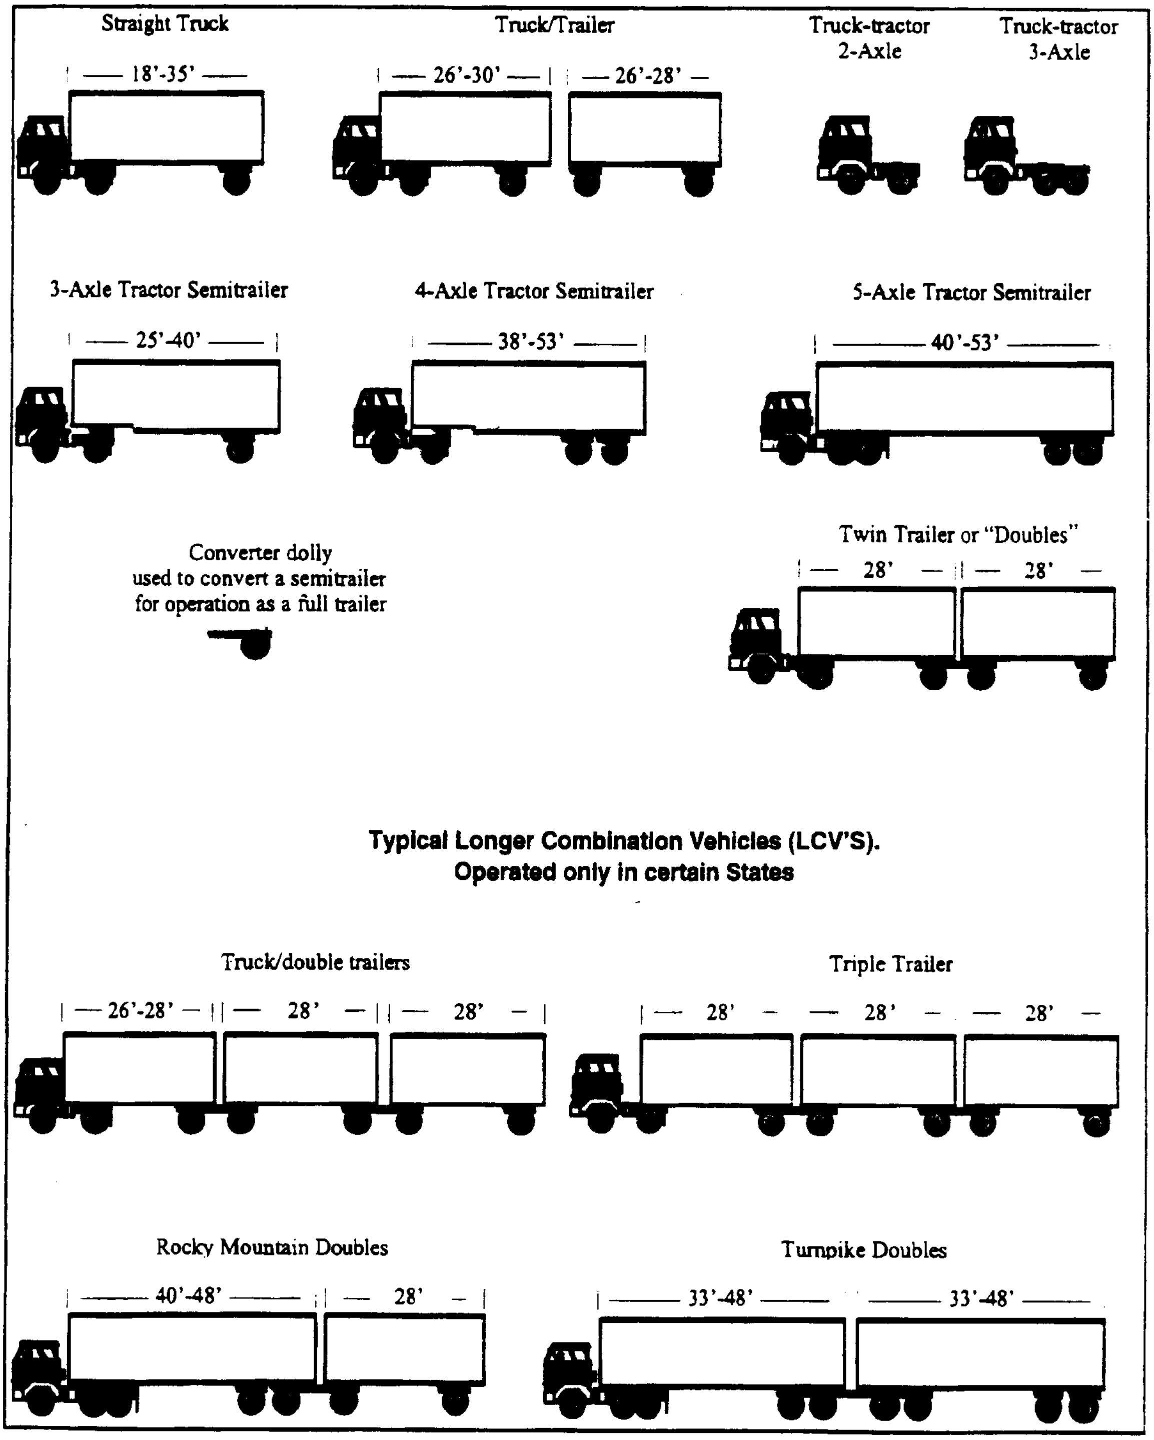
The types of trucks that travel these roads are diverse, ranging from small pickup trucks to large tractor trailer combination units. Methods of quantifying these vehicles vary as well. This section presents information from a variety of sources, including the Census Bureau and trucking associations. Different groups use various benchmarks to quantify the trucking industry. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

According to the American Trucking Associations (ATA), the total number of commercial trucks in 1993 was 16.2 million, with approximately 3.9 million commercial trailers registered in the same period. The ATA reports 322,739 interstate motor carriers on file with the U.S. Department of Transportation (DOT) as of January 5, 1995. Eighty-two percent of those operate fewer than six trucks, and 96 percent operate 28 or fewer trucks. 59,310 for-hire carriers were authorized by the Interstate Commerce Commission (ICC), to haul goods.

Types of trucks and trucking establishments are defined by various classifications. Exhibit 6 shows the shape and size of different truck types. This diagram does not include smaller trucks such as pickups, panels, vans, and utility trucks which are usually not counted in industry statistics because they are often used for personnel purposes.

In general, trucking establishments falls into two broad categories: private and for-hire. Private carriers are shippers, manufacturers, merchants, and others who use their own vehicles or leased trucks under their direct control for moving their own goods. For-hire carriers are compensated for providing transportation of freight belonging to another entity.

Exhibit 6
Truck Types



There are three types of interstate for -hire carriers: common, contract, and exempt carriers. Common carriers transport freight for the general public at published rates. Contract carriers are those in stipulated types of operations, such as trucks used only to carry newspapers, or vehicles used incidentally to support air transport. (*Motor Trucking Engineering Handbook*, James W. Fitch, Society of Automotive Engineers, 1994).

For-hire carriers regulated by the ICC were classified by size of operating revenue. The ICC was abolished by an act of Congress in December 1995, with remaining essential functions transferred to a newly created Surface Transportation Board (STB) within the Department of Transportation. ICC statistics reported prior to the ICC's abolishment are referenced in this document. As of January 1, 1994, the ICC defined Class I carriers as those establishments with annual revenues greater than $10 million, Class II carriers with annual revenues between $3 and $10 million, and Class III carriers with annual revenues of less than $3 million.

IV.A.2. Industry Size and Geographic Distribution

As discussed in Section IV.A.1 above, variation in facility counts occur across data sources due to many factors, including reporting and definition differences. This document does not attempt to reconcile these differences.

Industry Size

Trucking companies are diverse, ranging from large employers to private transporters who work for themselves and have no additional employees. A concise discussion of the trucking industry is complicated by the different methods used by the Census Bureau, the ICC, and trucking associations to estimate the size of the trucking industry. In some cases, as with most census data, only those companies with payrolls – those that pay drivers who were not also owners – are tracked. In addition, only those trucking companies formerly regulated by the ICC were required to report data.

The trucking industry consists of approximately 111,000 establishments with payrolls, employing nearly 1.6 million people. This does not include small, independent truckers who have no employees other than themselves. The total number of truck drivers holding commercial drivers licenses as of June 1995 exceeded 6.5 million. In 1993, these drivers drove 656.6 billion miles (American Trucking Trends, 1995). According to the American Trucking Associations (ATA), 7.8 million people were employed throughout the economy in jobs that relate to trucking activity and 2.8 million heavy-duty truck drivers (including linehaul, local, courier, government, etc.) were employed in 1994. In 1993, $226.9 billion was paid in wages relating to trucking activity.

Over 88 percent of trucking companies are small businesses, as defined by the Small Business Administration. According to the ATA, of the 359,787 interstate motor carriers on file with the Office of Motor Carriers, 82 percent operate six or few trucks, while 96 percent operate 28 or fewer trucks (as of February 1996).

Exhibit 7 illustrates the facility size distribution for those motor freight transportation and warehousing facilities with payrolls, based on the latest complete Census Bureau data (1992).

Exhibit 7
Facility Size Distribution of Trucking Industry*

Industry	SIC Code	Total Employees	Total Number of Facilities	Employees per Facility
Local Trucking Without Storage	4212	354,742	49,870	7.11
Trucking, Except Local	4213	758,435	40,821	18.6
Local Trucking with Storage	4214	64,417	4,512	14.3
Courier Services, Except by Air	4215	307,061	5,966	51.5
Farm Product Warehousing and Storage	4221	6,497	584	11.1
Refrigerated Warehousing and Storage	4222	18,963	929	20.4
General Warehousing and Storage	4225	49,091	6,753	7.3
Special Warehousing and Storage, NEC*	4226	20,594	1,452	14.2
Terminal and Joint Terminal Maintenance Facilities for Motor Freight Transportation	4231	295	21	14.1
Total		1,580,095	110,908	14.2

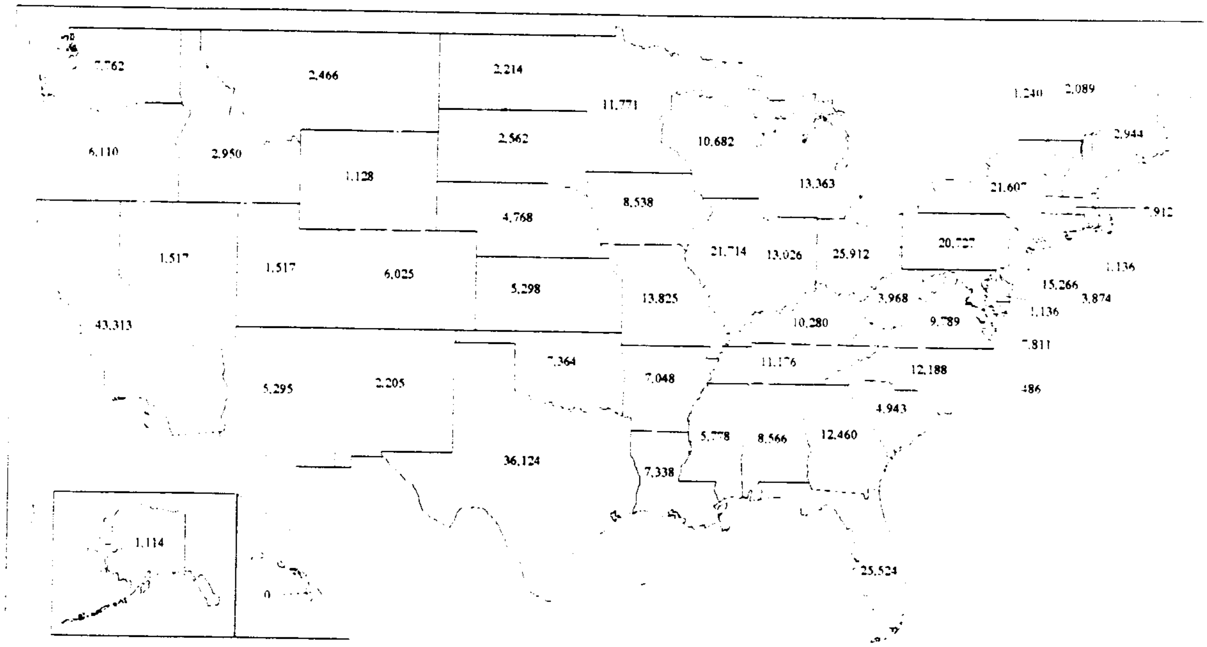
Source: Compiled from official 1992 statistics of the U.S. Bureau of the Census.
**Facilities with payrolls only.*

As demonstrated in Exhibit 7, the majority of establishments and employees in the trucking industry which maintain payrolls are classified in SIC Code 4212, Local Trucking Without Storage. This category includes dump trucking, general freight, and garbage and trash collection. Trucking, except local (SIC 4313), accounts for most of the other establishments and persons employed in the trucking industry. General freight trucking accounts for most trucking industry facilities.

Geographic Distribution

Reflecting the national importance of highway transit, the trucking industry is widely dispersed, with every State reporting the existence of at least 400 industry establishments (U.S. Bureau of the Census). The numbers in Exhibit 8 include both businesses with and without payrolls. All businesses covered by the economic censuses are included, except direct sales retail and tax exempt service businesses.

Exhibit 8
Geographic Distribution of Trucking Industry Facilities



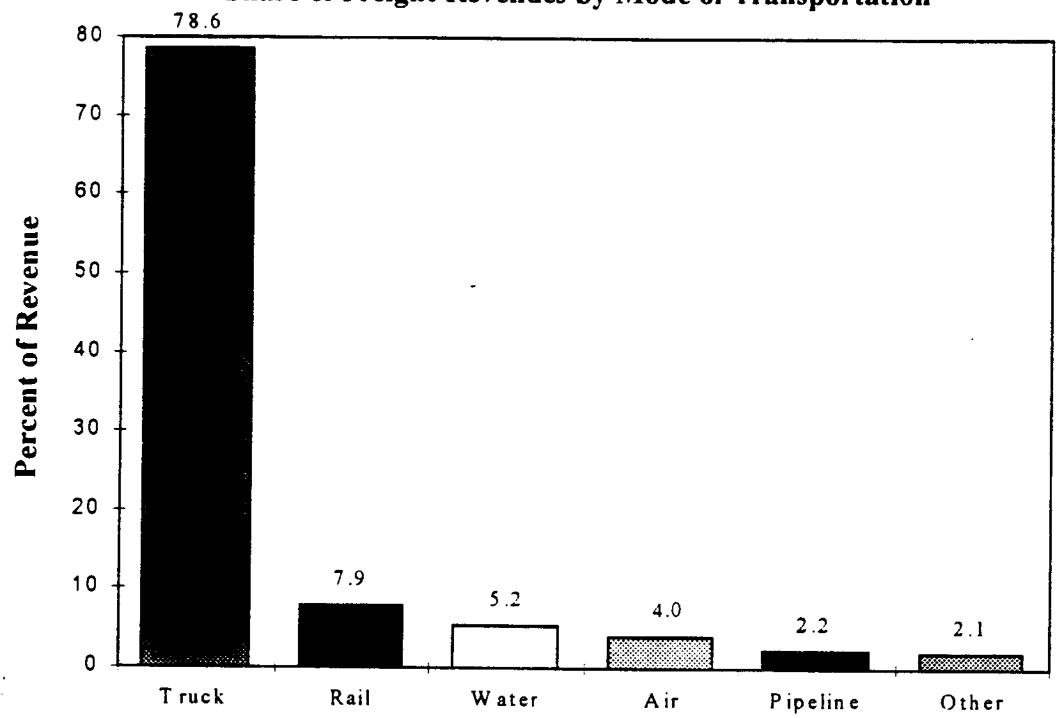
Source: Compiled from official 1992 statistics of the U.S. Bureau of the Census.

Although the trucking industry is highly represented throughout the country, motor freight facilities are most heavily concentrated around the Great Lakes States (Minnesota, Wisconsin, Illinois, Indiana, Michigan, and Ohio). Reflecting the important trade routes between these States and the Northeast, this concentrated area extends through Pennsylvania and New York. The five largest States in terms of number of trucking establishments with payrolls are California, Texas, Ohio, Florida, and New York.

R0075294

Exhibit 8 illustrates the number of trucking establishments as recorded by the Bureau of the Census. These numbers do not correlate to those presented in Exhibit 9, also from the Bureau of the Census, due to the different scope of the census data.

Exhibit 9
Share of Freight Revenues by Mode of Transportation



Source: American Trucking Trends, 1995

IV.A.3. Economic Trends

In terms of revenue, trucking accounts for the vast majority of total U.S. freight services. Exhibit 8 illustrates the trucking industry's enormous share of total freight revenue. This reflects trucking's higher revenues-per-ton and per-ton mile (a ton-mile equals the movement of one ton of weight over a one mile distance), compared to the rail and barge sectors, which generally carry lower-valued bulk commodities. Thus, the trucking industry's share of tons shipped (43 percent) and ton-miles (27 percent) is much lower than its share of revenues (U.S. Industrial Outlook 1994 – Transportation).

The growing use of rail transport and rail transport of truck containers and trailers has offered economic competition to motor freight companies. According to the ATA, by the year 2003, trucking will lose 1.9 percent of its share of total 1993 revenue – primarily to air and rail intermodal – but trucks will still account for 76.7 percent of freight transportation revenue.

Reportedly, the estimated profit margin of the companies and independent truckers averages one to two percent.

The following economic information is from the Census Bureau's *1993 Motor Freight Transportation and Warehousing Survey Report*. As with the census data conveyed in Exhibit 7, this survey excludes private motor carriers that operate as auxiliary establishments to non-transportation companies, as well as independent owner-operators with no paid employees. As a result, the dollar volume estimates and estimates of year-to-year percentage change presented in this report should not be interpreted as representing measurements of total trucking industry activity.

Revenue in 1993 for the for-hire trucking and courier services industry (excluding air courier services) was estimated at $135.9 billion, up six percent from 1992. Long-distance trucking, which accounted for approximately 75 percent of all motor carrier revenue, was up 5.6 percent over 1992. Local trucking revenue rose 9.6 percent from 1992 to approximately $31.6 billion in 1993. Truckload shipments accounted for approximately 61 percent of motor carrier revenue in 1993 and increased 6.8 percent from 1992.

Nearly 48 percent of motor carrier revenue comes from transporting manufactured products, such as furniture, hardware, glass products, textiles and apparel, and the delivery of small packages. Revenue in 1993 from the transport of metal products rose 8.8 percent from 1992. Expenses totaled $127.9 billion in 1993, up 5.8 percent from 1992. Revenue for the courier services industry, excluding air courier services (SIC 4215), rose 7.7 percent in 1992 to approximately $20.2 billion in 1993. The Truck Inventory and Use Summary (TIUS), part of the Census Bureau's Census of Transportation, provides data on the physical and operational characteristics of the U.S. truck population. According to TIUS, an increasing proportion of trucks are being used mainly for "personal transportation," i.e., commuting to work, outdoor recreation, etc. In 1992, almost 70 percent of all trucks were identified as being for personal use; in 1987 the proportion was 66 percent, and in 1982 only 57 percent.

Annual payroll accounted for approximately 33 percent of all trucking expenses, totaling $41.5 million for 1993. Purchased transportation rose 7.6 percent from 1992, while the cost of fuels and maintenance and repair expenses rose 6.7 percent and 7.0 percent, respectively.

Public Warehouse Services

Total operating revenue for public warehousing services increased 8.6 percent from 1992 to $8.1 billion. Total operating expenses rose 8.4 percent from 1992 to $6.8 billion. Employer contributions to employee benefit plans were up to 7.2 percent and represented almost eight percent of the warehousing industry's total operating expenses.

Over 50 percent of all revenue was from general warehousing and storage (SIC 4225). Revenue from refrigerated warehousing and storage (SIC 4222) increased 3.3 percent to $1.7 billion, and accounted for 21 percent of the warehousing industry's total operating revenue in 1993.

Revenue in 1993 for farm product warehousing and storage (SIC 4221), which represents approximately eight percent of the warehousing industry's total operating revenue, increased 9.2 percent to $686 million from 1992, while expenses for the industry were up 7.8 percent to $593 million over the same period.

IV.B. Operations in the Trucking Industry

This section provides an overview of commonly-employed processes within the trucking industry, broken down by operations. This discussion is not exhaustive; the operations discussed here are intended to represent the major sources of environmental hazards from trucking operations. The operations discussed include materials transport, truck maintenance, truck washing, tank truck cleaning, and transport operations.

IV.B.1. Truck Terminals and Maintenance Facilities

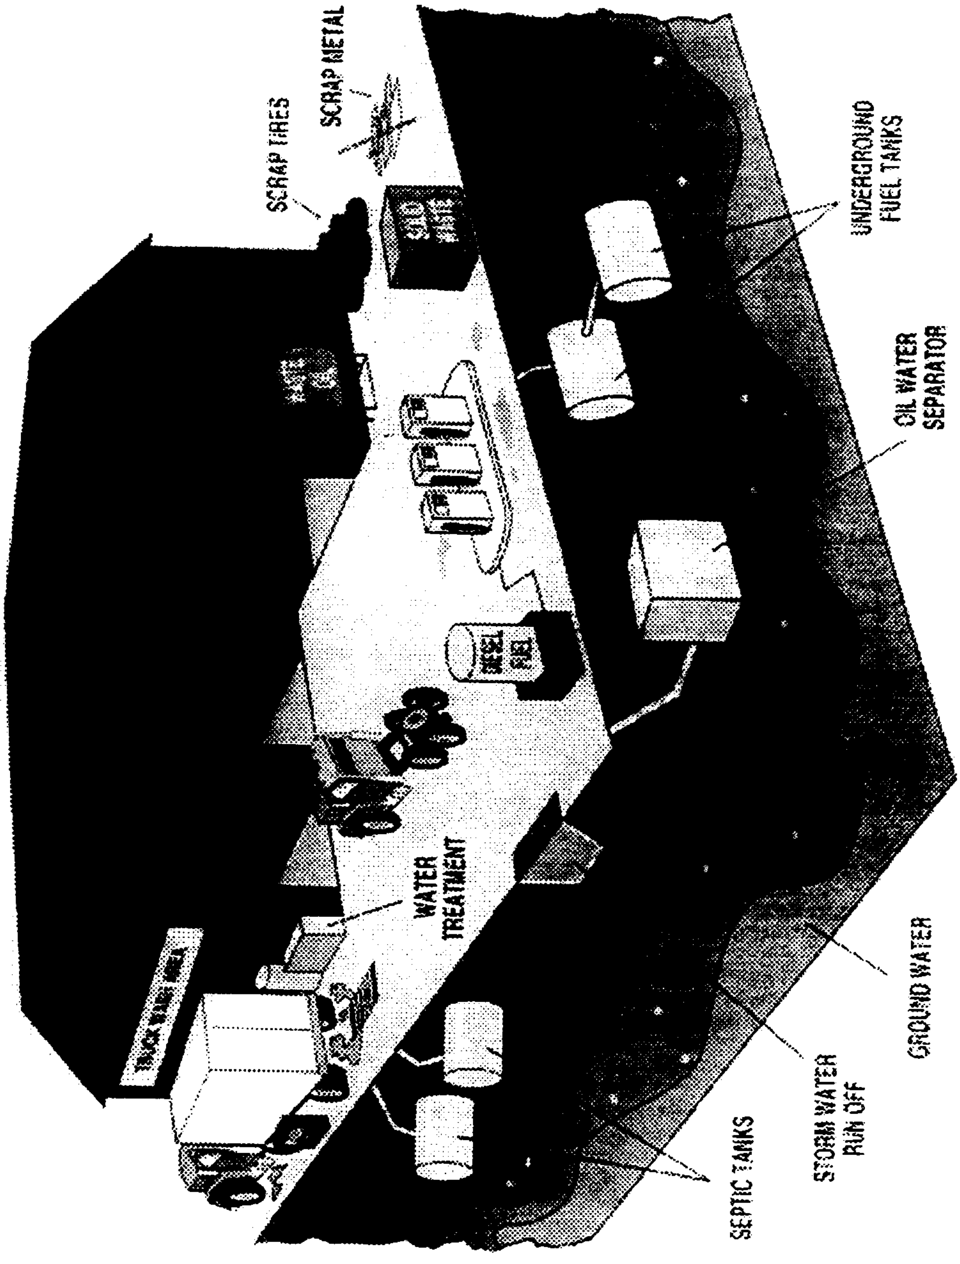
Many segments of the trucking industry operate their own truck terminals and maintenance facilities. Truck terminals are places where trucks come to consolidate and transfer loads of shipped goods. Terminals typically have large parking and staging areas for tractors and trailers, and a loading dock, from which freight is moved between trailers. Truck maintenance facilities, which may be located on the same property as the maintenance facilities, which may be located on the same property as the terminals, perform routine vehicle maintenance activities which are similar to those performed in the automotive service industry. These activities include replacement of fluids (e.g., motor oil, radiator coolant, transmission fluid, brake fluid), replacement of non-repairable equipment (e.g., brake shoes/pads, shocks, batteries, belts, mufflers, electrical components, water pumps),and repair of fixable equipment (e.g., brake calipers/rotors/drums, alternators, fuel pumps, carburetors). Some maintenance terminals also have fueling facilities, repair vehicle bodies, wash trucks, and perform painting operations.

Truck maintenance involves the regular changing of a number of fluids. Automotive fluids used to maintain trucks include brake fluid, transmission fluid, gear oil, radiator fluid, and motor oil. Truck parts removed for repair often require cleaning to allow for better visual inspection of the parts and to remove contaminated lubricants/greases that would lead to early failure of the repaired part. Rags are often used to clean up a fluid spill or to wipe grease from a part being repaired. If necessary, clean lubricants/greases are applied to the parts during reassembly.

Parts cleaning often involves the use of a parts washer. Washers used in the trucking industry include solvent parts washers, hot tanks, and jet spray washers. A solvent parts washer recirculates solvent continuously from the solvent drum to the solvent wash tray where the parts are cleaned. Old solvent is typically replaced with fresh solvent on a monthly basis. The solvents used for parts cleaning contain petroleum-based ingredients or mineral spirits. Carburetor cleaner contains methylene chloride. Electrically heated tanks are also used to clean parts. Parts are placed in a tank of hot aqueous detergent or caustic solution to achieve cleaning and air or mechanical agitation is employed to increase cleaning efficiency. Jet spray washers also use hot aqueous solutions for cleaning, but in this application, rotating jets spray the parts with cleaner. Both hot tanks and jet sprays are usually serviced monthly by removing the spent cleaner and sludge and recharging the washer with fresh detergent. Sludge that accumulates in the waste sump of the pressure spray cleaning bays and in area wash-down clarifiers is often taken off site to a local municipal landfill.

Truck maintenance facilities may also perform fueling operations. Fueling facilities typically dispense diesel fuel. Exhibit 10 shows the layout of a typical truck maintenance facility.

Exhibit 10
Typical Trucking Maintenance Facility



Source: Stormwater Pollution Prevention Manual for the Trucking Industry ATA, 1993

R0075299

IV.B.2. Truck Washing

Trucks can be washed manually or by using a fixed wash bay system. Dry washing, by using dry rags and a spray bottle, can be an option for manual truck washing. Manual washing includes hand-held wash systems, hand-held wand systems, and hand brushing with soap. Fixed bay washing operations involve fixed equipment, such as drive-through wash racks or gantry wash systems. Typically, wash bay systems include chemical storage facilities. chemical and water application arches, water reclamation systems, and waste water treatment systems.

IV.B.3. Tank Truck Cleaning

Tank trucks typically haul a wide range of liquid and dry bulk commodities. including food-grade products such as milk and corn syrup, and industrial process chemicals. Many aspects of transportation and labeling, as well as spills and releases of these materials, are regulated by the Research Special Programs Administration (RSPA) of the DOT. Because the material being transported is loaded directly into a tank truck without any sort of container. these trucks require special cleaning to remove residual cargo. Washing, rinsing, and drying methods vary depending on the facility's equipment, the last cargo carried, and the next cargo to be carried. Some cargoes may require only a water rinse, while others may need a series of wash and rinse cycles using different wash solutions.

Prior to tank cleaning, residual cargo, or heel, is removed. Heel volume from tank trucks is typically five to ten gallons (EPA Office of Water and *Preliminary Data Summary for the Transportation Equipment Cleaning Industry*, U.S. EPA, 1989, and EPA Office of Water, Engineering Analysis Division, 1995). Heel can be sent to an off-site Treatment Storage and Disposal Facility (TSDF) or can be treated on site if it is an aqueous solution. If organic, it may be put into containers for later treatment as a hazardous waste.

Tank truck washing is performed either manually with hand-held sprayers, or automatically with high pressure spinner nozzles or "butterworths." With automatic washing, high pressure spinner nozzles are inserted through the main tank hatch, and wash solution and rinse water is automatically sprayed onto the tank surface at 100-600 p.s.i. while rotating around vertical and horizontal axes.

Washing solution may consist of detergent solution, caustic solution, organic solvents, or steam. Any wash solution can be used with either the manual or automatic washing method, although worker safety is a concern when manually spraying solvent and caustic wash solutions. Some facilities have the capability to recycle washing solutions within a closed system, and periodically change to fresh water solutions. Tanks can be rinsed with hot or cold water, and dried with passive or forced air.

IV.B.4. Transport Operations

Transport operations refer to all operations performed by a truck while on the road. These operations include loading and unloading cargo, running the truck engine, and fuel consumption. Commercial trucking transportation operations consumed approximately 36 billion gallons of oil in 1993, or about 63 percent of total U.S. consumption. This figure, according to the ATA, includes 23 billion gallons of diesel fuel and 13 billion gallons of gasoline.

IV.C. Raw Material Inputs and Pollution Outputs

IV.C.1. Truck Terminals and Maintenance

Materials Spills and Releases

In truck terminals, spills and releases of hazardous material shipments are the main environmental issue of concern. Hazardous waste transportation is a highly regulated and specialized segment of the trucking industry, covered by extensive EPA (40 CFR) and DOT (49 CFR) regulations while the waste is in transit. Due to the additional insurance and safety requirements, the majority of general freight trucking companies do not have the authority nor desire to transport hazardous waste.

Truck Maintenance

Maintenance facilities handle vehicle fluids that are used during normal trucking operations, including oil, transmission fluid, brake fluid, and antifreeze. The quantities of waste materials vary depending on the size of the facility and the types of maintenance activities that are performed.

Oil, transmission fluid, and other liquids that are replaced, must be collected and stored for later disposal. The storage, disposal, and transportation of used oil is regulated by EPA and is a primary environmental concern in the trucking industry. Generators of used oil must meet on-site management standards for storage prior to shipment off-site or burning on-site for energy recovery. Storage containers must be in good condition without leaks and clearly labeled with the words "USED OIL." If a release occurs (spill or leak), the generator must stop and contain the release, clean up and properly manage the released used oil, and repair or replace any leaking containers.

Fluids such as antifreeze must be evaluated for hazardous waste characteristics and dealt with accordingly if spilled or released. Antifreeze consists of water and ethylene glycol. Neither of these ingredients demonstrates hazardous waste characteristics, however, as a result of use, the antifreeze may become hazardous based on metals or benzene content.

Sludge that accumulates in the maintenance facility floor drains can contain oil, grease, solvents, and dirt from routine operations. The hazardous/non-hazardous nature of the sludge will determine the applicable disposal regulations.

Truck Repair

Repair activities typically produce several types of waste materials in addition to the parts themselves (i.e., batteries, brake parts, etc.), including oil, coolants, and solvents. Oil rags can be considered a "used oil" waste. Shop rags which are used to wipe up a hazardous waste (i.e., paint thinner) may be a hazardous waste.

Spent lead-acid batteries are exempt from regulation as a hazardous waste provided they are recycled. Generators of spent lead-acid batteries may store and/or transport those batteries without waste activity notifications or permits as long as the batteries are ultimately reclaimed. In some States, a new battery cannot be purchased without the return of a used battery.

Used tires are a significant waste produced at truck maintenance facilities. Old tires are not acceptable for landfill disposal unless they have been shredded or quartered. Tires can be returned to a central location for processing or recycling. Used truck tires are usually retreaded or recycled. Used tires otherwise ready to be scrapped might be categorized as hazardous waste.

Parts Washing

Parts washing solvents and residual liquids such as petroleum distillates, mineral spirits, and naphtha are all considered hazardous wastes due to ignitability. Filters removed from parts whose units may also be hazardous due to toxicity (presence of metals and/or benzene) and ignitability. Even filters which are not hazardous may still not be acceptable for landfill disposal due to hydrocarbon content.

Air emissions occur when the solvent is sprayed onto parts and when parts are improperly drained of solvent. Many air quality control districts specify that equipment cannot be designed so as to provide a fine spray mist (which leads to high evaporation rates) and that parts must be properly drained before removal from the washer. For washers in which the solvent bath is always exposed to the atmosphere (i.e., wash tanks), the lid must be kept closed whenever the tank is not in use.

Fueling Operations

Fueling operations may result in fuel spills or releases. Waste diesel fuel may be a hazardous waste because its flash point ranges from 120°F to 160°F and because it may contain concentrations of heavy metals and benzene in excess of regulatory limits. Diesel fuel spills and releases – both underground and above ground – are a significant concern in the trucking industry in terms of stormwater run-off and land contamination.

IV.C.2. Truck Washing

The waste streams generated by vehicle washing operations are variable. If vehicles are washed often, they enter the washing operation relatively clean, and the waste wash water generated is cleaner thana waste stream generated from washing vehicles that are washed only occasionally. The technology used to wash the vehicle will also affect the waste stream. For example, if a two-step acid-detergent wash is used, acid or salts will be found in the waste stream that would not be present if the vehicle was steam cleaned. Season and location can also affect the waste stream generated, for example, vehicles in the northeast often bring in heavy mud and road salt in the winter months.

Vehicle washing is a regulated maintenance activity under the NPDES program. Wastewater from vehicle washing and floor drain discharge is considered industrial waste. The hazardous or nonhazardous nature of the wastewater determines the applicable disposal regulations.

IV.C.3. Tank Cleaning

The primary pollutant output from tank cleaning operations is wastewater contaminated with tank residues and cleaning solutions. Specific outputs include: spent cleaning fluids, fugitive volatile organic compound (VOC) emissions, water treatment system sludges, and tank residues. The quantities of these outputs vary widely from facility to facility depending on the type of cargo and cleaning methods. For example, an independent owner/operator tank truck cleaning facility serving a large number of different users will generate wastewater containing many ore contaminants than a shipper operated facility serving trucks all carrying the same cargo.

Tank heels from a shipment of hazardous waste greater than 0.3 percent of weight of the tank capacity continue to be regulated by RCRA after the discharge of the waste at a TSDF. Under current regulation, the use of solvents to further rinse out tanks is not considered treatment; however, certain State RCRA programs regulate these processes more stringently and should be contacted to determine if a treatment permit is required.

IV.C.4. Transport Operations

Transport operations have the potential to generate three types of waste: the release or spill of a hazardous waste during loading and unloading operations; the spill or release of vehicle fluids such as oil or antifreeze during travel; and, most significant, the emissions generated during fuel combustion. As discussed above, engines, especially those of heavy duty trucks, generate several forms of air pollution. Among common substances released to the air from truck engines are hydrocarbons, carbon monoxide, oxides of nitrogen, sulfur compounds, and particulate matter. A description of each of these pollutants follows, while more information about EPA regulations governing emissions is provided in Section VII.

Hydrocarbons: Although hydrocarbon emissions are not problematic when they leave the vehicle, some hydrocarbons react in the atmosphere to promote the formation of photochemical smog. Ozone concentration is generally used to measure the extent of this photochemical reaction. Hydrocarbon emission standards have been set to meet the National Ambient Air Quality Standard (NAAQS) for ozone.

Exhibit 11
Hydrocarbons Emission Sources

Hydrocarbons Emissions Source	Percentage of Total Emissions
Stationary Fuel Combustion	3.1%
Industrial Processes	13.3%
Passenger Cars - Gasoline Engine	17.8%
Light-Duty Trucks - Gasoline Engine	6.4%
Heavy-Duty Vehicles - Gasoline Engine	0.8%
Diesel Engine Vehicles	1.8%
Other	56.8%

Source: ATA

Carbon Monoxide: Carbon monoxide (CO) is a byproduct of incomplete fuel combustion. The chemical is a colorless, tasteless, odorless gas that displaces oxygen in the body. At high concentration in confined areas, CO can be injurious to health. EPA has set a NAAQS and a vehicle emission standard for CO.

Exhibit 12
Carbon Monoxide Emission Sources

Carbon Monoxide Emissions Source	Percentage of Total Emissions
Stationary Fuel Combustion	7.1%
Industrial Processes	5.7%
Passenger Cars - Gasoline Engine	44.0%
Light-Duty Trucks - Gasoline Engine	14.5%
Heavy-Duty Vehicles - Gasoline Engine	2.9%
Diesel Engine Vehicles	1.9%
Other	23.8%

Source: ATA

Nitrogen Oxides: Emissions of nitrogen oxides (NO_X) are a significant contributor to the creation of nitrogen dioxide, and are ingredients in the formation of smog, although they play an ambiguous role in the process; at times No_x appear to promote smog, while at other times they seem to inhibit smog in urban areas.

Exhibit 13
Nitrogen Oxides Emission Sources

Nitrogen Oxides Emissions Source	Percentage of Total Emissions
Stationary Fuel Combustion	50.6%
Industrial Processes	3.8%
Passenger Cars - Gasoline Engine	15.2%
Light-Duty Trucks - Gasoline Engine	4.9%
Heavy-Duty Vehicles - Gasoline Engine	0.8%
Diesel Engine Vehicles	11.4%
Other	13.2%

Source: ATA

Sulfur Compounds: Sulfur compounds are oxides that aggravate the respiratory system and may cause respiratory disease. Very dense smog is generally attributed to the buildup of SO and particulates during periods of little air movement. Motor vehicles of all types, including passenger cars, contribute only 4.2 percent of ambient sulfur compounds.

Particulates: Particulates are particles of solid material that are products of incomplete combustion, such as soot and fly ash. Small particles may remain suspended in the air for long periods of time, while larger particles return to the ground as dust. Suspended particles cause reduced visibility and increased health hazards from other contaminants by providing a surface to carry chemicals into human lungs.

Exhibit 14 summarizes the pollution outputs from those operations in the trucking industry discussed in this document.

Exhibit 14
Process Material Input/Pollutant Output from Trucking Operations

Activity	Material Input	Air Emissions	Process Wastes
Truck Terminals and Maintenance Facilities	Motor oil, brake fluid, transmission fluid, coolants, solvents, parts cleaning solutions, lubricants, truck cargo	Possible CFC and VOC emissions	Used oil, used automotive fluids, solvents, coolants, used rags, used cleaning solutions, spilled or released truck cargo
Vehicle Exterior Washing	Detergent, caustic solution, organic solvents, steam	VOC emissions	Oil and grease, suspended solids, detergents, pH, metals
Tank Cleaning	Residuals from shipments, cleaning fluids – detergent, caustic solution, organic solvents, steam	VOC emissions	Spent cleaning fluids, water treatment system sludges, tank residues
Transport Operations	Gas and diesel fuels, alternative fuels, motor oil, brake fluid, transmission fluid, coolant, truck cargo	Hydrocarbons, carbon monoxide, oxides of nitrogen, sulfur compounds, particulates	Used oil, used automotive fluids, spilled or released truck cargo

V. PIPELINES

V.A. Characterization of Pipelines

V.A.1. Industry Characterization

The history of oil and gas pipelines as they are used today begins with the first commercial oil well, drilled in 1859. The first oil pipeline – 109 miles long, with a diameter of six inches – was laid from Bradford to Allentown, Pennsylvania, in 1879. Since the late 1920s, virtually all oil and gas pipelines have been welded steel, a departure from the early versions made from wrought iron. Although the first cross-country pipeline was laid in 1930, connecting Chicago, Minneapolis, and other cities, it was not until World War II, with frequent disruptions in coastal tanker traffic, that large-scale pipelines were laid connecting different regions of the country. In the 1960s, larger-diameter pipelines proved their economic advantage when a line consisting of 32, 34, and 36 inch diameters was built from Houston to New York, and a 40-inch pipeline was constructed connecting Louisiana to Illinois. Discovery of oil on Alaska's North Slope precipitated the construction of the country's largest pipeline, the 48-inch diameter Trans-Alaskan Pipeline, or Alyeska (*Oil and Gas Pipeline Fundamentals*, Kennedy, 1994).

By 1994, U.S. interstate pipeline mileage totaled nearly 410,000 miles, of which over 250,000 miles transported gas and over 158,000 shipped liquid oil and petroleum. Natural gas is delivered to U.S. consumers through a network of 1.2 million miles of buried pipe and 429 underground storage reservoirs that are linked to more than 1,200 local gas distribution companies.

Throughout this section, distinctions are made between gas and oil pipelines. Although the fundamental design and purpose of these two systems are similar, there are differences in their conveyance systems. Distinctions are also made for product pipelines and breakout tanks which are defined below.

Oil Pipelines

Crude oil must undergo refining before it can be used as product. Once oil is pumped from the ground, it travels through pipes to a tank battery. One or more tank batteries may be installed in a single field, each serving a number of individual wells. A typical tank battery contains a separator to separate oil, gas, and water; a fired heater to break water/oil emulsions to promote removal of water from the oil; and tanks for storing the oil until it is shipped as crude oil by truck or, more commonly, by a gathering line connected to storage tanks. From these tanks, the oil is moved through large diameter, long-distance trunk lines to refineries or to other storage terminals.

R0075308

Trunk lines rely on pumps to initiate and maintain pipeline pressure at the level required to overcome friction, changes in elevation, or other pressure-decreasing factors. Pumps are required at the beginning of the line and are spaced along the pipeline to adequately propel the oil along.

Gas Pipelines

The purpose of gas-gathering and gas transmission pipelines is similar to that of crude-gathering and crude trunk lines, but operating conditions and equipment are quite different. Gas pipelines operate at higher pressures than do crude lines, and use compressors instead of pumps to force the gas along. Unlike oil, gas does not undergo refining, and transmission lines connect directly to utility companies that distribute the gas to consumers via small, metered pipelines. Gas is often treated in scrubbers or filters to ensure it is "dry" prior to distribution.

Gas-well flowlines connect individual gas wells to field gas-treating and processing facilities or to branches of a larger gathering system. The gas is processed at the treating facility to remove water, sulfur, acid gases, hydrogen sulfide, or carbon dioxide. Most field gas processing plants also remove hydrocarbon liquids from the produced as stream. From field processing facilities, the dried, cleaned natural gas enters the gas transmission pipeline system, analogous to the oil trunk line system.

Products Pipelines

Once oil is refined, product pipelines transport it to storage and distribution terminals. Refined oil products include automotive gasoline, diesel, home heating oils, ammonia, and other liquids. Other products pipelines transport liquefied petroleum gases (LPG) and natural gas liquids (NGL) from processing plants, where oil and gas are produced, to refineries and petrochemical plants.

Breakout Tanks

Breakout tanks are above ground tanks used to relieve surges in a hazardous liquid pipeline systems or to receive and store hazardous liquid transported by a pipeline for reinjection and continued transportation by the pipeline.

V.A.2. Industry Size and Geographic Distribution

Variation in facility counts occur across data sources due to many factors, including reporting and definition differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source. The Bureau of the Census segregates economic data depending on whether an establishment maintains a payroll. In the transportation industry, many owners/operators are independent businesses with no employees, while others, including companies involved with pipelines, hire contracted employees who are reported under other entities' payrolls. The following data is available only for establishments with payrolls.

Industry Size

According to the Census Bureau, the pipeline industry consists of approximately 4,900 establishments and employs nearly 170,000 people. Exhibit 15 illustrates the facility size distribution for the industry based on 1992 U.S. Census Bureau data.

Exhibit 15
Facility Size Distribution of Pipeline Industry*

Industry	SIC Code	Total Employees	Total Number of Facilities	Employees per Facility
Crude Petroleum Pipelines	4612	10,355	405	25.6
Refined Petroleum Pipelines	4613	5,578	358	15.6
Pipelines, NEC**	4619	846	81	10.4
Natural Gas Transmission	4922	12,928	515	25.1
Natural Gas Transmission and Distribution	4923	69,311	1,648	42.1
Natural Gas Distribution	4924	65,239	1,734	37.6
Mixed, Manufactured, or Liquefied Petroleum Gas Production and/or Distribution	4925	445	71	6.3
Gas and Other Services Combined	4932	4,459	124	36.0
Total		169,161	4936	34.3

Source: Compiled from official 1992 statistics of the U.S. Bureau of the Census.
**Facilities with Payrolls only*
***Not Elsewhere Classified*

Geographic Distribution

State data is available only for those facilities with payrolls, as discussed above. Because the Census Bureau does not segregate data for the natural gas sectors covered by this profile, State-by-State information is available only for oil pipelines. The oil pipeline industry is anchored in the Southwest, with Texas, Louisiana, and Oklahoma accounting for over one-third of all reported establishments. California, with 55 pipeline facilities, and Illinois, with 41, have the next highest numbers of oil lines.

Exhibit 16 illustrates the number of oil pipeline establishments per State as recorded by the U.S. Census for 1992.

Exhibit 16
Geographic Distribution of Oil Pipelines*

**Establishments with payroll only.*

V.A.3. Economic Trends

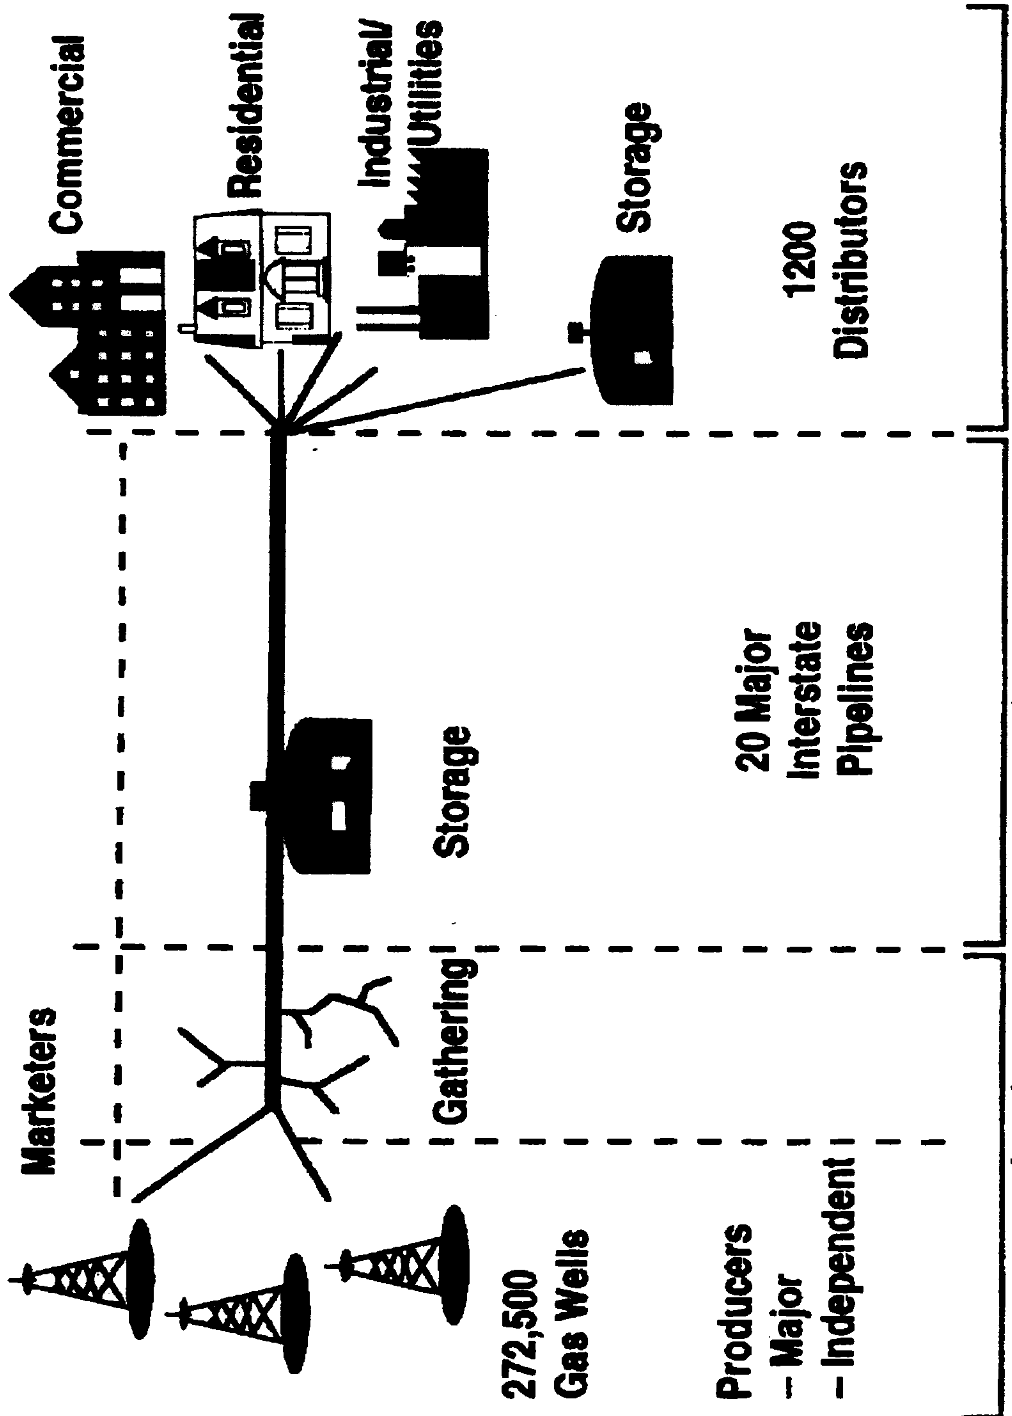
Most gathering and long-distance pipelines in the U.S. are owned by pipeline companies whose sole function is to operate a pipeline system. Historically, natural gas in the U.S. was purchased by the pipeline company from the producer, transported to market, then resold to a local distribution company. Now, most gas is sold directly to the local distribution company the producer, and pipeline companies provide only a transportation service. Oil, on the other hand, has traditionally been transported in the U.S. via pipeline by a shipper/owner, who is generally a refiner as well (Kennedy).

Annual reports filed for 1994 with the Federal Energy Regulatory Commission (FERC) show that both natural-gas and petroleum liquids pipeline companies increased their net incomes in 1994 despite declining operating figures. The ongoing shift of natural gas pipelines to primarily transportation providers was reflected by an increase in volumes of gas moved for others while volumes sold declined. Liquids pipelines moved nearly the same number of barrels in 1994 as in 1993, but showed an increase in barrel-miles, a measure of heightened efficiencies (Oil and Gas Journal, November 1995).

The nearly 410,000 miles of pipeline in the U.S. in 1994 represents a 2.2 percent, 9,000 mile, decline from the previous year. All pipeline mileage operated to move natural gas in interstate service declined nearly 4,000 miles, while mileage used in deliveries of petroleum liquids fell more than 5,000 miles. Transmission pipeline mileage showed little change from 1993 to 1994. Transmission mileage accounted for 77.5 percent of all natural gas mileage reported to FERC. The more than 128,000 miles of crude oil and product trunk lines represented more than 80 percent of all liquids mileage operated.

Natural gas companies have completed the shift from being marketers to being transporters that began when the FERC began implementing a series of regulatory orders that increased efficiency and heightened competition by establishing open-access transportation. This allowed traditional pipeline customers to buy gas from other sellers and have the pipelines provide transportation only. A final piece of regulatory restructuring occurred in 1992 with the release of FERC Order 636, requiring pipelines to offer gas sales, transportation, and storage services separately. In 1994, gas pipeline companies moved nearly 20 times as much gas for other companies as they sold from their own systems. Exhibit 17 demonstrates the relationship between pipelines, marketers, producers, and users of natural gas.

Exhibit 17
Natural Gas Delivery Infrastructure



U.S. crude oil and product oil trunk line traffic also increased in 1994. Crude oil traffic increased by 33 percent, while product traffic saw a modest rise of nearly three percent.

A solid measure of the profitability of oil and natural gas pipeline companies is the portion of operating income that is net income. For liquid pipeline companies in 1994, income as a portion of operating revenues was 29.5 percent, up from 25.4 percent in 1993. Income as a portion of revenues for natural gas companies was 14.3 percent, a marked increase from the 9.1 percent level reported in 1993.

Available information concerning future construction for the gas pipeline industry indicates a slow growth rate. Based on filings during the 12 months ending June 30, 1995, 725 new miles of land pipeline were proposed, and nearly 78,000 horsepower of new or additional compression were applied for.

The world oil price (the average cots of imported crude oil for U.S. refiners) is not expected to move significantly in 1996 from its current level of approximately $16 per barrel. Despite the continued rise in world oil demand over the forecast period, expected to exceed one million barrels per day per year, world oil production capacity increases should accommodate the demand growth in a balanced manner, keeping average prices relatively flat.

V.B. Operations in the Pipeline Industry

Gas and oil pipelines are essentially similar, with the greatest operational difference resulting from the varying needs of transporting gas versus liquid. Oil pipelines require pumps to propel their liquid contents, while gas lines rely on compression to force the resource through the pipe. In both pump and compressor stations, corrosion of piping and vessels must be monitored constantly to prevent failure.

Most pipelines fall into three groups: gathering, trunk/transmission, or distribution. One type of gathering pipeline is flowlines. Flowlines are small-diameter pipelines that are owned by the producer and connect individual oil or gas wells to central treatment, storage, or processing facilities in the field. Another gathering system made up of larger-diameter lines, normally owned by a pipeline company rather than an oil or gas producer, connects these field facilities to the large-diameter, long-distance trunk or transmission line. In some cases, individual wells are connected directly to the pipeline company's gathering system. Crude trunk lines move oil from producing areas to refineries for processing. Gas transmission lines carry natural gas from producing areas and treatment/processing facilities to city utility companies and other customers. Through distribution networks of small pipelines and metering facilities, utilities distribute natural gas to commercial, residential, and industrial users.

Refined liquids and products, such as gasoline, kerosene, fuel oil, and jet fuel are transported thousands of miles throughout the U.S. in product pipelines. Efficient long distance transport by pipeline requires high operating pressures, typically 500-1200 psi. Liquefied petroleum gases such as propane, butane, and their mixtures, are usually liquids under normal line operating pressures, so the pipelines transporting them are classified as liquid lines. Pump stations are needed on liquid lines at line friction, and elevation changes. Storage structures, such as tank farms for liquids and, increasingly, underground salt caverns for propane, are also used as buffers in transmission network operations and to distribution points of contact. Common pipeline operations are discussed below.

V.B.1. Pigging

Pipeline pigs are used for multiple purposes in both liquid and natural gas pipelines. A mechanical pig consists of a steel body with rubber or plastic cups attached to seal against the inside of the pipeline and to allow pressure to move the pig through the line. Brushes and scrapers are attached to the pig to facilitate cleaning or other functions. Pigs and spheres are forced through the pipeline by the pressure of the flowing fluid.

Mechanical pigs have traditionally been used to clean or segregate fluids within liquid pipelines. Mechanical pigs are most often used in gas pipelines to clean the line and maintain maximum efficiency. Downstream of compressor stations, lubricating oil from the compressors needs to be removed from the gas lines. On the intake side of both compressor and pump stations, cleaning pigs are used to prevent unwanted materials from contaminating the pumps or compressors. Recently, the use of pigs has increased as sophisticated instruments are used to monitor pipeline conditions and detect potential problems.

Large amounts of debris can be removed by a pig run over a long distance. For example, assume a pig is run in a 24-inch diameter pipeline that is 100 miles long and removes 0.016 inches of wax material from the wall of the pipeline. After 100 miles, the pig would be pushing a plug of wax about 1,450 feet long (Kennedy). Several sweeps by the pig may be required to effectively clean the line. Both brush and scraper pigs contain holes that allow fluid to bypass the pig, preventing buildups in front of the machine that could cause plugging.

V.B.2. Pipeline Leaks

Pipeline leaks are considered either small, medium, or large. Small leaks are below the limits of current computational pipeline monitoring leak detection capabilities. They can be detected with chemical sensing cables or by finding small pools of leaking product or dead vegetation on the pipeline right of way. They result from small, stable fractures or small corrosion holes that result in leak rates usually less than one percent of flow. Many vendor- and company-developed systems can detect leaks as small as 0.1 percent flow in field tests, but pipeline operators are not counting on this capability and are continuing with visual inspections (US DOT/RSPA/Volpe Center 1995). Small leaks can stay small and go unnoticed for weeks.

Medium leaks are detectable with some inferential leak detection methods, but are not large enough to cause a loss of working line pressure. Spill rates as high as 100 bbls per hour have gone undetected for up to a day on large lines without the use of sophisticated detection systems. Medium leaks are caused by fractures that remain narrow and by worn gaskets and valve stem packings.

Large leaks result in a rapid loss of working line pressure, which will generate an alarm to the dispatcher, even without a leak detection system (LDS). They are caused by third party damage and by unstable fractures that can grow many feet in length. Many high carbon steels used before 1`970 are prone to unstable fracture. Hydrogen gas, generated by cathodic protection systems with excessively high voltage, and hydrogen sulfide, found in sour crude oil, can make steel brittle and more prone to such fractures.

Improvements in materials, construction technologies, and inspection and monitoring techniques have reduced the incidence of damage to pipelines. In Western Europe, for example, gas leaks have dropped by 30 percent in the past 20 years, despite an aging pipeline system.

V.B.3. Pipeline Inspections

More than half of the gas transmission pipeline capacity in the U.S. will be over 40 years old by the year 2000. It is becoming increasingly important to guarantee the structural integrity of these pipelines through structural monitoring and periodic inspections. In addition, pipelines in unstable terrain must be monitored using geotechnical instruments such as inclinometers and pezometers, as well as by direct measurement of pipeline deformations, using strain gauges. Over the past 50 years, methods for performing these tasks have steadily improved.

Leak detection methods may be divided into two categories, direct and inferential. Direct methods detect leaking commodity outside the pipeline. Inferential methods deduce a leak by measuring and comparing the amount of product moving through various points on a line.

Traditionally, pipelines have been inspected visually by walking along this line or patrolling the pipeline route from the air. Today, leak detection ha become more thorough, in part to meet environmental and safety regulations. A thorough inspection program requires both systematic periodic controls (e.g., patrolling the line or cathodic protection measurements) and specific occasional controls (e.g., in-line inspection or hydrostatic retesting). Inspection programs must address the needs of the pipeline, requiring a detailed knowledge of construction characteristics, past and present service conditions, the local environment, and maintenance history. Factors influencing the rate of detection include the type of fluid, the accuracy of measuring systems, line size, pipe thickness, length of the line, analytical equipment, and the experience of the personnel involved.

One successful inspection technology is the instrument internal inspection device, commonly referred to as the smart pig. Growing out of earlier technology (mechanical pigs used for cleaning), smart pigs carry detection and logging tools that store data on the state of the pipeline including data on metal loss, pits, gouges, and dents while moving through the pipeline system. The smart pig is launched from a pig launcher (a spur off the mainline), run through the pipeline segment, trapped, and removed from the pipeline. The data is then downloaded from the start pig data storage unit and analyzed.

The smart pig technology is based on the use of a single "sensor," called magnetic flux leakage, or MFL. MFL pigs can detect metal loss, usually the result of corrosion. Based on limited data, smart pigs are able to detect approximately 60 percent of pipe defects. They cannot detect stress corrosion cracking, longitudinal cracks, small defects, or gouges and dents caused by excavation damage. An emerging technology called ultrasonic sensor technology can detect smaller cracks and defects. However, sensors currently require liquid to serve as a contact between the sensor and the material being inspected. Research is underway to develop ultrasonic sensors that can function in a dry natural gas pipeline. One of the most difficult inspection hurdles is the many miles of pipes that cannot be inspected using pigs. Design constraints such as intrusive valves, varying pipe diameters, and sharp turns make internal pipe inspection difficult.

Another inspection practice is to measure the amount of pressure and volume in a pipeline. This is done through metering. Metering measures the amount of flow in and out of a pipeline segment. This approach is effective using both simple and complex leak detection systems. The detection of small leaks can be enhanced by sophisticated instrumentation and the use of computer models.

Natural gas pipelines can be inspected for leaks with surface-sampling instruments by the flame-ionization principle. These units are made up of a sampling probe with a pump to draw an atmospheric sample to a detection cell. In the cell, the sample envelops a small hydrogen flame and carbon ions flow to a collector plate, causing an imbalance in the circuit that deflects the indicating meter. Because natural gas weighs less than air, it rises to the ground surface as it progresses through the atmosphere. Leaks in liquid natural gas pipelines are not as easily detected, and the soil around the line must be tested for constituents like propane and butane. Exhibit 18 shows some of the practices used to monitor pipelines and the types of damage they can reveal.

V.B.4. Glycol Dehydration Units

Glycol dehydration units are commonly used to remove water vapor from natural gas. Glycol dehydration of natural gas streams helps prevent corrosion and the formation of hydrates in pipelines. Up to 40,000 glycol dehydration units may be operating in the U.S. Approximately 17 to 18 trillion cubic feet per year of natural gas is currently dehydrated in North America, with a large fraction of that amount being treated in the United States.

During the water removal process, the glycol picks up other compounds from the natural gas that can become part of waste streams. The most significant issue is air emissions from the reboiler still vent. Increasing regulatory pressure has made emissions of benzene, toluene, ethylbenzene, the xylene isomers (BTEX), and volatile organic compounds (VOC) from the reboiler still vent of glycol dehydration units a major concern of the natural gas industry.

Varying amounts of water accompany the production of natural gas, depending on the temperature and pressure of the gas and the age of the field. In addition to the produced water, most natural gas is saturated with water vapor at the production temperature and pressure. The water vapor content of saturated natural gas can be estimated given the temperature and pressure of the gas. For example, at 800 psig and 80°F, natural gas may contain as much as 38 pounds of water per million standard cubic feet (MMSCF). In addition, sour natural gas (i.e., gas containing significant concentrations of hydrogen sulfide and carbon dioxide) will have a higher water content than sweet gas.

As the pressure and temperature vary in the gas pipeline, water can combine with the natural gas molecules (e.g., methane, ethane, and propane) to form solid hydrates that can block or plug a pipeline. Hydrates are crystalline structures composed primarily of water and hydrocarbons; methane can form hydrate cells with up to 136 molecules of water. Hydrates may also incorporate other gases such as hydrogen sulfide, ammonia, carbon dioxide, acetylene, and bromine into their structure.

Initially, small hydrate crystals will form in the flowing gas when free liquid water is present at the proper temperature and pressure. These small crystals become condensation nuclei, and, as they collide and stick together, larger crystals are formed. They will also accumulate on obstructions such as valves, orifice meters, or sharp objects where pressure and flow rate changes occur. Eventually, these crystals can grow to become a solid block of hydrates that can completely close off a pipeline or other equipment at high pressure.

Water also increases the corrosivity of the acid gases in the natural gas. Upon cooling, water may condense in the pipeline and cause slug flow, resulting in increased pipeline corrosion, erosion, and pressure drop.

To prevent the formation of hydrates at pipeline pressures and to limit corrosion, natural gas must be dehydrated before it is sent to the pipeline. In the U.S., the typical pipeline specification for the water content of the gas is 7 lb/MMSCF of natural gas.

V.C. Pollution Outputs and Causes of Pipeline Leaks

Unlike the other pollution output sections in the document, this section reflects the importance of determining the causes of pipeline ruptures, rather than focusing on the material released. By definition, most pollution outputs associated with pipelines are the oil and gas resources and products that the pipelines convey.

The Federally-regulated pipeline system has consistently improved its safety record over the last 25 years. However, there are still about 20 large (1,000 barrels or more) spills on the DOT's Office of Pipeline Safety (OPS) regulated liquids lines each year (US DOT/RSPA/Volpe Center 1995). Between 1988 and 1994, the OPS received 1,401 reports of hazardous-liquid spills on U.S. pipelines in which operators claimed a total of 1.2 million barrels of lost product and $220 million in property damage, as well as a number of injuries and fatalities.

Large crude and other viscous product spills are difficult and expensive to clean up. Lighter products, such as gasoline and highly volatile liquids pose less of a cleanup problem, but the risk of fire and explosion is significant. Much of the improvement in the pipeline safety record over the last 25 years has resulted from technical developments such as those in pipeline components, construction, inspection, and corrosion control.

V.C.1. Pipeline Failures

According to the DOT, for gas pipelines, 40 percent of leak/spill incidents are due to outside force or third-party damage; 21 percent are due to corrosion; 16 percent to material construction defects, and 23 to operational causes. For oil pipelines, only 18 percent of incidents are due to outside force or third-party damage; 20 percent due to corrosion, 16 percent due to material construction defect, and 45 percent to operational incidents (US DOT National Pipeline Safety Summit 1994, Data prepared by the NJ Institute of Technology). Exhibits 19 and 20 provide more specific breakdowns of the causes of pipeline leaks for hazardous liquid pipelines and natural gas pipelines as well as a breakdown of the resulting damage.

Exhibit 19
Hazardous Liquid Pipeline Incident Summary by Cause - 1994

Cause	Number of Incidents	Percent of Total Incidents	Property Damage	Percent of Total Damages	Deaths	Injuries
Internal Corrosion	9	3.69	$282,000	0.50	0	0
External Corrosion	38	15.57	$1,833,043	3.25	0	0
Defective Weld	21	8.61	$4,320,680	7.65	0	0
Incorrect Operation	8	3.28	$15,600	0.03	0	0
Defective Pipe	11	4.51	$2,154,000	3.82	0	0
Outside Damage	57	23.36	$35,593,513	63.05	0	1,853
Malf.. of Equipment	22	9.02	$1,159,517	2.05	0	1

V.C.2. Glycol Dehydration - Inlet Separator

The inlet separator removes liquid water, heavy hydrocarbons, brine solution, and particulate matter such as sand, pipeline scale, and rust, or iron sulfide from the incoming natural gas. The vessel is typically sized on the basis of operating pressure and gas throughput to ensure that adequate separation occurs and carryover is prevented. The liquid level must be regulated or checked regularly so that plugs or upsets do not result in carryover; one way to do this is to install a high-liquid-level shutdown. The liquid drain line should be protected from freezing; if this line is frozen or plugged, the separator will not remove any liquids. A mist eliminator in the top of the separator is usually sufficient to reduce or prevent the carryover of liquid droplets and particulate matter, although a filter may be required if aerosols or compressor oils are present in the gas stream.

The inlet separator is considered by many to be the most important part of a glycol unit, because a properly designed inlet separator can eliminate many downstream problems. If the inlet separator is undersized or poorly designed, contaminants may be carried over into the absorber, resulting in the following problems in downstream equipment:

- Free liquid water may enter the absorber and overload the glycol in the absorber, which may prevent the gas from being dried to pipeline specifications.
- Hydrocarbon contamination of the glycol may cause foaming.
- Heavy hydrocarbons may foul the heat exchange surfaces in the reboiler, resulting in poor heat transfer, localized thermal degradation of the glycol, inadequate glycol regeneration, and eventual fire tube failures.
- Sodium chloride and calcium chloride may enter the system. Sodium chloride often precipitates in the reboiler, calcium chloride precipitates in the coldest portions of the system such as the absorber. Salt contamination may ultimately necessitate replacement of the glycol.

V.C.3. Breakout Tank Leakage

Leaking above ground storage tanks pose several environmental problems. First, leaking above ground tanks can seriously contaminate groundwater, often making it impossible to ever return the groundwater to drinking water standards. Groundwater is a source of drinking water for over half the country; in rural areas, nearly all residents drink water from groundwater wells. Pipeline-related facilities are frequently located in populated areas that may rely on groundwater for drinking. Leaking tanks can also pose health and fire hazards to nearby buildings or infrastructures such as sewers, since gaseous components can migrate into these enclosed areas and concentrate to toxic or combustible levels.

VI. POLLUTION PREVENTION/WASTE MINIMIZATION

VI.A. Introduction

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways, such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasibly. In the waste management hierarchy, if source reduction is not feasible the next alternative is recycling of wastes, followed by energy recovery, and waste treatment as a last alternative.

In order to encourage these approaches, this section provides both general and company-specific descriptions of pollution prevention activities that have been implemented within the pharmaceutical industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can be, or are being, implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must be examined to determine how each option affects air, land and water pollutant releases.

VI.B. Rail Transportation

VI.B.1. Water Discharge

At locomotive maintenance facilities, eliminating water from the clean up processes may enable a facility to seal off the floor drains and attain zero discharge. Spent solvents and cleaning solutions are often toxic and/or hazardous and should be disposed of in an environmentally safe manner rather than by pouring them into the storm drain or waste water line. If hazardous cleaning agents (e.g., solvents) are used, care should be taken to wear protective safety gear and follow good housekeeping practices (e.g., clear labeling of all chemicals and wastes to avoid misuse and potential injury or contamination).

If a discharge is going to a wastewater treatment facility, it should be pretreated. Pretreatment means reducing the amount of pollutants in a discharge before it proceeds to a municipal wastewater treatment plant. If waste water is discharged directly or indirectly (i.e., via percolation or injection wells) into a stream, a facility must obtain and comply with the terms of an NPDES or State permit.

When disposing of wastewater, the following activities will foster pollution prevention:

- If a municipal treatment plant is not available, or it will not accept the waste, route the waste to a tank or container for proper accumulation, treatment, and disposal.

- Keep wastewater from service bays out of storm drains by constructing berms around hazardous material storage areas to keep spills from leaving the storage area.

- Do not discharge industrial wastes to septic systems, drain fields, dry wells, cesspools, pits, or separate storm drains or sewers. Facilities that use these types of disposal systems may be in violation of Federal, State, or local requirements.

- If there is a floor drain in the facility, it should be plumbed to an oil/water separator or appropriate wastewater treatment facility.

- Alternatives to water cleaning include recycled solvents in self contained solvent sinks. Dry cleaning can include cleaning by wire brush or bake oven.

Waste minimization in equipment cleaning may be achieved by reducing the amount of water used to clean large equipment. A reduction in water usage will translate into a reduction in the volumes of generated waste waters.

Axle protective coatings can be removed with 140 solvent or a similar non-hazardous or aqueous solvent to avoid hazardous waste generation. The use of hazardous cleaning compounds in outdoor large equipment cleaning can also be avoided by using a detergent/water mixture or steam. In these processes, waste waters must be channeled properly for treatment or disposal.

For small cleaning operations, it is possible to switch from hazardous organic-based to non-hazardous aqueous-based solvents. This will reduce the amount of hazardous waste generated from cleaning operations. Solvent recycling can also decrease hazardous waste production from small parts cleaning.

Spent solvents can be cleaned and recycled with a solvent still. Spent solvent, if hazardous, must be treated and disposed of as hazardous waste, unless recycled properly. Solvents should not be poured down sewer drains, mixed with used oil, or stored in open containers that allow them to evaporate. Certain aqueous parts washers can use detergents instead of solvents.

VI.B.2. Oil

Most facilities in the rail industry recycle used oil. Recycling used oil requires equipment like a drip table with a used oil collection bucket to collect oil dripping off parts. Drip pans can be placed under locomotive or rail cars awaiting repairs in case they are leaking fluids. Some facilities use absorbent materials (e.g., pigmat) to catch drips or spills during activities where oil drips might occur. One facility has established a reuse system for its waste oil: waste oil is transported to another facility where it is used for fuel. This method decreased disposal and heating costs while reducing landfill waste loads. Used oil burning of this nature has permitting implications that a facility needs to follow. Used oil burning can also occur in on-site space heaters under certain circumstances. Recycling used oil by sending it to a commercial recycling facility saves money and protects the environment. To encourage recycling, the publication "How To Set Up A Local Program To Recycle Used Oil" is available at no cost from the RCRA/Superfund Hotline at 1-800-424-9346 or 1-703-412-9810.

Another pollution prevention alternative some railroads have initiated is the use of retention tanks on locomotives. Locomotive retention tanks catch leaking oil from the engine compartment. The tanks are subsequently drained to an appropriate waste treatment facility during routine maintenance and servicing.

Spent petroleum-based fluids and solids should be sent to a recycling center wherever possible. Solvents that are hazardous waste must not be mixed with used oil, or, under RCRA regulations, the entire mixture may be considered hazardous waste. Non-listed hazardous wastes can be mixed with waste oil, and as long as the resulting mixture is not hazardous, can be handled as waste oil. All used drip pans and containers should be properly labeled.

A Material Safety Data Sheets (MSDS) logbook should be kept in a central location and be easily accessible during an emergency. Along with MSDS's, an emergency response plan should posted at all times and each employee should know where it is and what procedures are included in it. All employees should be aware of and understand the properties and potential adverse effects of the materials they handle.

Facilities should conduct audits of the spill possibilities at their facilities. Spills can be avoided by determining those locations and situations where spill events are likely to take place and making employees aware of them. Some facilities have posted signs at likely spill locations or conducted training with their employees on spill awareness and preparedness. In addition, MSDS sheets can be centralized for easy access in case of a spill event. A folder or binder can be used for this purpose and should be maintained by a designated MSDS collection person.

VI.B.3. Waste from Maintenance and Repair Operations

Batteries may be recycled through suppliers. Batteries should be stored in an open rack or in a water tight, secondary containment area like a concrete bin with sealer on the floor and walls. Batteries should be inspected for leaks and/or cracks as they are received at the facility. Acid residue from cracked or leaking batteries is likely to be hazardous waste under RCRA because it is likely to demonstrate the characteristic of corrosivity, and may contain lead and other metals. Many waste batteries must therefore be handled as hazardous waste. Lead acid batteries are not considered a hazardous waste as long as they are recycled. Facilities have many battery disposal options: recycling on site, recycling through a local rail facility, recycling through a supplier, or direct disposal. Facilities should explore all options to find one that is right for the facility. In general, recycling batteries may reduce the amount of hazardous waste stored at a facility, and thus the facility's responsibilities under RCRA. The following best management practices are recommended when sorting used batteries:

- Palletize and label them by battery type (e.g., lead acid, nickel, and cadmium)
- Protect them from the weather with a tarp, roof, or other means
- Store them in an open rack or in a water tight secondary containment unit to prevent leaks
- Inspect and document them for cracks and leaks as they come in to your storage program. If a battery is dropped, treat it as if it is cracked
- Avoid skin contact with leaking or damaged batteries
- Neutralize acid spills and dispose of the resulting waste as hazardous if it still exhibits a characteristic of a hazardous waste.

Coolants for locomotives are not glycol based, but are a nitrate-based corrosion inhibitor in water. These type of waste coolants can be disposed to most POTWs. Though much of the activities associated with vehicles takes place at off-site service centers, some maintenance is performed on this type of equipment, where coolants from maintenance vehicles and fleet vehicles should be collected and recycled and not mixed with locomotive coolant. Solvents containing chlorinated hydrocarbons should be stored in separate containers and disposed of properly. When possible, coolant should be discharged when the locomotive has stopped and is at a location where the coolant can be collected and managed. Locomotive operators should be familiar with the spill reporting requirements of the States in which they operate, and act accordingly when a coolant discharge takes place.

Metal scrap from old machine parts that is likely to be contaminated with oil (e.g., wheel truing scrap), should be stored under a roof or covered with tarpaulin to protect it from the elements. This scrap metal should also be protected from rain water to eliminate the potential of contaminated runoff. Metal scrap can be recycled if sorted and properly stored. Labeled recycling containers can be placed around the shop for easy access and later sorting.

Liquid drum containers, if stored outdoors, should be in a berm and on a paved impermeable surface or in a secondary containment unit to prevent spills from running into water bodies.

Metal filings from parts machining should be collected and recycled if possible. In no case should the filings be allowed to fall into a storm drain.

VI.B.4. Paint

To reduce the amount of wastes created by painting operations, all paint should be used until containers are completely empty. "Empty" containers of latex paint may be disposed of as solid waste. Used containers of hazardous substances may need to be disposed of as hazardous wastes, if they are not completely empty. To prevent environmental problems, it is possible to switch from hazardous organic-based to non-hazardous aqueous-based paints. Also, paint may be purchased in recyclable and/or returnable containers to reduce disposal costs.

VI.B.5. Fueling

Self-locking fueling nozzles minimize the risk of both fuel spillage and air pollution by ensuring a secure seal between the fuel source and tank. During locomotive fueling, personnel should look for fuel drippage and spillage. Catchment pans on either side of and between the rails will collect fuel spills and prevent soil contamination. These pans should be drained to an oil-water separator or retention tank. These pans can be cleaned periodically by railroad personnel to remove fuel debris and accumulated wastes for proper disposal. In case of a spill, facilities should keep the following on hand: absorbent booms, pads, or blankets to help contain spills and soak up pooling liquid; rubber gloves and boots; and a shovel.

VI.C. Trucking

VI.C.1. Truck Terminal and Maintenance Facilities

Trucks require regular changing of fluids, including oil, coolant, and others. To minimize releases to the environment, these fluids should be drained and replaced in areas where there are no connections to storm drains or municipal sewers. Minor spills should be cleaned prior to reaching drains. Used fluids should be collected and stored in separate containers. Automotive fluids can often be recycled. For example, brake fluid, transmission gear, and gear oil are recyclable. Some liquids are able to be legally mixed with used motor oil which, in turn, can be reclaimed.

During the process of engine and parts cleaning, spills of fluids are likely to occur. The "dry shop" principle encourages spills to be cleaned immediately, without waiting for the spilled fluids to evaporate into the air, be transmitted to land, or to contaminate other surfaces. The following techniques help prevent spills from happening:

- Collect leaking or dripping fluids in designated drip pans or containers. Keep all fluids separated so that they may be properly recycled.
- Keep a designated drip pan under the truck while unclipping hoses, unscrewing filters, or removing other parts. The drip pan prevents splattering of fluids and keeps chemicals from penetrating the shop floor or outside area where the maintenance is taking place.
- Immediately transfer used fluids to proper containers. Never leave drip pans or other open containers unattended.

Radiator fluids are often acceptable to antifreeze recyclers. This includes fluids used to flush out radiators during cleaning. Reusing the flushing fluid minimizes waste discharges. If a licensed recycler does not accept the spent flushing fluids, consider changing to another brand of fluid that can be recycled.

If the maintenance facility services air conditioners, special equipment must be used to collect the Freon or other refrigerant because it is not permissible to vent the refrigerant to the atmosphere. Reusing the refrigerant on site is less costly than sending the refrigerant to an off site recycler.

VI.C.2. Vehicle Washing

Vehicle washing has become a major environmental compliance issue for most companies that operate a fleet of vehicles. The following pollution prevention activities will help ensure that a facility is addressing potential sources of pollution:

- Waste water discharge can be prevented by dry washing vehicles using a chemical cleaning and waxing agent, rather than detergent and water. The dry washing chemical is sprayed on and wiped off with rags. No waste water is generated. Dry washing is labor intensive and creates solid waste that must be disposed of properly.

- Waste water can be contained by washing at a low point of the facility, blocking drains from the facility using a containment dike or blanket, or washing on a built-in or a portable containment pad.

- Waste water can be disposed of by evaporation from the containment area, or by discharging the waste water to a sanitary sewer system. (Pretreatment of waste wash water generated from manual washing before disposal to the sanitary sewer is not usually required for vehicle exterior (no undercarriages or engines) washing. Permission must be obtained from the sewer district before waste wash water can be drained, pumped, or vacuumed to a sanitary sewer connection.

VI.C.3. Stormwater Pollution Prevention

Under the Clean Water Act NPDES requirements, discussed in more detail below, truck maintenance facilities must maintain a stormwater pollution prevention plan. The following information is taken from *Stormwater Pollution Prevention Plan for the Trucking Industry*, American Trucking Associations, 1993.

An effective pollution prevention plan for trucking facilities strives to prevent pollution at the source, before it enters the environment. This is best done by properly addressing the following potential sources of pollution:

- Underground and above ground storage tanks of petroleum fuel

- Drips, spills, and releases from fueling operations

- Routine maintenance, including tire, battery, fluids, and oil changes

- Containers of antifreeze, solvents, used oil, and other liquid wastes

- Management of shop drains (sometimes connected to an oil-water separator) which may accumulate oil, grease, and other shop wastes

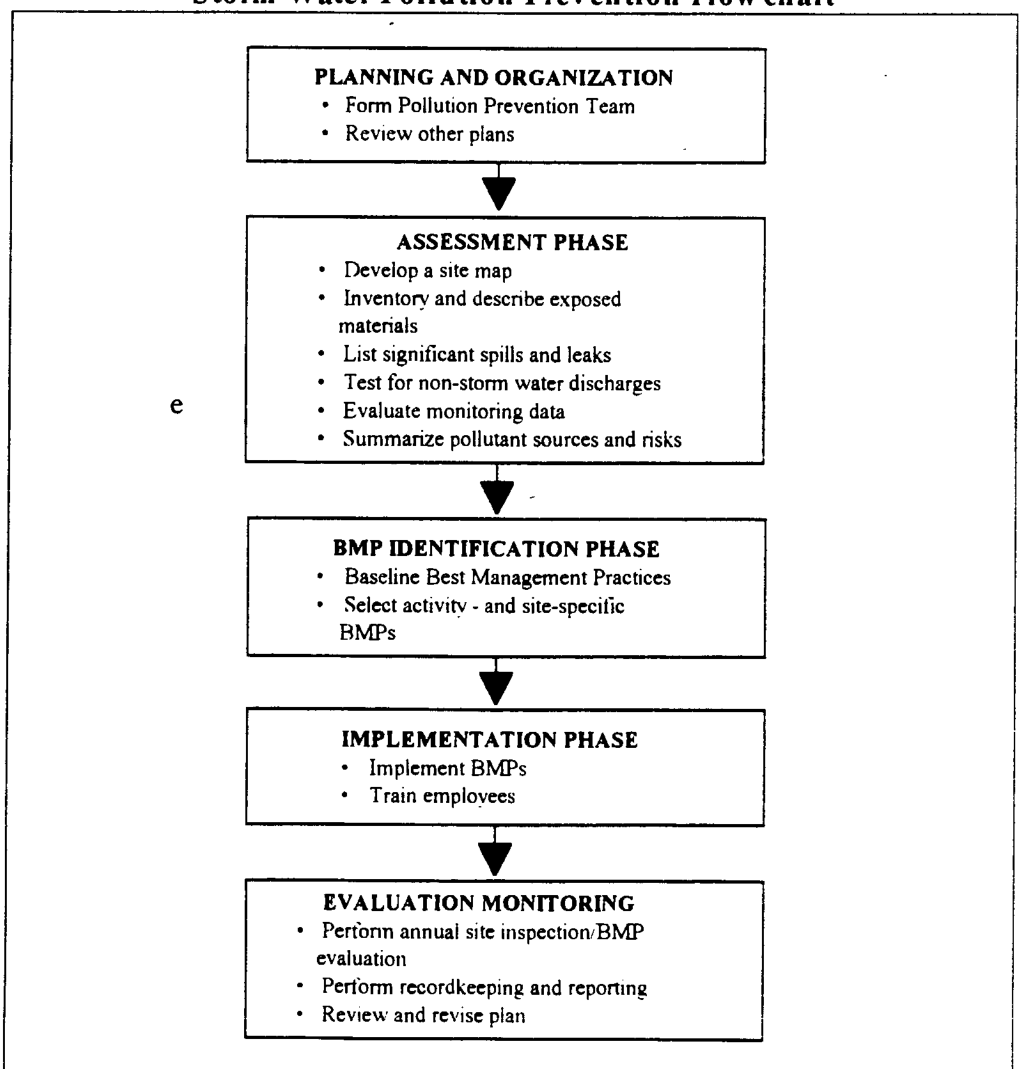
- Vehicle washing operations

- Storage of scrap tires and batteries.

The American Trucking Associations has developed a flowchart, duplicated as Exhibit 21, that directs the attention of facility managers to the sources of environmental contamination, and alerts them to the practices that best ensure

Exhibit 21
Storm Water Pollution Prevention Flowchart

EXHIBIT 21
Storm Water Pollution Prevention Flow chart



Source: Stormwater Pollution Prevention Manual for the Trucking Industry, ATA, 1995.

VI.C.4. Alternatively-Fueled Vehicles

One way to reduce vehicle emissions from the trucking industry is to switch to alternative fuels. Natural gas vehicles, for example, are a viable alternative to gasoline-and diesel-powered transportation. Almost any gasoline- or diesel-powered vehicle can be converted to run on natural gas including, light-duty trucks and vans, medium-duty trucks, and even heavy-duty trucks such as semi-tractors. Converting a gasoline-powered vehicle to run on natural gas involves installing a natural gas fuel system and storage tanks without removing any existing equipment. Diesel conversions are somewhat more complicated because they also involve reducing compression and adding a sparked-ignition system. Other fuels suitable for trucks can include methanol, ethanol, and propane.

Some of the momentum to switch to alternative fuels such as natural gas is coming from legislation. Over the past few years, Congress has passed even stricter clean-air laws, as well as incentives to encourage the use of alternative fuels. Federal (and in some areas State) tax deductions for Alternative Fuel Vehicles (AFVs) and related refueling equipment are available. The maximum tax deductions range from $2,000 to $50,000 for each AFV and up to $100,000 on refueling stations. Deductions on vehicles, including original equipment manufactured vehicles or after-market conversions, apply to the incremental cost of an AFV over the cost of its gasoline or diesel counterpart. The deduction for AFVs can be taken by either an individual or a business, but the deduction on refueling equipment applies only to businesses.

VI.D. Pipelines

VI.D.1. Direct Leak Detection Enhancements

Direct leak detection is typically performed by line patrols who inspect the pipeline right-of-way for pools of leaking product and dead vegetation. Section 195.412 of the Federal pipeline safety regulation requires that hazardous liquid pipelines be patrolled 26 times each year. A new technology for direct leak detection is chemical sensing cable buried along the pipeline right of way. Some cable systems can detect the presence and location of hydrocarbon vapors. Other cables locate leaks by absorbing liquids, which results in a loss in the cables' electrical conductivity at an identifiable location. Sensing cables can offer superior detection times, sensitivity, and location accuracy, especially in gathering lines, where the flows can be too irregular for other methods. These cables must be buried close to the pipeline to work well, and some liquid sensing cables must be dug up and replaced after every detection. New burying methods are being developed for these cables to lower their operating cost.

VI.D.2. Supervisory Control and Data Acquisition (SCADA) Systems

The traditional inferential method of leak detection is called line balance, where one measures the volume of product sent into the pipeline and compares it with the volume that comes out the other end. Enhancement of this method and others are used by SCADA and LDS systems to provide the dispatcher with information that suggests a possible leak. SCADA systems give pipeline dispatchers the ability to effectively monitor pipeline conditions and control a pipeline's operation from a central location. SCADA systems include pipeline sensing devices, a communications network, a centralized or distributed data processing system, and a user interface for the dispatcher.

SCADA systems continuously monitor, transmit, and process pipeline information for the control room dispatcher. Monitoring is conducted using Remote Terminal Units (RTUs), which are placed at intervals along the pipeline and at associated facilities, such as pump stations and delivery terminals. RTUs periodically collect data from field instruments, which measure pressure, temperature, flow, and product density. RTUs can also receive information from vapor detectors and tank level gauges in pipeline system routing and storage areas. RTUs process this information to varying degrees and transmit it for analysis to a central computer through a communications network. Information from RTUs may be transmitted by company-owned lines, by a commercial telephone service, or by using ground- or satellite-based microwave or radio communication.

The leak detection capabilities of most SCADA systems can be enhanced with additional leak detection software and user interfaces. Field instruments specifically designed for leak detection are also available for SCADA systems, such as acoustic sensors and hydrocarbon cables.

VI.D.3. Hydrostatic Testing

Pipeline and utility companies test the pipes that comprise their system both before they are buried and when they suspect that a section of pipe may need maintenance. Hydrostatic testing is the process of filling a section of pipe with water and pressurizing it to a level above normal operating levels. This verifies the integrity of the pipeline.

Depending on the location of the pipeline, the water used in a hydrostatic test is drawn from a local river, stream, or lake; taken from municipal supplies; or trucked to the site. After air is bled from the pipeline, a pump raises the pressure inside the pipe to the pre-determined testing level, where it is maintained and monitored during the test period. Precision measurement instruments are used to monitor pressures, and a record is maintained to chart the results.

VI.D.4. Cathodic Protection

Corrosion in pipelines is a common phenomenon, and must be controlled to effectively prevent pipeline leaks or structural problems. Although modern pipes are constructed of high quality steel, this will nevertheless corrode over time. Corrosion results from an electrical current that naturally flows from a pipe into the surrounding soil. As this occurs, metal loss, or corrosion, results.

One way to impede this process is to insulate the metal from the soil. This occurs in the manufacturing process, when the pipe is coated. The coating is rechecked at the construction site using a detector that looks for imperfections or gouges that could occur during transportation. New coating is then applied at the welded joints between pipe sections, first by sandblasting the weld, and then applying the new coat.

To further protect the pipeline from corrosion, anodes or "ground beds" are constructed at strategic points along the pipeline. These groundbeds provide cathodic protection by inducing a very small electrical charge into the soil. impeding the flow of electrons to the pipe.

The rectifier that induces the current into the ground bed is regularly checked by pipeline personnel, who ensure that the system is applying sufficient current to maintain cathodic protection to the pipeline. A single 200 foot ground bed can protect as much as 50 miles of pipeline, but the low voltages used does not harm animals or plants in the vicinity.

VI.D.5. Smart Pigs

Surveying a working pipeline for damage or corrosion can be disruptive to consumers if sections of the pipeline must be taken out of service. One nondestructive method of evaluation is a device called a smart pig. Smart pigs are designed for use inside larger operating pipelines (as opposed to smaller distribution lines) to identify possible corrosion defects or abnormalities. Smart pigs are self-contained units consisting of three to five sections held together by universal joints, allowing them to negotiate bends in the line. A typical pig will have a recorder section for storing survey data, a magnetic section that creates the magnetic field used to measure pipeline flaws, and a drive section holding the battery power for the unit. Around the perimeter of the pig are the transducers that measure the fluctuations in the magnetic field indicating possible wall abnormalities.

The smart pig is placed into the pipeline at a pig launcher, which is a spur off the mainline. Once the pig has been loaded, the launcher is pressurized so that the pig enters the mainline. The pig will travel between five to ten miles per hour while collecting data about the pipeline. To enable the pig to record its location while gathering data, devices called above ground markers (AGMs) are placed at regular intervals along the surveyed pipeline.

The pig is removed from service at a pig trap or receiver. Crews prepare the receiving site with a catch pan to collect pipeline liquids pushed ahead of the pig. After removing the pig and placing it back into a holding trough, survey personnel remove the tape recorder and download its records. The tape is placed onto a special playback machine that feeds the data into instruments that analyze the information and print out a log revealing information like the location of potential corrosion sites or other anomalies not recognizable by above-ground inspection methods.

VI.D.6. Breakout Tanks

To prevent spills and leaks, above ground tanks should have secondary containment underneath tank bases and piping (or move piping above ground for daily visual inspection) to capture any releases before soil or groundwater is contaminated. Corrosion protection should be added to tank bottoms. Regular groundwater water monitoring should be employed and baseline measurements should be taken at the time of installation.

VI.D.7. Proper Training

In a DOT study of remote control spill reduction technology, most pipeline operators interviewed felt that the critical link in reducing the number of incidents and the volume of pipeline spills lies with dispatcher training. They frequently indicated that there was no substitute for a well-trained dispatcher, especially not a software unit designed to automatically shut down the pipeline. The dispatcher is often the final decision-maker in the process of leak detection and pipeline shutdown. If dispatchers fail to recognize a problematic situation and fail to intervene, unchecked spills are likely to be large.

VII. Summary of Applicable Federal Statutes and Regulations

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section VII.A contains a general overview of major statutes
- Section VII.B contains a list of regulations specific to this industry
- Section VII.C contains a list of pending and proposed regulations.

The descriptions within Section VII are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarification of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other State or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VII.A. General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities must obtain a permit either from EPA or from a State agency which EPA has authorized to implement the permitting program if they store hazardous wastes for more than 90 days before treatment or disposal. Facilities may treat hazardous wastes stored in less-than-ninety-day tanks or containers without a permit. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 States and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

Identification of Solid and Hazardous Wastes (40 CFR Part 261) lays out the procedure every generator must follow to determine whether the material in question is considered a hazardous waste, solid waste, or is exempted from regulation.

Standards for Generators of Hazardous Waste (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

Land Disposal Restrictions (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet LDR treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

Used Oil Management Standards (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil), additional tracking and paperwork requirements must be satisfied.

RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities that store such waste, including large quantity generators accumulating waste prior to shipment off-site.

Underground Storage Tanks (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that must be met by December 22, 1998.

Boilers and Industrial Furnaces (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law known commonly as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National

Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as removals. EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

EPCRA §302 requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

EPCRA §304 requires the facility to notify the SERC and the LEPC in the event of a release equaling or exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

EPCRA §311 and §312 require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

EPCRA §313 requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, known commonly as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The National Pollutant Discharge Elimination System (NPDES) program (CWA §502) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized 42 States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set the conditions and effluent limitations on the facility discharges.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated the NPDES storm water permit application regulations. These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, consult the regulation.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing, 32 (except 323)-stone, clay, glass, and concrete, 33-primary metals, 3441-fabricated structural metal, and 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national pretreatment program (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention, Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities that could reasonably be expected to discharge oil in harmful quantities prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR §112.20) and for PCB transformers and PCB-containing items were revised and finalized in 1995.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, volatile organic compounds (VOCs), ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under section 110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and may go into effect as early as late 1997.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title I, section 112(c) of the CAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV of the CAA establishes a sulfur dioxide nitrous oxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs) and chloroform, were phased out (except for essential uses) in 1996.

EPA's Clean Air Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities (www.epa.gov ttn then select Directory and then CATC).

R0075348

VII.B. Industry Sector Specific Regulations

The transportation industry is regulated by several different Federal, State, and local agencies. As noted earlier, several government entities regulate specific transportation sectors. For example, the Department of Transportation's (DOT's) Research and Special Program Administration is designed to ensure the safe, reliable and environmentally sound operation of the nation's pipeline transportation system. The DOT has traditionally established national standards that are not affected by local or State laws.

EPA has traditionally relied on delegation to States to meet environmental standards, in many cases without regard to the methods used to achieve certain performance standards. This has resulted in States with more stringent air, water, and hazardous waste requirements than the Federal minimums. This document does not attempt to discuss State standards, but rather highlights relevant Federal laws and proposals that affect the rail, trucking, and pipeline industries.

VII.B.1. Rail Transportation

RCRA

Railroad facilities produce a variety of RCRA regulated wastes in the course of normal operations and utilize underground storage tanks for product and fuel storage. Many railroad facilities qualify as hazardous waste generators under RCRA law. Under RCRA, it is the facility's responsibility to determine whether or not a waste is hazardous. See 40 CFR 261.31 - 261.33 for a full list of EPA hazardous wastes.
Some examples of hazardous wastes produced during railroad operations include solvent residues from parts cleaning and spent nickel cadmium batteries. Used oil is currently not listed as a hazardous waste under RCRA; however, if used oil meets one of the hazardous waste characteristics (e.g., ignitable) or is mixed with a listed hazardous waste, it must be stored and disposed of as a hazardous waste. Most waste oil generated by a railroad (e.g., spilled diesel fuel, motor oil) is not a hazardous waste, but cutting oil, hydraulic oils, and any oil containing heavy metals may require hazardous waste handling.

Potential RCRA hazardous wastes generated during railroad operations include:

- Absorbent materials contaminated with hazardous substances
- Aerosol cans, still pressurized
- Cutting oils, hydraulic oils, and oil with heavy metals contamination
- Grit blast wastes
- Ignitable paint thinners
- Lead-based or ignitable paint and related wastes
- Lead acid batteries, non-recycled
- Nickel cadmium, nickel iron, and carbonaire batteries
- Oil filters constructed with "terne"metal (a lead-tin alloy)
- Solvents and solvent sludge.

Clean Water Act

The CWA is set up to regulate two types of water pollution: one from a point source (e.g., an outflow pipe from a parts-washing basin), the other from a non-point source (e.g., non-drained ground where oil has dripped). The CWA applies to a variety of railroad operations. Any railroad operation that produces a wastewater (e.g., locomotive, rail car, and small parts washing) or deposits substances on the ground that may be carried away by stormwater (e.g., fuel and oil spills), will trigger CWA requirements.

The CWA requires the following from railroads:

- NPDES or POTW permits
- Stormwater discharge permits
- Spill prevention control and countermeasure (SPCC) plans and spill reporting.

Exhibit 22
Clean Water Act Requirements Applicable to Railroads

NPDES Permits	Stormwater Discharge Permits	SPCC Plans and Spill Reporting
• Sets limits on volume and nature of discharge • Sets limits on quantity of certain pollutants • Contains monitoring and reporting requirement • *Note: facilities discharging to POTW's do not require NPDES permits.*	• For certain industrial facilities, required if stormwater drains to a municipal separate storm sewer system or directly to receiving water • Required for facilities involved in vehicle maintenance or equipment cleaning • Site maps, drainage and discharge structures, and other information required by permit applications	• Triggered by oil or petroleum product storage in excess of 660 gallons in a single tank or 1,320 gallons in aggregate at facility • Local environmental representatives to be contacted in case of discharge • Documentation of storage vessels, types of containment, emergency equipment available, etc.

The CWA also requires facilities to develop SPCC plans for petroleum products, such as oil, if they are stored in large quantities at a particular railroad. SPCC plans document the location of storage vessels, types of containment, dangers associated with a major release of material from the tanks, types of emergency equipment available at each site, and procedures for notifying the appropriate regulatory and emergency agencies. No SPCC plan is considered complete until it has been reviewed and certified by a Registered Professional Engineer.

Clean Air Act

The CAA establishes two major categories for air pollution regulation: mobile sources (e.g., automobiles, locomotives) and stationary sources (e.g., power boilers, solvent-based cleaning stations). Possible air pollution sources for the railroad industry include boilers, incinerators, forges, foundries, painting or refinishing operations, shop blasting and dust collection control systems, degreasers, and the filling and maintaining of fuel storage tanks.

The CAA regulations on chlorofluorocarbons (CFCs) and asbestos-containing materials also affect railroad operations. Equipment containing CFCs, such as refrigeration units or air conditioning systems, are common. In addition, many old railroad facilities have asbestos-containing materials in floor tiles, ceiling tiles, siding, or thermal system insulation.

Title II of the 1990 CAA Amendments deals with "mobile sources" and seeks to phase in a new set of limits on emissions between 1994 and 1998. If necessary, the EPA has discretion to implement an additional round of mobile source emission limits in 2003.

Section 213(a)(5) of the CAA requires EPA to regulate emissions from locomotives. EPA is expecting to propose locomotive emission regulations in the latter part of 1996 and issue final regulations in the latter part of 1997. The final regulations are expected to impose emission limits on remanufactured and new locomotives.

TSCA

Railroad operations may be affected by TSCA with respect to electrical equipment, such as transformers, containing PCBs. TSCA regulations require proper use, inspection, labeling and marking, recordkeeping, storage, reporting, transportation, management, and disposal of all equipment containing PCBs.

CERCLA

Under CERCLA, incidents must be immediately reported when any spill or release exceeds the Reportable Quantity (RQ). Such a release must be reported if it:

- Occurs on a railroad's property.
- Occurs during transport
- Occurs at a mechanical fixed facility like repair shops or engineering operations.

EPCRA

EPCRA requires companies to identify their facilities to enforcement agencies and provide certain data about the chemicals used at those facilities. EPCRA does not require the reporting of spills that are confined to the boundaries of a facility. All railroads with fixed facilities should maintain Material Safety Data Sheets (MSDSs) for the materials used or stored at the facility. Hard copies should be kept at the facility's site or be available by computer or fax. The transportation of hazardous materials and storage incident to such transportation is exempted from EPCRA requirements.

FIFRA

FIFRA regulations are applicable to railroad operations where herbicides are used to control weeds and brush, or when pesticides and rodenticides are used for pest control in company buildings. FIFRA can also apply to the field application of creosote when bridge timbers or switch ties are installed.

Railroad operations should only apply herbicides, both general and restricted use, according to label instructions. Certification is required for use of restricted use herbicides. Railroads often use outside contractors to apply these products. The National Railroad Contractors Association, an organization comprised of railroad weed control contractors, provides training for restricted use herbicide applicators.

Oil Pollution Act of 1990

See page 84.

VII.B.2. Trucking

Clean Water Act - NPDES Requirements

As discussed above under the general description of the Clean Water Act, EPA published storm water regulations on November 16, 1990, which require certain dischargers of storm water to waters of the U.S. to apply for NPDES permits. According to the final rule, facilities with a "storm water discharge associated with industrial activities" are required to apply for a storm water permit." The rule states that transportation facilities classified as SIC 40, 41, 42 (except 4221-4225), 43, 44, and 5171 which have vehicle maintenance shops, equipment cleaning operations, or airpost deicing operations are considered to have a storm water discharge associated with industrial activity. However, only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airpost deicing operations, or which are otherwise identified under paragraphs (b)(14)(I)-(xi) of section 122.26 are considered to be associated with industrial activity.

Storm water discharges associated with industrial activity that reach waters of the U.S. through municipal separate storm sewer systems (MS4s) are also required to obtain NPDES storm water permit coverage. Discharges of storm water to a combined sewer system or to a POTW are excluded.

The storm water regulation presents two options for storm water discharges associated with industrial activity. The first option is to submit an individual application consisting of NPDES Forms 1 and 2F. The second option is to file a Notice of Intent (NOI) to be covered under a general permit. Regardless of which permit option a facility selects, the resulting storm water discharge permit will most likely contain a requirement to develop and implement a Storm Water Pollution Prevention Plan. Trucking companies which store petroleum products in quantities over 1320 gallons in above ground tanks are also required to develop a Spill Prevention Control and Countermeasures plan (SPCC).

Clean Air Act - Emissions Standards

The most significant CAA regulations under the CAA that affect the trucking industry address mobile source air emissions from truck engines. EPA has set limits on exhaust emissions from new heavy-duty engines. EPA considers heavy-duty truck engines to be those in vehicles weighing at least 8500 pounds gross vehicle weight rating (GVWR). In 1994, the regulations required all heavy-duty truck engines to reduce the emission of nitrogen oxides (NOx) from 5.0g/bhp-hr to 4.0 g/bhp-hr by 1998. Emissions standards are also set for hydrocarbons (HC), carbon monoxide (CO), and particulates (PM). Exhibit 23 displays the past, current, and future emission standards for heavy-duty truck engines.

Exhibit 23
Heavy-Duty Truck Engine Emission Standards
(g/bhp-hr measured during EPA heavy-duty engine test)

Model Year	NOx	HC	CO	PM
1991	6	1.3	15.5	0.6
1994	5	1.3	15.5	0.25
1998	4	1.3	15.5	0.1

Source: Motor Trucking Engineering Handbook. 1994.

CAA regulations mandate the use of alternate fuels for fleets of vehicles in the 8500-26,000 pound class that operate in 22 of the country's most polluted areas. These fleets will be required to purchase 50 percent of their new or replacement vehicles as clean fuel vehicles in any one of the covered areas. Alternative fuels are defined by their ability to reduce NOx and non-methane hydrocarbon emissions by a combined 50 percent from diesel baseline levels. although a 30 percent reduction is permitted if 50 percent is unattainable.

In large part due to the 1993 introduction of congressionally mandated low-sulfur, limited aromatic diesel fuel, manufacturers of diesel engines have been able to closely approach the 1994 emission limits and to focus their efforts on controlling particulates. New engine designs have been used to achieve more efficient and cleaner combustion (*Motor Trucking Engineering Handbook*, James W. Fitch, 1994).

Truck maintenance facilities may face CAA issues for vapor recovery systems on underground fuel tanks, waste oil to energy shop heaters, vehicle painting operations, or CFC recycling and recovery systems.

RCRA

Hazardous waste transportation is a highly regulated and specialized segment of the trucking industry, covered by extensive EPA and DOT regulations. The majority of general freight trucking companies do not transport hazardous waste. Nevertheless, RCRA issues at trucking facilities include several non-transportation activities.

Some fluids used in truck maintenance are considered hazardous waste, requiring specific storage treatment, and disposal. Waste accumulated or generated during trucking maintenance may cause facilities to be considered small or large quantity generators depending on the volume waste. The primary RCRA issues for maintenance facilities are used oil, lead-acid motor vehicle batteries, vehicle maintenance fluids, and scrap tire disposal.

EPCRA

Most trucking companies do not store listed chemicals for use in their facilities. The only exception is diesel fuel or gasoline, which when stored at facilities in quantities slightly over 10,000 gallons, requires reporting to Local Emergency Response Commissions (LERCs) and State Emergency Response Commissions (SERCs). Chemicals in transition are exempt from inventory reporting under EPCRA. This includes all hazardous materials shipments in packages or bulk quantities.

OPA

OPA imposes contingency planning and readiness requirements on certain facilities defined to include rolling stock and motor vehicles. These requirements may affect some trucking establishments.

VII.B.3. Pipelines

Almost all of the petroleum feed stock and products used in the U.S. are, at some point, transported through a Federally-regulated pipeline. The Office of Pipeline Safety (OPS), part of the DOT's Research and Special Programs Administration, regulate essentially all of the approximately 155,000 miles of hazardous liquid pipelines in the U.S., as well as the approximately 255,000 miles of gas transmission lines.

RCRA

Natural gas pipelines do not generate significant quantities of listed hazardous waste. Typical pipeline wastes include condensate, cleaning solvents, and used oil. Each gas pipeline compressor station typically produces an average of 20,000 gallons of used oil each year. This figure depends on the amount of maintenance performed on engines, how often the engines are running, and how much oil is drained from the engines. Under RCRA, used oil is not necessarily a hazardous waste and most gas pipeline companies sell it to refiners.

Water contaminated with constituents of crude oil and petroleum can be regulated under RCRA. Oil pipelines generate hazardous waste when hydrocarbons are mixed with water through pressure testing during installation or through settling in tank bottoms. Oil pipelines can also generate hazardous sludge that results from pigging operations. At pig receipt sites, scraper and cleaning pigs deposit waste materials that often contain hazardous levels of benzene and/or metals.

With regard to storage tanks, RCRA covers hazardous wastes (rather than products) stored in tanks, and such tanks must have secondary containment. EPA has the authority to issue administrative orders requiring cleanup or product releases causing "imminent and substantial endangerment to health or the environment."

OPA

Under the Oil Pollution Act (OPA), the owner or operator of an oil pipeline is liable for removal costs and damages caused by the discharge of oil onto a U.S. shoreline or into navigable waters. The OPA also imposes requirements on affected facilities concerning contingency planning and readiness. Under previous EPA regulations, facilities with the potential to discharge oil were required to have spill prevention, control, and countermeasure (SPCC) plans. Under new requirements, facilities that could be reasonably expected to cause "substantial harm" to the environment by a discharge of oil into navigable waters may be required to adopt such plans.

The DOT's Office of Pipeline Safety (OPS) is responsible for implementing OPA requirements as they apply to onshore oil pipelines that could reasonably be expected to cause significant and substantial harm to the environment by discharging oil into the navigable waters of the U.S. and adjoining shorelines. The OPA applies to all oil pipelines, whether or not they are currently exempt from existing Federal regulations or statutes.

Storage tank facilities that could cause significant and substantial harm to the environment by discharging to navigable water must develop facility response plans and submit them to the Federal government for approval. The act includes extensive liability provisions for spills to navigable waters.

Pipeline Safety Act

Congress passed the Pipeline Safety Act in 1992. The most far-reaching effect of the Act is the expansion of OPS' traditional safety mission to include environmental protection. Major provisions in the Act relate to excess flow valves, cast iron pipelines, gathering lines, customer-owned service lines, underwater inspection and burial, underwater abandoned pipeline facilities, low internal stress pipelines, and emergency flow restricting devices, and contain increased inspection requirements including use of "smart pigs," and operator qualification testing. The Act also provides a statutory basis for the DOT's Research and Special Programs Administration (RSPA), which had been initially established by the Secretary of Transportation in 1977. The RSPA Administrator is to be appointed by the President and confirmed by the Senate.

Natural Gas Pipeline Safety Act and the Hazardous Liquid Pipeline Safety Act

The Natural Gas Pipeline Safety Act (NGPSA) of 1968 provides for Federal safety regulation of pipeline facilities used in the transportation of natural gases. The Hazardous Liquid Pipeline Safety Act (HLPSA) of 1979 provides for safety regulation of pipeline facilities used in the transportation of hazardous liquids. Both provide a framework for promoting pipeline safety through exclusive Federal regulation of interstate pipeline facilities, and Federal delegation to the States for all or part of the responsibility for intrastate pipeline facilities. To provide expertise during development of pipeline safety regulations, NGPSA and HLPSA established two pipeline safety advisory committees, the Technical Pipeline Safety Standards Committee and the Technical Hazardous Liquid Pipeline Safety Standards Committee, respectively. The Committees review proposed regulations for technical feasibility, reasonableness, and practicability. The Committees also provide advice to the DOT on pipeline safety and environmental issues.

TSCA

Some natural gas pipelines used PCBs in their system through the 1980s. PCBs were widely used in transformers, as heat transfer fluids, and in some types of compressor lubricants. In 1989, the Gas Research Institute began a program to deal with the management of PCB residue. The first step involved measuring and analyzing statistical data on PCB contamination of gas transmission pipelines and reviewing remediation programs involving condensate, soil, pipelines, and surface facilities. The Gas Research Institute developed information on physical properties and analytical methods for PCB condensate mixtures, the soil-water partitioning behavior of these mixtures, and an evaluation of the risks associated with typical pipeline operations and PCB abandonment.

CAA

The Clean Air Act affects pipeline system design, operation, and maintenance. Materials such as carbon dioxide, hydrogen sulfide, and mercaptan sulfur are often present in the field gathering systems that move natural gas from wells to processing plants. Pipeline operators must track emissions from compressor and pump stations. Fugitive emissions of benzene from seals on pumps, compressors, valves, meters, and storage tanks must also be evaluated and controlled.

In areas that meet Federal clean air standards, new or modified "major sources" (e.g., tank farms) must install "Best Available Control Technology" (BACT). In areas that do not meet Federal clean air standards, new or modified major sources must utilize "Lowest Achievable Emission Rate" technology, which must be at least as stringent as BACT; existing major sources must utilize designated "Reasonably Available Control Technology," which may be less stringent than BACT. For major sources that emit "Hazardous Air Pollutants," EPA is developing "Maximum Achievable Control Technology" regulations.

CWA

The Spill Prevention Control and Countermeasures (SPCC) program covers petroleum above ground tank facilities that may affect "navigable waters." The SPCC program requires reporting of spills to navigable waters and development of contingency plans that must be kept on-site. EPA has the authority to issue administrative orders requiring cleanup.

SDWA

Regulations promulgated under the Safe Drinking Water Act classify underground injection wells according to the type of operation or substance involved. 40 CFR §144.6(b) describes Class II injection wells as those which inject fluids:

- Which are brought to the surface in connection with natural gas storage operations, or conventional oil or natural gas production and may be commingled with waste waters from gas plants which are an integral part of production operations, unless those waters are classified as a hazardous waste at the time of injection.
- For enhanced recovery of oil or natural gas; and
- For storage of hydrocarbons which are liquid at standard temperature and pressure.

Many wells associated with the oil and gas industry, including salt water injection wells, enhanced recovery wells, and wells injecting liquid hydrocarbons for storage, are likely to be regulated under the Underground Injection Control (UIC) program.

Under the UIC, wells are required to obtain and adhere to the requirements of operating permits. The permit application must prove to the permitting authority (usually the State) that operation of the underground injection well will not endanger drinking water sources. Class II permits are issued for the life of the well, but can be reviewed every five years.

VII.C. Pending and Proposed Regulatory Requirements

Regulations are currently under development for the transportation equipment cleaning industry. These regulations, when effective, will impact railroads that clean the interior of tank cars, hopper cars, and box cars, and produce wastewater. If a tank car has carried hazardous materials, its car cleaning waste waters may require proper handling under RCRA in addition to that for normal waste waters due to contamination from leftover tank contents or "heel."

In addition there may soon be an effluent guideline on Metal Products and Machinery, which will apply to the rail industry especially for metal machining shops.

VIII. COMPLIANCE AND ENFORCEMENT HISTORY

VIII.A. Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

VIII.B. Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within

the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (April 1, 1992 to March 31, 1997) and the other for the most recent twelve-month period (April 1, 1996 to March 31, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across EPA Regions for certain sectors.[1] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of

[1] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

records for that facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times, e.g., a facility with 3 enforcement actions counts as 3.

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VIII.C. Industry Sector Compliance History

Exhibits 24-31 illustrate recent enforcement activity within the transportation industry. Of the 12,904 inspections conducted at rail, trucking, and oil and gas pipeline facilities over a five year period, 774, or 6 percent, resulted in enforcement actions. Of the three transportation industries addressed by this profile, the pipeline industry has received greater scrutiny from Federal and State inspectors, although certain portions of the trucking industry have also been subject to environmental compliance inspections. While the greatest number of inspections of rail facilities addressed the CWA, the trucking industry had more RCRA inspections while the pipeline industry was subject to the most inspections under the CAA.

IX. Review of Major Legal Actions

This section provides summary information about major cases that have affected this sector. As indicated in EPA's Enforcement Accomplishments Reports from 1992-1994, several significant enforcement actions were resolved between 1992-1994 involving the rail, trucking, and pipeline industries. Characterizations of the types of enforcement actions taken are provided for each of the cited cases.

IX.A. Review of Major Cases

IX.A.1. Rail

U.S. v. Consolidated Rail Corporation, CAA, 1992

U.S. District Court entered a second amendment to consent order resolving EPA's CAA contempt action against Consolidated Rail Corporation (Conrail). The amendment requires Conrail to pay $165,000 in penalties for past violations. In addition, it allows the company to apply encrusting agents in lieu of water to control fugitive dust. The amendment is based on a consent order EPA and Conrail negotiated in 1986 to resolve violations of Ohio's State Implementation Plan (SIP).

U.S. v. CSX Transportation, CWA, 1993

CSX Transportation signed a consent decree to pay $3.00,000 in civil penalties and perform four Supplemental Environmental Projects (SEPs) valued at $4,000,000 for alleged violations of CWA for exceeding NPDES limits.

Burlington Northern, Multi-media, 1994

EPA Region V sought $279,078 to recover costs incurred consistent with the NCP under CERCLA and OPA, natural resource damages totaling $250,000, and CWA penalties totaling $2,500,000 for three incidents of railroad derailment.

In the matter of Burlington Northern Railroad, EPCRA, 1994

A RCRA consent order was issued for the contamination of groundwater, and a 1993 unilateral administrative order, based on a multimedia inspection, required the defendant to cease discharge of oil and chlorinated waters.

Southern Pacific Transportation Corporation, 1994

A train derailment caused the release of a herbicide into the Sacramento River killing all plant life for 42 miles. The settlement provided for recovery of $36 million in response costs. The decree also required payment of a $500,000 civil penalty (the statutory maximum for the violation). Defendants must also establish a $14 million fund for natural resource damages.

U.S. v. Norfolk & Western Railway Company, 1994

Criminal plea agreement and settlement resulted in the U.S. receiving $500,000 fine and $500,000 restitution. Missouri received $700,000 fine and $1.7 million in restitution, $1 million for creation of a park, and establishment of a $2.2 million environmental awareness program.

IX.A.2. Trucking

U.S. v. The Carborundum Company, et al. , CERCLA, 1994

On March 30, 1994, a consent decree was lodged in the District Court of New Jersey which partially settles Region II's cost recovery claims relating to the Caldwell Trucking Company Superfund site in Fairchild Township, New Jersey. From 1950 through the mid 1970s, Caldwell Trucking hauled septage and other wastes from residential, commercial, and industrial customers and disposed of these wastes in unlined lagoons at the site. The nine settling defendants agreed to pay $2.46 million for EPA's past and future costs and agreed to perform all scheduled remedial and natural resource restoration work at the site, valued at an additional $32 million. New Jersey will also receive its first natural resource damage payment under CERCLA, in the amount of $984,000, and the U.S. Department of the Interior will receive $40,000 for its assessment and monitoring costs.

U.S. v. Gomer's Diesel and Electric Company, RCRA, 1994

Gomer's Diesel and Electric Co., with automotive and truck maintenance facilities located in Belgrade, Great Falls, and Missoula, Montana, was sentenced on March 24, 1994, following a plea of guilty to one-count of unlawful transportation of a hazardous waste in violation of RCRA. The company was placed on supervised probation for two years and fined $100,000, $50,000 of which was suspended in recognition of remediation conducted at its Belgrade facility.

Hamner, Inc., Corpus Christi, CWA, 1994

An administrative Class I complaint was issued against Hamner, Inc. Corpus Christi, Texas, on May 24, 1994, with a proposed penalty of $9,108 for violations of the CWA. The corporation's tanker truck overturned, discharging approximately 24 barrels of petroleum naphtha. The petroleum naphtha entered navigable waters of the U.S. in quantities determined to be harmful. The oil did not enter a major waterway, no drinking water supply was affected, and there were no signs of damage to wildlife or aquatic life. Settlement negotiations are underway.

IX.A.3. Pipelines

U.S. v. Shell Oil Pipeline Corporation, Criminal Enforcement, 1992

Pipeline rupture caused an 860,000 gallon oil spill into the Mississippi, Gasconade, and Missouri rivers. Shell pleaded guilty to violation of the Refuse Act and agreed to pay $8,400,000 in fines, restitution, and settlements.

U.S. v. Texaco, CERCLA, 1993

Texaco entered a consent decree for performance of a remedial design and remedial action at the Pacific Cost Pipeline Superfund site in California. The RA is valued at $4,000,000. Texaco also agreed to reimburse California for response costs, the U.S. for future response costs, and EPA for past RI/FS costs.

U.S. v. Transwestern Pipeline Company, TSCA, 1993

A consent decree was terminated when the defendant met all terms and conditions of settlement (including payment of a penalty of $375,000 and groundwater monitoring). Under the decree, 144,991 tons of PCB contaminated soil and debris were removed and disposed in TSCA landfill.

U.S. v. Tennessee Gas Pipeline Co., CWA, 1993

Court entered final order for dismissal after parties agreed to a penalty of $725,000 for unauthorized discharges of PCBs from a pumping station.

U.S. v. U.S. Oil and U.S. v. Texaco, OPA, 1993

U.S. Oil agreed to pay civil penalties of $425,000 and Texaco agreed to pay $480,000 in penalties. Both were made to acquire and install state-of-the-art spill detection and prevention equipment valued at $800,000 for each company. Both were also required to reimburse for Federal spill response costs of $60,000 and $125,000 respectively. The actions represent the first judicial penalties assessed under OPA.

IX.B. Supplemental Environmental Projects (SEPs)

Below is a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

Exhibit 32 contains a sample of SEPs from the transportation industry. The information contained in the chart is not comprehensive and provides only a sample of the types of SEPs developed for the transportation industry.

Exhibit 32
Supplemental Environmental Projects in the Transportation Industry

Case Name	Statute	Estimated Cost to Company	Environmentally Beneficial Activities
General Chemical Company	CAA	$90,000.	Facility was to purchase and install an Airless Paint Spray Unit and Fanu Robotics Spray Unit in order to reduce total VOC releases to the atmosphere by 10 percent.
Thatcher Chemical Company	EPCRA §304	Not Known	SEP included the construction of a building with scrubbing equipment for enclosing loading products to prevent future releases into the environment to be completed by January 24, 1994.
CSX Transportation	CAA	$ 4,000,000	Company was required to: • Perform NPDES compliance audits at 21 active CSX railroad yards • Conduct multi-media risk assessment audit at 61 inactive facilities • Provide environmental awareness training program for managers • Develop best management practices manual and a seminar on storm water runoff at railroad yards.

X. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. This section of the notebook also contains a listing and description of national and regional trade associations.

X.A. Sector-Related Environmental Programs and Activities

Environmental compliance assurance activities have been conducted by the major trade associations for each of the transportation sectors covered in this report. The following examples represent some of the industry initiatives that promote compliance, or assess methods to reduce environmental contamination.

X.A.1. Rail

Waste Minimization Assessment for a Manufacturer of Rebuilt Railway Cars and Components

U.S. EPA funded a pilot project to assist small- and medium-size manufacturers wishing to minimize their generation of hazardous waste, but lacking the expertise to do so. The Agency established Waste Minimization Assessment Centers (WMACs) at selected universities, adapting procedures from EPA's *Waste Minimization Opportunity Assessment Manual*. The WMAC team at the University of Tennessee inspected a plant that rebuilds approximately 2,000 railway cars each year and that refurbishes wheel assemblies and air brake systems. The team issued a report and made a number of recommendations for minimizing hazardous waste outputs.

X.A.2. Trucking

Consolidated Compliance Reviews

The trucking industry has worked with the Department of Transportation, Federal Highway Administration (FHWA), to develop streamlined processes for conducting compliance reviews. As a result, the FHWA now conducts all record reviews and inspection activities in a "one stop" process.

The original process involved several different inspections. The first type of inspection focused on compliance with ICC rules and operating authority licenses. The second type of inspection focused on safety compliance issues. Additional inspections were conducted to ensure compliance with hazardous materials transportation regulations were added in the 1980's. More recently, driver drug testing was added to the inspection requirements.

DOT-FHWA's compliance review is now conducted with the inspector using a lap-top computer with built in prompters, programs to generate checklists, work sheets, tabulations, and regulations and interpretations. These tools allow the inspector to cover all the components of the inspection in "one stop." The compliance review often occurs at corporate headquarters. The system was developed in 1986; currently, about 200 DOT-FHWA inspectors use the system.

Inspectors receive six weeks of training when they come into the DOT-FHWA, including training on case development, regulations, compliance reviews, and sensitivity. Inspectors do not need permission before entering a facility but usually call in advance so the appropriate staff and records can be available. Unannounced inspections may occur if criminal activity is suspected.

DOT-FHWA inspectors are providing more and more technical assistance to the regulated community. They have education packages on specific issues, such as hazardous materials, and "On Guard" announcements of new safety problems or rules affecting the industry.

Cooperative Hazardous Materials Enforcement Development

The Cooperative Hazardous Materials Enforcement Development (COHMED) program is an outreach activity of the U.S. DOT's Research and Special Programs Administration (RSPA). COHMED works to promote coordination, cooperation, education, and communication for Federal, State, local agencies, and industry having enforcement, response, and management responsibilities for the safe transportation of hazardous materials. Through education and training, COHMED participants are able to improve current programs, and develop new programs to enhance hazardous materials safety.

COHMED conducts semi-annual conferences and hazardous materials seminars. COHMED also publishes a quarterly newsletter, "The Reporter," and the "Bullet" when expedient dissemination of information is required. COHMED participation is open to Federal, State, local agencies, and industry involved in enforcement, emergency response or planning and preparedness. For more information call (202) 366-4900.

CHEMTREC

CHEMTREC is a pubic service organization established by the Chemical Manufacture's Association and its members in 1971 to provide first responders, the transportation industry, medical professionals, and others access to response information and technical assistance from chemical industry experts for incidents involving hazardous materials. The Center is staffed by trained communicators who can contact thousands of chemical manufacturers. shippers, distributors, and carriers. Through these contacts, CHEMTREC can teleconference responders at the scene of an incident with technical experts to provide immediate advice and assistance. CHEMTREC can also immediately provide and transmit, via fax, product Material Safety Data Sheets or other specific product information. The CHEMTREC Center can be reached 24 hours a day, 7 days a week at 1-800-424-9300.

TRANSCAER

TRANSCAER is an outreach program that focuses on assisting communities that do not host a major chemical facility but have major transportation routes within their jurisdiction. TRANSCAER is sponsored by the chemical manufacturing, distribution and transportation industries. TRANSCAER's objectives are to ensure that communities are prepared to handle hazardous materials transportation emergencies and that an ongoing dialogue exists with the public about chemical transportation. The program provides assistance for communities to develop and evaluate their emergency response plan for hazardous material transportation incidents. For more information contact the TRANSCAER Task Group at c/o CMA, 1300 Wilson Blvd., Arlington, VA. 22209.

CMA's Lending Library

Since 1985, the CMA's Lending Library has provided free access to videotape training programs on hazardous materials and handling hazardous materials incidents. Contact the CMA Publication Fulfillment department at (202) 887-1253 for ordering information.

X.A.3. Pipelines

The giant Alaska company Alyeska has undertaken the most expensive corrosion repair program in the industry's history with a campaign to inspect pipelines for corrosion, repair damaged sections, and replace pipe sections as needed. The estimated costs of this effort from 1991-1996 are $600-800 million. External and internal corrosion at some of the 800-mile line's pump stations was discovered with the help of a corrosion detection pig that exceeded Federal standards for corrosion detection and mitigation (U.S. Petroleum Strategies, Bob Williams, 1991).

X.B. EPA Voluntary Programs

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative developed by EPA that focuses on improving environmental performance, encouraging voluntary compliance, and building working relationships with stakeholders. EPA initiated a one year pilot program in 1995 by selecting 12 projects at industrial facilities and federal installations that demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, pollution prevention, community involvement, and mentor programs. In return for participating, pilot participants received public recognition and were given a period of time to correct any violations discovered during these experimental projects.

EPA is making plans to launch its full-scale Environmental Leadership Program in 1997. The full-scale program will be facility-based with a 6-year participation cycle. Facilities that meet certain requirements will be eligible to participate, such as having a community outreach/employee involvement programs and an environmental management system (EMS) in place for 2 years. (Contact: http://es.inel.gov/elp or Debby Thomas, ELP Deputy Director, at 202-564-5041)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline 202-260-8590, Web: http://www.epa.gov/ProjectXL, or Christopher Knopes at EPA's Office of Policy, Planning and Evaluation 202-260-9298)

Climate Wise Program

EPA's ENERGY STAR Buildings Program is a voluntary, profit-based program designed to improve the energy-efficiency in commercial and industrial buildings. Expanding the successful Green Lights Program, ENERGY STAR Buildings was launched in 1995. This program relies on a 5-stage strategy designed to maximize energy savings thereby lowering energy bills, improving occupant comfort, and preventing pollution -- all at the same time. If implemented in every commercial and industrial building in the United States, ENERGY STAR Buildings could cut the nation's energy bill by up to $25 billion and prevent up to 35% of carbon dioxide emissions. (This is equivalent to taking 60 million cars of the road). ENERGY STAR Buildings participants include corporations; small and medium sized businesses; local, federal and state governments; non-profit groups; schools; universities; and health care facilities. EPA provides technical and non-technical support including software, workshops, manuals, communication tools, and an information hotline. EPA's Office of Air and Radiation manages the operation of the ENERGY STAR Buildings Program. (Contact: Green Light/Energy Star Hotline at 1-888-STAR-YES or Maria Tikoff Vargas, EPA Program Director at 202-233-9178 or visit the ENERGY STAR Buildings Program website at http://www.epa.gov/appdstar/buildings/)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program saves money for businesses and organizations and creates a cleaner environment by reducing pollutants released into the atmosphere. The program has over 2,345 participants which include major corporations, small and medium sized businesses, federal, state and local governments, non-profit groups, schools, universities, and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. As of March 1997, participants had lowered their electric bills by $289 million annually. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and an information hotline. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Green Light/Energy Star Hotline at 1-888-STARYES or Maria Tikoff Vargar, EPA Program Director, at 202-233-9178 the)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1997, the program had about 500 companies as members, one third of whom are Fortune 1000 corporations. Members agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports. To member companies, EPA, in turn, provides technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne Oxley, EPA Program Manager, 703-308-0199)

$NICE^3$

The U.S. Department of Energy is administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics ($NICE^3$). By providing grants of up to 45 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, and demonstrate new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the forest products, chemicals, petroleum refining, steel, aluminum, metal casting and glass manufacturing sectors. (Contact: http//www.oit.doe.gov/access/nice3, Chris Sifri, DOE, 303-275-4723 or Eric Hass, DOE, 303-275-4728)

Design for the Environment (DfE)

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202) 260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at http://es.inel.gov/dfe.

X.C. Trade Association/Industry-Sponsored Activity

The trade associations that represent the transportation industry are a valuable source of economic and environmental compliance data. The following subsections list major transportation trade organizations and highlight environmental initiatives sponsored by some of these groups.

X.C.1. Railroad Tank Car Safety Research and Test Project

Since 1970 the Railway Progress Institute (RPI) and Association of American Railroads (AAR) have cosponsored the RPI-AAR Railroad Tank Car Safety Research and Test Project. The purpose of the project, initiated following several fatal tank car crashes in the late 1960s, is to identify and understand the causes of tank car punctures and ruptures in accidents and to develop engineering solutions. Results of this continuing project have led to the development and introduction of several devices to improve tank car crash worthiness, including double-shelf couplers and head and thermal protection systems. In addition, the program has produced a database of more than 35,000 records of tank cars damaged over the past 30 years (*Ensuring Railroad Tank Car Safety*, Transportation Research Board, National Research Council, 1994).

The research conducted on tank car safety has resulted in the implementation of regulation to increase the safety of certain hazardous material cars. DOT HM-175 which was finalized in September 1995, covers a wide range of tank car safety related issues, including new tank car specifications for halogenated organic compounds. This effort has resulted in significantly safer tank cars for these materials.

In addition, there have been several improvements in an industry agreement between the AAR, the Chemical Manufacturers Association (CMA), and RPI, including:

- Thicker tank cars made of stronger steel;
- Elimination of bottom outlets, a common source of releases in accidents; and
- A full height head shield to protect the end of the tank from punctures in accidents.

X.C.2. The North American Non-Accident Release Reduction Program

The North American Non-Accident Release Reduction Program was initiated in June 1995 by the rail industry. A "Non-Accident Release" (NAR) is any unintended release of a hazardous commodity from a railroad car not caused by a train accident. Most NAR's involve small quantity releases, but some have been very costly and all have the potential for serious injury. The North American NAP Program is an awareness campaign designed to alert shippers and carriers to repeated instances of NARs of hazardous commodities from rail tank cars and encourage positive action to prevent recurrence.

General oversight of the NAR Program rests with AAR's Hazardous Materials Working Committee and the NAR General Committee, made up of representatives from shippers, carriers, car owners, and industry associations. The NAR Program has two sub-committees, a Technical Subcommittee and a Communications/Regulatory Subcommittee. The Technical group reviews NAR data and attempts to develop technical solutions to identified problems. The Communications/Regulatory group works on program publicity and government (regulatory) relations.

NAR data is collected by carriers and reported to AAR, who enters it into an NAR database, keeping all business data confidential. When a threshold number of releases has been recorded for any given company, AAR prepares an "action package" outlining the details of each release and forwards the information to a designated individual at that company. Recipients of action packages are encouraged to take whatever actions are appropriate to address the causes of the releases, advising AAR of their response. The NAR General Committee has set a goal to reduce the number of NARs from hazardous materials tank cars in North America by 25 percent over a two year period. The North American NAR Program is an expansion of a successful program started in Canada in 1992. NAR's in Canada were reduced 32% over a two year period after implementation of the program.

X.C.3. Environmental Compliance Handbook for Short Line Railroads

As part of its mandate to clarify and communicate environmental regulatory responsibilities to the freight and rail industry, EPA's Freight, Economy, and the Environmental Work Group has worked with the Federal Railroad Administration (FRA) to prepare a handbook on EPA regulations applicable to short line railroads. The handbook is a "plain English" guide to short line railroad environmental responsibilities and the laws that created them. The handbook also provides State and Federal agency contacts and Hotlines.

X.C.4. Environmental Training Publications and Videotapes

The American Trucking Associations (ATA) has developed numerous documents and videotapes to help those in the trucking industry to better understand applicable environmental regulations and to assist them in compliance. Following is a list of some the materials offered by the ATA. For a more complete catalogue listing these and other products, contact the ATA document center at (800) ATA-LINE.

- *Stormwater Best Management Practices: Guidance for Vehicle Maintenance Facilities (video)* - Identifies practical and effective best management practices that can be used in vehicle washing, fueling, and loading areas.

- *Used Oil: A Guidebook to Best Management Practices* - Helps the user determine the company's responsibilities and develop procedures that are productive, cost-efficient, and in compliance with Federal and State guidelines.

- *Hazardous Waste Regulations for the Trucking Industry* - Outlines and explains hazardous waste regulations as they relate to the trucking industry.

- *Stormwater: Pollution Prevention for the Trucking Industry* - Explains how to write a pollution prevention plan and covers the five general phases of a plan in detail.

- *Vehicle Washing Compliance Manual* - Provides a State-by-State review of applicable regulations affecting vehicle washing and a survey of vehicle washing technology.

X.C.5. Pipeline Integrity Programs - Natural Gas and Hazardous Liquid One-Call Systems

More than 60 percent of pipeline accidents are the result of third-party damage. One-call systems were developed to reduce the number of incidents involving accidental pipeline ruptures.

Contractors and homeowners who work in the vicinity of natural gas and hazardous liquid lines can learn of their location via a single telephone number. This number is supplied in 48 of the 50 States and in Canada by various one-call systems, and is usually posted on pipeline markers along the pipe route.

Each one-call system is an organization funded by member underground utilities. The system acts as a computerized link between people digging around pipelines and the operators of these conveyance systems. When a contractor or homeowner calls the toll-free number, the one-call operator takes information regarding the time and location of planned work and immediately notifies all members with underground facilities in the excavation area.

When a member receives notification of planned excavation in its area, its operators are responsible for determining the potential hazards to the line. If the work does have the potential to affect the pipeline, the company will dispatch crews within 24 to 72 business hours to locate and mark the pipeline's route. After determining the direction and width of the pipe, personnel use a series of flags or spray paint to mark the exact location of the system. If the work will cross the pipeline, crews also test for exact pipeline depth.

X.C.6. Summary of Trade Associations

The trade and professional organizations serving the transportation industry are presented below, classified by industry sector.

Rail

Association of American Railroads 50 F Street, NW Washington, D.C. 20001 Phone: (202) 639-2839 Fax: (202) 639-2465	Members: 64 Staff: 607 Budget: $48,800,000

The Association of American Railroads (AAR) is the coordinating and research agency of the American railway industry. Membership is comprised of the larger, Class I, railroads. Focus areas include: railroad operation and maintenance, statistics, medical problems, cooperative advertising and public relations, rates, communication, safety, and testing of railroad equipment. The AAR was founded in 1934 and maintains a library of current and historical volumes and periodicals. The AAR also operates an on-line database of all railcars, trailers, and containers used in North America called Universal Machine Language Equipment Register. Publications include the quarterly *Official Railway Equipment Register*, the biweekly *Rail News Update*, and the annual *Railroad Facts*. The AAR also publishes studies, statistical reports, and general information publications.

National Railway Labor Conference 1901 L Street, NW, Suite 500 Washington, D.C. 20036 Phone: (202) 862-7200 Fax: (202) 862-7230	Members: 150 Staff: 25 Budget: $4,100,000

The National Railway Labor Conference (NRLC), founded in 1963, serves as a management collective bargaining agency for the railroad industry. NRLC represents railroads as well as switching and terminal companies and compiles statistics on the industry.

Trucking

American Trucking Associations 2200 Mill Road Alexandria, VA 22314 Phone: (703) 838-1844 Fax: (703) 838-1992	Members: 4,100 Staff: 300 Budget: $45,000,000

The American Trucking Associations (ATA), founded in 1933, represents motor carriers, suppliers. State trucking associations, and national conferences of trucking companies. The ATA works to influence the decisions of Federal, State, and local governmental bodies to promote increased efficiency, productivity, and competitiveness in the trucking industries. ATA promotes highway and driver safety, supports highway research projects, and studies technical and regulatory problems of the trucking industry. ATA and its affiliated conferences provide extensive educational opportunities and products to assist trucking companies with safety, OSHA, and environmental regulation. In addition, the association provides members with a guide to Federal and State regulations and offers a comprehensive accounting service for carriers of all sizes. An information center containing numerous ATA and other publications is available to members and the public.

Association of Waste Hazardous Materials Transporters 2200 Mill Road Alexandria, VA 22314 Phone: (703) 838-1703 Fax: (703) 519-1866	Members: 75 Staff: 2

The Association of Waste Hazardous Materials Transporters represents carriers that transport PCBs, used oil, and hazardous and radioactive waste by truck and rail.

National Tank Truck Carriers 2200 Mill Road Alexandria, VA 22314 Phone: (703) 838-1960 Fax: (703) 864-5753	Members: 260 Staff: 7 Budget: $1,000,000

The National Tank Truck Carriers (NTTC) was founded in 1945 and represents common or contract tank truck carriers transporting liquid and dry bulk commodities, chemicals, food processing commodities, petroleum, and related products. NTTC promotes Federal standards of construction, design, operation, and use of tank trucks and equipment. NTTC sponsors schools, conducts research, and produces periodicals, including the annual *Cargo Tank Hazardous Materials Regulations* and *Hazardous Commodities Handbook*

R0075388

Regional and Distribution Carriers Conference 2200 Mill Road, Suite 540 Alexandria, VA 22314 Phone: (703) 838-1990 Fax: (703) 836-6870	Members: 375 Staff: 5

The Regional and Distribution Carriers Conference (RDCC) consists of companies participating in trucking for hire, including local cartage and short haul. RDCC was founded in 1943 and represents motor haul carriers rendering distribution services beyond commercial zones. RDCC is affiliated with ATA and conducts an executive management seminar and exhibit. RDCC produces a monthly newsletter and several informational phamplets.

Interstate Truck Carriers Conference 2200 Mill Road, 3rd Floor Alexandria, VA 22314 Phone: (703) 838-1950 Fax: (703) 836-6610	Members: 800 Staff: 7 Budget: $800,000

The Interstate Truck Carriers Conference (ITCC) consists of contract carriers, irregular route common carriers, shippers, and others related to the motor carrier industry. ITCC was founded in 1983 and serves as an industry spokesperson for this part of the trucking industry. ITCC represents their members' interests before Congress, the Interstate Commerce Commission, and the courts. ITCC is affiliated with ATA and has a refrigerated carrier division as well as a political action committee. ITCC conducts a management development seminar at Notre Dame University and produces bulletins and newsletters.

Pipelines

Interstate Natural Gas Association of America 555 13th Street, NW, Suite 300 West Washington, DC 20004 Phone: (202) 626-3200 Fax: (202) 626-3249	Members: 35 Staff: 30

The Interstate Natural Gas Association of America (INGAA) represents transporters of natural gas. INGAA has established committees on issues regarding regulatory and government affairs, policy analysis, and the environment. INGAA produces *Interstate Natural Gas Association of American - Washington Report*, a weekly newsletter that covers legislative

R0075389

and regulatory developments affecting the industry which is available to both members and non-members.

American Petroleum Institute 1220 L Street, NW Washington, DC 20005 Phone: (202) 682-8000 Fax: (202) 682-8030	Members: 300 Staff: 500

The American Petroleum Institute (API) works to ensure cooperation between industry and government on all matters of mutual concern. API conducts research, sets standards, provides information services, and maintains a large library. API was founded in 1919 and represents corporations in the petroleum and allied industries, including producers, refiners, marketers, and transporters of crude oil, lubricating oil, gasoline, and natural gas. API has committees on industry technical issues, health, environment and safety, and government affairs and produces many standards, periodicals, books, and manuals.

Association of Oil Pipe Lines 1101 Vermont Avenue, NW, Suite 604 Washington, DC 20005 Phone: (202) 408-7970 Fax: (202) 408-7983	Members: 80 Staff: 3

The Association of Oil Pipe Lines (AOPL), founded in 1947, consists of oil pipeline companies which are generally regulated carriers. AOPL compiles and presents statistical and other data related to the pipeline industry to Congress, government departments, agencies and commissions, trade associations, and the public. AOPL is affiliated with API and produces several publications, including *Oil Pipelines of the United States: Progress and Outlook*.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.epa.gov/comply/sector/index.html

or use

www.epa.gov/oeca - then select the button labeled Industry and Gov't Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

Superintendent of Documents, Mail Stop: SSOP, Washington, DC 20402-9328
ISBN 0-16-048271-2

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., ET, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via the Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

VOCs -	Volatile Organic Compounds

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the

information included. each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete. accurate and up-to-date summaries.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project. 401 M St., SW (2223-A), Washington. DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the EnviroSen$e World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in. procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen. please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE INORGANIC CHEMICALS INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the inorganic chemicals industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

The inorganic chemical industry manufactures over 300 different chemicals accounting for about 10 percent of the total value of chemical shipments in the U.S.[1] This industry categorization corresponds to Standard Industrial Classification (SIC) code 281 Industrial Inorganic Chemicals established by the Bureau of Census to track the flow of goods and services within the economy. The 281 category includes alkalies and chlorine (SIC 2812), industrial gases (SIC 2813) (e.g., hydrogen, helium, oxygen, nitrogen, etc.), inorganic pigments (SIC 2816), and industrial inorganic chemicals, not elsewhere classified (SIC 2819). Approximately two-thirds of the value of shipments for the inorganic chemical industry, including over 200 different chemicals, are classified under industrial inorganic chemicals, not elsewhere classified (SIC 2819). The industry does not include those establishments primarily manufacturing organic chemicals, agricultural pesticides, drugs, soaps, or cosmetics. However, the 281 industry group does include a significant number of integrated firms that are engaged in the manufacture of other types of chemicals at the same site. Conversely, many manufacturing facilities not categorized under SIC 281, especially organic chemicals facilities (SIC 286), fertilizer plants (SIC 287), pulp and paper mills (SIC 26), and iron and steel mills (SIC 331), produce and use inorganic chemicals in their processes at the same facility.[2] For example, a significant number of inorganic chemical manufacturing processes are part of very large chemical manufacturing or pulp manufacturing facilities, making characterization strictly by SIC code difficult.

Whenever possible, this notebook describes the entire inorganic chemical industry. In many cases, however, specific details relating to some of the topics covered by the notebook (facility size, economic trends, geographic distribution, pollutant releases, pollution prevention issues, and applicable regulations) vary depending on the type of inorganic chemical manufacturing process. The large number of different industrial processes used in the inorganics industry could not all be covered in this notebook. As a result, most sections of this notebook describe the entire inorganic chemical industry as a whole. These sections are usually augmented with information specific to the largest single industrial process within the industry: chlorine and caustic soda production (SIC 2812). Section III. Industrial Process Description, rather than attempting to describe every inorganic chemical manufacturing process, deals solely with the production of chlorine and caustic soda.

II.B. Characterization of the Inorganic Chemical Industry

II.B.1. Product Characterization

Inorganic Chemicals Industry

The inorganic chemical industry manufactures chemicals which are often of a mineral origin, but not of a basic carbon molecular. Inorganic chemicals are used at some stage in the manufacture of a great variety of other products. The industry's products are used as basic chemicals for industrial processes (i.e., acids, alkalies, salts, oxidizing agents, industrial gases, and halogens); chemical products to be used in manufacturing products (i.e., pigments, dry colors, and alkali metals): and finished products for ultimate consumption (i.e., mineral fertilizers, glass, and construction materials). The largest use of inorganic chemicals is as processing aids in the manufacture of chemical and nonchemical products. Consequently, inorganic chemicals often do not appear in the final products.[3]

Chlor-alkali Sector

The chlor-alkali industry produces mainly chlorine, caustic soda (sodium hydroxide), soda ash (sodium carbonate), sodium bicarbonate, potassium hydroxide, and potassium carbonate. In 1992, chlorine and caustic soda production accounted for about 80 percent of the chlor-alkali industry's value of shipments and, in terms of weight, were the eighth and ninth largest chemicals produced in the U.S., respectively. Chlorine and caustic soda are co-products produced in about equal amounts primarily through the electrolysis of salt (brine).[4]

The majority of domestic chlorine production (70 percent) is used in the manufacturing of organic chemicals including: vinyl chloride monomer, ethylene dichloride, glycerine, glycols, chlorinated solvents, and chlorinated methanes. Vinyl chloride, which is used in the production of polyvinyl chloride (PVC) and many other organic chemicals, accounts for about 38 percent of the total domestic chlorine production. The pulp and paper industry consumes approximately 15 percent of U.S. chlorine production, and about eight percent is used in the manufacturing of other inorganic chemicals. Other major uses are disinfection treatment of water, and the production of hypochlorites. More than two-thirds of all chlorine is consumed in the same manufacturing plant in the production of chemical intermediates.[5]

The largest users of caustic soda are the organic chemicals industry (30 percent) and the inorganic chemicals industry (20 percent). The primary uses of caustic soda are in industrial processes, neutralization, and off-gas scrubbing; as a catalyst; and in the production of alumina, propylene oxide, polycarbonate resin, epoxies, synthetic fibers, soaps, detergents, rayon, and cellophane. The pulp and paper industry uses about 20 percent of total domestic caustic soda production for pulping wood chips, and other processes. Caustic soda is also used in the production of soaps and cleaning products, and in the petroleum and natural gas extraction industry as a drilling fluid.[6]

II.B.2. Industry Size and Geographic Distribution

Inorganic Chemical Industry

The inorganic chemical industry is characterized by a relatively large number of small facilities. The Bureau of the Census identified 665 companies operating 1,429 facilities within SIC 281 in 1992.[a] Most of these facilities were classified under SIC 2819 -- industrial inorganic chemicals, not elsewhere classified -- which are typically smaller facilities producing specialty inorganic chemicals. The Bureau of Census employment data for 1992 (Exhibit 1) indicated that about 63 percent of inorganic chemical facilities employed fewer than 20 people. A significant portion of inorganic chemicals are produced and used within the same plant in the manufacturing of organic chemicals. The number of these facilities and the number of people employed in the inorganic chemical production portion of the industrial processes is not included in this data.

[a] Variation in facility counts occur across data sources due to many factors including, reporting and definition differences. This notebook does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

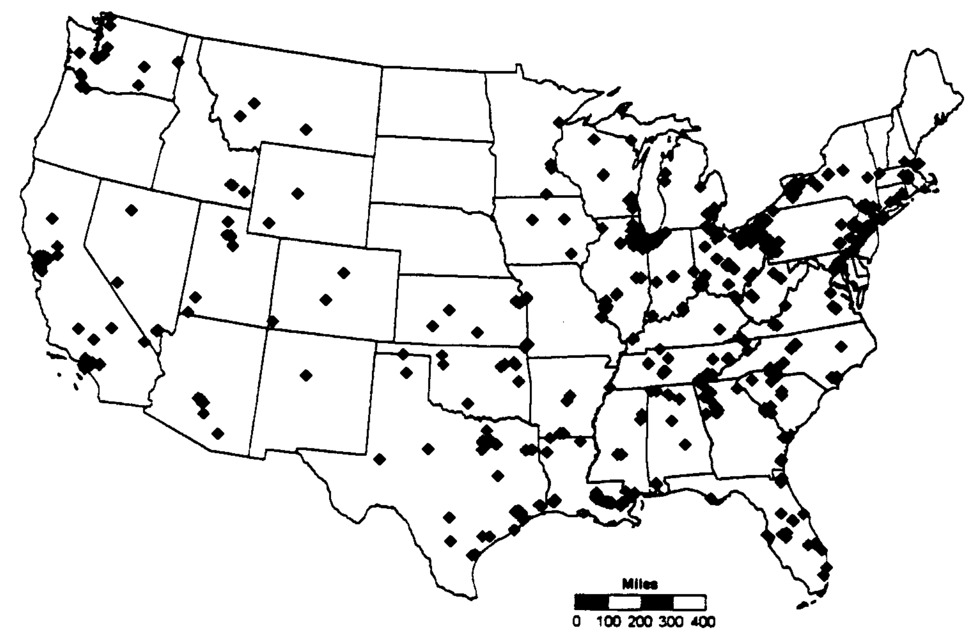
Exhibit 1: Inorganic Chemicals Industry Dominated by a Large Number of Small Facilities

	Inorganic Chemicals		Chlor-alkali	
Employees per Facility	**Number of Facilities**	**Percentage of Facilities**	**Number of Facilities**	**Percentage of Facilities**
1-9	682	48%	12	24%
10-19	212	15%	6	12%
20-49	253	18%	3	6%
50-249	221	15%	23	44%
250-999	51	3%	6	12%
1,000->2,500	10	1%	1	2%
Total	1,429	100%	51	100%

Source: Bureau of the Census, 1992 Census of Manufacturers.

Inorganic chemical facilities are typically located near consumers and to a lesser extent raw materials. The largest use of inorganic chemicals is in industrial processes for the manufacture of chemicals and nonchemical products; therefore, facilities are concentrated in the heavy industrial regions along the Gulf Coast, both east and west coasts, and the Great Lakes region. Since a large portion of inorganic chemicals produced are used by the organic chemicals manufacturing industry, the geographical distribution of inorganic facilities is very similar to that of organic chemicals facilities (Exhibit 2).

Exhibit 2: Inorganic Chemicals Facilities Distribution



(Source: U.S. EPA Toxic Release Inventory Database, 1993)

Chlor-alkali Sector

The alkali and chlorine industry, however, consists of a relatively small number of medium to large facilities. The Bureau of the Census identified 34 companies operating 51 facilities within the SIC 2812 in 1992. According to The Chlorine Institute (an industry trade group), there were 25 companies operating 52 chlorine production plants in 1989. The Bureau of Census employment data for 1992 indicated that about 60 percent of those employed in the chlor-alkali industry worked at facilities with over 50 employees (Exhibit 1).[7,8]

The distribution of the chlor-alkali sector differs from that of the inorganic chemicals industry as a whole. Since chlorine and caustic soda are co-products produced in almost equal amounts, the distribution of the caustic soda manufacturing industry is essentially the same as the chlorine manufacturing industry. Chlorine is difficult to store and transport economically; therefore, chlorine and caustic soda are produced near the

R0075413

chlorine consumers which are primarily chemical manufacturers and pulping operations. Consequently, chlor-alkali facilities are concentrated near the chemical industries along the Gulf Coast, followed by the Great Lakes region as shown in the table below. Other important areas are in the vicinity of the pulp mills of the Southeast and Northwest (Exhibit 3). In 1989, almost half of the chlorine plants in the U.S. (72 percent of domestic chlorine production) were located along the Gulf Coast. Two states, Louisiana and Texas, accounted for two-thirds of the domestic chlorine production.[9]

Exhibit 3: Chlorine Capacity Located Primarily Along Gulf Coast, Southeast, Northwest, and Great Lakes Region

State	Number of Chlorine Plants	Annual Capacity (thousand tons per year)	Percent of Total U.S. Operating Capacity
Louisiana	9	4,068	37%
Texas	5	3,314	30%
New York	4	652	6%
Alabama	5	592	5%
Washington	4	503	5%
West Virginia	2	392	3%
Georgia	3	246	2%
Tennessee	1	230	2%
Other States (14)	19	1,139	10%
U.S. Total	52	11,136	100%

Ward's Business Directory of U.S. Private Companies, produced by Gale Research Inc., compiles financial data on U.S. companies including those operating within the inorganic chemicals manufacturing industry. Ward's ranks U.S. companies, whether they are a parent company, subsidiary or division, by sales volume within the 4-digit SIC codes that they have been assigned as their primary activity. Exhibit 4 lists the top ten inorganic chemical manufacturing companies in the U.S. Readers should note that: 1) Companies are assigned a 4-digit SIC that most closely resembles their principal industry; and 2) Sales figures include total company sales, including sales derived from subsidiaries and operations not related to the manufacture of inorganic chemicals. Additional sources of company specific financial information include Standard & Poor's *Stock Report Services*, Dunn & Bradstreet's *Million Dollar Directory*, Moody's Manuals, and annual reports.

Exhibit 4: Top U.S. Companies with Inorganic Chemical Manufacturing Operations

Rank[a]	Company[b]	1993 Sales (millions of dollars)
1	Dow Chemical Co. - Midland, MI	18,800
2	Hanson Industries, Inc. - Iselin, NJ	6,092
3	WR Grace and Co. - Boca Raton, FL	6,049
4	Occidental Chemical Corp. - Dallas, TX	4,600
5	BOC Group, Inc. - Murray Hill, NJ	4,500
6	FMC Corp. - Chicago, IL	3,899
7	Eastman Kadak Co. - Kingsport, TN	3,740
8	Air Products and Chemicals, Inc. - Allentown, PA	2,931
9	ARCO Chemical Co. - Newtown Square, PA	2,837
10	Ethyl Corp. - Richmond, VA	2,575

Note: [a] When *Ward's Business Directory* listed both a parent and subsidiary in the top ten, only the parent company is presented above to avoid double counting sales volumes. Not all sales can be attributed to the companies' inorganic chemical manufacturing operations.
[b] Companies shown listed SICs 2812, 2813, 2816 and 2819 as primary activities.

II.B.3. Economic Trends

Inorganic Chemicals Industry

The Bureau of the Census estimated that there were 1,429 facilities in the inorganic chemical industry in 1992. The industry employed 103,000 people and had a total value of shipments of $27.4 billion. The total value of shipments for the inorganic chemicals industry increased about one percent per year between 1992 and 1994. These values do not include inorganic chemicals manufactured for captive use within a facility nor the value of other non-industrial inorganic chemical products manufactured by the same facility. It does, however, include intra-company transfers which are significant in this industry. The inorganic chemical industry's growth rate is expected to continue to increase with the growth of the economy. The U.S. is a net exporter of inorganic chemicals with most exports shipped to the European Community (EC) followed by Canada and Mexico. This positive trade balance increased significantly in 1993 to $1.7 billion and is expected to continue as the European economy improves. By comparison, the 1992 Census of Manufactures for Industrial Organic Chemicals reports a 1992 value of shipments for organic chemicals of $64.5 billion and a total employment of 125,100 people. The 1992 value of shipments for the entire chemical industry (SIC 28) totaled $292.3 billion with an employment of 850,000 people.[10]

Because inorganic chemicals are used in the manufacturing of many products, the industry tends to grow at the same rate as overall industrial production. In the late 1980s, the industry experienced high growth rates and, in the early 1990s, the industry saw little real growth in output, as a reflection of the U.S. economy's recession. The industry has historically had low profit margins which, in recent years, have decreased further with increasing pollution abatement costs.[11]

Chlor-alkali Sector

The Bureau of the Census data for 1992 shows that there were 51 facilities within the inorganic chemicals industry that manufactured alkalies and chlorine. These chlor-alkali facilities employed 8,000 people and had a total value of shipments of $2.8 billion. This was an increase of 1.7 percent from 1991. The chlor-alkali industry as a whole is expected to grow at its past rate of 1.5 times gross domestic product (GDP) growth through the 1990s. Because chlorine and caustic soda are electrolysis co-products, the production of one product can depend on the demand of the other product. The market pull has switched several times between caustic soda and chlorine in the past few decades. Presently, chlorine demand is controlling production: consequently, there is a current excess availability of caustic

R0075416

soda in the U.S. This excess material is typically exported to fill a significant demand outside the U.S. The consumption of caustic soda is growing faster than the consumption of chlorine, however, and domestic caustic soda demand is expected to control production in the coming years.[12]

After reaching record high levels in the late 1970s, chlorine production declined in the early 1980s due in part to the economic recession between 1980 and 1982. Chlorine production increased slowly through the 1980s and, as of 1992, had not reached the record high levels and growth rates of the 1970s. This is due in part to the relative maturity of the chlorine usage industries and more recent environmental pressures aimed at curtailing chlorine use. Regulatory restrictions on the production or disposal of some products which require large amounts of chlorine to manufacture (i.e., chlorofluorocarbons, PVC, and chlorinated solvents) have adversely affected the market. Chlorine's commercial appeal has been further reduced by initiatives such as the International Joint Commission of Great Lakes Water Quality (a Canada-U.S. environmental oversight group) and a number of environmental groups which call for a gradual phaseout or an immediate ban of chlorine and chlorinated compounds as industrial feedstocks.[13]

The production of caustic soda is very dependent on the short term and long term chlorine demand and production because chlorine cannot be stored economically. Increased demand for chlorine must be met immediately by increased chlorine production via electrolysis of brine and, consequently, caustic soda production. Domestic and export demand for caustic soda was very strong in the 1980s with the pick up of the world economy and an increase in pulp and paper production. In the late 1980s, there was a worldwide shortage of caustic soda due to increased demand and lower U.S. chlorine production. The demand for caustic soda is expected to continue to grow in the coming years; however, there are a number of uncertainties that may limit the growth rate. Some industries have begun switching from caustic soda to soda ash where possible to avoid caustic soda shortages. Soda ash, which is extremely plentiful in the U.S., is obtained almost entirely from natural sources of trona ore. Demand for caustic soda may also decrease as pulp mills increase their reclamation of caustic soda from spent pulping liquor.[14]

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the inorganic chemical industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A. Industrial Processes in the Inorganic Chemical Industry

Chlorine and caustic soda are co-products of electrolysis of saturated aqueous solutions of sodium chloride, NaCl (salt water or brine). In addition, relatively small amounts (by weight) of hydrogen gas are produced in the process. The overall chemical reaction is as follows:

$$2\ NaCl + 2\ H_2O \rightarrow 2\ NaOH + Cl_2 + H_2$$

Energy, in the form of direct current (d-c) electricity, is supplied to drive the reaction. The amount of electrical energy required depends on the design of the electrolytic cell, the voltage used, and the concentration of brine used. For each ton of chlorine produced, 1.1 tons of sodium hydroxide and 28 kilograms of hydrogen are produced.

Three types of electrolysis processes are used for the manufacture of chlorine, caustic soda, and hydrogen from brine:

- Mercury Cell Process
- Diaphragm Cell Process
- Membrane Cell Process

Virtually all chlorine produced in the U.S. is manufactured by one of these three electrolysis processes. Each electrolytic cell consists of an anode and cathode in contact with the brine solution. Exhibit 5 shows the basic elements. inputs and outputs of each type of electrolytic cell. The distinguishing feature of each cell type is the method employed to separate and prevent the mixing of the chlorine gas and sodium hydroxide. Consequently, each process produces a different purity of chlorine gas and a different concentration of caustic soda. Exhibit 6 is a summary of the major differences between each cell type. In 1988, diaphragm cells accounted for 76 percent of all domestic chlorine production, followed by mercury cells with 17 percent, and membrane cells with five percent. The industry is moving away from mercury and diaphragm cells and is moving towards the use of membrane cells. Membrane cells are a relatively recent development which have fewer adverse effects on the environment and produce a higher quality product at a lower cost than the other methods.[15,16]

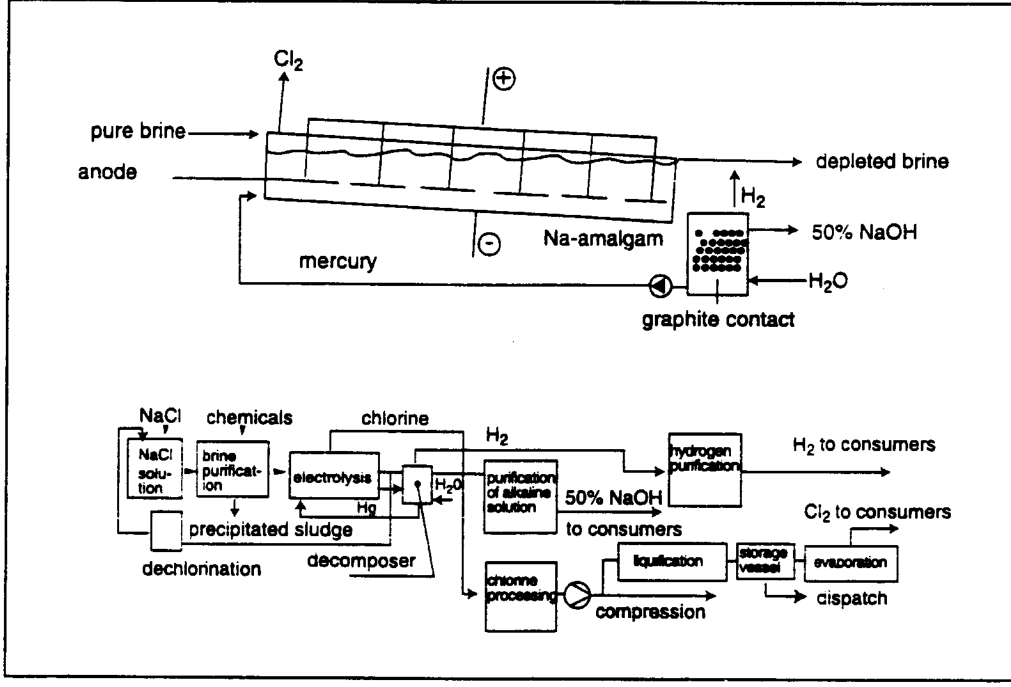
III.A.1. Mercury Cell

The mercury cell process consists of slightly inclined steel troughs through which a thin layer of mercury (about three mm) flows over the bottom (Exhibit 7). The cells are operated at 75 to 85 °C and atmospheric pressure. The mercury layer serves as the cathode for the process and the saturated brine solution (25.5 percent NaCl by weight) flows through the troughs above the mercury. The anodes are usually incorporated into the cell covers and are suspended horizontally in the brine solution. The height of the anodes within the brine is adjusted to the optimal height either manually or through an automatic computer controlled system.[17]

Electrolytic cell anodes were made of graphite until the late 1960s when anodes of titanium coated with ruthenium oxide (RuO_2) and titanium oxide (TiO_2) were developed. The RuO_2 and TiO_2 anodes, termed DSA (dimensionally stable) anodes, are more stable than the graphite anodes (i.e., they do not need to be replaced as frequently) and are more energy efficient.[18]

R0075421

Exhibit 7: Mercury Electrolysis Cell and Flow Diagram



(Source: Industrial Inorganic Chemistry, Büchner, et al., 1989.)

The chlorine gas is produced at the anodes where it moves upward through gas extraction slits in the cell covers. Sodium ions are absorbed by the mercury layer and the resulting sodium and mercury mixture, called the amalgam, is processed in "decomposer" cells to generate sodium hydroxide and reusable mercury. The amalgam entering the decomposer cell has a sodium concentration of approximately 0.2 to 0.5 percent by weight. The decomposer consists of a short-circuited electrical cell where graphite serves as the anode and the amalgam serves as the cathode. The amalgam and water flowing through the cell come into direct contact with the graphite. The hydrolysis of the water on the graphite in the presence of the amalgam results in a strong exothermic reaction generating mercury to be reused in the electrolytic cell, a 50 percent caustic soda solution, and hydrogen gas. Mercury cells are operated to maintain a 21 to 22 percent by weight NaCl concentration in the depleted brine leaving the cell. The dissolved chlorine is removed from the depleted brine solution, which is then resaturated with solid salt and purified for further use. Some facilities purge small amounts of brine solution and use new brine as make-up in order to prevent the build up of sulfate impurities in the brine.[19,20]

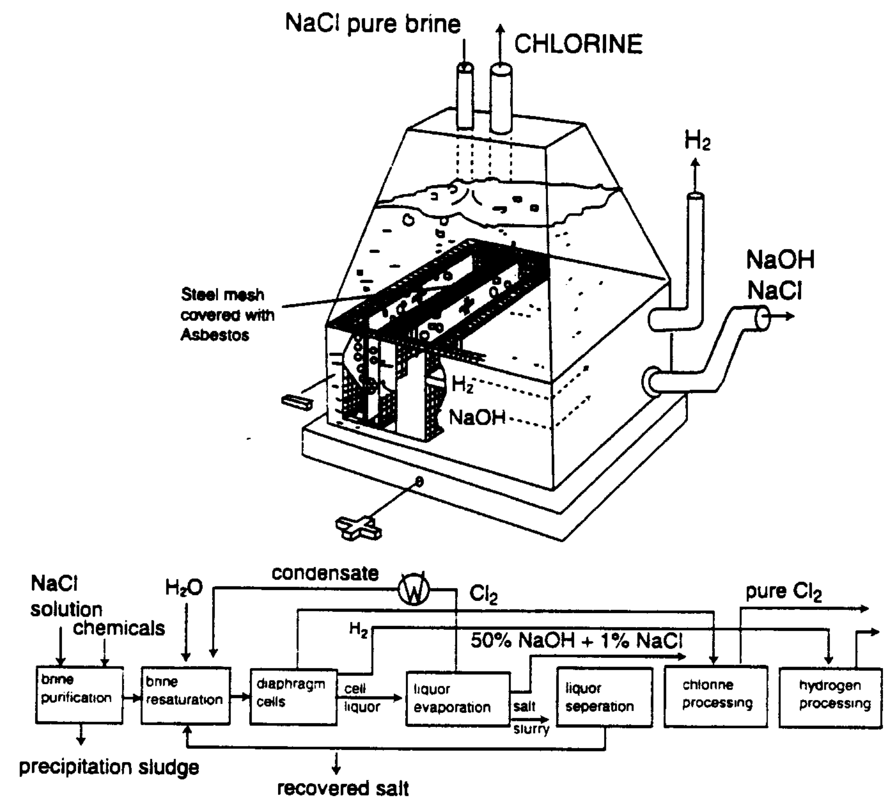
The mercury process has the advantage over diaphragm and membrane cells in that it produces a pure chlorine gas with no oxygen, and a pure 50 percent caustic soda solution without having to further concentrate a more dilute solution. However, mercury cells operate at a higher voltage than diaphragm and membrane cells and, therefore, use more energy. The process also requires a very pure brine solution with little or no metal contaminants. Furthermore, elaborate precautions must be taken to avoid releases of mercury to the environment.

III.A.2. Diaphragm Cell

In the diaphragm cell process, multiple cells consisting of DSA anode plates and cathodes are mounted vertically and parallel to each other (Exhibit 8). Each cell consists of one anode and cathode pair. The cathodes are typically flat hollow steel mesh or perforated steel structures covered with asbestos fibers, which serve as the diaphragm. The asbestos fiber structure of the diaphragm prevents the mixing of hydrogen and chlorine by allowing liquid to pass through to the cathode, but not fine bubbles of chlorine gas formed at the anodes. The diaphragm also hinders the back-diffusion to the anode of hydroxide (OH^-) ions formed at the cathode. The cells are operated at 90 to 95 °C and atmospheric pressure. Brine flows continuously into the anode chamber and, subsequently, through the diaphragm to the cathode. As in the mercury cell process, chlorine gas is formed at the anodes; however, in the diaphragm process, caustic soda solution and hydrogen gas are formed directly at the cathode. The chlorine gas is drawn off from above the anodes for further processing. The hydrogen gas is drawn off separately from the cathode chambers.[21,22]

Two basic types of diaphragm cells are in use today. The first, monopolar cells, have an electrode arrangement in which the anodes and cathodes are arranged in parallel. As a result of this configuration, all cells have the same voltage of about three to four volts; up to 200 cells can be constructed in one circuit. The second basic type of diaphragm cell is the bipolar cell, in which the anode of one cell is directly connected to the cathode of the next cell unit. This type of arrangement minimizes voltage loss between cells; however, since the total voltage across the entire set of cells is the sum of the individual cell voltages, the number of cells per unit is limited. To compensate for the reduced anode and cathode surface area in the bipolar configuration, bipolar units tend to be much larger than monopolar units. Production of chlorine and caustic soda by the diaphragm process is split approximately equally between monopolar and bipolar systems.[23]

Exhibit 8: Typical Diaphragm Electrolysis Cell and Flow Diagram



(Source: Industrial Inorganic Chemistry, Büchner, et al., 1989)

Diaphragm cells are operated such that about 50 percent of the input NaCl is decomposed resulting in an effluent mixture of brine and caustic soda solution containing eight to 12 percent NaOH and 12 to 18 percent NaCl by weight. This solution is evaporated to 50 percent NaOH by weight at which point all of the salt, except a residual 1.0 to 1.5 percent by weight, precipitates out. The salt generated is very pure and is typically used to make more brine. Because the brine and caustic soda solution are mixed in a single effluent, a fresh brine solution (no recycled brine) is constantly entering the system. The diaphragm cell process does not, therefore, require a brine purge to prevent sulfate build up, or treatment to remove entrained chlorine gas, as in the mercury cell process.[24]

Diaphragms are constructed of asbestos because of its chemical and physical stability and because it is a relatively inexpensive and abundant material. Beginning in the early 1970s, asbestos diaphragms began to be replaced by diaphragms containing 75 percent asbestos and 25 percent fibrous polytetrafluoroethylene (PTFE). These diaphragms, trade named Modified Diaphragms, are more stable and operate more efficiently than the fully asbestos diaphragms. Modified Diaphragms are the most common diaphragms currently in use.[25]

Diaphragm cells have the advantage of operating at a lower voltage than mercury cells and, therefore, use less electricity. In addition, the brine entering a diaphragm cell can be less pure than that required by mercury and membrane cells. The chlorine gas produced by the diaphragm process, however, is not pure and must be processed to remove oxygen, water, salt, and sodium hydroxide. Another disadvantage of the process is that the caustic soda produced contains chlorides and requires evaporation to bring it to a usable concentration.[26]

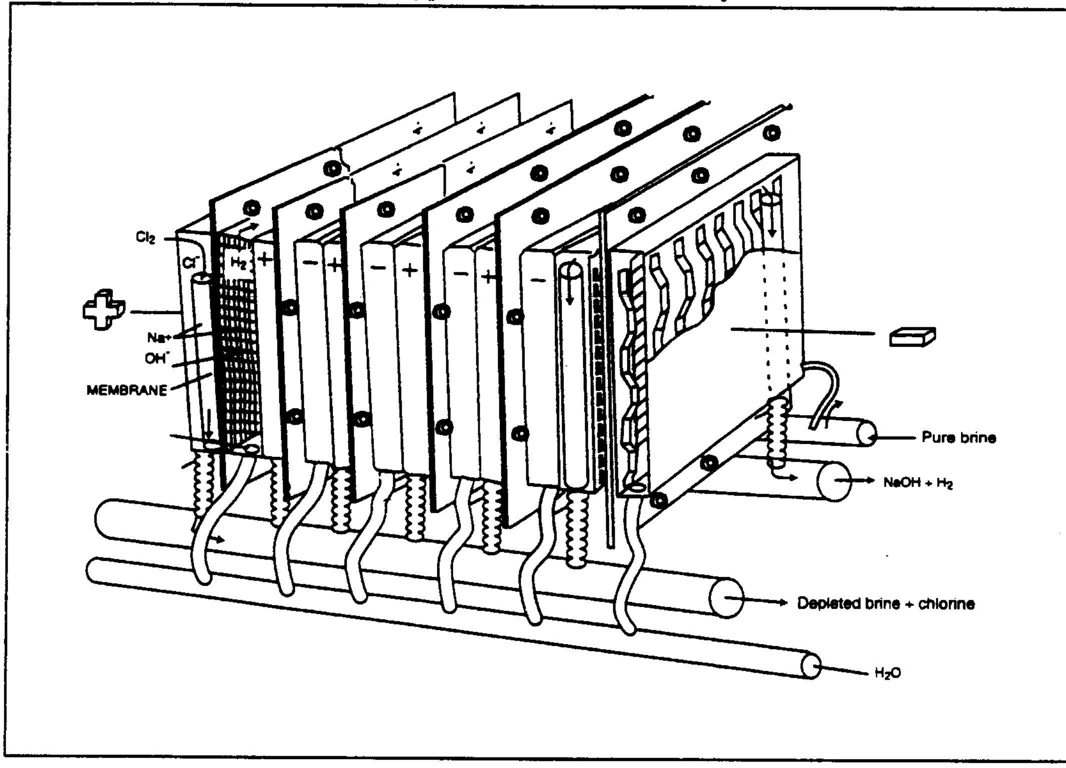
III.A.3. Membrane Cell

In the membrane cell process, the anode and cathode are separated by a water-impermeable ion-conducting membrane (Exhibit 9). Brine solution flows through the anode compartment where chlorine gas is generated. The sodium ions migrate through the membrane to the cathode compartment which contains flowing caustic soda solution. Water is hydrolyzed at the cathode, releasing hydrogen gas and hydroxide (OH^-) ions. The sodium and hydroxide ions combine to produce caustic soda which is typically brought to a concentration of 32 to 35 percent by recirculating the solution before it is discharged from the cell. The membrane prevents the migration of chloride ions from the anode compartment to the cathode compartment; therefore, the caustic soda solution produced does not contain salt as in the diaphragm cell process. Depleted brine is discharged from the anode compartment and resaturated with salt.[27]

The cathode material used in membrane cells is either stainless steel or nickel. The cathodes are often coated with a catalyst that is more stable than the substrate and that increases surface area and electrical conductivity. Coating materials include Ni-S, Ni-Al, and Ni-NiO mixtures, as well as mixtures of nickel and platinum group metals. Anodes are typically of the DSA type.[28]

The most critical components of the membrane cells are the membranes themselves. The membranes must remain stable while being exposed to chlorine on one side and a strong caustic solution on the other. Furthermore, the membranes must have low electrical resistance, and allow the transport of sodium ions and not chloride ions and reinforcing fabric, and a perfluorocarboxlate polymer all bonded together.

Exhibit 9: Typical Membrane Electrolysis Cell



(Source: Industrial Inorganic Chemistry, Büchner, et al., 1989.)

Membrane cells can be configured either as monopolar or bipolar. As in the case of the diaphragm cell process, the bipolar cells have less voltage loss between the cells than the monopolar cells; however, the number of cells connected together in the same circuit is limited.[29]

Membrane cells have the advantages of producing a very pure caustic soda solution and of using less electricity than the mercury and diaphragm processes. In addition, the membrane process does not use highly toxic materials such as mercury and asbestos. Disadvantages of the membrane process are that the chlorine gas produced must be processed to remove oxygen and water vapor, and the caustic soda produced must be evaporated to increase the concentration. Furthermore, the brine entering a membrane cell must be of a very high purity, which often requires costly additional purification steps prior to electrolysis.[30]

III.A.4. Auxiliary Processes

Brine Purification

Approximately 70 percent of the salt used in chlorine gas production is extracted from natural salt deposits; the remainder is evaporated from seawater. Salt from natural deposits is either mined in solid form or is leached from the subsurface. Leaching involves the injection of freshwater into subterranean salt deposits and pumping out brine solution. Brine production from seawater typically occurs by solar evaporation in a series of ponds to concentrate the seawater, precipitate out impurities, and precipitate out solid sodium chloride. Regardless of the method used to obtain the salt, it will contain impurities that must be removed before being used in the electrolysis process. Impurities primarily consist of calcium, magnesium, barium, iron, aluminum, sulfates, and trace metals. Impurities can significantly reduce the efficiency of the electrolytic cells, by precipitating out and subsequently blocking a diaphragm or damaging a membrane depending on the process used. Certain trace metals, such as vanadium, reduce the efficiency of mercury cells and cause the production of potentially dangerous amounts of hydrogen gas. Removal of impurities accounts for a significant portion of the overall costs of chlor-alkali production, especially in the membrane process. [31]

In addition to the dissolved natural impurities, chlorine must be removed from the recycled brine solutions used in mercury and membrane processes. Dissolved chlorine gas entering the anode chamber in the brine solution will react with hydroxide ions formed at the cathode to form chlorate which reduces product yields. In addition, chlorine gas in the brine solution will cause corrosion of pipes, pumps, and containers during further processing of the brine. In a typical chlorine plant, HCl is added to the brine solution leaving the cells to liberate the chlorine gas. A vacuum is applied to the solution to collect the chlorine gas for further treatment. To further reduce the chlorine levels, sodium sulfite or another reducing agent is added to remove the final traces of chlorine. Dechlorinated brine is then resaturated with solid salt before further treating to remove impurities.[32]

Depending on the amount of impurities in the salt and the electrolysis process utilized, different purification steps will be required. Brine solution is typically heated before treatment to improve reaction times and precipitation of impurities. Calcium carbonate impurities are precipitated out through treatment with sodium carbonate; magnesium, iron, and aluminum are precipitated out through treatment with sodium hydroxide; and sulfates are precipitated out through the addition of calcium chloride or barium carbonate. Most trace metals are also precipitated out through these processes. Flocculants are sometimes added to the clarifying equipment to

R0075427

improve settling. The sludges generated in this process are washed to recover entrained sodium chloride. Following the clarification steps, the brine solution is typically passed through sand filters followed by polishing filters. The brine passing through these steps will contain less than four parts per million (ppm) calcium and 0.5 ppm magnesium which is sufficient purification for the diaphragm and mercury cell processes. For brine to be used in the membrane process, however, requires a combined calcium and magnesium content of less than 20 parts per billion (ppb). Brine for the membrane process is, therefore, passed through ion exchange columns to further remove impurities.[33]

Chlorine Processing

The chlorine gas produced by electrolytic processes is saturated with water vapor. Chlorine gas from the diaphragm process also contains liquid droplets of sodium hydroxide and salt solution. The first steps in processing the chlorine to a usable product consists of cooling the chlorine to less than ten degrees centigrade and then passing it through demisters or electrostatic precipitators to remove water and solids. Next the chlorine is passed through packed towers with concentrated sulfuric acid flowing countercurrently. The water vapor is absorbed by the sulfuric acid and the dry chlorine gas is then passed through demisters to remove sulfuric acid mist. If the chlorine is to be liquefied, liquid chlorine is then added to the gas to further purify the chlorine and to prechill it prior to compression. Prechilling is primarily carried out to prevent the temperature from reaching the chlorine-steel ignition point during compression.[34]

Chlorine gas is either used in gaseous form within the facility, transferred to customers via pipeline, or liquefied for storage or transport. Liquid chlorine is of a higher purity than gaseous chlorine and is either used within the facility or is transferred via rail tank car, tank truck, or tank barge. The demand for liquid chlorine has increased in recent years and, in 1987, accounted for about 81 percent of chlorine produced in the U.S.[35]

Chlorine liquefaction processes typically liquefy only about 90-95 percent of the chlorine. This gas and the chlorine gas left inside tank truck tanks, rail car tanks, or barges after removal of liquid chlorine is impure and must be recovered in a chlorine recovery unit. The gas is compressed and cooled using cold water followed by Freon. The chilled gas is fed up through a packed column in which carbon tetrachloride flows downward absorbing the chlorine. The chlorine-rich carbon tetrachloride is fed to a chlorine stripper in which the chlorine and carbon tetrachloride separate as they are heated. The chlorine gas is cooled and scrubbed of carbon tetrachloride using liquid chlorine and the resulting pure chlorine is sent to the chlorine liquefaction system.[36]

Caustic Soda Processing

Caustic soda solution generated from chlor-alkali processes is typically processed to remove impurities and to concentrate it to either a 50 percent or 73 percent water-based solution or to anhydrous caustic soda. The caustic soda from the mercury and membrane processes is relatively pure. Product from the mercury process requires only filtration to remove mercury droplets. The evaporators used to concentrate the caustic soda solution in the diaphragm process are typically multi-stage forced circulation evaporators. The evaporators have salt settling systems to remove precipitated salt. Sodium borohydride is often added to reduce corrosion of the equipment. Evaporators for the membrane process are usually much simpler than those for the diaphragm process because the salt concentration in the membrane cell caustic solution is very low.[37]

Hydrogen Processing

The hydrogen produced in all of the electrolytic processes contains small amounts of water vapor, sodium hydroxide, and salt which is removed through cooling. The hydrogen produced during the mercury cell process also contains small amounts of mercury which must be removed by cooling the hydrogen gas to condense the mercury and treating with activated carbon.[38]

III.B. Raw Material Inputs and Pollution Outputs in the Production Line

Inputs and pollutant outputs of the chlor-alkali industry are relatively small both in number and volume in comparison to the chemical manufacturing industry as a whole. The inputs are primarily salt and water as feedstocks: acids and chemical precipitants used to remove impurities in the input brine or output chlorine and caustic soda; and freon used for liquefying and purifying the chlorine gas produced. The major pollutant outputs from all three electrolytic processes are chlorine gas emissions (both fugitive and point source); spent acids: freon (both fugitive and point source); impurities removed from the input salt or brine; and pollutants originating from electrolytic cell materials and other system parts.

Pollutant outputs have decreased in recent years as the industry moves away from the mercury and diaphragm cell processes to the more efficient (in terms of material and energy inputs and outputs) membrane cell process. In addition, improved cell part materials have been developed, such as DSA anodes and Modified Diaphragms, which are more stable and create less undesirable byproducts.

Inputs and pollutant outputs from the auxiliary processes such as brine purification, chlorine processing, caustic soda processing, and hydrogen processing are described in Section III.B.4.

III.B.1. Mercury Cell

Wastewater streams from mercury cell facilities arise from the chlorine drying process, brine purge, and miscellaneous sources. Small amounts of mercury are found in the brine purge and miscellaneous sources which include floor sumps and cell wash water. Before treatment, mercury concentrations (principally in the form of mercuric chloride, $HgCl_4^{2-}$) typically range from 0 to 20 ppm. Thereby segregating most mercury bearing wastewater streams from non-mercury bearing wastewater streams. Prior to treatment, sodium hydrosulfide is used to precipitate mercuric sulfide. The mercuric sulfide is removed through filtration before the water is discharged.[39]

Air emissions consist of mercury vapor and chlorine gas released in relatively small amounts as fugitive emissions from the cells: and in the tail gases of the chlorine processing, caustic soda processing, and hydrogen processing. Process tail gases are wet scrubbed with caustic soda or soda ash solutions to remove chlorine and mercury vapor. Residual chlorine emissions in tail gases after treatment are less than one kg per 1,000 kg of chlorine produced and mercury emissions are negligible. The tail gas scrubber water is typically reused as brine make-up water.[40]

Solid wastes containing mercury include: solids generated during brine purification; spent graphite from decomposer cells; spent caustic filtration cartridges from the filtration of caustic soda solution; spilled mercury from facility sumps; and mercury cell "butters," which are semisolid amalgams of mercury with barium or iron formed when an excess of barium is used during salt purification. Most mercury bearing solid wastes are shipped off-site to outside reclaimers who recover the mercury. The remaining wastes are disposed of in secure landfills using either chemical or physical methods to recover maximum feasible amount of mercury.[41]

III.B.2. Diaphragm Cell

Wastewater streams from the diaphragm cell process originate from the barometric condenser during caustic soda evaporation, chlorine drying, and from purification of salt recovered from the evaporators. These wastewaters and their treatment are described below in Section III.B.4. The use of lead and graphite anodes and asbestos diaphragms generates lead, asbestos, and chlorinated hydrocarbons in the caustic soda and chlorine processing waste streams. Lead salts and chlorinated hydrocarbons are generated from corrosion of the anodes, and asbestos particles are formed by the degradation of the diaphragm with use. Over the past twenty years, all but a few diaphragm cell facilities have switched from the use of lead and graphite anodes with asbestos diaphragms to DSA anodes and Modified Diaphragms which resist corrosion and degradation. The lead, asbestos, and chlorinated hydrocarbon contaminants are, therefore, no longer discharged in significant amounts from most diaphragm cell chlor-alkali facilities. Those facilities that discharged caustic processing wastewater streams to on-site lagoons may, however, still have significant levels of these contaminants on-site.[42]

Chlorine is released in relatively small amounts as fugitive emissions from the cells and in the process tail gases. Process tail gases are wet scrubbed with soda ash or caustic soda solutions to remove chlorine. Residual chlorine emissions in tail gases after treatment are negligible. The spent caustic solution is neutralized prior to discharge.[43]

Solid wastes generated in the diaphragm process consist primarily of solids generated during brine purification and scrapped cell parts including, cell covers, piping and used diaphragms. Discarded cell parts are either landfilled on-site, as is typically the case for spent diaphragms, or shipped off-site for disposal. Used cathodes and DSA anodes are shipped off-site for recovery of their titanium content.[44]

III.B.3. Membrane Cell

Wastewater from the diaphragm cell process originates from the barometric condenser during caustic soda evaporation, chlorine drying, and wash water from the ion exchange resin used to purify the brine solution. The ion exchange wash water consists of dilute hydrochloric acid with small amounts of dissolved calcium, magnesium, and aluminum chloride. The wastewater is combined with the other process wastewaters and treated by neutralization.[45]

Chlorine is released in relatively small amounts as fugitive emissions from the cells and in the process tail gases. Process tail gases are wet scrubbed with soda ash or caustic soda solutions to remove chlorine. Residual chlorine emissions in tail gases after treatment are negligible. The spent caustic solution is neutralized prior to discharge.[46]

Solid waste generated in the diaphragm process consists primarily of solids generated during brine purification and used cell parts which include membranes, cathodes and DSA anodes. The used membranes are typically returned to the supplier and the used cathodes and DSA anodes are shipped off-site for recovery of their titanium content.[47]

III.B.4. Auxiliary Processes

Brine Purification

Brine solutions are typically treated with a number of chemicals to remove impurities prior to input to the electrolytic cells. In the case of mercury and membrane cell systems, the brine is first acidified with HCl to remove dissolved chlorine. Next, sodium hydroxide and sodium carbonate are added to precipitate calcium and magnesium ions as calcium carbonate and magnesium hydroxide. Barium carbonate is then added to remove sulfates which precipitate out as barium sulfate. The precipitants are removed from the brine solution by settling and filtration. Pollutant outputs from this process include fugitive chlorine emissions and brine muds.[48]

Brine muds are one of the largest waste streams of the chlor-alkali industry. On average, about 30 kilograms (kg) of brine mud are generated for every 1,000 kg of chlorine produced. The volume of mud will vary, however, depending on the purity of the salt used. Some facilities use pre-purified (i.e., chemical grade) evaporated salts which will produce only 0.7 to 6.0 kg of brine mud per 1,000 kg of chlorine produced. Brine mud typically contains magnesium hydroxide, calcium carbonate, and, in most cases, barium sulfate. Mercury cell brine muds usually contain mercury either in the elemental form or as the complex ion, mercuric chloride ($HgCl_4^{2-}$). Mercury- containing brine muds are typically disposed of in a RCRA Subtitle C landfill after treatment with sodium sulfide which converts the mercury to an insoluble sulfide.[49]

Brine muds are usually segregated from other process wastes and stored in lagoons on-site. When the lagoons become filled, the brine mud is either dredged and landfilled off-site, or drained and covered over. Some plants that use brine solution leached from subterranean deposits inject brine muds into the salt cavities that are no longer being used.[50]

Chlorine Processing

The chlorine gas recovered from electrolytic cells is cooled to remove water vapor. The condensed water is usually recycled as brine make-up although some facilities combine this waste stream with other waterborne waste streams prior to treatment. The remaining water vapor is removed by scrubbing the chlorine gas with concentrated sulfuric acid. The chlorine gas is then compressed and cooled to form liquid chlorine. Between six kg and 35 kg of 79 percent sulfuric acid wastewater is generated per 1,000 kg of chlorine produced. The majority of the spent sulfuric acid waste is shipped off-site for refortification to concentrated sulfuric acid or for use in other processes. The remainder is used to control effluent pH and/or is discharged to water or land disposed.[51]

The process of purifying and liquefying impure chlorine gas involves the absorption of the chlorine in a stream of carbon tetrachloride. The chlorine is subsequently removed in a stripping process in which the carbon tetrachloride is either recovered and reused, or is vented to the atmosphere.[52]

Caustic Soda Processing

Caustic soda solution generated from chlor-alkali processes is typically processed to remove impurities and, in the case of the diaphragm and membrane processes, is concentrated to either a 50 percent or 73 percent water-based solution or to anhydrous caustic soda. About five tons of water must be evaporated per ton of 50 percent caustic soda solution produced. The water vapor from the evaporators is condensed in barometric condensers and, in the case of the diaphragm process, will primarily contain about 15 percent caustic soda solution and high concentrations of salt. If sodium sulfate is not removed during the brine purification process, salt recovered from the evaporators is often recrystallized to avoid sulfate buildup in the brine. If the salt is recrystallized, the wastewater from sodium hydroxide processing will also contain sodium sulfates. Significant levels of copper may also be present in the wastewater due to corrosion of pipes and other equipment. Wastewater from the membrane process contains caustic soda solution and virtually no salt or sodium sulfates.[53]

Caustic soda processing wastewater is typically neutralized with hydrochloric acid, lagooned, and then discharged directly to a receiving water or land disposed. The caustic soda generated from the mercury process only requires filtration to remove mercury droplets which are typically recovered for reuse.

Hydrogen Processing

The hydrogen produced in all of the electrolytic processes contains small amounts of water vapor, sodium hydroxide, and salt which is removed through cooling. Condensed salt water and sodium hydroxide solution is either recycled as brine make-up or treated with other waterborne waste streams. The hydrogen produced during the mercury cell process, however, also contains small amounts of mercury which must be removed prior to liquefaction. Most of the entrained mercury is extracted by cooling the gas. The condensed mercury is then returned to the electrolytic cells. Some facilities further purify the hydrogen gas of mercury using activated carbon treatment. Spent activated carbon is typically shipped off-site as a hazardous waste.[54]

III.C. Management of Chemicals In Wastestream

The Pollution Prevention Act of 1990 (PPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has increased and the portions treated or managed through treatment on-site have decreased between 1992 and 1995 (projected). While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The PPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 10 shows that the inorganic chemicals industry managed about 1.7 trillion pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, 15 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 85 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns E, F and G, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns H, I and J, respectively. The remaining portion of the production related wastes (11 percent), shown in column D, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

Exhibit 10: Source Reduction and Recycling Activity for Inorganic Chemicals Industry (SIC 281) as Reported within TRI

A	B	C	D	On-Site			Off-Site		
				E	F	G	H	I	J
Year	Quantity of Production-Related Waste (10^6 lbs.)[a]	% Released and Transferred[b]	% Released and Disposed[c] Off-site	% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated
1992	1,642	16%	12%	42%	0%	42%	<1%	<1%	3%
1993	1,712	15%	11%	45%	0%	40%	<1%	<1%	3%
1994	1,759	---	11%	47%	<1%	39%	<1%	<1%	3%
1995	1,732	---	10%	48%	0%	40%	<1%	<1%	3%

[a] Within this industry sector, non-production related waste is < 1% of production related wastes for 1993.
[b] Total TRI transfers and releases as reported in Section 5 and 6 of Form R as a percentage of production related wastes.
[c] Percentage of production related waste released to the environment and transferred off-site for disposal.

R0075435

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act. TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. TRI is not specific to the chemical industry. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases, please note that in general, toxic chemical releases across all industries have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7 percent between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- is the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- include all air emissions from industry activity. Point emission occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of toxic chemicals in waste to on-site landfills, land treated or incorporation into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Inorganic Chemical Industry

The 1993 TRI data presented in Exhibits 11 and 12 for inorganic chemicals manufacturing covers 555 facilities. These facilities listed SIC 281 (industrial inorganic chemicals) as a primary SIC code. The Bureau of Census identified 1,429 facilities manufacturing inorganic chemicals. More than half of these facilities, however, have fewer than 20 employees, many of which are likely to be below the TRI reporting thresholds of employment (TRI reporting threshold is greater than 10 employees) and/or chemical use and, therefore, are not required to report to TRI.

According to TRI data, in 1993 the inorganic chemical industry released (discharged to the air, water, or land without treatment) and transferred (shipped off-site) a total of 250 million pounds of 112 different chemical toxic chemicals. This represents about 10 percent of the TRI releases and transfers of the chemical manufacturing industry and about three percent of the total releases and transfers of all manufacturers that year. In comparison, the organic chemical industry (SIC 286) produced 438 million pounds that year, almost twice that of the inorganic chemical industry.[55]

The chemical industry's <u>releases</u> have been declining in recent years. Between 1988 and 1993 TRI emissions from chemical companies (all those categorized within SIC 28, not just inorganic chemical manufacturers) to air, land, and water were reduced 44 percent, which is slightly above the average for all manufacturing sectors reporting to TRI.[56]

Because the chemical industry (SIC 28) has historically released more TRI chemicals than any other industry, the EPA has worked to improve environmental performance within this sector. This has been done through a combination of enforcement actions, regulatory requirements, pollution prevention projects, and voluntary programs (e.g. 33/50). In addition, the chemical industry has focused on reducing pollutant releases. For example, the Chemical Manufacturers Association's (CMA's) Responsible Care initiative is intended to reduce or eximinate chemical manufacturers' waste. All 184 members of the CMA, firms that account for the majority of U.S. chemical industry sales and earnings, are required to participate in the program. Participation involves demonstrating a commitment to the program's mandate of continuous improvement in environment, health, and safety. In June of 1994, the CMA approved the use of a third-party verification of management plans to meet these objectives.

Exhibits 11 and 12 present the number and volumes of chemicals released and transferred by inorganic chemical facilities, respectively. The frequency with which chemicals are reported by facilities within a sector is one indication of the diversity of operations and processes. Many of the TRI chemicals are released or transferred by only a small number of facilities which indicates a wide diversity of production processes, particularly for specialty inorganics -- over 70 percent of the 110 chemicals reported are released or transferred by fewer than 10 facilities.

The inorganic chemical industry releases 69 percent of its total TRI poundage to the water (including 67 percent to underground injection and two percent to surface waters), 14 percent to the air, and 17 percent to the land. This release profile differs from other TRI industries which average approximately 30 percent to the water, 59 percent to air, and 10 percent to land. Examining the inorganic chemical industry's TRI reported toxic chemical releases highlights the likely origins of the large water releases for the industry (Exhibit 11).

As presented in Exhibit 11, on-site underground injection of essentially one chemical, hydrochloric acid, accounts for the largest portion, 55 percent, of the inorganic chemical industry's total releases and transfers as reported in TRI. Only five facilities of the 555 identified facilities reported releasing hydrochloric acid through underground injection. Two of these facilities accounted for over 85 percent of the total hydrochloric acid injected to the subsurface, or 42 percent of the inorganic chemical industry's total releases and transfers. Land disposal accounted for the next largest amount, 17 percent, of the industry's total releases. The largest single chemical released to the air by the inorganic chemical industry, carbonyl sulfide, is only emitted by eleven facilities manufacturing certain inorganic pigments.

Discharges to POTWs accounted for 43 percent of the industry's total transfers of TRI chemicals. Ammonia, hydrochloric acid, and sulfuric acid account for over 66 percent of the 70 million pounds transferred off-site. Finally, approximately 22 million pounds, accounting for 31 percent of the total, are transferred off-site for treatment (Exhibit 12).

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear on the first list. The second list contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations -- some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibit 13: Top 10 TRI Releasing Inorganic Chemicals Facilities[b]

Rank	Facility	Total TRI Releases in Pounds
1	Du Pont Delisle Plant - Pass Christian, MS	58,875,734
2	Du Pont Johnsonville Plant - New Johnsonville, TN	51,215,700

IV.B. Summary of Selected Chemicals Released

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), and the Hazardous Substances Data Bank (HSDB), accessed via TOXNET. TOXNET is a computer system run by the National Library of Medicine. It includes a number of toxicological databases managed by EPA, the National Cancer Institute, and the National Institute for Occupational Safety and Health.[d] HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure

[c] Being included on this list does not mean that the release is associated with non-compliance with environmental laws.

[d] Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory).

potential, exposure standards and regulations, monitoring and analysis methods, and additional references. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB. For more information on TOXNET, contact the TOXNET help line at 800-231-3766.

Hydrochloric Acid (CAS: 7647-01-1)

Sources. Hydrochloric acid is one of the highest volume chemicals produced by the inorganic chemical industry. Some of its more common uses are as a pickling liquor and metal cleaner in the iron and steel industry, as an activator of petroleum wells, as a boiler scale remover, and as a neutralizer of caustic waste streams. The largest release of hydrochloric acid by the inorganic chemical industry is in the form of underground injection of spent hydrochloric acid used to manufacture chlorosulfonic acid and other products.[57]

Toxicity. Hydrochloric acid is primarily a concern in its aerosol form. Acid aerosols have been implicated in causing and exacerbating a variety of respiratory ailments. Dermal exposure and ingestion of highly concentrated hydrochloric acid can result in corrosivity.

Ecologically, accidental releases of solution forms of hydrochloric acid may adversely affect aquatic life by including a transient lowering of the pH (i.e., increasing the acidity) of surface waters.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of hydrochloric acid to surface waters and soils will be neutralized to an extent due to the buffering capacities of both systems. The extent of these reactions will depend on the characteristics of the specific environment.

Physical Properties. Concentrated hydrochloric acid is highly corrosive.

Chromium and Chromium Compounds (CAS: 7440-47-3; 20-06-4)

Sources. Chrome pigments, chromates, chromic acid, chromium salts, and other inorganic chromium compounds are some of the larger volume products of the inorganic chemicals industry. Chrome is used as a plating element for metal and plastics to prevent corrosion, and as a constituent of certain steels and inorganic pigments. Most chromium wastes released to the environment by the inorganic chemicals industry are land disposed in the form of chromium containing sludges.

Toxicity. Although the naturally-occurring form of chromium metal has very low toxicity, chromium from industrial emissions is highly toxic due to strong oxidation characteristics and cell membrane permeability. The majority of the effects detailed below are based on Chromium VI (an isomer that is more toxic than Cr III). Exposure to chromium metal and insoluble chromium salts affects the respiratory system. Inhalation exposure to chromium and chromium salts may cause severe irritation of the upper respiratory tract and scarring of lung tissue. Dermal exposure to chromium and chromium salts can also cause sensitive dermatitis and skin ulcers.

Ecologically, although chromium is present in small quantities in all soils and plants, it is toxic to plants at higher soil concentrations (i.e., 0.2 to 0.4 percent in soil).

Carcinogenicity. Different sources disagree on the carcinogenicity of chromium. Although an increased incidence in lung cancer among workers in the chromate-producing industry has been reported, data are inadequate to confirm that chromium is a human carcinogen. Other sources consider chromium VI to be a known human carcinogen based on inhalation exposure.

Environmental Fate. Chromium is a non-volatile metal with very low solubility in water. If applied to land, most chromium remains in the upper five centimeters of soil. Most chromium in surface waters is present in particulate form as sediment. Airborne chromium particles are relatively unreactive and are removed from the air through wet and dry deposition. The precipitated chromium from the air enters surface water or soil. Chromium bioaccumulates in plants and animals, with an observed bioaccumulation factor of 1,000,000 in snails.

Carbonyl Sulfide (CAS: 463-58-1)

Sources. Carbonyl sulfide is the largest volume chemical released to the air by the inorganic chemicals industry. Carbonyl sulfide is primarily generated by a relatively small number of facilities hydrolyzing ammonium or potassium thiocyanate during the manufacturing of inorganic pigments and dyes.[58]

Toxicity. Exposure to low to moderate concentrations of carbonyl sulfide causes eye and skin irritation and adverse central nervous system effects such as giddiness, headache, vertigo, amnesia, confusion, and unconsciousness. If ingested, gastrointestinal effects include profuse salivation, nausea, vomiting and diarrhea. Moderate carbonyl sulfide poisoning also causes rapid breathing and heartbeat, sweating, weakness, and muscle cramps. Exposure to very high concentrations of carbonyl sulfide causes sudden collapse, unconsciousness, and death from sudden respiratory paralysis. Recovery from sublethal exposure is slow, but generally complete. Degradation products of carbonyl sulfide (especially hydrogen sulfide) can result in toxic symptoms and death.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released to soil or surface waters, carbonyl sulfide will rapidly volatilize. It is not expected to adsorb to soil sediments or organic matter nor is it expected to bioconcentrate in fish and aquatic organisms. Carbonyl sulfide is hydrolyzed in water to carbon dioxide and hydrogen sulfide. Carbonyl sulfide is expected to have a long residence time in the atmosphere. Atmospheric removal of carbonyl sulfide may occur by slow reactions with other gases, and may also occur through adsorption by plants and soil microbes.

Manganese and Manganese Compounds (CAS: 7439-96-5; 20-12-2)

Sources. Manganese is both a product and chemical intermediate of the inorganic chemical industry. Manganese is used as a purifying and scavenging agent in metal production, as an intermediate in aluminum production and as a constituent of non-ferrous alloys to improve corrosion resistance and hardness.[59]

Toxicity. There is currently no evidence that human exposure to manganese at levels commonly observed in ambient atmosphere results in adverse health effects. However, recent EPA review of the fuel additive MMT (methylcyclopentadienyl manganese tricarbonyl) concluded that use of MMT in gasoline could lead to ambient exposures to manganese at a level sufficient to cause adverse neurological effects in humans.

Chronic manganese poisoning bears some similarity to chronic lead poisoning. Occurring via inhalation of manganese dust or fumes, it primarily involves the central nervous system. Early symptoms include languor, speech disturbances, sleepiness, and cramping and weakness in legs. A stolid mask-like appearance of face, emotional disturbances such as absolute detachment broken by uncontrollable laughter, euphoria, and a spastic gait with a tendency to fall while walking are seen in more advanced cases. Chronic manganese poisoning is reversible if treated early and exposure stopped. Populations at greatest risk of manganese toxicity are the very young and those with iron deficiencies.

Ecologically, although manganese is an essential nutrient for both plants and animals, in excessive concentrations manganese inhibits plant growth.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Manganese is an essential nutrient for plants and animals. As such, manganese accumulates in the top layers of soil or surface water sediments and cycles between the soil and living organisms. It occurs mainly as a solid under environmental conditions, though may also be transported in the atmosphere as a vapor or dust

Ammonia (CAS: 7664-41-7)

Sources. Ammonia is used in many chemical manufacturing processes and is the building block for all synthetic nitrogen products. Its prevalence and its volatile and water soluble characteristics allow it to be readily released to the air and water. In the inorganic chemical manufacturing industry, ammonia can be either a feedstock or a by-product. Some of the more common inorganic chemical industry processes using or producing ammonia include the manufacturing of: ammonium chloride, ammonium hydroxide, ammonium thiosulfate, ammonium nitrate, hydrazine, and hydrogen cyanide.

Toxicity. Anhydrous ammonia is irritating to the skin, eyes, nose, throat, and upper respiratory system. Ecologically, ammonia is a source of nitrogen (an essential element for aquatic plant growth), and may therefore contribute to eutrophication of standing or slow-moving surface water, particularly in nitrogen-limited waters such as the Chesapeake Bay. In addition, aqueous ammonia is moderately toxic to aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Ammonia combines with sulfate ions in the atmosphere and is washed out by rainfall, resulting in rapid return of ammonia to the soil and surface waters. Ammonia is a central compound in the environmental cycling of nitrogen. Ammonia in lakes, rivers, and streams is converted to nitrate.

Physical Properties. Ammonia is a corrosive and severely irritating gas with a pungent odor.

IV.C. Other Data Sources

In addition to chemicals covered under TRI, many other chemicals are released. For example, the EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., VOCs. SO_x, NO_x, CO. particulates) from many chemical industry sources.

The EPA Office of Air's Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 15 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM_{10}), total particulate (PT), sulfur dioxide (SO2) and volatile organic compounds (VOCs).

Exhibit 15: Pollutant Releases (short tons/year)

Industry Sector	CO	NO_2	PM_{10}	PT	SO_2	VOC

IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following figure and table do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release Book.

Exhibit 16 is a graphical representation of a summary of the 1993 TRI data for the inorganic chemicals industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 17 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the inorganic chemicals, the 1993 TRI data presented here covers 555 facilities. These facilities listed SIC 2812-2819 (inorganic chemicals) as a primary SIC code.

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimize environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitute toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the inorganic chemical manufacturing industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section also provides the context (in terms of type of industry and/or type of process affected) in which the pollution prevention technique can effectively be used.

There have been numerous cases have where the chemical industry has simultaneously reduced pollutant outputs and operating costs through pollution prevention techniques. In the inorganic chemicals manufacturing sector, however, economically viable pollution prevention opportunities are not as easily identified as in other sectors. The relatively small size and limited resources of a typical inorganic chemical facility limits the number of feasible pollution prevention options. The limited resources available to the industry eliminates many pollution prevention options that require significant capital expenditures such as process modifications and process redesign. In addition, the inorganic chemicals industry's products are primarily commodity chemicals for which the manufacturing processes have been developed over many years. Commodity chemical manufacturers redesign their processes infrequently so that redesign of the reaction process or equipment is unlikely in the short term. In addition, the industry's process equipment has been amortized over long periods of time making cost-effective process equipment improvements scarce. As a result, pollution prevention in the inorganic chemicals industry is somewhat restricted to the less costly options, such as minor process modifications, operational changes, raw material substitutions, and recycling.

Pollution prevention in the chemical industry in process specific. As such it is difficult to generalize about the relative merits of different pollution prevention strategies. The age and size of the facility, and the type and number of its processes will determine the most effective pollution prevention strategy. Brief descriptions of some of the more widespread, general pollution prevention techniques found to be effective at inorganic chemicals facilities are provided below. Many of these pollution prevention opportunities can be applied to the petrochemical industry as a whole due to the many similar processes found throughout the industry. It should be noted that many of the ideas identified below as pollution prevention opportunities, aimed at reducing wastes and reducing materials use, have been carried out by the chemicals manufacturing industry for many years as the primary means of improving process efficiencies and increasing profits.

In chlor-alkali production, pollution prevention options have been demonstrated for both the mercury cell and diaphragm cell processes; however, the best opportunity to reduce pollutant outputs, conserve energy, and reduce costs in the chlor-alkali industry are in the conversion to the membrane cell process. In terms of energy consumption, the membrane cell process uses only about 77 percent of that of the mercury cell process and about 90 percent of that of the diaphragm cell process. The membrane cell process also generates significantly less airborne and waterborne pollutants and solid wastes (see Section III.B. - Raw Material Inputs and Pollution Outputs).

Substitute raw materials. The substitution or elimination of some of the raw materials used in the manufacturing of inorganic chemicals can result in substantial waste reductions and cost savings. Because impurities in the feed stream can be a major contributor to waste generation, one of the most common substitutions is to use a higher purity feedstock. This can be accomplished either by working with suppliers to get a higher quality feed or by installing purification equipment. Raw materials can also be substituted with less toxic and less water soluble materials to reduce water contamination, and with less volatile materials to reduce fugitive emissions. Sometimes certain raw materials can be eliminated all together. The need for raw materials that end up as wastes should be reexamined to determine if raw materials can be eliminated by modifying the process and improving control.

Improve reactor efficiencies. Since the chemical products are primarily created inside the process reactor, it can be the primary source for waste (off-spec) materials. One of the most important parameters dictating the reactor efficiency is the quality of mixing. A number of techniques can be used to improve mixing, such as installing baffles in the reactor, a higher rpm motor for the agitator, a different mixing blade design, multiple impellers, and pump recirculation. The method used to introduce feed to the reactor can also have an effect on the quality of mixing. A feed distributor can be added to equalize residence time through the reactor, and feed streams can be added at a point in time closer to the ideal reactant concentration. This will avoid secondary reactions which form unwanted by-products.

Improve catalyst. The catalyst plays a critical role in the effectiveness of chemical conversion in the reactor. Alternative chemical makeups and physical characteristics can lead to substantial improvements in the effectiveness and life of a catalyst. Different catalysts can also eliminate by-product formation. Noble metal catalysts can replace heavy metal catalysts to eliminate wastewater contaminated with heavy metals. The consumption of catalysts can be reduced by using a more active form and emissions and effluents generated during catalyst activation can be eliminated by obtaining the catalyst in the active form.

Optimize processes. Process changes that optimize reactions and raw materials use can reduce waste generation and releases. Many larger facilities are using computer controlled systems which analyze the process continuously and respond more quickly and accurately than manual control systems. These systems are often capable of automatic startups, shutdowns. and product changeover which can bring the process to stable conditions quickly, minimizing the generation of off-spec wastes. Other process optimization techniques include: equalizing the reactor and storage tank vent lines during batch filling to minimize vent gas losses; sequencing the addition of reactants and reagents to optimize yields and lower emissions; and optimizing sequences to minimize washing operations and cross-contamination of subsequent batches.

Reduce heat exchanger wastes and inefficiencies. Heat exchangers are often the source of significant off-spec product wastes generated by overheating the product closest to the tube walls. The best way to reduce off-spec product from overheating is by reducing the heat exchanger tube wall temperature. This can be accomplished through a number of techniques which do not reduce the overall heat transferred such as: reducing the tube wall temperature and increasing the effective surface area of the heat exchanger; using staged heating by first heating with waste heat, then low pressure steam, followed by superheated high pressure steam; monitor and prevent fouling of the heat exchanger tubes so that lower temperature heat sources can be used; using noncorroding tubes which will foul less quickly than tubes that corrode.

Improve wastewater treatment and recycling. A large portion of the inorganic chemical industry's pollutants leave the facilities as wastewater or wastewater treatment system sludge. Improved treatment and minimization of wastewater are effective pollution prevention opportunities that often do not require significant changes to the industrial processes. Modern wastewater treatment technologies such as ion exchange, electrolytic cells.

reverse osmosis, and improved distillation, evaporation, and dewatering can often be added to existing treatment systems. Wastewater streams containing acids or metals can be concentrated enough to be sold commercially as a product by slightly altering the manufacturing process, adding processing steps, and segregating wastewater streams. Furthermore, many wastewater streams can be reused within the same or different processes, significantly reducing discharges to the wastewater treatment system. An ion exchange system installed in a mercury cell chlor-alkali plant reduced mercury by 99 percent in the facility's effluent. An inorganic chemicals plant making photochemistry solution generated a wastewater containing silver. Electrolytic cells were installed that recovered 98 percent of the silver and an evaporator was added that concentrated the remaining liquid for disposal resulting in a 90 percent reduction in waste volume.

Prevent leaks and spills. The elimination of sources of leaks and spills can be a very cost effective pollution prevention opportunity. Leaks and spills can be prevented by installing seamless pumps and other "leakless" components, maintaining a preventative maintenance program, and maintaining a leak detection program.

Improve inventory management and storage. Good inventory management can reduce the generation of wastes by preventing materials from exceeding their shelf life, preventing materials from being left over or not needed, and reducing the likelihood of accidental releases of stored material. Designating a materials storage area, limiting traffic through the area, and giving one person the responsibility to maintain and distribute materials can reduce materials use, and the contamination and dispersal of materials.

Exhibit 18 summarizes the above pollution prevention opportunities and provides additional examples provided by the Chemical Manufacturers Association.

Exhibit 18: Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
Byproducts Coproducts		
Quantity and Quality	▪ Process inefficiencies result in the generation of undesired by-products and co-products. Inefficiencies will require larger volumes of raw materials and result in additional secondary products. Inefficiencies can also increase fugitive emissions and wastes generated through material handling.	▪ Increase product yield to reduce by-product and co-product generation and raw material requirements.
Uses and Outlets	▪ By-products and co-products are not fully utilized, generating material or waste that must be managed.	▪ Identify uses and develop a sales outlet. Collect information necessary to firm up a purchase commitment such as minimum quality criteria, maximum impurity levels that can be tolerated, and performance criteria.
Catalysts		
Composition	▪ The presence of heavy metals in catalysts can result in contaminated process wastewater from catalyst handling and separation. These wastes may require special treatment and disposal procedures or facilities. Heavy metals can be inhibitory or toxic to biological wastewater treatment units. Sludge from wastewater treatment units may be classified as hazardous due to heavy metals content. Heavy metals generally exhibit low toxicity thresholds in aquatic environments and may bioaccumulate.	▪ Catalysts comprised of noble metals, because of their cost, are generally recycled by both onsite and offsite reclaimers.
Preparation and Handling	▪ Emissions or effluents are generated with catalyst activation or regeneration.	▪ Obtain catalyst in the active form. ▪ Provide in situ activation with appropriate processing/activation facilities.
	▪ Catalyst attrition and carry over into product requires de-ashing facilities which are a likely source of wastewater and solid waste.	▪ Develop a more robust catalyst or support.

R0075462

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Catalysts (cont'd)		
Preparation and Handling (cont')	▪ Catalyst is spent and needs to be replaced.	▪ In situ regeneration eliminates unloading/loading emissions and effluents versus offsite regeneration or disposal.
	▪ Pyrophoric catalyst needs to be kept wet, resulting in liquid contaminated with metals.	▪ Use a nonpryrophoric catalyst. Minimize amount of water required to handle and store safely.
	▪ Short catalyst life.	▪ Study and identify catalyst deactivation mechanisms. Avoid conditions which promote thermal or chemical deactivation. By extending catalyst life, emissions and effluents associated with catalyst handling and regeneration can be reduced.
Effectiveness	▪ Catalyzed reaction has by-product formation, incomplete conversion and less-than-perfect yield.	▪ Reduce catalyst consumption with a more active form. A higher concentration of active ingredient or increased surface area can reduce catalyst loadings.
		▪ Use a more selective catalyst which will reduce the yield of undesired by-products.
	▪ Catalyzed reaction has by-product formation, incomplete conversion and less-than perfect yield.	▪ Improve reactor mixing/contacting to increase catalyst effectiveness.
		▪ Develop a thorough understanding of reaction to allow optimization of reactor design. Include in the optimization, catalyst consumption and by-product yield.
Intermediate Products		
Quantity and Quality	▪ Intermediate reaction products or chemical species, including trace levels of toxic constituents, may contribute to process waste under both normal and upset conditions.	▪ Modify reaction sequence to reduce amount or change composition of intermediates.
	▪ Intermediates may contain toxic constituents or have characteristics that are harmful to the environment.	▪ Modify reaction sequence to change intermediate properties. ▪ Use equipment design and process control to reduce releases.

R0075463

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Process Conditions/ Configuration		
Temperature	▪ High heat exchange tube temperatures cause thermal cracking/decomposition of many chemicals. These lower molecular weight by-products are a source of "light ends" and fugitive emissions. High localized temperature gives rise to polymerization of reactive monomers, resulting in "heavies" or "tars." such materials can foul heat exchange equipment or plug fixed-bed reactors, thereby requiring costly equipment cleaning and production outage.	▪ Select operating temperatures at or near ambient temperature whenever possible. ▪ Use lower pressure steam to lower temperatures. ▪ Use intermediate exchangers to avoid contact with furnace tubes and walls. ▪ Use staged heating to minimize product degradation and unwanted side reactions. ▪ Use a super heat of high-pressure steam in place of furnace. ▪ Monitor exchanger fouling to correlate process conditions which increase fouling, avoid conditions which rapidly foul exchangers. ▪ Use online tube cleaning technologies to keep tube surfaces clean to increase heat transfer. ▪ Use scraped wall exchangers in viscous service. ▪ Use falling film reboiler, pumped recirculation reboiler or high-flux tubes.
	▪ Higher operating temperatures imply "heat input" usually via combustion which generates emissions.	▪ Explore heat integration opportunities (e.g., use waste heat to preheat materials and reduce the amount of combustion required.)
	▪ Heat sources such as furnaces and boilers are a source of combustion emissions.	▪ Use thermocompressor to upgrade low-pressure steam to avoid the need for additional boilers and furnaces.
	▪ Vapor pressure increases with increasing temperature. Loading/ unloading, tankage and fugitive emissions generally increase with increasing vapor pressure.	▪ If possible, cool materials before sending to storage. ▪ Use hot process streams to reheat feeds.

R0075464

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Process Conditions/ Configuration (cont'd)		
Temperature (cont'd)		▪ Add vent condensers to recover vapors in storage tanks or process.
		▪ Add closed dome loading with vapor recovery condensers.
	▪ Water solubility of most chemicals increases with increasing temperature.	▪ Use lower temperature (vacuum processing).
Pressure	▪ Fugitive emissions from equipment.	▪ Equipment operating in vacuum service is not a source of fugitives; however, leaks into the process require control when system is degassed.
	▪ Seal leakage potential due to pressure differential.	▪ Minimize operating pressure.
	▪ Gas solubility increases with higher pressures.	▪ Determine whether gases can be recovered, compressed, and reused or require controls.
Corrosive Environment	▪ Material contamination occurs from corrosion products. Equipment failures result in spills, leaks, and increased maintenance costs.	▪ Improve metallurgy or provide coating or lining.
		▪ Neutralize corrosivity of materials contacting equipment.
		▪ Use corrosion inhibitors.
		▪ Improve metallurgy or provide coating or lining.
	▪ Increased waste generation due to addition of corrosion inhibitors or neutralization.	▪ Improve metallurgy or provide coating or lining or operate in a less corrosive environment.
Batch vs. Continuous Operations	▪ Vent gas lost during batch fill.	▪Equalize reactor and storage tank vent lines.
		▪Recover vapors through condenser, adsorber, etc.
	▪ Waste generated by cleaning/purging of process equipment between production batches.	▪ Use materials with low viscosity. Minimize equipment roughness.

R0075465

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Process Conditions/ Configuration (cont'd)		
Batch vs. Continuous Operations (cont'd)		▪ Optimize product manufacturing sequence to minimize washing operations and cross-contamination of subsequent batches.
	▪ Process inefficiencies lower yield and increase emissions.	▪ Sequence addition of reactants and reagents to optimize yields and lower emissions.
	▪ Continuous process fugitive emissions and waste increase over time due to equipment failure through a lack of maintenance between turnarounds.	▪Design facility to readily allow maintenance so as to avoid unexpected equipment failure and resultant release.
Process Operation/Design	▪ Numerous processing steps create wastes and opportunities for errors.	▪ Keep it simple. Make sure all operations are necessary. More operations and complexity only tend to increase potential emission and waste sources.
	▪ Nonreactant materials (solvents, absorbents, etc.) create wastes. Each chemical (including water) employed within the process introduces additional potential waste sources; the composition generated wastes also tends to become more complex.	▪ Evaluate unit operation or technologies (e.g., separation) that do not require the addition of solvents or other nonreactant chemicals.
	▪ High conversion with low yield results in wastes.	▪ Recycle operations generally improve overall use of raw materials and chemicals, thereby increasing the yield of desired products while at the same time reducing the generation of wastes. A case-in-point is to operate at a lower conversion per reaction cycle by reducing catalyst consumption, temperature, or residence time. Many times, this can result in a higher selectivity to desired products. The net effect upon recycle of unreacted reagents is an increase in product yield, while at the same time reducing the quantities of spent catalyst and less desirable by-products.

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Process Conditions/ Configuration (cont'd)		
Process Operation/Design	▪ Non-regenerative treatment systems result in increased waste versus regenerative systems.	▪ Regenerative fixed bed treating or desiccant operation (e.g.. aluminum oxide, silica, activated carbon, molecular sieves, etc.) will generate less quantities of solid or liquid waste than nonregenerative units (e.g., calcium chloride or activated clay). With regenerative units though, emissions during bed activation and regeneration can be significant. Further, side reactions during activation/regeneration can give rise to problematic pollutants.
Product		
Process Chemistry	▪ Insufficient R&D into alternative reaction pathways may miss pollution opportunities such as reducing waste or eliminating a hazardous constituent.	▪ R&D during process conception and laboratory studies should thoroughly investigate alternatives in process chemistry that affect pollution prevention.
Product Formulation	▪ Product based on end-use performance may have undesirable environmental impacts or use raw materials or components that generate excessive or hazardous wastes.	▪ Reformulate products by substituting different material or using a mixture of individual chemicals that meet end-use performance specifications.
Raw Materials		
Purity	▪ Impurities may produce unwanted by-products and waste. Toxic impurities, even in trace amounts, can make a waste hazardous and therefore subject to strict and costly regulation.	▪ Use higher purity materials. ▪ Purify materials before use and reuse if practical. ▪ Use inhibitors to prevent side reactions.
	▪ Excessive impurities may require more processing and equipment to meet product specifications, increasing costs and potential for fugitive emissions, leaks, and spills.	▪ Achieve balance between feed purity, processing steps, product quality, and waste generation.

R0075467

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Raw Materials (cont'd)		
Purity (cont'd)	▪ Specifying a purity greater than needed by the process increases costs and can generate more waste generation by the supplier.	▪ Specify a purity no greater than what the process needs.
	▪ Impurities in clean air can increase inert purges.	▪Use pure oxygen.
	▪ Impurities may poison catalyst prematurely resulting in increased wastes due to yield loss and more frequent catalyst replacement.	▪Install guard beds to protect catalysts.
Vapor Pressure	▪ Higher vapor pressures increase fugitive emissions in material handling and storage.	▪ Use material with lower vapor pressure.
	▪ High vapor pressure with low odor threshold materials can cause nuisance odors.	▪ Use materials with lower vapor pressure and higher odor threshold.
Water Solubility	▪ Toxic or nonbiodegradable materials that are water soluble may affect wastewater treatment operation, efficiency, and cost.	▪ Use less toxic or more biodegradable materials.
	▪ Higher solubility may increase potential for surface and groundwater contamination and may require more careful spill prevention, containment, and cleanup (SPCC) plans.	▪ Use less soluble materials.
	▪ Higher solubility may increase potential for storm water contamination in open areas.	▪ Use less soluble materials. ▪ Prevent direct contact with storm water by diking or covering areas.
	▪ Process wastewater associated with water washing or hydrocarbon/water phase separation will be impacted by containment solubility in water. Appropriate wastewater treatment will be impacted.	▪ Minimize water usage. ▪ Reuse wash water. ▪ Determine optimum process conditions for phase separation. ▪ Evaluate alternative separation technologies (coalescers, membranes, distillation, etc.)

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Raw Materials (cont'd)		
Toxicity	▪ Community and worker safety and health concerns result from routine and nonroutine emissions. Emissions sources include vents, equipment leaks, wastewater emissions, emergency pressure relief, etc.	▪ Use less toxic materials. ▪ Reduce exposure through equipment design and process control. Use systems which are passive for emergency containment of toxic releases.
	▪ Surges or higher than normal continuous levels of toxic materials can shock or miss wastewater biological treatment systems resulting in possible fines and possible toxicity in the receiving water.	▪ Use less toxic material. ▪ Reduce spills, leaks, and upset conditions through equipment and process control. ▪ Consider effect of chemicals on biological treatment; provide unit pretreatment or diversion capacity to remove toxicity. ▪ Install surge capacity for flow and concentration equalization.
Regulatory	▪ Hazardous or toxic materials are stringently regulated. They may require enhanced control and monitoring; increased compliance issues and paperwork for permits and record keeping; stricter control for handling, shipping, and disposal; higher sampling and analytical costs; and increased health and safety costs.	▪ Use materials which are less toxic or hazardous. ▪ Use better equipment and process design to minimize or control releases; in some cases, meeting certain regulatory criteria will exempt a system from permitting or other regulatory requirements.
Form of Supply	▪ Small containers increase shipping frequency which increases chances of material releases and waste residues from shipping containers (including wash waters).	▪ Use bulk supply, ship by pipeline, or use "jumbo" drums or sacks. ▪ In some cases, product may be shipped out in the same containers the material supply was shipped in without washing.
	▪ Nonreturnable containers may increase waste.	▪ Use returnable shipping containers or drums.
Handling and Storage	▪ Physical state (solid, liquid, gaseous) may raise unique environmental, safety, and health issues with unloading operations and transfer to process equipment.	▪ Use equipment and controls appropriate to the type of materials to control releases.

R0075469

Exhibit 18 (cont.): Process/Product Modifications Create Pollution Prevention Ops.

Area	Potential Problem	Possible Approach
Raw Materials (cont'd)		
Handling and Storage (cont'd)	▪ Large inventories can lead to spills, inherent safety issues and material expiration.	▪ Minimize inventory by utilizing just-in-time delivery.
Waste Streams		
Quantity and Quality	▪ Characteristics and sources of waste streams are unknown.	▪ Document sources and quantities of waste streams prior to pollution prevention assessment.
	▪ Wastes are generated as part of the process.	▪ Determine what changes in process conditions would lower waste generation of toxicity.
		▪ Determine if wastes can be recycled back into the process.
Composition	▪ Hazardous or toxic constituents are found in waste streams. Examples are: sulfides, heavy metals, halogenated hydrocarbons, and polynuclear aromatics.	▪ Evaluate whether different process conditions, routes, or reagent chemicals (e.g., solvent catalysts) can be substituted or changed to reduce or eliminate hazardous or toxic compounds.
Properties	▪ Environmental fate and waste properties are not known or understood.	▪ Evaluate waste characteristics using the following type properties: corrosivity, ignitability, reactivity, BTU content (energy recovery), biodegradability, aquatic toxicity, and bioaccumulation potential of the waste and of its degradable products, and whether it is a solid, liquid, or gas.
Disposal	▪ Ability to treat and manage hazardous and toxic waste unknown or limited.	▪ Consider and evaluate all onsite and offsite recycle, reuse, treatment, and disposal options available. Determine availability of facilities to treat or manage wastes generated.

Exhibit 19: Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Compressors, blowers, fans	▪ Shaft seal leaks Piston rod seal leaks Vent streams	▪ Seal-less designs (diaphragmatic, hermetic or magnetics) ▪ Design for low emissions (internal balancing, double inlet, gland eductors) ▪ Shaft seal designs (carbon rings, double mechanical seals, buffered seals) ▪ Double seal with barrier fluid vented to control device	▪ Preventive maintenance program
Concrete pads, floors, sumps	▪ Leaks to groundwater	▪ Water stops ▪ Embedded metal plates ▪ Epoxy sealing ▪ Other impervious sealing	▪ Reduce unnecessary purges, transfers, and sampling ▪ Use drip pans where necessary
Controls	▪ Shutdowns and Start-ups generate waste and releases	▪ Improve on-line controls ▪ On-line instrumentation ▪ Automatic start-up and shutdown ▪ On-line vibration analysis ▪ Use "consensus" systems (e.g., shutdown trip requires two out of three affirmative responses)	▪ Continuous versus batch ▪ Optimize on-line run time ▪ Optimize shutdown interlock inspection frequency ▪ Identify safety and environment critical instruments and equipment
Distillation	▪ Impurities remain in process streams	▪ Increase reflux ratio ▪ Add section to column ▪ Column intervals ▪ Change feed tray	▪ Change column operating conditions - reflux ratio - feed tray - temperature - pressure - etc.

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Distillation (cont'd)	▪ Impurities remain in process streams (cont'd)	▪ Insulate to prevent heat loss ▪ Preheat column feed ▪ Increase vapor line size to lower pressure drop	▪ Clean column to reduce fouling
	▪ Large amounts of contaminated water condensage from stream stripping	▪ Use reboilers or inert gas stripping agents	▪ Use higher temperature steam
General manufacturing equipment areas	▪ Contaminated rainwater	▪ Provide roof over process facilities ▪ Segregate process sewer from storm sewer (diking) ▪ Hard-pipe process streams to process sewer	▪ Return samples to process ▪ Monitor stormwater discharge
	▪ Contaminated sprinkler and fire water	▪ Seal floors ▪ Drain to sump ▪ Route to waste treatment	
	▪ Leaks and emissions during cleaning	▪ Design for cleaning ▪ Design for minimum rinsing ▪ Design for minimum sludge ▪ Provide vapor enclosure ▪ Drain to process	▪ Use drip pans for maintenance activities ▪ Rinse to sump ▪ Reuse cleaning solutions

R0075472

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Heat exchangers	▪ Increased waste due to high localized temperatures	▪ Use intermediate exchangers to avoid contact with furnace tubes and walls ▪ Use staged heating to minimize product degradation and unwanted side reactions. (waste heat >>low pressure steam >>high pressure steam) ▪ Use scraped wall exchangers in viscous service ▪ Using falling film reboiler, piped recirculation reboiler or high-flux tubes ▪ Use lowest pressure steam possible	▪ Select operating temperatures at or near ambient temperature whenever possible. These are generally most desirable from a pollution prevention standpoint ▪ Use lower pressure steam to lower temperatures ▪ Monitor exchanger fouling to correlate process conditions which increase fouling, avoid conditions which rapidly foul exchangers ▪ Use on-line tube cleaning techniques to keep tube surfaces clean
	▪ Contaminated materials due to tubes leaking at tube sheets	▪ Use welded tubes or double tube sheets with inert purge. Mount vertically	▪ Monitor for leaks
	▪ Furnace emissions	▪ Use super heat of high-pressure steam in place of a furnace	
Piping	▪ Leaks to groundwater Fugitive emissions	▪ Design equipment layout so as to minimize pipe run length ▪ Eliminate underground piping or design for cathodic protection if necessary to install piping underground ▪ Use welded fittings ▪ Reduce number of flanges and valves	▪ Monitor for corrosion and erosion ▪ Paint to prevent external corrosion

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Piping (cont'd)	▪ Leaks to groundwater Fugitive emissions (cont'd)	▪ Use all welded pipe ▪ Use secondary containment ▪ Use spiral-wound gaskets ▪ Use plugs and double valves for open end lines ▪ Change metallurgy ▪ Use lined pipe	
	▪ Releases when cleaning or purging lines	▪ Use "pigs" for cleaning ▪ Slope to low point drain ▪ Use heat tracing and insulation to prevent freezing ▪ Install equalizer lines	▪ Flush to product storage tank
Pumps	▪ Fugitive emissions from shaft seal leaks	▪ Mechanical seal in lieu of packing ▪ Double mechanical seal with inert barrier fluid ▪ Double machined seal with barrier fluid vented to control device ▪ Seal-less pump (canned motor magnetic drive) ▪ Vertical pump	▪ Seal installation practices ▪ Monitor for leaks
	▪ Fugitive emissions from shaft seal leaks	▪ Use pressure transfer to eliminate pump	
	▪ Residual "heel" of liquid during pump maintenance	▪ Low point drain on pump casing	▪ Flush casing to process sewer for treatment

R0075474

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Pumps (cont'd)	▪ Injection of seal flush fluid into process stream	▪ Use double mechanical seal with inert barrier fluid where practical	▪ Increase the mean time between pump failures by: - selecting proper seal material; - aligning well; - reducing pipe-induced stress; - maintaining seal lubrication
Reactors	▪ Poor conversion or performance due to inadequate mixing	▪ Static mixing ▪ Add baffles ▪ Change impellers	▪ Add ingredients with optimum sequence
		▪ Add horsepower ▪ Add distributor	▪ Allow proper head space in reactor to enhance vortex effect
	▪ Waste by-product formation	▪ Provide separate reactor for converting recycle streams to usable products	▪ Optimize reaction conditions (temperature, pressure, etc.)
Relief Valve	▪ Leaks	▪ Provide upstream rupture disc	
	▪ Fugitive emissions	▪ Vent to control or recovery device	▪ Monitor for leaks and for control efficiency
	▪ Discharge to environment from over pressure	▪ Pump discharges to suction of pump ▪ Thermal relief to tanks ▪ Avoid discharge to roof areas to prevent contamination of rainwater	▪ Monitor for leaks
	▪ Frequent relief	▪ Use pilot operated relief valve ▪ Increase margin between design and operating pressure	▪ Reduce operating pressure ▪ Review system performance

R0075475

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Sampling	▪ Waste generation due to sampling (disposal, containers, leaks, fugitives, etc.)	▪ On line in situ analyzers ▪ System for return to process ▪ Closed loop ▪ Drain to sump	▪ Reduce number and size of samples required ▪ Sample at the lowest possible temperature ▪ Cool before sampling
Tanks	▪ Tank breathing and working losses	▪ Cool materials before storage ▪ Insulate tanks ▪ Vent to control device (flare, condenser, etc.) ▪ Vapor balancing ▪ Floating roof ▪ Floating roof ▪ Higher design pressure	▪ Optimize storage conditions to reduce losses
	▪ Leak to groundwater	▪ All aboveground (situated so bottom can routinely be checked for leads) ▪ Secondary containment ▪ Improve corrosion resistance	▪ Monitor for leaks and corrosion
	▪ Large waste heel	▪ Design for 100 percent de-inventory	▪ Recycle to process if practical
Vacuum Systems	▪ Waste discharge from jets	▪ Substitute mechanical vacuum pump ▪ Evaluate using process fluid for powering jet	▪ Monitor for air leaks ▪ Recycle condensate to process

Exhibit 19 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Valves	▪ Fugitive emissions from leaks	▪ Bellow seals ▪ Reduce number where practical ▪ Special packing sets	▪ Stringent adherence to packing procedures
Vents	▪ Release to environment	▪ Route to control or recovery device	▪ Monitor performance

Source: Chemical Manufacturers Association. *Designing Pollution Prevention into the Process. Research. Development and Engineering.*

It is critical to emphasize that pollution prevention in the chemical industry is process specific and oftentimes constrained by site-specific considerations. As such, it is difficult to generalize about the relative merits of different pollution prevention strategies. The age, size, and purpose of the plant will influence the most effective pollution prevention strategy. Commodity chemical manufacturers redesign their processes infrequently so that redesign of the reaction process or equipment is unlikely in the short term. Here, operational changes are the most feasible response. Specialty chemical manufacturers are making a greater variety of chemicals and have more process and design flexibility. Incorporating changes at the earlier research and development phases may be possible for them.

R0075477

VI. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section VI.A. contains a general overview of major statutes
- Section VI.B. contains a list of regulations specific to this industry
- Section VI.C. contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and record keeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil** storage and disposal regulations (40 CFR Part 279) do not define **Used Oil Management Standards** impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

R0075481

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized approximately forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing, or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control** (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to

R0075486

manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50 through 99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA

Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Requirements

The inorganic chemical industry is affected by nearly all federal environmental statutes. In addition, the industry is subject to numerous laws and regulations from state and local governments designed to protect and improve health, safety, and the environment. A summary of the major federal regulations affecting the chemical industry follows.

Federal Statutes

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA), passed in 1976, gives the Environmental Protection Agency comprehensive authority to regulate any chemical substance whose manufacture, processing, distribution in commerce, use, or disposal may present an unreasonable risk of injury to health or the environment. Three sections are of primary importance to the inorganic chemical industry. Section 5 mandates that chemical companies submit to EPA pre-manufacture notices that provide information on health and environmental effects for each new product and test existing products for these effects. To date, over 20,000 premanufacturing notices have been filed. Section 4 authorizes the EPA to require testing of certain substances. Section 6 gives the EPA authority to prohibit, limit, or ban the manufacture, process, and use of chemicals. Under Section 6 of TSCA, EPA has banned most uses of asbestos. In 1990, however, the chlor-alkali industry was able to show that it did not have difficulty meeting the required exposure limits for asbestos fibers, and the use of asbestos as a diaphragm material was exempted from the TSCA ban.

Clean Air Act

The Clean Air Act Amendments of 1990 set National Emission Standards for Hazardous Air Pollutants (NESHAP) from industrial sources for 41 pollutants to be met by 1995 and for 148 other pollutants to be reached by 2003. Several provisions affect the inorganic chemical industry. The EPA will promulgate maximum achievable control technology (MACT) standards and Lowest Achievable Emission Rates will be required in NAAQS non-attainment areas (Iliam Rosario, U.S. EPA, OAQPS, WAM for Chlorine Production NESHAP (919)-541-5308). An information collection request survey was sent out to the chlor-alkali industry in 1992. The data obtained from the survey will be analyzed and. based on the results. EPA will propose MACT standards (or EPA may propose that no new standards are necessary) for the chlor-alkali industry by 1997. For any subject facility, a six year extension of MACT requirements is available if they can demonstrate early emission reductions.

The Clean Air Act Amendments of 1990 contain provisions to phase out the use of ozone depleting chemicals such as chlorofluorocarbons, halons, carbon tetrachloride, and methyl chloroform. as required by the Montreal Protocol on Substances that Deplete the Ozone Layer. The chlor-alkali industry has been and will continue to be significantly affected by these provisions due to decreases in the demand for chlorine as a feedstock in manufacturing these chemicals. In addition, many of these chemicals are used extensively by the industry to process chlorine.

Clean Water Act

The Clean Water Act, first passed in 1972 and amended in 1977 and 1987, gives EPA the authority to regulate effluents from sewage treatment works. chemical plants, and other industrial sources into waters. The act sets "best available technology" standards for treatment of wastes for both direct and indirect (to a Publicly Owned Treatment Works) discharges. Effluent guidelines for the chlor-alkali industry were last updated in 1984 (40 CFR Section 415). EPA is currently conducting a study to assess the need for new effluent guidelines. (Contact: George Zipf, U.S. EPA, Office of Water, 202-260-2275)

Restrictions on dioxin emissions in the wastewater from pulp mills are having significant effects on the chlor-alkali industry. Dioxins are formed during the chlorine bleaching process and are subsequently released to rivers and streams. Many mills are switching from chlorine to alternative bleaching agents in response to the effluent restrictions. Pulp mills accounted for about 15 percent of the chlorine demand in the U.S. in 1982 and 11 percent in 1992. The demand for chlorine for pulp bleaching is expected to continue to decrease through the 1990s.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) of 1976 gives the EPA authority to establish a list of solid and hazardous wastes, and to establish standards and regulations for handling and disposing of these wastes. New wastes specific to the inorganic chemical industry have not been added to the RCRA list since the original waste listings in 1980. EPA is currently under a consent order, however, to propose new hazardous waste listings for the industry by March 1997, and to finalize by March 1998.

(Contact: Rick Brandes, U.S. EPA, Office of Solid Waste, 202-260-4770) The Act also requires companies to establish programs to reduce the volume and toxicity of hazardous wastes. It was last amended in 1984 when Congress mandated some 70 new programs for the hazardous waste (Subtitle C) program. Included were tighter standards for handling and disposing of hazardous wastes, land disposal prohibitions, corrective action (or remediation) regulations, and regulations for underground storage tanks. The inorganic chemical industry is strongly affected by the RCRA regulations because of the disposal costs for hazardous waste and the record keeping requirements.

Occupational Safety and Health Act

The Occupational Safety and Health Act gave the Department of Labor the authority to set comprehensive workplace safety and health standards including permissible exposures to chemical in the workplace and authority to conduct inspections and issue citations for violations of safety and health regulations. The chemical industry is subject to hazard identification standards established by OSHA, which require extensive documentation of chemicals in trade and in the workplace and mandate warning labels on containers. The industry is also subject to OSHA's Hazard Communication Standard and various state and local laws, which give workers the right to know about hazardous chemicals in the workplace.

Hazardous Materials Transportation Act

The Hazardous Materials Transportation Act (HMTA) gives the Department of Transportation authority to regulate the movement of hazardous materials. Chemical manufacturers must comply with regulations governing shipment preparation, including packaging, labeling and shipping papers; handling, loading and unloading; routing emergency and security planning; incident notifications; and liability insurance. The chemical manufacturers must also comply with operating requirements for vehicle, vessel, and carrier transportation of hazardous materials by road, rail, air, and sea. The chemicals covered by the HMTA span a broad list of substances, including hazardous wastes normally regulated by RCRA and hazardous materials that DOT designates as hazardous for the purposes of transportation that may not be considered hazardous under RCRA. These regulations especially apply to chlorine gas which can cause significant risk during transport.

Pollution Prevention Act

The Pollution Prevention Act makes it a national policy of the United States to reduce or eliminate the generation of waste at the source whenever feasible. The EPA is directed to undertake a multi-media program of information collection, technology transfer, and financial assistance to enable the states to implement this policy and to promote the use of source reduction techniques. The reorganization of the Office of Compliance by industry sector is part of EPA's response to this act.

State Statutes

Toxics Use Reduction Act, Massachusetts

The Massachusetts Toxics Use Reduction Act affects those facilities that use, manufacture, or process more than a specified amount of substances that are on the Massachusetts toxic or hazardous substances list. Facilities must submit annual reports on the amounts of substances used, manufactured, or processed and must pay annual fees based on these amounts. In addition, facilities must prepare toxics use reduction plans which show in-plant changes in production processes or raw materials that would reduce, avoid, or eliminate the use or generation of toxic or hazardous substances. The Massachusetts toxic or hazardous substance list initially consists of those substances listed under §313 of EPCRA and will eventually include those substances listed under CERCLA. New Jersey has recently passed a similar act.

VI.C. Pending and Proposed Regulatory Requirements

Resource Conservation and Recovery Act (RCRA)

The Resource Conservation and Recovery Act (RCRA) listed waste streams specific to the inorganic chemical industry have not been updated since the original RCRA hazardous wastes list developed in 1980. EPA is under a court-ordered deadline to propose and finalize additional waste listings for the industry by March 1997 and March 1988, respectively. The Office of Solid Waste will begin assessing the need for new listings by early 1996. (Contact: Rick Brandes, U.S. EPA, Office of Solid Waste, 202-260-4770)

Clean Air Act

The new NESHAP standards for the inorganic chemical industry are scheduled to be promulgated by EPA by 1997. (Contact: Iliam Rosario, U.S. EPA, OAQPS, WAM for Chlorine Production NESHAP, 919-541-5308) The standards required will, in most cases, be in the form of MACT standards. Lowest Achievable Emission Rates will be required in NAAQS non-attainment areas. An information collection request survey was sent out to the chlor-alkali industry in 1992. The data obtained will be analyzed and used to assess the need for NESHAP standards in the chlor-alkali industry.

The chlor-alkali industry will continue to be affected by the provisions to phase out the use of ozone depleting chemicals as required by the Montreal Protocol on Substances that Deplete the Ozone Layer. The demand for chlorine as a feedstock in manufacturing these chemicals, which accounted for about 15 percent of total domestic demand in 1990, will continue to decline through the 1990s. In addition, costs of purifying and liquefying chlorine gas may increase as the cost of carbon tetrachloride and refrigerants increases, and as alternative processes are introduced.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections or enforcement actions, and solely reflect EPA, state, and local compliance assurance activity that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[e] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information

[e] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with three enforcement actions counts as one). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with three enforcement actions counts as three).

R0075496

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. Reported inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance. Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame. but do not distinguish between the severity of the noncompliance. Percentages within this column may exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Inorganic Chemical Industry Compliance History

Exhibit 20 provides an overview of the reported compliance and enforcement data for the inorganic chemical industry over the past five years (August 1990 to August 1995). These data are also broken out by EPA Region thereby permitting geographical comparisons. A few points evident from the data are listed below.

- Slightly more than half of the TRI reporting inorganic chemical facilities in the EPA databases were inspected over the five year period resulting in an average of 11 months between inspections of these facilities.

- On average, the states carried out three times the number of inspections as the Regions; however, the percentage of state led actions varied across the Regions from 44 percent to 96 percent.

- The enforcement to inspection rate varied significantly from Region to Region. Region IX had the highest enforcement to inspection rate as well as the highest percentage of state led actions.

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 21 and 22 allow the compliance history of the inorganic chemical manufacturing sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Exhibits 21 and 22 permit the identification of trends in compliance and enforcement records of the industry by comparing data covering the last five years to that of the past year. Some points evident from the data are listed below.

- The inorganic chemicals industry has a relatively low frequency of inspections compared to most of the other sectors shown. On average, the number of months between inspections at inorganic chemicals facilities has been only about twice that of organic chemicals facilities.

- Over the past five years the inorganic chemical industry has had a ratio of enforcement actions to inspections lower than most of the other sectors listed including the organic chemicals sector. This difference has continued over the past year.

- Enforcement actions are brought against only about 10 percent of the facilities with violations; lower than most other sectors listed.

Exhibits 23 and 24 provide a more in-depth comparison between the inorganic chemicals industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Exhibits (21 and 22), the data cover the last five years (Exhibit 23) and the last one year (Exhibit 24) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- Inspections of inorganic chemical facilities are split relatively evenly between Clean Air Act, Clean Water Act, and RCRA, although RCRA accounts for a significantly larger portion of the total actions brought against the inorganic chemicals industry over the past five years.

- Significantly more Clean Water Act inspections are carried out at inorganic chemicals facilities in comparison to the organic chemicals industry, although the Clean Water Act accounts for a smaller portion of the total actions brought against inorganic chemicals facilities.

- Over the past year RCRA inspections have accounted for a significantly smaller portion of the enforcement actions brought against the industry and the Clean Air Act has taken a far greater share.

VII.C. Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

VII.C.1. Review of Major Cases

Historically, OECA's Enforcement Capacity and Outreach Office does not regularly compile information related to major cases and pending litigation within an industry sector. The staff are willing to pass along such information to Agency staff as requests are made. In addition, summaries of completed enforcement actions are published each fiscal year in the Enforcement Accomplishments Report. To date, these summaries are not organized by industry sector. (Contact: Office of Enforcement Capacity and Outreach 202-260-4140)

VII.C.2. Supplementary Environmental Projects

Supplemental environmental projects (SEPs) are an enforcement option that requires the non-compliant facility to complete specific projects. Regional summaries of SEPs undertaken in the 1993 and 1994 federal fiscal years were reviewed. Five SEPs were undertaken that involved inorganic chemical manufacturing facilities, as shown in Exhibit 25.

CERCLA violations engendered three out of the five SEPs identified; the fourth and fifth were due to a CAA violation and a TSCA violation. Due to regional reporting methods, the specifics of the original violations are not known and, for one SEP, details of the actual project were not available.

One of the five projects was conducted at a facility that manufactures both inorganic and organic chemicals. This project has been included in both industry sector project summaries. The FY 1993 and 1994 SEPs for inorganic chemical manufacturers fall into four categories: process related projects; control and recovery technology inprovement or installation; leak prevention; and donations to the community.

•Process related projects

A Region IV project carried out in 1993 entailed specific process changes intended to reduce chlorinated wastes at the facility. In conjunction with other non-process components of the project, the implementation cost was $93,000.

•Control and recovery technology improvement/installation

A Louisiana facility, the combined organic and inorganic chemical manufacturer, implemented a SEP to reduce emissions from returned gas canisters. The SEP involved the installation of recovery technologies to reduce emissions of residual CFC and HCFC from the used canisters. The cost to the company was $158,400.

•Leak prevention

A Region IV facility constructed retaining walls around underground storage tanks to prevent hazardous leachate from reaching groundwater. The cost to the company was $46,200.

•Donations to Community

Following a CERCLA violation, a facility in Texas donated emergency and computer equipment to the Local Emergency Planning Commission (LEPC) which could be used in the planning and responding to potential chemical emergencies. The facility also agreed to participate in LEPC activities and to provide technical assistance.

Exhibit 25: FY-1993-1994 Supplemental Environmental Projects Overview: Inorganic Chemical Manufacture

General Information				Violation Information					Pollutant Reduction		
FY	Docket #	Company Name	State/ Region	Type	Initial Penalty	Final Penalty	SEP Credit	SEP Cost to Company	Pollutant of Concern	Pollutant Reduction	Supplemental Environmental Projects Description
93	--	LaRoche Chemicals, Inc.	LA	*CAA	$88,360	$25,000	---	$158,400	CFC/HCFC	---	Company purchased, installed, and operated equipment for recovery of residual CFCs and HCFCs in used gas cylinders returned by customers
93	---	Coastal Chemicals	Reg. 4	CERCLA 103/EPCRA 304	$90,000	$2,000	---	$93,000	chlorinated waste	---	Altered process to reduce chlorinated wastes, provided computer and Cameo training for county EMA, donated funds to LEPC for hazards analysis, and held response exercises at plant
93	---	Scholle Corp.	Reg. 4	CERCLA, EPCRA	$40,000	$10,000	---	$46,200	---	---	Constructed retaining walls around underground storage tanks to prevent hazardous material leachate from reaching groundwater
93	6-93-16	ALCOA	TX	CERCLA 103(a)	$25,000	$3,000	---	$10,000	---	---	Donated emergency and/or computer equipment to LEPC for response/planning for chemical emergencies, agreed to participate in LEPC activities and to provide technical assistance
94	---	Anzon, Inc.	Reg.III	TSCA	N/A	N/A	N/A	$198,000	---	---	N/A

*Facilities identified as combined inorganic and organic chemical manufacturers

Violation Information Terms
Initial penalty: Initial proposed cash penalty for violation
Final penalty: Total penalty after SEP negotiation
SEP credit: Cash credit given for SEP so that, Final penalty - SEP credit = Final cash penalty
SEP cost to company: Actual cost to company of SEP implementation

NOTE: Due to differences in terminology and level of detail between regional SEP information, in some cases the figure listed as Final penalty may be the Final cash penalty after deduction for SEP credit

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

None identified.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of seventeen chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given out to participants meeting their 1992 goals. The list of chemicals includes seventeen high-use chemicals reported in the Toxics Release Inventory. Exhibit 26 lists those companies participating in the 33/50 program that reported the SIC code 281 to TRI. Many of the companies shown listed multiple SIC codes and, therefore, are likely to carry out operations in addition to inorganic chemicals manufacturing. The SIC codes reported by each company are listed in no particular order. In addition, the number of facilities within each company that are participating in the 33/50 program and that report SIC 281 to TRI is shown. Finally, each company's total 1993 releases and transfers of 33/50 chemicals and the percent reduction in these chemicals since 1988 are presented.

The inorganic chemicals industry as a whole used, generated or processed almost all of the seventeen target TRI chemicals. Of the target chemicals, chromium and chromium compounds, lead and lead compounds, and nickel and nickel compounds are released and transferred most frequently and in similar quantities. These three toxic chemicals account for about nine percent of TRI releases and transfers from inorganic chemical facilities. Seventy-five companies, representing 168 facilities, listed under SIC 281 (inorganic chemicals) are currently participating in the 33/50 program. This accounts for 30 percent of the facilities reporting to SIC code 281 to TRI which is significantly higher than the average for all industries of 14 percent participation. (Contact: Mike Burns, 202-260-6394 or the 33/50 Program, 202-260-6907)

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and state agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct violations discovered during these experimental projects. Forty proposals were received from companies, trade associations, and federal facilities representing many manufacturing and service sectors. Two chemical companies (Ciba Geigy of St. Gabriel, LA and Akzo Chemicals of Edison, NJ), one pharmaceutical manufacturer (Schering Plough of Kenilworth, NJ), and one manufacturer of agricultural chemicals (Gowan Milling of Yuma, AZ) submitted proposals. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Jon Kessler, Office of Policy Analysis, 202-260-4034)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; federal, state and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Maria Tikoff 202-233-9178 or the Green Light/Energy Star Hotline, 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA, in turn, provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn 202-260-0700 or the WasteWi$e Hotline, 800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman 202-260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, 303-275-4729)

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Environmental Programs

Global Environmental Management Initiative

The Global Environmental Management Initiative (GEMI) is made up of a group of leading companies dedicated to fostering environmental excellence by business. GEMI promotes a worldwide business ethic for environmental management and sustainable development to improve the environmental performance of business through example and leadership. In 1994, GEMI's membership consisted of about 30 major corporations including Amoco Corporation.

National Pollution Prevention Roundtable

The National Pollution Prevention Roundtable published *The Pollution Prevention Yellow Pages* in September 1994. It is a compilation of information collected from mail and telephone surveys of state and local government pollution prevention programs. (Contact: Natalie Roy 202-543-7272) The following state programs listed themselves as having expertise in pollution prevention related to inorganic chemical manufacture and use. The contacts listed below (Exhibit 27) are also likely to be aware of various state- and local-level initiatives affecting the inorganic chemical industry.

Center for Waste Reduction Technologies

Center for Waste Reduction Technologies, under the aegis of the American Institute of Chemical Engineers, sponsors research on innovative technologies to reduce waste in the chemical processing industries. The primary mechanism is through funding of academic research.

National Science Foundation and the Office of Pollution Prevention and Toxics

The National Science Foundation and EPA's Office of Pollution Prevention and Toxics signed an agreement in January of 1994 to coordinate the two agencies' programs of **basic research related to pollution prevention**. The collaboration will stress research in the use of less toxic chemical and synthetic feedstocks, use of photochemical processes instead of traditional ones that employ toxic reagents, use of recyclable catalysts to reduce metal contamination, and use of natural feedstocks when synthesizing chemicals in large quantities.

Chemical Manufacturers Association

The **Chemical Manufacturers Association** funds research on issues of interest to their members particularly in support of their positions on proposed or possible legislation. They recently funded a study to characterize the environmental fate of organochlorine compounds.

Responsible Care Program

The **Responsible Care Program** of the Chemical Manufacturers Association requires members to pledge commitment to six codes that identify 106 management practices that companies must carry out in the areas of community awareness and emergency response, pollution prevention, process safety, distribution, employee health and safety, and product stewardship.

ISO 9000

ISO 9000 is a series of international total quality management guidelines. After a successful independent audit of their management plans, firms are qualified to be ISO 9000 registered. In June of 1993, the International Standards Organization created a technical committee to begin work on new standards for environmental management systems. The new standards are called ISO 14000 and are expected to be issued in 1996.

VII.C.2. Summary of Trade Associations

Chemical Industry

American Chemical Society
1155 16th Street, NW
Washington, D.C. 20036
Phone: (202) 872-8724
Fax: (202) 872-6206

Members: 145,000
Staff: 1700
Budget: $192,000,000

The American Chemical Society (ACS) has an educational and research focus. The ACS produces approximately thirty different industry periodicals and research journals, including *Environmental Science and Technology* and *Chemical Research in Toxicology*. In addition to publishing, the ACS presently conducts studies and surveys; legislation monitoring, analysis, and reporting; and operates a variety of educational programs. The ACS library and on-line information services are extensive. Some available on-line services are *Chemical Journals Online*, containing the full text of 18 ACS journals, 10 Royal Society of Chemistry journals, and five polymer journals. and the Chemical Abstracts Service (CAS), which provides a variety of information on chemical compounds. Founded in 1876, the ACS is presently comprised of 184 local groups and 843 student groups nationwide.

Chemical Manufacturers Association
2501 M St., NW
Washington, D.C. 20037
Phone: (202) 887-1164
Fax: (202) 887-1237

Members: 185
Staff: 246
Budget: $36,000,000
Contact: Joseph Mayhew

Presently, the principle focus of the Chemical Manufacturers Association (CMA) is on regulatory issues facing chemical manufacturers at the local, state, and federal level. At its inception in 1872, the focus of the CMA was on serving chemical manufacturers through research. Research is still ongoing at the CMA, however, as the CHEMSTAR program illustrates. CHEMSTAR consists of a variety of self-funded panels working on single-chemical research agendas. This research fits in with the overall regulatory focus of the CMA; CHEMSTAR study results are provided to both CMA membership and regulatory agencies. Other initiatives include the "responsible care" program. Membership in the CMA is contingent upon enrollment in the "responsible care" program, which includes six codes of management practice (including pollution prevention) that attempt to "go beyond simple regulatory compliance." The CMA also conducts workshops and technical symposia, promotes in-plant safety, operates a chemical emergency center (CHEMTREC) which offers guidance in chemical emergency situations, and operates the Chemical Referral Center which provides chemical health and safety information to the public. Publications include: *ChemEcology*, a 10-issue-per-year newsletter covering environmental, pollution-control, worker-safety, and federal and state regulatory actions, and the *CMA Directory*, a listing of the CMA membership. The CMA holds an annual meeting in White Sulphur Springs, WV.

Chlor-alkali Industry

The Chlorine Institute, Inc.
2001 L Street, N.W.
Suite 506
Washington, D.C. 20036
Phone: (202) 223-2790
Fax: (202) 223-7225

Members: 200
Budget: $1.500,000
Contact: Gary Trojak

The Chlorine Institute, Inc. was established in 1924 and represents companies in the U.S., Canada, and other countries that produce, distribute, and use chlorine, sodium and potassium hydroxides, and sodium hypochlorite; and that distribute and use hydrogen chloride. The Institute is a non-profit scientific and technical organization which serves as a safety, health, and environmental protection center for the industry.

Chlorine Chemistry Council
2501 M Street, N.W.
Washington, D.C. 20037
Phone: (202) 887-1100
Fax: (202) 887-6925

Members: 30
Staff: 24
Budget: $14.000.000
Contact: Kip Howlett Jr.

The Chlorine Chemistry Council (CCC), established in 1993, is a business council of the Chemical Manufacturers Association (CMA) and is made up of producers and users of chlorine and chlorine-related products. With involvement from all stakeholders, the CCC works to promote science-based public policy regarding chlorine chemistry and is committed to develop and produce only those chemicals that can be manufactured, transported, used, and disposed of safely. CCC facilitates risk-benefit analyses and product stewardship through the collection, development, and use of scientific data on health, safety, and environmental issues. CCC hopes to heighten public awareness of chlorine chemistry and its many societal benefits by collaborating with the public health and scientific community in assessing and communicating chlorine-related human health and environmental issues.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the inorganic chemicals industry a list of contacts and publications are provided below:

INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers are included on the following page.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., ET, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via the Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the

information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project. 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Environ$ense World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE IRON AND STEEL INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the iron and steel industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

The iron and steel industry is categorized by the Bureau of the Census under the Standard Industrial Classification (SIC) code 33, primary metal industries. The industry is further classified by the three-digit codes 331. Steel Works, Blast Furnaces, and Rolling and Finishing Mills, and 332 Iron and Steel Foundries. Since steel works, blast furnaces, and rolling and finishing mills account for the majority of environmental releases. employees, and value of shipments, this profile concentrates on the three-digit SIC 331. The environmental releases associated with foundries are similar to the steel casting and finishing processes included under SIC 331. therefore SIC 332 will not be addressed in this notebook. Some sections of the profile focus specifically on industries in the four-digit SIC 3312, since virtually all establishments producing primary products (iron and steel) under SIC 3312, also produce secondary products that fall under some of the other iron and steel SIC codes under SIC 331.

II.B. Characterization of the Iron and Steel Industry

II.B.1. Industry Size and Geographic Distribution

There are approximately 1,118 manufacturing facilities under SIC 331 according to *1992 Census of Manufactures* data.[1] The payroll totaled $9.3 billion for a workforce of 241,000 employees, and value of shipments totaled $58 billion. Net shipments of steel mill products for all grades including carbon, alloy, and stainless totaled 92.7 million net tons in 1993[2] and 95.1 million net tons in 1994.[3] In terms of environmental issues, value of shipments, and number of employees, SIC 3312 (Blast Furnaces and Steel Mills), is the most significant four-digit code under SIC 331. The 1992 Census data reported 247 establishments under SIC 3312, with an estimated 172,000 employees, a payroll of $7 billion, and a value of shipments totaling $42 billion. For the same year, the American Iron and Steel Institute estimated 114 companies operated 217 iron and steel facilities: this estimate included any facility with one or more iron or steelmaking operation.[4]

The *1987 Census of Manufactures*[5] further categorizes SIC 3312 by the type of steel mill: integrated or non-integrated. A fully integrated facility produces steel from raw materials of coal, iron ore, and scrap. Non-integrated plants do not have all of the equipment to produce steel from coal, iron ore, and scrap on-site, instead they purchase some of their raw materials in a processed form.

SIC Diversity

The Bureau of the Census categorizes the three- and four-digit SIC codes related to iron and steel as follows:

SIC 331 - Steel works, blast furnaces, coke ovens, rolling and finishing mills
- 3312 - Steel works, blast furnaces, and rolling mills
- 3313 - Electrometallurgical products, except steel
- 3315 - Steel wiredrawing and steel nails and spikes
- 3316 - Cold-rolled steel sheet, strip, and bars
- 3317 - Steel pipe and tubes

The remainder of the industries classified under SIC code 33 cover the ferrous and non-ferrous foundries, and smelting, refining, and shaping of nonferrous metals which are not covered in this profile.

Two Steel Industries

In the past fifteen years, the U.S. steel industry has lost over 61 percent of its employees and 58 percent of its facilities. Slow growth in demand for steel, markets lost to other materials, increased imports, and older, less efficient production facilities are largely to blame for the industry's decline. While the integrated steel industry was contracting, a group of companies, called minimills, more than doubled their capacity in the same period and they continue to expand into new markets. Minimills use electric arc furnaces (EAFs) to melt scrap and other materials to make steel products, instead of using coke, iron ore, and scrap as the integrated producers do. In addition to fundamentally different production technologies, other differences between the integrated steel mills and minimill are also significant: minimills have narrow product lines, they often have small, non-unionized work forces that may receive higher pay per hour than a comparable unionized work force, but without union benefits. Additionally, minimills typically produce much less product per facility (less than 1 million tons of steel per year). Lower scrap prices in the 1960s and 1970s created opportunities for the minimill segment of the market to grow rapidly. Initially, the EAF technology could only be used in the production of low quality long products, such as concrete reinforcing bar, but over the years minimill products have improved in quality and have overcome technological limitations to diversify their product lines. Recently, minimills have entered new markets, such as flat-rolled products, however, more than half of the market for quality steel products still remains beyond minimill capability. The EAF producers do face the problems of fluctuating scrap prices which are more volatile than the prices of raw materials used by integrated producers.

Geographic Distribution

The highest geographic concentration of mills is in the Great Lakes region, where most integrated plants are based (Exhibit 1). According to the *1987 Census of Manufactures*, 46 percent of steel mills are located in six Great Lakes states: New York, Pennsylvania, Ohio, Indiana, Illinois, and Michigan, with a heavy concentration of steel manufacturing in the Chicago area. Approximately 80 percent of the U.S. steelmaking capacity is in these states. The South is the next largest steel-producing region, although there are only two integrated steel plants. Steel production in the western U.S. is limited to one integrated plant and several minimills. Historically, the mill sites were selected for their proximity to water (tremendous amounts are used for cooling and processing, and for transportation) and the sources of their raw materials, iron ore and coal. Traditional steelmaking regions included the Monongahela River valley near Pittsburgh and along the Mahoning River near Youngstown, Ohio. The geographic concentration of the industry continues to change as minimills are built anywhere electricity and scrap are available at a reasonable cost and there is a local market for a single product.

Size Distribution

Large, fully-integrated steel mills have suffered considerably in the last 15 years, largely due to loss of market share to other materials, competition, and the high cost of pension liabilities. In comparing the *1992 Census of Manufacture* data with the data from 1977, these changes are clear. While the number of establishments under SIC 3312 fell by 58 percent from 504 facilities in 1977 to 247 in 1992, the absolute number of integrated mills has always been small, and the reduction is largely due to a drop in the number of small establishments. A more relevant statistic is the reduction in employees during the same time period. The work force for these facilities was dramatically reduced as plants closed or were reorganized by bankruptcy courts. Those that remained open automated and streamlined operations resulting in a 61 percent reduction in the number of production employees over the same 15 year period. Approximately 172,000 were still employed in SIC 3312 establishments in 1992.

The *1987 Census of Manufactures* breaks the SIC code 3312 down into four sub-industries: Fully-integrated (consists of coke ovens, blast furnaces, steel furnaces, and rolling and finishing mills), partially integrated with blast furnace (consists of blast furnaces, steel furnaces, and rolling and finishing mills), partially integrated without blast furnaces (consists of steel furnaces and either rolling and finishing mills or a forging department; includes mini mills), and non-integrated (all others, including stand-alone rolling and finishing mills, and stand-alone coke plants). This division highlights some important characteristics about the size of facilities in this industry. Only 8 percent (20 plants) of the establishments under SIC 3312 in 1987 were fully integrated mills. However, 46 percent of the industry's employees worked in these 20 plants.

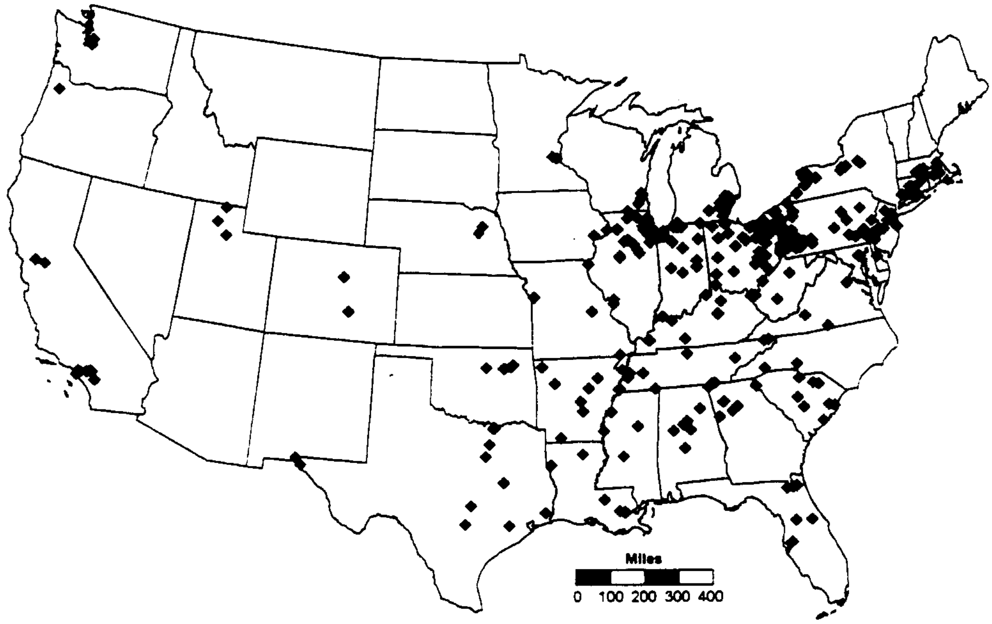

Exhibit 1: Geographic Distribution of SIC 331 Establishments: Steel Works, Blast Furnaces, and Rolling and Finishing Mills

Top Steel Producers

Market Share Reporter, published by Gale Research Inc., annually compiles reported market share data on companies, products, and services. The 1995 edition ranks top U.S. steel producers by 1993 sales in millions of dollars, as shown in Exhibit 2.

Exhibit 2: Top U.S. Iron and Steel Producers

Rank	Company	1993 Sales (millions of dollars)
1	US Steel Group - Pittsburgh, PA	5,422
2	Bethlehem Steel Corp. - Bethlehem, PA	4,219
3	LTV Corp. - Dallas, TX	3,868
4	National Steel Corp. - Pittsburgh, PA	2,418
5	Inland Steel Industries, Inc. - Chicago, IL	2,175
6	Armco Inc. - Parsippany, NJ	1,595
7	Weirton Steel Corp. - Weirton, WV	1,201
8	Wheeling-Pittsburgh Steel - Pittsburgh, PA	1,047

II.B.2. Product Characterization

The iron and steel industry produces iron and steel mill products, such as bars, strips, and sheets, as well as formed products such as steel nails, spikes, wire, rods, pipes, and non-steel electrometallurgical products such as ferroalloys. Under SIC 3312, Blast Furnaces and Steel Mills, products also include coke, and products derived from chemical recovery in the coking process such as coal tar and distillates.

Historically, the automotive and construction sectors have been the two largest steel consuming industries. Consequently, fluctuations in sales and choice of materials in these industries have a significant impact on the iron and steel industry. Over the last two decades, the structure of the steelmaking industry has changed dramatically due to new technologies, foreign competition, and loss of market share to other materials. Many of the large, fully-integrated facilities have closed, and those that are still operating, have reduced their workforce, increased automation, and invested in new technologies to remain competitive.

II.B.3. Economic Trends

Domestic Market

After years of collapsing markets, bankruptcies, mill closings and layoffs, the steel industry experienced a turnaround in 1993. Shipments were at their highest level since 1981.[6] For the first time since 1989, steelmakers were able to boost their prices. This increase in demand is due in part to the weak dollar, which makes importing foreign steel more expensive than it used to be. The relatively high level of shipments was also attributable to a strong demand from the steel industry's two largest customers - the automotive and construction sectors.[7] Recently, prices for steel sold to the automotive industry have been set in long-term contracts. The prices set in the automotive contracts tend to influence the steel prices of other contract negotiations, such as those with appliance manufacturers. Overall, more than half of all steel sold in the U.S. is covered by long-term contracts; the rest is sold on the spot market.

International Trade

Problems in international steel trade intensified in the last 5 years due in large part to a worldwide weakening in demand. With the exception of China, where rapid economic growth has led to a steady increase in steel demand, the export market has been weak. The "voluntary restraint arrangements" that limited imports in the 1980s expired in 1992. Since then, the U.S. steel industry has discouraged imports by filing complaints that products are being dumped - sold at less than the cost of production. Similar cases have also been filed against U.S. exporters. To address the problems of unfairly traded steel, most major steel-producing countries have participated in multilateral steel agreement (MSA) negotiations under the General Agreement on Tariffs and Trade (GATT).[8]

Steel imports for 1992 totaled 15.2 million metric tons. From 1989 to 1993, the quantity of steel imported was fairly consistent, from 15.7 million metric tons in 1989 to 15.3 million metric tons estimated for 1993. The exception is a slight dip to 14.3 million metric tons in 1991. The forecast for 1994, at 16.3 million metric tons, is a more significant increase than has been seen in the last five years. The export market has seen slightly more variability over the same time period, with a high of 5.7 million metric tons exported in 1991, and 3.8 million metric tons in exports forecast for 1994.[9]

Labor

According to *1992 Census of Manufactures*, there were an estimated 172,000 people employed in SIC 3312 industries, with a payroll of $7 billion. This was a 61 percent decrease from 1977 levels of 442,000 employees, and a 42% reduction from 1982 levels of 295,000 employees. This dramatic reduction in workforce was primarily due to reductions at the large integrated facilities. For example, the U.S. Steel plant in Gary, Indiana, employed 30,000 people during the plant's peak employment in 1953. In 1992, there were about 8,000 employees working at the 4,000-acre facility.

This reduction in workforce, coupled with investments in new equipment, automation, and management restructuring has resulted in the increased productivity that was essential for integrated mills to remain competitive in the face of the severe competitive pressures both from EAF producers in the U.S. and from abroad. With these changes, the U.S. industry has become one of the lowest-cost producers in the developed world. Productivity in steelmaking is often measured in man-hours per ton of finished steel. For every ton produced, American steelmakers spend 5.3 man-hours, compared with 5.6 for the Japanese and Canadian industries, and 5.7 for the British, French, and Germans. The increase in productivity is also reflected in changes in the value added by manufacture, as reported by the Census. During the ten year period where employment in the industry dropped by 42% (1982 - 1992), the value added by manufacture increased by 39% from $11.8 million in 1982 to $16.5 million in 1992.

Problems from such a sizable workforce reduction persist. The industry says one big cost is "legacy costs" - obligations to pay pensions and health benefits to the tens of thousands of retirees and their spouses. Some integrated companies have five retired workers for every active employee. For many of the large, integrated facilities, these pensions are underfinanced. Of the 50 most underfinanced pension plans, five are in the steel industry. This puts the newer minimills, who do not have such legacy costs, at a clear competitive advantage.

In addition to pension payments, major U.S. steel producers are now paying out an average $5.30 per hour worked, 17 percent of total hourly employment costs, for health care. The industry argues that these high costs place it at a disadvantage with its major foreign competitors, some of whom pay no direct health care expenses.

Long-term Prospects

Production of steel products in 1993 totaled 89.0 million net tons which represents an 89.1 percent capacity utilization. Shipments for 1994 rose to 95.1 million net tons and it is forecasted that demand will stay high, with industry capacity utilization increasing through 1995.[10] After years of losing market share to other materials, steel appears to be regaining a competitive position. In the automotive market, some parts that were recently made of plastic. such as fenders, roofs, and hoods, are being returned to steel. The decades-long downtrend in steel content in automobiles appears to have slowed and recently has actually reversed. According to Ford Motor Company, the average vehicle built in 1993 contained 1,726 pounds of steel, up from 1,710 pounds in 1992, marking the second consecutive yearly increase. A further increase is anticipated in 1994 due to new and expanding applications of steel. In addition to increased orders from the automotive sector. the residential construction sector is a potentially rich market for steel producers. Steel framing for houses is being promoted as a light-weight. high strength alternative to wood framing. A galvanized steel frame for a 2,000 square foot house would weigh approximately one-fourth the weight of a lumber structure.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the iron and steel industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A. Industrial Processes in the Iron and Steel Industry

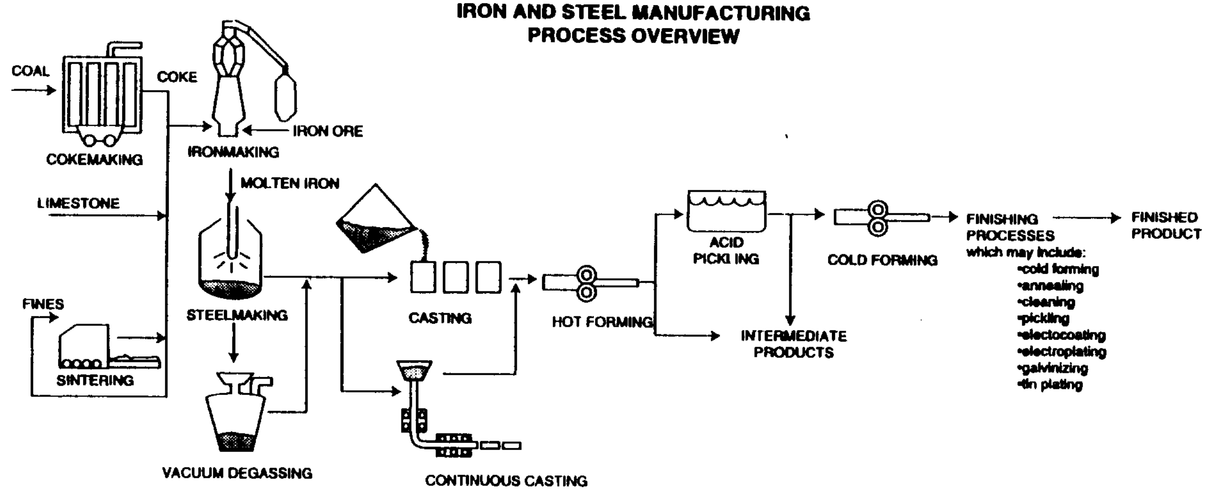
In view of the high cost of most new equipment and the relatively long lead time necessary to bring new equipment on line in the steel industry, changes in production methods and products in the steel industry are typically made gradually. Installation of major pieces of new steelmaking equipment may cost millions of dollars and require additional retrofitting of other equipment. Even new process technologies that fundamentally improve productivity, such as the continuous casting process (described below), are adopted only over long periods of time. Given the recent financial performance of the steel industry, the ability to raise the capital needed to purchase such equipment is limited.

Environmental legislation is challenging the industry to develop cleaner and more efficient steelmaking processes at the same time competition from substitute materials are forcing steelmakers to invest in cost-saving and quality enhancing technologies. In the long term, the steel industry will likely continue to move towards more simplified and continuous manufacturing technologies that reduce the capital costs for new mill construction and allow smaller mills to operate efficiently. The companies that excel will be those that have the resources and foresight to invest in such technologies.

Steel is an alloy of iron usually containing less than one percent carbon. The process of steel production occurs in several sequential steps (Exhibit 3). The two types of steelmaking technology in use today are the basic oxygen furnace (BOF) and the electric arc furnace (EAF). Although these two technologies use different input materials, the output for both furnace types is molten steel which is subsequently formed into steel mill products. The BOF input materials are molten iron, scrap, and oxygen. In the EAF, electricity and scrap are the input materials used. BOFs are typically used for high tonnage production of carbon steels, while EAFs are used to produce carbon steels and low tonnage alloy and specialty steels. The processes leading up to steelmaking in a BOF are very different than the steps preceeding steelmaking in an EAF; the steps after each of these processes producing molten steel are the same.

When making steel using a BOF, cokemaking and ironmaking precede steelmaking; these steps are not needed for steelmaking with an EAF. Coke, which is the fuel and carbon source, is produced by heating coal in the absence of oxygen at high temperatures in coke ovens. Pig iron is then produced by heating the coke, iron ore, and limestone in a blast furnace. In the BOF, molten iron from the blast furnace is combined with flux and scrap steel where high-purity oxygen is injected. This process, with cokemaking, ironmaking, steelmaking, and subsequent forming and finishing operations is referred to as fully integrated production. Alternatively, in an EAF, the input material is primarily scrap steel, which is melted and refined by passing an electric current from the electrodes through the scrap. The molten steel from either process is formed into ingots or slabs that are rolled into finished products. Rolling operations may require reheating, rolling, cleaning, and coating the steel. A description of both steelmaking processes follows:

EXHIBIT 3
IRON AND STEEL MANUFACTURING
PROCESS OVERVIEW



III.A.1. Steelmaking Using the Basic Oxygen Furnace

The process of making steel in a Basic Oxygen Furnace (BOF) is preceded by cokemaking and ironmaking operations. In cokemaking, coke is produced from coal. In ironmaking, molten iron is produced from iron ore and coke. Each of these processes and the subsequent steelmaking process in the BOF are described below.

Cokemaking
Coal processing in the iron and steel industry typically involves producing coke, coke gas and by-product chemicals from compounds released from the coal during the cokemaking process (Exhibit 4). Coke is carbon-rich and is used as a carbon source and fuel to heat and melt iron ore in ironmaking. The cokemaking process starts with bituminous pulverized coal charge which is fed into the coke oven through ports in the top of the oven. After charging, the oven ports are sealed and the coal is heated at high temperatures (1600 to 2300°F) in the absence of oxygen. Coke manufacturing is done in a batch mode where each cycle lasts for 14 to 36 hours. A coke oven battery comprises a series of 10 to 100 individual ovens, side-by-side, with a heating flue between each oven pair. Volatile compounds are driven from the coal, collected from each oven, and processed for recovery of combustible gases and other coal byproducts.[11] The solid carbon remaining in the oven is the coke. The necessary heat for distillation is supplied by external combustion of fuels (e.g., recovered coke oven gas, blast furnace gas) through flues located between ovens.[12] At the end of the heating cycle, the coke is pushed from the oven into a rail quench car. The quench car takes it to the quench tower, where the hot coke is cooled with a water spray. The coke is then screened and sent to the blast furnace or to storage.

In the by-products recovery process, volatile components of the coke oven gas stream are recovered including the coke oven gas itself (which is used as a fuel for the coke oven), naphthalene, ammonium compounds, crude light oils, sulfur compounds, and coke breeze (coke fines). During the coke quenching, handling, and screening operation, coke breeze is produced. Typically, the coke breeze is reused in other manufacturing processes on-site (e.g., sintering) or sold off-site as a by-product.[13]

The cokemaking process is seen by industry experts as one of the steel industry's areas of greatest environmental concern, with air emissions and quench water as major problems. In efforts to reduce the emissions associated with cokemaking, U.S. steelmakers are turning to technologies such as pulverized coal injection, which substitutes coal for coke in the blast furnace. Use of pulverized coal injection can replace about 25 to 40 percent of coke in the blast furnace, reducing the amount of coke required and the associated emissions. Steel producers also inject other fuels, such as natural gas, oil, and tar/pitch to replace a portion of the coke.

Quench water from cokemaking is also an area of significant environmental concern. In Europe, some plants have implemented technology to shift from water quenching to dry quenching which eliminates suspected carcinogenic particulates and VOCs. However, major construction changes are required for such a solution and considering the high capital costs of coke batteries, combined with the depressed state of the steel industry and increased regulations for cokemaking, it is unlikely that new facilities will be constructed. Instead, industry experts expect to see an increase in the amount of coke imported.

Ironmaking

In the blast furnace, molten iron is produced (Exhibit 4). Iron ore, coke, and limestone are fed into the top of the blast furnace. Heated air is forced into the bottom of the furnace through a bustle pipe and tuyeres (orifices) located around the circumference of the furnace. The carbon monoxide from the burning of the coke reduces iron ore to iron. The acid part of the ores reacts with the limestone to create a slag which is drawn periodically from the furnace. This slag contains unwanted impurities in the ore, such as sulfur from the fuels. When the furnace is tapped, iron is removed through one set of runners and molten slag via another. The molten iron is tapped into refractory-lined cars for transport to the steelmaking furnaces. Residuals from the process are mainly sulfur dioxide or hydrogen sulfide, which are driven off from the hot slag. The slag is the largest by-product generated from the ironmaking process and is reused extensively in the construction industry.[14] Blast furnace flue gas is cleaned and used to generate steam to preheat the air coming into the furnace, or it may be used to supply heat to other plant processes. The cleaning of the gas may generate air pollution control dust in removing coarse particulates (which may be reused in the sintering plant or landfilled), and water treatment plant sludge in removing fine particulates by venturi scrubbers.

Sintering is the process that agglomerates fines (including iron ore fines, pollution control dusts, coke breeze, water treatment plant sludge, coke breeze, and flux) into a porous mass for charging to the blast furnace.[15] Through sintering operations, a mill can recycle iron-rich material, such as mill scale and processed slag. Not all mills have sintering capabilities. The input materials are mixed together, placed on a slow-moving grate and ignited. Windboxes under the grate draw air through the materials to deepen the combustion throughout the traveling length of the grate. The coke breeze provides the carbon source for sustaining the controlled combustion. In the process, the fine materials are fused into the sinter agglomerates, which can be reintroduced into the blast furnace along with ore. Air pollution control equipment removes the particulate matter generated during the thermal fusing process. For wet scrubbers, water treatment plant sludge are generally land disposed waste. If electrostatic precipitators or baghouses are used as the air pollution control equipment, the dry particulates captured are typically recycled as sinter feedstock, or are landfilled as solid waste.

Steelmaking Using the Basic Oxygen Furnace

Molten iron from the blast furnace, flux, alloy materials, and scrap are placed in the basic oxygen furnace, melted and refined by injecting high-purity oxygen. A chemical reaction occurs, where the oxygen reacts with carbon and silicon generating the heat necessary to melt the scrap and oxidize impurities. This is a batch process with a cycle time of about 45 minutes. Slag is produced from impurities removed by the combination of the fluxes with the injected oxygen. Various alloys are added to produce different grades of steel. The molten steel is typically cast into slabs, beams or billets.

The waste products from the basic oxygen steelmaking process include slag, carbon monoxide, and oxides of iron emitted as dust. Also, when the hot iron is poured into ladles or the furnace, iron oxide fumes are released and some of the carbon in the iron is precipitated as graphite (kish). The BOF slag can be processed to recover the high metallic portions for use in sintering or blast furnaces, but its applications as a saleable construction materials are more limited than the blast furnace slag.

Basic oxygen furnaces are equipped with air pollution control systems for containing, cooling, and cleaning the volumes of hot gases and sub-micron fumes that are released during the process. Water is used to quench or cool the gases and fumes to temperatures at which they can be effectively treated by the gas cleaning equipment. The resulting waste streams from the pollution control processes include air pollution control dust and water treatment plant sludge. About 1,000 gallons of water per ton of steel (gpt) are used for a wet scrubber. The principal pollutants removed from the off-gas are total suspended solids and metals (primarily zinc, and some lead).[16]

EXHIBIT 4
IRON AND STEEL MANUFACTURING
COKEMAKING AND IRONMAKING

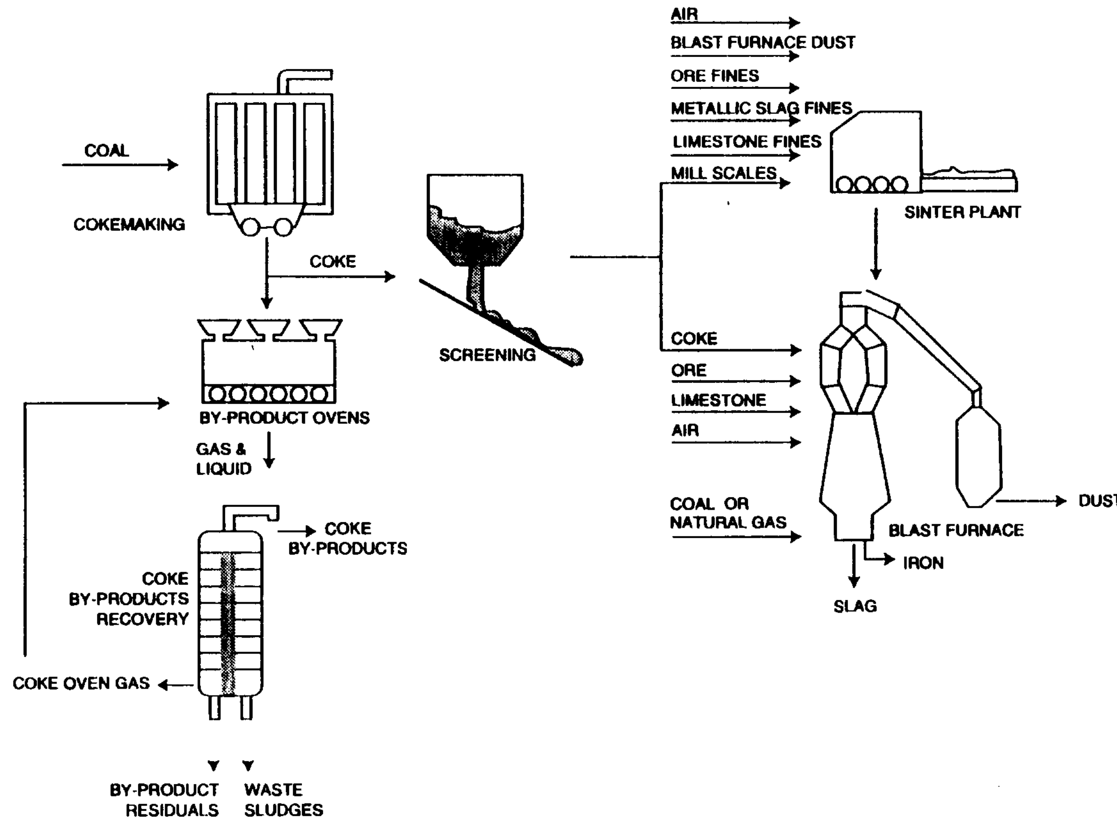


EXHIBIT 5
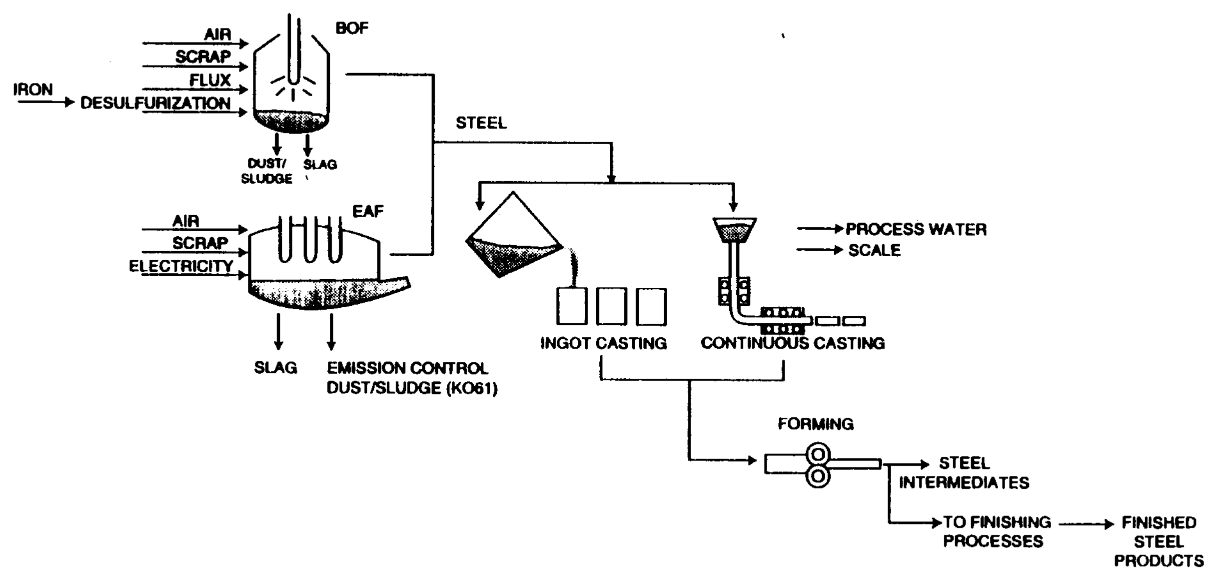
IRON AND STEEL MANUFACTURING
STEELMAKING



III.A.2. Steelmaking Using the Electric Arc Furnace (EAF)

In the steelmaking process that uses an electric arc furnace (EAF), the primary raw material is scrap metal, which is melted and refined using electric energy. During melting, oxidation of phosphorus, silicon, manganese, carbon and other materials occurs and a slag containing some of these oxidation products forms on top of the molten metal.[17] Oxygen is used to decarburize the molten steel and to provide thermal energy. This is a batch process with a cycle time of about two to three hours. Since scrap metal is used instead of molten iron, there are no cokemaking or ironmaking operations associated with steel production that uses an EAF.

The process produces metal dusts, slag, and gaseous products. Particulate matter and gases evolve together during the steelmaking process and are conveyed into a gas cleaning system. These emissions are cleaned using a wet or dry system. The particulate matter that is removed as emissions in the dry system is referred to as EAF dust, or EAF sludge if it is from a wet system and it is a listed hazardous waste (RCRA K061). The composition of EAF dust can vary greatly depending on the scrap composition and furnace additives. The primary component is iron or iron oxides, and it may also contain flux (lime and/or fluorspar), zinc, chromium and nickel oxides (when stainless steel is being produced) and other metals associated with the scrap. The two primary hazardous constituents of EAF emission control dust are lead and cadmium.[18] Generally, 20 pounds of dust per ton of steel is expected, but as much as 40 pounds of dust per ton of steel may be generated, depending on production practices.[19] Oils are burned off "charges" of oil-bearing scrap in the furnace. Minor amounts of nitrogen oxides and ozone are generated during the melting process. The furnace is extensively cooled by water; however, this water is recycled through cooling towers.

III.A.3. Forming and Finishing Operations

Whether the molten steel is produced using a BOF or an EAF, to convert it into a product, it must be solidified into a shape suitable and finished.

Forming

The traditional forming method, called ingot teeming, has been to pour the metal into ingot molds, allowing the steel to cool and solidify. The alternative method of forming steel, called continuous casting accounted for more 86% of raw steel produced in the U.S. in 1992[20], compared with approximately 30 percent in 1982. The continuous casting process bypasses several steps of the conventional ingot teeming process by casting steel directly into semifinished shapes. Molten steel is poured into a reservoir from which it is released into the molds of the casting machine. The metal is cooled as it descends through the molds, and before emerging, a hardened outer shell is formed. As the semifinished shapes proceed on the runout table, the center also solidifies, allowing the cast shape to be cut into lengths.

Process contact water cools the continuously cast steel and is collected in settling basins along with oil, grease, and mill scale generated in the casting process. The scale settles out and is removed and recycled for sintering operations, if the mill has a Sinter Plant. Waste treatment plant sludge is also generated.[21]

The steel is further processed to produce slabs, strips, bars, or plates through various forming operations. The most common hot forming operation is hot rolling, where heated steel is passed between two rolls revolving in opposite directions. Modern hot rolling units may have as many as 13 stands, each producing an incremental reduction in thickness. The final shape and characteristics of a hot formed piece depend on the rolling temperature, the roll profile, and the cooling process after rolling. Wastes generated from hot rolling include waste treatment plant sludge and scale.

In subsequent cold forming, the cross-sectional area of unheated steel is progressively reduced in thickness as the steel passes through a series of rolling stands. Generally, wires, tubes, sheet and strip steel products are produced by cold rolling operations. Cold forming is used to obtain improved mechanical properties, better machinability, special size accuracy, and the production of thinner gages than hot rolling can accomplish economically.[22] During cold rolling, the steel becomes hard and brittle. To make the steel more ductile, it is heated in an annealing furnace.

Process contact water is used as a coolant for rolling mills to keep the surface of the steel clean between roller passes. Cold rolling operations also produce a waste treatment plant sludge, primarily due to the lubricants applied during rolling. Grindings from resurfacing of the worn rolls and disposal of used rolls can be a significant contributor to the plant's wastestream.

Finishing

One of the most important aspects of a finished product is the surface quality. To prevent corrosion, a protective coating may be applied to the steel product. Prior to coating, the surface of the steel must be cleaned so the coating will adhere to the steel. Mill scale, rust, oxides, oil, grease, and soil are chemically removed from the surface of steel using solvent cleaners, pressurized water or air blasting, cleaning with abrasives, alkaline agents or acid pickling. In the pickling process, the steel surface is chemically cleaned of scale, rust, and other materials. Inorganic acids such as hydrochloric or sulfuric acid are most commonly used for pickling. Stainless steels are pickled with hydrochloric, nitric, and hydrofluoric acids. Spent pickle liquor may be a listed hazardous waste (RCRA K062), if it contains considerable residual acidity and high concentrations of dissolved iron salts. Pickling prior to coating may use a mildly acidic bath which is not considered K062.

Steel generally passes from the pickling bath through a series of rinses. Alkaline cleaners may also be used to remove mineral oils and animal fats and oils from the steel surface prior to cold rolling. Common alkaline cleaning agents include: caustic soda, soda ash, alkaline silicates, phosphates.

Steel products are often given a coating to inhibit oxidation and extend the life of the product. Coated products can also be painted to further inhibit corrosion. Common coating processes include: galvanizing (zinc coating), tin coating, chromium coating, aluminizing, and terne coating (lead and tin). Metallic coating application processes include hot dipping, metal spraying, metal cladding (to produce bi-metal products), and electroplating. Galvanizing is a common coating process where a thin layer of zinc is deposited on the steel surface.

III.B. Raw Material Inputs and Pollution Outputs

Numerous outputs are produced as a result of the manufacturing of coke, iron, and steel, the forming of metals into basic shapes, and the cleaning and scaling of metal surfaces. These outputs, categorized by process (RCRA waste code provided where applicable), include:

Cokemaking

Inputs:

- Coal, heat, quench water

Outputs:

- Process residues from coke by-product recovery (RCRA K143, K148)
- Coke oven gas by-products such as coal tar, light oil, ammonia liquor, and the remainder of the gas stream is used as fuel. Coal tar is typically refined to produce commercial and industrial products including pitch, creosote oil, refined tar, naphthalene, and bitumen.
- Charging emissions (fine particles of coke generated during oven pushing, conveyor transport, loading and unloading of coke that are captured by pollution control equipment. Approximately one pound per ton of coke produced are captured and generally land disposed).
- Ammonia, phenol, cyanide and hydrogen sulfide
- Oil (K143 and K144)
- Lime sludge, generated from the ammonia still (K060)
- Decanter tank tar sludge (K087)
- Benzene releases in coke by-product recovery operations
- Naphthalene residues, generated in the final cooling tower
- Tar residues (K035, K141, K142, and K147)
- Sulfur compounds, emitted from the stacks of the coke ovens
- Wastewater from cleaning and cooling (contains zinc, ammonia still lime (K060), or decanter tank tar (K087), tar distillation residues (K035))
- Coke oven gas condensate from piping and distribution system; may be a RCRA characteristic waste for benzene.

Ironmaking

Inputs:

- Iron ore (primarily in the form of taconite pellets), coke, sinter, coal. limestone, heated air

Outputs:

- Slag, which is either sold as a by-product, primarily for use in the construction industry, or landfilled
- Residual sulfur dioxide or hydrogen sulfide
- Particulates captured in the gas, including the air pollution control (APC) dust or waste treatment plant (WTP) sludge
- Iron is the predominant metal found in the process wastewater
- Blast furnace gas (CO)

Steelmaking

Inputs:

- In the steelmaking process that uses a basic oxygen furnace (BOF), inputs include molten iron, metal scrap, and high-purity oxygen
- In the steelmaking process that uses an electric arc furnace (EAF), the primary inputs are scrap metal, electric energy and graphite electrodes.
- For both processes, fluxes and alloys are added, and may include: fluorspar. dolomite, and alloying agents such as aluminum, manganese, and others.

Outputs:

- Basic Oxygen Furnace emission control dust and sludge, a metals-bearing waste.
- Electric Arc Furnace emission control dust and sludge (K061); generally, 20 pounds of dust per ton of steel is expected, but as much as 40 pounds of dust per ton of steel may be generated depending on the scrap that is used.
- Metal dusts (consisting of iron particulate, zinc, and other metals associated with the scrap and flux (lime and/or fluorspar)) not associated with the EAF.
- Slag.
- Carbon monoxide.
- Nitrogen oxides and ozone, which are generated during the melting process.

Forming, Cleaning, and Descaling

Inputs:

- Carbon steel is pickled with hydrochloric or sulfuric acid: stainless steels are pickled with hydrochloric, nitric, and hydrofluoric acids.
- Various organic chemicals are used in the pickling process.
- Alkaline cleaners may also be used to remove mineral oils and animal fats and oils from the steel surface. Common alkaline cleaning agents include: caustic soda, soda ash, alkaline silicates, phosphates.

Outputs:

- Wastewater sludge from rolling, cooling, descaling, and rinsing operations which may contain cadmium (D006), chromium (D007), lead (D008)
- Oils and greases from hot and cold rolling
- Spent pickle liquor (K062)
- Spent pickle liquor rinse water sludge from cleaning operations
- Wastewater from the rinse baths. Rinse water from coating processes may contain zinc, lead, cadmium, or chromium.
- Grindings from roll refinishing may be RCRA characteristic waste from chromium (D007)
- Zinc dross

III.C. Management of Chemicals in the Production Process

The Pollution Prevention Act of 1990 (PPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has increased and the portions treated or managed through energy recovery on-site have decreased between 1992 and 1995 (projected). While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The PPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 6 shows that the iron and steel industry managed about 1.3 billion pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, over half (52%) was either transferred off-site or released to the environment, and most of this quantity was recycled off-site (typically in a metals recovery process). Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 48% of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns E, F and G, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns H, I and J, respectively. The remaining portion of the production related wastes (15% for 1993), shown in column D, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

Exhibit 6: Source Reduction and Recycling Activity for Iron and Steel Industry (SIC 331) as Reported within TRI

A	B	C	D	On-Site			Off-Site

[a] Does not include any accidental, non-production related wastes.
[b] Total TRI transfers and releases as reported in Section 5 and 6 of Form R as a percentage of production related wastes; this value may not equal the sum of the percentages released and transferred due to reporting errors in Section 8.
[c] Percentage of production related waste released to the environment and transferred off-site for disposal.

R0075560

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases, please note that in general, toxic chemical releases reported in TRI have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7% between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- is the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emission occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for storm water runoff and non-point losses must also be included.

Releases to Land -- includes disposal of toxic chemicals in waste to on-site landfills, land treated or incorporation into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Iron and Steel Industry

This section summarizes TRI data of facilities involved in the production of iron and steel products who report their operations under SIC 331. These include blast furnaces and steel mills, steel wire manufacture, and cold rolled steel products but also include a small number of nonferrous operations (such as facilities manufacturing nonferrous electrometalurgical products under SIC 3313). The *Census of Manufactures* reports 1,118 iron and steel establishments under SIC 331. Although 381 iron and steel facilities filed

TRI reports in 1993 (under SIC 3312, 3313, 3315, 3316. 3317), the 155 facilities (41 percent) classified under SIC 3312 (blast furnaces and steel mills) are responsible for over 75 percent of reported releases and transfers. TRI information is likely to provide a fairly different profile for the facilities not reporting under 3312 (non-steel producing facilities).

According to TRI data, the iron and steel industry released and transferred a total of approximately 695 million pounds of pollutants during calendar year 1993. These releases and transfers are dominated by large volumes of metal-bearing wastes. The majority of these wastes (70 percent or 488 million pounds) are transferred off-site for recycling, typically for recovery of the metal content. *Transfers* of TRI chemicals account for 86 percent of the iron and steel industry's total TRI-reportable chemicals (609 million pounds) while *releases* make up 14 percent (85 million pounds). Metal-bearing wastes account for approximately 80 percent of the industry's transfers and over fifty percent of the releases.

Releases from the industry continue to decrease, while transfers increased from 1992 to 1993. The increase in transfers is likely due to increased off-site shipments for recovery of metals from wastes. This shift may also have contributed to the decrease in releases. Another factor influencing an overall downward trend since 1988 in releases and transfers is the steel mill production decrease during the 1988 to 1993 period. In addition, pollution control equipment and a shift to new technologies, such as continuous casting, are responsible for significant changes in the amount and type of pollutants released during steelmaking. Finally, the industry's efforts in pollution preventing also play a role in driving pollutant release reductions.

Evidence of the diversity of processes at facilities reporting to TRI is found in the fact that the most frequently reported chemical (sulfuric acid) is reported by only 41 percent of the facilities; the sixth most frequently reported chemical was used by just one-fourth of TRI facilities. The variability in facilities' pollutant profile may be attributable to a number of factors. Fewer than 30 of the facilities in the TRI database for SIC 331 are fully integrated plants making coke, iron, and steel products. The non-integrated facilities do not perform one or more of the production steps and, therefore, may have considerably different emissions profiles. Furthermore, steel making operations with electric arc furnaces have significantly different pollutant profiles than those making steel with basic oxygen furnaces.

Releases

The iron and steel industry releases just 14 percent of its TRI total poundage. Of these releases, over half go to on-site land disposal, and one quarter of releases are fugitive or point source air emissions (Exhibit 7). Manganese, zinc, chromium, and lead account for over 90 percent of the on-site land disposal. The industry's air releases are associated with volatilization, fume or aerosol formation in the high temperature furnaces and byproduct processing. Ammonia, lighter weight organics, such as methanol, acids and metal contaminants found in the iron ore are the principal types of chemicals released to the air. In addition to air releases of chemicals reported in TRI, the iron and steel industry is a significant source of particulates, carbon monoxide, nitrogen oxides and sulfur compounds due to combustion. Ammonia releases account for the largest part of the fugitive releases (approximately 42 percent) and 1,1,1-trichloroethane, hydrochloric acid, zinc compounds, and trichloroethylene each contribute another 4 - 5 percent. Underground injection (principally of hydrochloric acid) makes up about 14 percent of the releases reported by the industry.

Transfers

Eighty percent of transfers reported by SIC 331 industries are sent off-site for recycling. Zinc, manganese, chromium, copper, nickel, and lead are the six metals transferred by the greatest number of facilities (Exhibit 8).

Acids used during steel finishing, such as hydrochloric, sulfuric, nitric, and phosphoric acids, account for another 17 percent of transfers. These acids are most often sent off-site for recycling or for treatment. Hydrochloric acids are also managed by on-site underground injection. The next class of chemicals of significant volume in TRI are solvents and lightweight carbon byproducts, including: 1,1,1-trichloroethane, trichloroethylene, phenol, xylene, methanol, and toluene. These solvents are primarily released as fugitive air emissions, but also from point sources. A small percentage of these solvents are transferred off-site for recycling.

Chemicals sent off-site for disposal (primarily zinc, sulfuric acid, manganese, and ammonium sulfate) account for another 10 percent of transfers. Only approximately 7 percent of chemicals transferred off-site go to treatment. These chemicals are primarily hydrochloric acid, sulfuric acid, and nitric acid. Only about one percent of transfers by weight are POTW discharges (mainly sulfuric acid). Another one percent of transfers are sent for energy recovery (with hydrochloric acid as the most significant contributor).

Exhibit 7: Releases for Iron and Steel Facilities (SIC 331) in TRI, by Number of Facilities Reporting (1993 Releases reported in pounds/year)

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector based on pounds released are listed below. Facilities that have reported only the SIC codes covered under this notebook appear on the first list. The second list contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations - some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibit 9: Top 10 TRI Releasing Iron and Steel Facilities[a]

Rank	Facility	Total TRI Releases in Pounds
1	Elkem Metals Co* - Marietta, OH	18,604,572
2	Northwestern Steel & Wire Co. - Sterling, IL	14,274,570

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reduction over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

[b] Being included on this list does not mean that the release is associated with non-compliance with environmental laws.

R0075571

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), and the Hazardous Substances Data Bank (HSDB), accessed via TOXNET. TOXNET is a computer system run by the National Library of Medicine. It includes a number of toxicological databases managed by EPA, the National Cancer Institute, and the National Institute for Occupational Safety and Health.[c] HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766.

Ammonia (CAS: 7664-41-7)

Sources. In cokemaking, ammonia is produced by the decomposition of the nitrogen-containing compounds which takes place during the secondary thermal reaction (at temperatures greater than 700°C (1296°F)). The ammonia formed during coking exists in both the water and gas that form part of the volatile products. The recovery of this ammonia can be accomplished by several different processes where the by-product ammonium sulfate is formed by the reaction between the ammonia and sulfuric acid.[23]

Toxicity. Anhydrous ammonia is irritating to the skin, eyes, nose, throat, and upper respiratory system.

Ecologically, ammonia is a source of nitrogen (an essential element for aquatic plant growth), and may therefore contribute to eutrophication of standing or slow-moving surface water, particularly in nitrogen-limited waters such as the Chesapeake Bay. In addition, aqueous ammonia is moderately toxic to aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

[c] Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory).

Environmental Fate. Ammonia combines with sulfate ions in the atmosphere and is washed out by rainfall, resulting in rapid return of ammonia to the soil and surface waters.

Ammonia is a central compound in the environmental cycling of nitrogen. Ammonia in lakes, rivers, and streams is converted to nitrate.

Physical Properties. Ammonia is a corrosive and severely irritating gas with a pungent odor.

Hydrochloric Acid (CAS: 7647-01-1)

Sources. During hot rolling, a hard black iron oxide is formed on the surface of the steel. This "scale" is removed chemically in the pickling process which commonly uses hydrochloric acid.[24]

Toxicity. Hydrochloric acid is primarily a concern in its aerosol form. Acid aerosols have been implicated in causing and exacerbating a variety of respiratory ailments. Dermal exposure and ingestion of highly concentrated hydrochloric acid can result in corrosivity.

Ecologically, accidental releases of solution forms of hydrochloric acid may adversely affect aquatic life by including a transient lowering of the pH (i.e.. increasing the acidity) of surface waters.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of hydrochloric acid to surface waters and soils will be neutralized to an extent due to the buffering capacities of both systems. The extent of these reactions will depend on the characteristics of the specific environment.

Physical Properties. Concentrated hydrochloric acid is highly corrosive.

Manganese and Manganese Compounds (CAS: 7439-96-5; 20-12-2)

Sources. Manganese is found in the iron charge and is used as an addition agent added to alloy steel to obtain desired properties in the final product. In carbon steel, manganese is used to combine with sulfur to improve the ductility of the steel. An alloy steel with manganese is used for applications involving relatively small sections which are subject to severe service conditions, or in larger sections where the weight saving derived from the higher strength of the alloy steels is needed.[25]

Toxicity. There is currently no evidence that human exposure to manganese at levels commonly observed in ambient atmosphere results in adverse health effects. However, recent EPA review of the fuel additive MMT

R0075573

(methylcyclopentadienyl manganese tricarbonyl) concluded that use of MMT in gasoline could lead to ambient exposures to manganese at a level sufficient to cause adverse neurological effects in humans.

Chronic manganese poisoning bears some similarity to chronic lead poisoning. Occurring via inhalation of manganese dust or fumes, it primarily involves the central nervous system. Early symptoms include languor, speech disturbances, sleepiness, and cramping and weakness in legs. A stolid mask-like appearance of face, emotional disturbances such as absolute detachment broken by uncontrollable laughter, euphoria, and a spastic gait with a tendency to fall while walking are seen in more advanced cases. Chronic manganese poisoning is reversible if treated early and exposure stopped. Populations at greatest risk of manganese toxicity are the very young and those with iron deficiencies.

Ecologically, although manganese is an essential nutrient for both plants and animals, in excessive concentrations manganese inhibits plant growth.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Manganese is an essential nutrient for plants and animals. As such, manganese accumulates in the top layers of soil or surface water sediments and cycles between the soil and living organisms. It occurs mainly as a solid under environmental conditions, though may also be transported in the atmosphere as a vapor or dust.

1,1,1-Trichloroethane (CAS: 71-55-6)

Sources. Used for surface cleaning of steel prior to coating.

Toxicity. Repeated contact of 1,1,1-trichloroethane (TCE) with skin may cause serious skin cracking and infection. Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations.

Exposure to high concentrations of TCE causes reversible mild liver and kidney dysfunction, central nervous system depression, gait disturbances, stupor, coma, respiratory depression, and even death. Exposure to lower concentrations of TCE leads to light-headedness, throat irritation, headache, disequilibrium, impaired coordination, drowsiness, convulsions and mild changes in perception.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of TCE to surface water or land will almost entirely volatilize. Releases to air may be transported long distances and may partially return to earth in rain. In the lower atmosphere, TCE degrades very slowly by photooxidation and slowly diffuses to the upper atmosphere where photodegradation is rapid.

Any TCE that does not evaporate from soils leaches to groundwater. Degradation in soils and water is slow. TCE does not hydrolyze in water, nor does it significantly bioconcentrate in aquatic organisms.

Zinc and Zinc Compounds (CAS: 7440-66-6; 20-19-9)

Sources. To protect steel from rusting, it is coated with a material that will protect it from moisture and air. In the galvanizing process, steel is coated with zinc.[26]

Toxicity. Zinc is a nutritional trace element; toxicity from ingestion is low. Severe exposure to zinc might give rise to gastritis with vomiting due to swallowing of zinc dusts. Short-term exposure to very high levels of zinc is linked to lethargy, dizziness, nausea, fever, diarrhea, and reversible pancreatic and neurological damage. Long-term zinc poisoning causes irritability, muscular stiffness and pain, loss of appetite, and nausea.

Zinc chloride fumes cause injury to mucous membranes and to the skin. Ingestion of soluble zinc salts may cause nausea, vomiting, and purging.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Significant zinc contamination of soil is only seen in the vicinity of industrial point sources. Zinc is a relatively stable soft metal, though burns in air. Zinc bioconcentrates in aquatic organisms.

IV.C. Other Data Sources

The toxic chemical release data obtained from TRI captures the vast majority of facilities in the iron and steel industry. It also allows for a comparison across years and industry sectors. Reported chemicals are limited however to the 316 reported chemicals. Most of the hydrocarbon emissions from iron and steel facilities are not captured by TRI.[27] The EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., total hydrocarbons, SOx, NOx, CO, particulates, etc.) from many iron and steel manufacturing sources.[28]

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 11 summarizes annual releases (from the industries for which a

Sector Notebook Profile was prepared) of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs). With 1.5 million short tons/year of carbon monoxide, the iron and steel industry emissions are estimated as more than twice as much as the next largest releasing industry, pulp and paper. Of the eighteen industries listed, the iron and steel industry also ranks as one of the top five releasers for NO_2, PM10, PT, and SO_2. Carbon monoxide releases occur during ironmaking (in the burning of coke, CO produced reduces iron oxide ore), and during steelmaking (in either the basic oxygen furnace or the electric arc furnace). Nitrogen dioxide is generated during steelmaking. Particulate matter may be emitted from the cokemaking (particularly in quenching operations), ironmaking, basic oxygen furnace (as oxides of iron that are emitted as sub-micron dust), or from the electric arc furnace (as metal dust containing iron particulate, zinc, and other materials associated with the scrap). Sulfur dioxide can be released in ironmaking or sintering.

Exhibit 11: Pollutant Releases (short tons/year)

Industry Sector	CO	NO_2	PM_{10}	PT	SO_2	VOC
U.S. Total	97,208,000	23,402,000	45,489,000	7,836,000	21,888,000	23,312,000

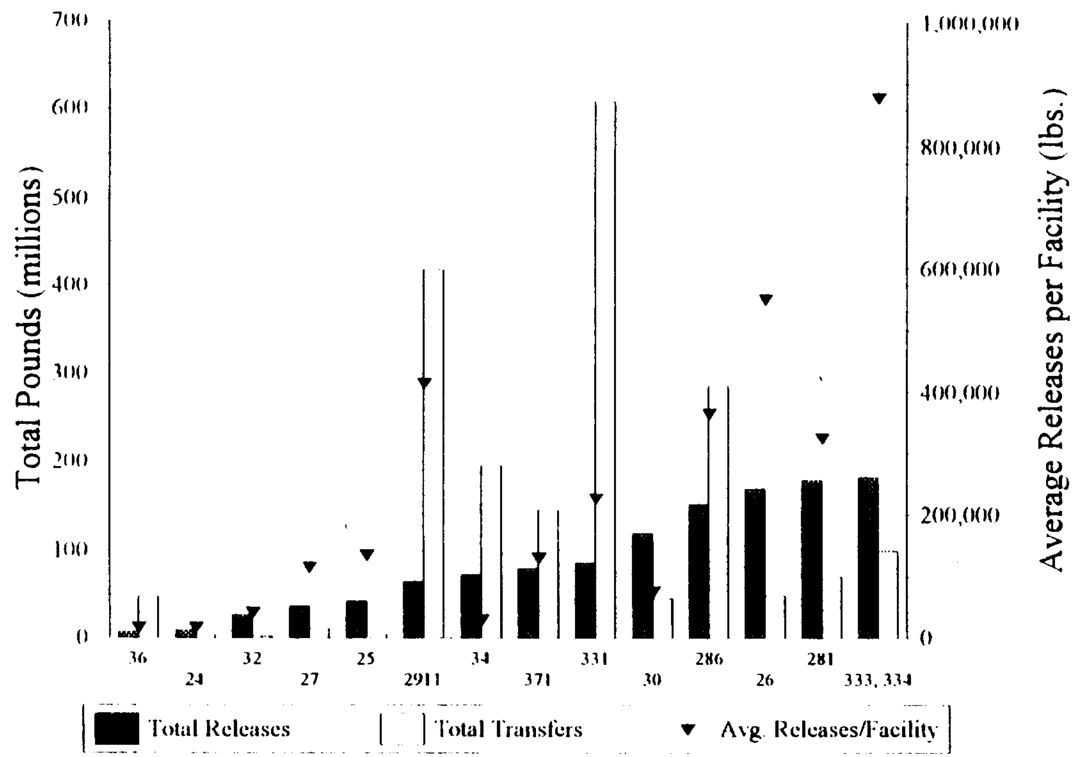
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following figure and table do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release Book.

Exhibit 12 is a graphical representation of a summary of the 1993 TRI data for the iron and steel industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangular points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 13 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the iron and steel industry, the 1993 TRI data presented here covers 381 facilities. These facilities listed SIC 331 (Steel Works, Blast Furnaces, and Rolling and Finishing Mills) as a primary SIC code.

Exhibit 12: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the iron and steel industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

Most of the pollution prevention activities in the iron and steel industry have concentrated on reducing cokemaking emissions, Electric Arc Furnace (EAF) dust, and spent acids used in finishing operations. Due to the complexity, size, and age of the equipment used in steel manufacturing, projects that have the highest pollution prevention potential often require significant capital investments. This section describes pollution prevention opportunities for each of the three focus areas (cokemaking, EAF dust, and finishing acids), and then lists some general pollution prevention opportunities that have been identified by the iron and steel industry.

Cokemaking

The cokemaking process is seen by industry experts as one of the steel industry's areas of greatest environmental concern, with coke oven air emissions and quenching waste water as the major problems. In response to expanding regulatory constraints, including the Clean Air Act National Emission Standards for coke ovens completed in 1993, U.S. steelmakers are turning to new technologies to decrease the sources of pollution from, and their reliance on, coke. Pollution prevention in cokemaking has focused on two areas: reducing coke oven emissions and developing cokeless ironmaking techniques. Although these processes have not yet been widely demonstrated on a commercial scale, they may provide significant benefits for the integrated segment of the industry in the form of substantially lower air emissions and wastewater discharges than current operations.

R0075581

Eliminating Coke with Cokeless Technologies

Cokeless technologies substitute coal for coke in the blast furnace, eliminating the need for cokemaking. Such technologies have enormous potential to reduce pollution generated during the steelmaking process. The capital investment required is also significant. Some of the cokeless technologies in use or under development include:

• *The Japanese Direct Iron Ore Smelting (DIOS) process.* This process produces molten iron directly with coal and sinter feed ore. A 500 ton per day pilot plant was started up in October, 1993 and the designed production rates were attained as a short term average. During 1995, the data generated will be used to determine economic feasibility on a commercial scale.

• *HIsmelt process.* A plant using the HIsmelt process for molten iron production, developed by HIsmelt Corporation of Australia, was started up in late 1993. The process, using ore fines and coal, has achieved a production rate of 8 tons per hour using ore directly in the smelter. Developers anticipate reaching the production goal of 14 tons per hour. During 1995, the data generated will be used to determine economic feasibility on commercial scale. If commercial feasibility is realized, Midrex is expected to become the U.S. engineering licensee of the HIsmelt process.

• *Corex process.* The Corex or Cipcor process has integral coal desulfurizing, is amenable to a variety of coal types, and generates electrical power in excess of that required by an iron and steel mill which can be sold to local power grids. A Corex plant is in operation in South Africa, and other plants are expected to be operational in the next two years in South Korea and India.

Reducing Coke Oven Emissions

Several technologies are available or are under development to reduce the emissions from coke ovens. Typically, these technologies reduce the quantity of coke needed by changing the method by which coke is added to the blast furnace or by substituting a portion of the coke with other fuels. The reduction in the amount of coke produced proportionally reduces the coking emissions. Some of the most prevalent or promising coke reduction technologies include:

• *Pulverized coal injection.* This technology substitutes pulverized coal for a portion of the coke in the blast furnace. Use of pulverized coal injection can replace about 25 to 40 percent of coke in the blast furnace, substantially reducing emissions associated with cokemaking operations. This reduction ultimately depends on the fuel injection rate applied to the blast furnaces which will, in turn be dictated by the aging of existing coking facilities, fuel costs, oxygen availability, capital requirements for fuel injection, and available hot blast temperature.

• *Non-recovery coke battery.* As opposed to the by-product recovery coke plant, the non-recovery coke battery is designed to allow combustion of the gasses from the coking process, thus consuming the by-products that are typically recovered. The process results in lower air emissions and substantial reductions in coking process wastewater discharges.

• *The Davy Still Autoprocess.* In this pre-combustion cleaning process for coke ovens, coke oven battery process water is utilized to strip ammonia and hydrogen sulfide from coke oven emissions.

• *Alternative fuels.* Steel producers can also inject other fuels, such as natural gas, oil, and tar/pitch, instead of coke into the blast furnace, but these fuels can only replace coke in limited amounts.

Recycling of Coke By-products

Improvements in the in-process recycling of tar decanter sludge, a RCRA listed hazardous waste (K087) are common practice. Sludge can either be injected into the ovens to contribute to coke yield, or converted into a fuel that is suitable for the blast furnace.

Reducing Wastewater Volume

In addition to air emissions, quench water from cokemaking is also an area of significant environmental concern. In Europe, some plants have implemented technology to shift from water quenching to dry quenching in order to reduce energy costs. However, major construction changes are required for such a solution and considering the high capital costs of coke batteries, the depressed state of the steel industry, and increased regulations for cokemaking, it is unlikely that this pollution prevention opportunity will be widely adopted in the U.S.

Electric Arc Furnace Dust

Dust generation in the EAF, and its disposal, have also been recognized as a serious problem, but one with potential for pollution prevention through material recovery. EAF dust is a RCRA listed waste (K061) because of its high concentrations of lead and cadmium. With 550,000 tons of EAF dust generated annually in the U.S., there is great potential to reduce the volume of this hazardous waste.[27] Steel companies typically pay a disposal fee of $150 to $200 per ton of dust. With an average zinc concentration of 19 percent, much of the EAF dust is shipped off-site for zinc reclamation. Most of the EAF dust recovery options are only economically viable for dust with a zinc content of at least 15 - 20 percent. Facilities producing specialty steels such as stainless steel with a lower zinc content, still have opportunities to recover chromium and nickel from the EAF dust.

In-process recycling of EAF dust involves pelletizing and then reusing the pellets in the furnace, however, recycling of EAF dust on-site has not proven to be technically or economically competitive for all mills. Improvements in technologies have made off-site recovery a cost effective alternative to thermal treatment or secure landfill disposal.

Pickling Acids

In finishing, pickling acids are recognized as an area where pollution prevention efforts can have a significant impact in reducing the environmental impact of the steel mill. The pickling process removes scale and cleans the surface of raw steel by dipping it into a tank of hydrochloric or sulfuric acid. If not recovered, the spent acid may be transported to deep injection wells for disposal, but as those wells continue to close, alternative disposal costs are rising.

Large-scale steel manufacturers commonly recover hydrochloric acid in their finishing operations, however the techniques used are not suitable for small- to medium-sized steel plants.[28] Currently, a recovery technique for smaller steel manufacturers and galvanizing plants is in pilot scale testing. The system under development removes iron chloride (a saleable product) from the hydrochloric acid, reconcentrates the acid for reuse, and recondenses the water to be reused as a rinse water in the pickling process. Because the only by-product of the hydrochloric acid recovery process is a non-hazardous. marketable metal chloride, this technology generates no hazardous wastes. The manufacturer projects industry-wide hydrochloric acid waste reduction of 42,000 tons/year by 2010. This technology is less expensive than transporting and disposing waste acid, plus it eliminates the associated long-term liability. The total savings for a small- to medium-sized galvanizer is projected to be $260,000 each year.

The pilot scale testing project is funded in part by a grant from the U.S. Department of Energy under the NICE[3] program (see section VIII.B. for program information) and the EPA. (Contact: Bill Ives, DOE, 303-275-4755)

To reduce spent pickling liquor (K062) and simultaneously reduce fluoride in the plant effluent, one facility modified their existing treatment process to recover the fluoride ion from rinse water and spent pickling acid raw water waste streams. The fluoride is recovered as calcium fluoride (fluorspar), an input product for steelmaking. The melt shop in the same plant had been purchasing 930 tons of fluorspar annually for use as a furnace flux material in the EAF at a cost of $100 per ton. Although the process is still under development, the recovered calcium fluoride is expected to be a better grade than the purchased fluorspar, which would reduce the amount of flux used by approximately 10 percent. Not only would the generation rate of sludge from spent pickling liquor treatment be reduced (resulting in a savings in off-site sludge disposal costs), but a savings in chemical purchases would be realized.

Other areas with pollution prevention opportunities

Other areas in iron and steel manufacturing where opportunities may exist for pollution prevention are listed below, in three categories: process modifications, materials substitution, and recycling.

Process Modification

Redesigning or modifying process equipment can reduce pollution output, maintenance costs, and energy consumption, for example:

• Replacing single-pass wastewater systems with closed-loop systems to minimize chemical use in wastewater treatment and to reduce water use.
• Continuous casting, now used for about 90% of crude steel cast in the U.S., offers great improvements in process efficiency when compared to the traditional ingot teeming method. This increased efficiency also results in a considerable savings in energy and some reduction in the volume of mill wastewater.

Materials Substitution

• Use scrap steel with low lead and cadmium content as a raw material, if possible.
• Eliminate the generation of reactive desulfurization slag generated in foundry work by replacing calcium carbide with a less hazardous material.

Recycling

Scrap and other materials are recycled extensively in the iron and steel industry to reduce the raw materials required and the associated pollutants. Some of these recycling activities include:
• Recycle or reuse oils and greases.
• Recover acids by removing dissolved iron salts from spent acids.
• Use thermal decomposition for acid recovery from spent pickle liquor.
• Use a bipolar membrane/electrodialytic process to separate acid from metal by-products in spent NO_3-HF pickle liquor.
• Recover sulfuric acid using low temperature separation of acid and metal crystals.

VI. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section VI.A. contains a general overview of major statutes
- Section VI.B. contains a list of regulations specific to this industry
- Section VI.C. contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and record keeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites: however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline. at (800) 424-9346. answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET. excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized approximately forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use

R0075590

classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing, or raw material storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, consult the regulation.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention, Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities posing a substantial threat of harm to the environment prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). As iron and steel manufacturing is an energy intensive industry, an important requirement affecting iron and steel facilities is oil response plans for above ground storage. There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR Part 112) and for PCB transformers and PCB-containing items are being revised and finalized in 1995.[29]

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

R0075593

The SDWA **Underground Injection Control** (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control

Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET. excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT)." The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide nitrous oxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.
Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2,000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Regulatory Requirements

The steel industry has invested substantial resources in compliance with environmental regulations. Expenditures for environmental air control totaled $279 million in 1991, while water and solid waste control combined totaled $66 million. This translates to 15 percent of total capital expenditures for the industry in 1991. The high percentage of total environmental capital expenditures for air control (81 percent) is primarily due to keeping coke ovens operating in compliance with the Clean Air Act. Although coke ovens are considered by many industry experts to be the biggest environmental problem of the iron and steel industry, environmental regulations affect the industry throughout all stages of the manufacturing and forming processes. An overview of how federal environmental regulations affect this industry follows.

Clean Air Act (CAA)

The CAA, with its 1990 amendments (CAAA), regulates the pollutants that steel mills can add to the air. Title I of the Act addresses requirements for the attainment and maintenance of the National Ambient Air Quality Standards (NAAQS) (40 CFR, §50). EPA has set NAAQS for six criteria pollutants, which states must plan to meet through state implementation plans (SIPs). NAAQS for nitrogen dioxide, lead, and particulate matter frequently affect the iron and steel industry.

One of the most significant impacts of the CAAA on the iron and steel industry is tied to the standards developed for toxic air emissions or Hazardous Air Pollutants (HAPs). For the steel industry, these standards, National Emission Standards for Hazardous Air Pollutants (NESHAPs), have a significant effect on the industry's coke ovens. In late 1991, the coking industry entered into a formal regulatory negotiation with EPA and representatives of environmental groups, state and local air pollution control agencies, and the steelworkers union to develop a mutually acceptable rule to implement the terms of the Act's coke oven provisions. After a year of discussions, an agreement on a negotiated rule was signed. In exchange for a standard that is structured to give operators certainty and flexibility in the manner they demonstrate compliance, the industry agreed to daily monitoring, to install flare systems to control upset events, and to develop work practice plans to minimize emissions. National Emissions Standards currently in effect that pertain to the iron and steel industry include:

- Coke Oven Batteries (40 CFR §63 Subpart L). As of April 1, 1992, there were 30 plants with 87 by-product coke oven batteries that would be affected by this regulation.

- Benzene Emissions from Coke By-product Recovery Plants (40 CFR §61 Subpart L). Regulates benzene sources in coke by-product recovery operations by requiring that specified equipment be enclosed and the emissions be ducted to an enclosed point in the by-product recovery process where they are recovered or destroyed. Monitoring requirements are also stated.

- Halogenated Solvent Cleaning (40 CFR §63 Subpart T). Emission standards for the source categories listed in §112(d), including solvents used in the iron and steel industry such as 1,1,1-trichloroethane, trichloroethylene, and methylene chloride.

- Chromium - Industrial Process Cooling Towers (40 CFR §63 Subpart Q). This standard will eliminate chromium emissions from industrial process cooling towers. Industrial process cooling towers using chromate-based water treatment programs have been identified as potentially significant sources of chromium air emissions: chromium compounds being among the substances listed as HAPs in §112(e).

The CAA also impacts the minimill segment of the industry. The Electric Arc Furnace was identified as a possible source of hazardous air pollutants subject to a MACT determination, however. EPA data indicates that the impact is much less than originally anticipated and there are currently no plans for establishing a MACT standard.

The 1990 CAAA New Source Review (NSR) requirements apply to new facilities, expansions of existing facilities, or process modifications. New sources of the "criteria" pollutants regulated by the NAAQS in excess of levels defined by EPA as "major" are subject to NSR requirements (40 CFR Section 52.21(b)(1)(i)(a)-(b)). NSRs are typically conducted by the state agency under standards set by EPA and adopted by the state as part of its state implementation plan (SIP). There are two types of NSRs: Prevention of Significant Deterioration (PSD) reviews for facilities in areas that are meeting the NAAQS, and Nonattainment (NA) reviews for areas that are violating the NAAQS. Permits are required to construct or operate the new source for PSD and NA areas.

For NA areas, permits require the new source to meet the lowest achievable emission rate (LAER) standards and the operator of the new source must procure reductions in emissions of the same pollutants from other sources in the NA area in equal or greater amounts to the new source. These "emission offsets" may be banked and traded through state agencies.

For PSD areas, permits require the best available control technology (BACT), and the operator or owner of the new source must conduct continuous on-site air quality monitoring for one year prior to the new source addition to determine the effects that the new emissions may have on air quality. This one year waiting period before construction can be disruptive to some mills' expansion plans. In several cases, mills looking to construct or expand have attempted to be reclassified as a "synthetic minor," where they ask the state to put tighter restrictions on their quantity of emissions allowed on their air permit. With these reduced emissions, they become a minor instead of a major source, thereby becoming exempt from the lengthy and expensive PSD review.

EPA sets the minimum standards for LAER and BACT for iron and steel mill NSRs in its new source performance standards (NSPS), 40 CFR 60:

- Standards of Performance for Steel Plants: Electric Arc Furnaces (40 CFR §60, Subpart AA). Regulates the opacity and particulate matter in any gases discharged from EAFs constructed after October 21, 1974 and on or before August 17, 1983. Also requires a continuous monitoring system for the measurement of the opacity of emissions discharged from control equipment.

- Standards of Performance for Steel Plants: Electric Arc Furnaces and Argon-Oxygen Decarburization Vessels (AODs) (40 CFR §60.

Subpart AAa). Regulates the opacity and particulate matter in any gases discharged from EAFs and AODs (used to blow argon and oxygen or nitrogen into molten steel for further refining) constructed after August 7, 1983. Also requires a continuous monitoring system for the measurement of the opacity of emissions discharged from EAF and AOD air pollution control equipment.

- Standards of Performance for Primary Emissions from Basic Oxygen Process Furnaces (BOPF) (40 CFR §60, Subpart N). Regulates the discharge of gases for particulate matter and opacity. These standards apply to BOPFs for which construction is commenced after June 11, 1973. Primary emissions refer to particulate matter emissions from the BOPF generated during the steel production cycle and captured by the BOPF primary control system.

- Standards of Performance for Secondary Emissions from Basic Oxygen Process Steelmaking Facilities (40 CFR §60, Subpart Na). Regulates the discharge of gases for particulate matter and opacity for BOPFs for which construction is commenced after January 20, 1983. Secondary emissions means particulate matter emissions that are not captured by the BOPF primary control system.

Clean Water Act (CWA)

The steel industry is a major water user and 40 CFR 420 established Effluent Limitations Guidelines and Standards for the Iron and Steel Manufacturing Point Source Category. These are implemented through the NPDES permit program and through state and local pretreatment programs. Part 420 contains production-based effluent limitations guidelines and standards, therefore steel mills with higher levels of production will receive higher permit discharge allowances. The regulation contains 12 subparts for 12 distinct manufacturing processes:

A. Cokemaking	G. Hot Forming
B. Sintering	H. Salt Bath Descaling
C. Ironmaking	I. Acid Pickling
D. Steelmaking	J. Cold Forming
E. Vacuum Degassing	K. Alkaline Cleaning
F. Continuous Casting	L. Hot Coating

The pollutants regulated by 40 CFR 420 are divided into three categories:

1. *Conventional Pollutants:* Total Suspended Solids, Oil and Grease, pH
2. *Nonconvention Pollutants:* Ammonia-N, Phenols
3. *Priority or Toxic Pollutants:* Total cyanide, total chromium, hexavalent chromium, total lead, total nickel, total zinc, benzene, benzo(a)pyrene, naphthalene, tertrachloroethylene.

Wastewater is often recycled "in-plant" and at the "end-of-pipe" to reduce the volume of discharge. Process wastewater is usually filtered, and/or clarified on-site before being directly or indirectly discharged. Oil and greases are removed from the process wastewater by several methods which include oil skimming, filtration, and air flotation. These oils can then be used as lubricants and preservative coatings. The remaining sludge contains waste metals and organic chemicals. Iron in the sludges can be recovered and reclaimed through sintering and pelletizing operations. Many steel mills discharge industrial waste water through sewers to publicly owned treatment works.

The Storm Water Rule (40 CFR 122.26(b)(14) subparts (i, ii)) requires the capture and treatment of storm water at primary metal industry facilities including iron and steel manufacturing. Management of storm water will reduce discharges with respect to conventional pollutants (suspended solids and biological oxygen demand (BOD)), as well as other pollutants, such as certain metals and oil and grease.

Resource Conservation and Recovery Act (RCRA)

Several RCRA-listed wastes are produced during coke, iron, and steelmaking, forming, and cleaning/descaling operations. These wastes are identified below by process.

Coke Manufacturing

- Tar residues (K035, K087, K141, K142, and K147)
- Oil (K143 and K144)
- Naphthalene residues (K145)
- Lime sludge (K060)
- Wastewater sump residues containing benzene and polynuclear aromatic hydrocarbons (K144)
- Coke oven gas condensate from transfer and distribution lines

Iron and Steel Manufacturing

- EAF emission control dust and sludge (K061). Annually, 550,000 short tons of K061 are produced; 90 percent of this waste (500,000 short tons) is managed for metal recovery.[29]

Finishing

- Wastewater sludge from cooling, descaling, and rinsing (D006, D007, D008, D009, D010, and D011)
- Spent pickle liquor (K062). An exemption for this waste is detailed in 40 CFR 261.3(c)(2)(ii)(A). 904,945 short tons of K062 are generated annually in the U.S. and 52 percent of this waste is managed for recovery of iron, chromium, and nickel.[30]

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

The metals and metal compounds used in steelmaking, as well as steelmaking process chemicals, are often found in steel mills' air emissions, water discharges, or waste shipments for off-site disposal include chromium, manganese, nickel copper, zinc, lead, sulfuric acid, and hydrochloric acid. Metals are frequently found at CERCLA's problem sites. When Congress ordered EPA and the Public Health Service's Agency for Toxic Substances and Disease Registry (ATSDR) to list the hazardous substances most commonly found at problem sites and that pose the greatest threat to human health, lead, nickel, and aluminum all made the list.[31] Several sites of former steel mills are on the National Priorities List. Compliance with the requirements of RCRA lessens the chances that CERCLA compliance will be an issue in the future.

VI.C. Pending and Proposed Regulatory Requirements

The iron and steel industry has been identified in the Source Reduction Review Project (SRRP) as an industry for which a more integrated (across environmental media) approach to rulemaking is warranted. Efforts such as the Office of Water's review of the need for revised effluent guidelines for the industry (described below) and the technology-based standards for coke oven emissions under the Clean Air Act Amendments will be coordinated among several media offices.

Clean Air Act

Even with the flexibility the industry gained through the formal negotiations to develop the rule to implement the coke oven provisions of the CAA, coke-producing steel companies face difficult decisions of how best to utilize scarce capital to meet the CAAA standards. Additionally, coke oven operators still face unknown technology-based standards in 2010 and risk-based standards in 2020.

The Act's air toxic provisions will also ultimately have other major impacts. Included on the list of chemicals under the air toxics program are compounds of chromium, nickel, manganese, cadmium and other heavy metals. Because many of these metals are routinely found in iron ore, scrap, and alloying materials that are processed in iron and steel plants, most steelmaking processes will be affected in some way. EPA's priority list of source categories calls for the development of regulations for most of these sources by 2000, but until EPA identifies the technology corresponding to MACT for these sources and promulgates regulations, it is difficult to determine the additional impacts and costs to the industry for this program.

Tightening the national ambient air quality standard for particulate matter (PM-10) may also affect the iron and steel industry. Under the CAAA, EPA will be reviewing the basis for the existing ambient air PM-10 standard. A lower standard may cause more areas of the country to be classified as non-attainment areas and would trigger requirements for states to impose much more stringent emission control standards for sources of particulate matter. including iron and steel sources.

Hydrochloric acid and chlorine are among the pollutants listed as hazardous air pollutants in §112 of the CAAA. Steel pickling processes that use hydrochloric acid have been identified by the EPA as potentially significant sources of hydrochloric acid and chlorine air emissions and, as such, a source category for which national emission standards are likely. EPA is expected to make a determination on the steel pickling process sometime in 1995, with the final rule promulgation scheduled for 11/96. Many facilities either are already in compliance, or they have the required control equipment, but need to upgrade it or perform maintenance procedure to come into compliance. (Contact: James Maysilles, EPA Office of Air Quality Planning and Standards, 919-541-3265).

Title III of the CAAA, requires EPA to develop national emission standards for hazardous air pollutants (NESHAP) from specific stationary sources including iron and steel mills (contact: Phil Murine, EPA Office of Air Quality Planning and Standards, 919-541-5289) and iron and steel foundries (contact: James Maysilles, EPA Office of Air Quality Planning and Standards, 919-541-3265). Both of these types of facilities have been identified by the EPA as potentially significant sources of air emissions of substances that are among the pollutants listed as hazardous air pollutants in §112 of the CAAA. As such, these industries may be source categories for which national emission standards may be warranted. In integrated iron and steel mills, air emission of HAPs may include compounds of chromium, lead, manganese, and polycyclic organic matter, in quantities sufficient to designate these facilities as major sources. Emission standards were to be developed for Electric Arc Furnaces also. However, EPA data does not show that EAFs emit sufficient hazardous pollutants to include them on the list of major sources of these pollutants. Therefore, a proposed regulatory action is scheduled to remove this category from the list of sources where new regulations will be promulgated.

Other, more general, proposed regulatory actions under the CAA have an effect on some facilities within the iron and steel industry. These include:

• Risk Management Program for Chemical Accidental Release Prevention (40 CFR 68). Requires facilities where a regulated substance is present (defined by the list, with threshold quantities, promulgated under §112(r)(3)) to prepare and implement a risk management plan and provide emergency response. The final rule will be promulgated by 3/29/96.

• New Source Review Reform (40 CFR 51, 52). This action will amend the new source review regulations to reduce the level of program complexity. The final rule will be promulgated 1/96.

R0075602

• Revised New Source Performance Standard for NOx (40 CFR 60, Subpart Db). Revisions apply to NOx emissions from fossil fuel-fired steam generating units, including industrial boilers and must reflect improvements in NOx reduction methods. The final rule will be promulgated by 12/31/96.

• Title V Federal Air Operating Permit Rules (40 CFR 70 and 71). Sets requirements for state permitting programs for major stationary air pollutants. Also establishes a federal permitting program for use where states fail to establish or implement an adequate program. The final rule will be promulgated by 11/95.

• Title V State Air Operating Permit Rules (40 CFR 70). Revisions of the state operating permit rules promulgated in 1992. This regulation is intended to restructure the process for issuing and revising permits, to give state agencies more flexibility. States will be allowed to issue a single permit covering both New Source Review and Title V permitting requirements.

Clean Water Act (CWA)

Since approximately 80 percent of the nation's integrated steelmaking capacity is located in the Great Lakes states, the current efforts to develop uniform water quality standards under the Great Lakes Water Quality Initiative may have a significant impact on the industry. According to the American Iron and Steel Institute (AISI), the industry is concerned with the establishment of uniform water quality guidance for all waters. AISI believes that states should be given the responsibility of designating uses and associated water quality standards for all water bodies within their jurisdictions. These designations, AISI believes, should take into account the feasibility of the attainment of swimmable and fishable waters where naturally occurring pollutants prevent its attainment, where pollution sources prevent attainment and correction of these sources would cause more environmental harm than good, or where attainment would result in unreasonable social and economic impacts. AISI concludes that requiring discharges of non-contact cooling water to be cleaner than when drawn from the stream or lake, while at the same time disregarding the water quality impacts of non-point sources such as urban or agricultural runoff, will impose huge costs, restrict growth, or force zero discharge on direct dischargers. By March 23, 1997, the Great lakes states (Illinois, Indiana, Michigan, Minnesota, New York, Pennsylvania, Ohio, and Wisconsin), as well as tribes in the area, must adopt rules and procedures consistent with the Water Quality Guidance for the Great Lakes System (40 CFR 132; also amends 122, 123, and 131). The Guidance places particular emphasis on decreasing bioaccumulative toxics and also provides a process for addressing both point and non-point source pollution.

The EPA is currently revisiting the CWA Effluent Guidelines and Standards for Iron and Steel Manufacturing Point Source Category. A two-year study is scheduled to be completed in late 1995 which reviews the existing regulations to determine what changes have been made in the industry since the 1982 regulations were promulgated. One focus of the project is to investigate the types of pollution prevention measures that have been implemented. The study was initiated as a result of a Natural Resources Defense Council (NRDC) consent decree. (Contact: George Jett, EPA Office of Water, 202-260-7151).

The Office of Water is also initiating a 3-year data collection and analysis effort (which began in 1994) to quantify the adverse impacts from cooling water intake structures and the efficacy of certain control mechanisms. Regulatory options will be developed and a regulation proposed based on the study results. This regulation may have a relatively significant impact on the iron and steel industry.

Resource Conservation and Recovery Act (RCRA)

Under RCRA, emission control dust and sludge from electric arc furnaces (EAF) are a listed hazardous waste (K061) and are subject to land disposal restrictions. This pollution control dust/sludge is composed of various metals: primarily iron with lesser concentrations of zinc, lead, cadmium, and sometimes nickel and chromium. The metals primarily recovered are iron or nickel alloys or zinc. Two or the primary hazardous constituents, lead and cadmium, are not initially recovered, although they are usually shipped off-site for further recovery. Annually, 550,000 short tons of K061 are produced; 90 percent of this waste (500,000 short tons) is managed for metal recovery.[32] EPA's treatment standards were originally based on high temperature metals recovery, but were recently revised to generic treatment levels. As a result, a generator may select one of a variety of options, including stabilization, as alternatives to recycling. Other recovery alternatives include: use as a fertilizer ingredient, use an ingredient in glass grit for abrasive blast, roofing shingles, glass ceramic or ceramic glaze, use as an ingredient in the production of cement, use as an ingredient in the production of special aggregates.[33]

Such recovery practices reduce the quantity of hazardous waste disposed of, however, the industry is concerned with the limitations that are placed on the disposal or uses of non-hazardous residuals from the high temperature metals recovery processes that might serve to discourage or inhibit metal recovery practices. According to several steel industry trade associations (SMA, SSINA, AISI), RCRA has discouraged metal recovery from hazardous wastes generated in steel production. For example, the derived-from rule has discouraged investment in on-site or regional recycling operations because of the additional cost of residual management. The trade associations also state that the lack of adequate metal recovery capacity in the U.S. requires their members to spend an average of $650,000 annually in transportation costs to ship K061 off-site, and a total of $1.4 million annually to recycle K061.[34] Other RCRA impediments stated by the trade associations include the 90-day storage limit for generators, and corrective action/financial assurance.

As part of a 1992 settlement agreement, EPA has agreed to propose (by June 30, 1995) and promulgate (by June 30, 1996) regulations for land disposal restrictions on mineral processing wastes. These regulations will set land disposal restrictions and standards for those mineral processing wastes that are found to be hazardous under RCRA Subtitle C. Currently, all extraction and beneficiation wastes, as well as 20 mineral processing wastes, are exempt from federal hazardous waste regulations.

Under a proposed regulation, "Hazardous Waste Management System: Amendment to Generic Exclusion for Encapsulated Uses (K061, K062, F006)," (40 CFR 261), the slags created from the treatment of pollution control dusts resulting from scrap metal recycling (i.e., electric arc furnace dust), will be reclassified as nonhazardous and be allowed for road-related uses if the toxic metals in the wastes have been reduced to safe levels by treatment. The final rule will be promulgated by 6/13/96.

Also under RCRA Subtitle C (40 CFR 261), the "Hazardous Waste Identification Rule" will be proposed in 1995 to allow listed wastes which are low risk to be removed from the hazardous waste regulatory scheme. This rule is intended to better align the burden of RCRA regulation with the risks being controlled.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

Steel companies involved in Superfund sites would be affected by changes under impending CERCLA reauthorization. Questions of liability, funding mechanisms, selection of remedial actions, and application of risk concepts are all of concern to the steel industry.

Safe Drinking Water Act (SDWA)

The 1986 SDWA amendments required EPA to complete a study of Class V underground injection wells. These are all wells not included in Classes I through IV; they vary from simple septic systems and shallow cesspools to deep, technically sophisticated wells with a wide range of environmental impacts. As a follow up to the study, EPA developed a strategy to assess whether additional controls of these wells would be appropriate. A proposed regulation on Class V wells is being developed as part of this strategy and could potentially affect some iron and steel facilities. Final rule promulgation is scheduled for 11/96.

Global Climate Change

Legislative initiatives that address global climate change will also affect the iron and steel industry. Steel is a highly energy intensive industry, where 15 to 20 percent of the manufacturing cost of steel is for energy. Most of that energy is derived from coal, principally in the form of coke. Consequently, a carbon tax could have a major impact on the steel industry. While such a tax is designed to reduce carbon dioxide emissions and to curb energy consumption, industry analysts expect such a tax would also results in 177,000 to 362,000 job losses across the country, according to Wilbur Steger, president of CONSAD Research Corp., as reported in the March 1993 issue of *Iron Age*.

Increasing the corporate average fuel economy (CAFE) of automobiles has been identified as a means of encouraging energy conservation and reducing carbon dioxide emissions. An increase in fuel economy standards may lead to downsizing automobiles, which will affect steel markets by reducing demand for certain steel products.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[d] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System,

[d] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

R0075608

Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1).

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

R0075609

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Reported inspections and enforcement actions under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

R0075610

VII.A. Iron and Steel Industry Compliance History

Exhibit 14 provides an overview of the reported compliance and enforcement data for the iron and steel industry over the past five years (August 1990 to August 1995). These data are also broken out by EPA Region thereby permitting geographical comparisons. A few points evident from the data are listed below.

- Eighty-five percent of iron and steel facility inspections occurred in Regions III, IV, and V, where the most facilities are located.

- Within the three regions where iron and steel mills are concentrated. the proportion of state-lead enforcement actions was significantly greater than federal action for Regions III and IV (87% state-lead and 91% state-lead, respectively). In Region V, the region with the greatest number of iron and steel facilities, enforcement actions were fairly evenly split between state-lead and federal-lead.

- Of the 275 facilities inspected over the five-year period examined. 115 had one or more enforcement actions (42%), however, the aggregate Enforcement to Inspection Rate across all Regions was 0.14 (499 enforcement actions/3,555 inspections).

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 15 and 16 allow the compliance history of the iron and steel sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Exhibits 15 and 16 permit the identification of trends in compliance and enforcement records of the industry by comparing data covering the last five years to that of the past year. Some points evident from the data are listed below.

- Of those sectors listed, facilities in iron and steel sector have been one of the most frequently inspected industries over the past five years with an average of 6 months between inspections. Only petroleum refining and pulp and paper facilities were inspected, on average, more frequently.

- Over the past year, the enforcement to inspection rate for the iron and steel industry has decreased from 0.14 for 1990 through 1995 to 0.09 for August 1994 through August 1995.

Exhibits 17 and 18 provide a more in-depth comparison between iron and steel industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Exhibits (Exhibits 15 and 16), the data cover the last five years (Exhibit 17) and the last one year (Exhibit 18) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- The percentage of inspections carried out under each environmental statute has changed little between the average of the past five years and that of the past year. Inspections are roughly divided equally among, CAA, CWA, and RCRA, although the past year has shown a slight increase in the percentage of CAA inspections and a slight decrease in the percentage of RCRA inspections.

- While approximately one-third of inspections are carried out under each statute (CAA, CWA, and RCRA), the majority of the enforcement actions are taken under RCRA.

VII.C. Review of Major Legal Action

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

VII.C.1. Review of Major Cases

The Office of Regulatory Enforcement does not regularly compile information related to major cases and pending litigation within an industry sector. The staff are willing to pass along such information to Agency staff as requests are made. (Contact: Pete Rosenberg 202-260-8869) In addition, summaries of completed enforcement actions are published each fiscal year in the *Enforcement Accomplishments Report*; the summaries are not organized by industry sector. (Contact: Robert Banks 202-260-8296).

VII.C.2. Supplementary Environmental Projects (SEPs)

Supplemental environmental projects (SEPs) are enforcement options that require the non-compliant facility to complete specific projects. Regional summaries of SEPs undertaken in the 1993 and 1994 federal fiscal years were reviewed. Three projects were undertaken that involved iron and steel facilities, as shown in Exhibit 19.

In the iron and steel sector, SEPs resulted from violations of EPCRA, CERCLA, and RCRA. Due to differences in regional descriptions, the specifics of the original violations are not known. The cost for the projects ranged from $53,000 to $900,000 corresponding to initial penalties ranging from $110,000 to $746,438.

R0075618

Exhibit 19: FY-1993-1994 Supplemental Environmental Projects Overview: Iron and Steel Manufacture

General Information				Violation Information					Pollution Reduction		
FY	Docket #	Company Name	State/ Region	Type	Initial Penalty	Final Penalty	SEP Credit	SEP Cost to Company	Pollutant Concern	Pollutant Reduction	Supplemental Environmental Project Description
93	---	Inland Steel Co.	IN	EPCRA 313	$260,000	$100,000	---	$165,000	Perchloro-ethylene	200,000 lbs/yr	Parts cleaning process modified by replacing perchloroethylene with a non-toxic
93	---	Follansbee Steel Division of the Louis Berkman Company	WV	CERCLA	$110,000	$72,250	$17,250	$53,000	Zinc compounds Sulfuric Acid	500 to 1,000 lb/yr air, 40,000 lb/yr zinc (100%)	Zinc preflux process eliminated and sulfuric acid spillage control installed
94	---	Indiana Steel and Wire/G.K. Technologies	IN	RCRA	$746,438	$425,000	---	$900,000	Ammonia	---	Will eliminate ammonia emissions through conversion of zinc plating line bath to eliminate the use of anhydrous ammonia

Violation Information Terms
Initial penalty: Initial proposed cash penalty for violation
Final penalty: Total penalty after SEP negotiation
SEP credit: Cash credit given for SEP so that, Final penalty - SEP credit = Final cash penalty
SEP cost to company: Actual cost to company of SEP implementation

NOTE: Due to differences in terminology and level of detail between regional SEP information, in some cases the figure listed as Final penalty may be the Final cash penalty after deduction for SEP credit

VIII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

Common Sense Initiative

The EPA's Common Sense Initiative (CSI) was announced in November of 1993 to encourage pollution prevention in a few pilot industrial sectors including: iron and steel, electronics, metal plating and finishing, automobiles, printing, and oil refining. The program shifts regulatory focus from concentrating on individual toxic chemicals and media, to industry-wide approaches to environmental problems. A subcommittee will be formed for each industry and a strategic plan will be drawn up to identify opportunities to coordinate rulemaking, to streamline record-keeping and permitting requirements, and to identify innovative approaches in pollution prevention and environmental technology. For the iron and steel industry, a subcommittee has been formed and four workgroups have been established. The workgroups include representatives from industry, EPA (federal and regional), state environmental agencies, public interest groups, trade associations, and research institutions. The iron and steel CSI workgroups include: Innovative Technology, Permits Process, Compliance, and Brownfields. Projects proposed by each of the workgroups are subject to approval by the subcommittee. Project approval is expected in May, 1995. Common Sense Initiative contacts at EPA are:

Designated Federal Official (EPA Office of Water):
Mahesh Podar, 202-260-5387

Subcommittee Co-Chair (EPA Office of Water):
Bob Perciasepe, 202-260-5700

Subcommittee Co-Chair (EPA Region V):
Dave Ullrich, 312-886-3000

OECA contact (Compliance Workgroup):
Maria Malave, 202-564-7027

OECA contact (Permits Process Workgroup):
Mike Calhoun, 202-564-6031

R0075620

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of seventeen chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33% as of 1992 and by 50% as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given out to participants meeting their 1992 goals. The list of chemicals includes seventeen high-use chemicals reported in the Toxics Release Inventory. Exhibit 20 lists those companies participating in the 33/50 program that reported the SIC code 331 to TRI. Many of the companies shown listed multiple SIC codes and, therefore, are likely to carry out operations in addition to the iron and steel industry. The SIC codes reported by each company are listed in no particular order. In addition, the number of facilities within each company that are participating in the 33/50 program and that report SIC 331 to TRI is shown. Finally, each company's total 1993 releases and transfers of 33/50 chemicals and the percent reduction in these chemicals since 1988 are presented.

Thirteen of the seventeen target chemicals are used in the iron and steel industry. Of all TRI chemicals released by the iron and steel industry, chromium and chromium compounds, a 33/50 target chemical, were released most frequently (from 347 facilities), and were the third greatest volume. Other target chemicals that were in the top ten TRI releases by volume and by number of facilities reporting that chemical released were nickel and nickel compounds, lead and lead compounds, and 1,1,1-trichloroethane. Approximately twelve percent of eligible iron and steel companies are currently participating in the program. Exhibit 20 shows that 49 companies comprised of 115 facilities reporting SIC 331 are participating in the 33/50 program. (Contact: Mike Burns 202-260-6394 or 33/50 Program 202-260-6907).

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and state agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentor programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. In the iron and steel industry, one company (California Steel of Fontana, California) submitted a proposal. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, 202-564-7023.)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; federal, state and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at 202-233-9065 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn, 202-260-0700 or the

WasteWi$e Hotline at 1-800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, 202-260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. The program has worked with the iron and steel industry to evaluate the feasibility of an on-site hydrochloric acid recovery system for galvanizers and small- to medium-sized steel manufacturers. (Contact: Bill Ives at DOE's Golden Field Office, 303-275-4755)

VII.B. EPA Voluntary Programs

Strategies for Pulp & Paper and Steel Industries

The U.S. Department of Energy is examining the relationships between productivity, energy efficiency and environmental compliance in the pulp & paper and steel industries. Productivity and energy efficiency investments often complement each other, but can conflict with end-of-pipe emission control projects designed to reduce regulated pollutants. By sponsoring this project, the DOE seeks to better understand such conflicts and use this information to help identify ways DOE and other federal agencies can help industry meet mutual goals in these important areas. The project consists of two phases: 1) industry field consultations will be conducted to discuss and clarify the issues; and 2) quantitative analysis will evaluate the interplay between productivity, energy efficiency, and pollution abatement investments. (Contact: Jeff Dowd at 202-586-7258)

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Industry Research Programs

Without technological changes, the requirements of the Clean Air Act affecting coke ovens may force the shutdown of many facilities. To avoid possible facility closings, the industry is actively investigating alternatives to the conventional coke-oven/blast furnace method of making iron. One promising technology, the direct steelmaking project which was jointly funded by the American Iron and Steel Institute (AISI) and the U.S. Department of Energy (DOE), concluded on March 31, 1994. This technology reduces, melts, and refines iron in a single reactor. An opt-in. DOE cost-sharing program for the smelting of steel plant waste oxides began on April 1, 1994. Based on the success of recent trials, and the further knowledge that was gained from this follow-on program, the technology is now well understood and fully developed. A feasibility study for a demonstration plan is being developed. Under a related project, the AISI and member companies are working with the U.S. Bureau of Mines on a jointly funded research project to improve the dewatering of a variety of steel plant sludges. Currently, the sludges contain too much moisture to permit economic recycling to recover metal values. (Contact: Dave Rice 801-584-4130).

Another cokeless ironmaking technology, called the Cipcor or Corex process, eliminates the need for a coke plant, has integral coal desulfurizing, is amenable to a variety of coal types, and produces a gas that can be used to fire a cogeneration plant. This project will begin in 1995; capital outlays are expected to reach $800 million. Under the DOE Clean Coal Technology Demonstration Program, the Corex construction project may receive a $150 million grant. For more information on the DOE project, contact J. Lee Bailey (216) 447-3235.

Instead of eliminating coke production, two research projects run by Bethlehem Steel are focused on reducing coke process emissions. The Sparrows Point facility on Chesapeake Bay was the proposed site for one project. At this facility, the Davy Still Autoprocess for pre-combustion cleaning of coke ovens was to be demonstrated. This process utilizes coke oven battery process water to strip ammonia and hydrogen sulfide from coke oven emissions. The facility was constructed but is not in operation due to a suspension of coke-making operations by Bethlehem Steel at that facility. Discussions are ongoing over re-establishment of coke production at Sparrows Point. The other Bethlehem Steel project is a demonstration plant of the British Steel blast furnace granulated coal injection process. In this process, granulated coal is used instead of oil and natural gas in the blast furnace. Unlike natural gas, granulated coal does not cause furnace temperature reductions when it is introduced and thus improves process efficiency. Pollutant outputs are reduced as coal sulphur is removed by flux and bound in the slag. The process replaces natural gas usage and reduces 40 percent of the coke requirement. The project facility, located in Burns Harbor, Indiana, is expected to be complete in January of 1995. The EPA project manager for the Bethlehem Steel projects is Jeff Summers (301) 903-4412.

Another project focussing on reduced emissions from cokemaking is a process under development by Calderon Energy. A small scale oven was constructed and operated in Alliance, Ohio and a full scale oven is under consideration for funding by the Department of Energy (DOE). For further DOE information, contact John Augustine (412) 892-4524.

VIII.C.2. Summary of Trade Associations

American Iron and Steel Institute
1101 17th Street, NW
Washington, DC 20036-4700
Phone: (202) 452-7100
Fax: (202) 463-6573

Members: 50 companies
Staff: 44
Budget:
Contact: Bruce Steiner,
VP-Environment and Energy

The American Iron and Steel Institute (AISI), founded in 1908, mainly represents integrated iron and steel manufacturers. Based on tonnage of production, AISI represents the companies responsible for 70 percent of U.S. steel manufacture. As the major trade group for the industry, AISI has a diverse agenda. The AISI conducts market development by working with major customer groups (e.g., automotive, machinery) to maintain and promote steel as the material of choice. The AISI is also involved in legislative and regulatory activities; AISI members rely on the organization to keep them abreast of legislative and regulatory developments. The AISI conducts research on manufacturing technology, basic materials, environmental quality control, energy, and fuel consumption. The AISI also compiles industry (including non-members) statistics through surveys. AISI publications are the *American Iron and Steel Institute-Annual Statistical Report*, as well as technical manuals and pamphlets on steel. The AISI holds several meetings and other workshops and seminars for member company representatives.

Specialty Steel Industry North America
3050 K Street, NW
Suite 400
Washington, DC 20007
Phone: 202-342-8630
Fax: 202-338-5534

Members: 21 companies

The Specialty Steel Industry of North America (SSINA) is a national trade organization comprised of 21 producers of specialty steel products, including stainless, electric, tool, magnetic, and other alloys. SSINA represents over 90 percent of the North American specialty steel industry. The primary purpose of SSINA is to promote and encourage a better understanding between members of the North American specialty steel industry and federal and state officials, and to provide and encourage governmental action in support of the continued growth of a strong North American specialty steel industry. SSINA is comprised of a number of task forces and committees which pursue issues of interest to the North American specialty steel industry, including domestic and international trade, environmental, critical materials matters, manufacturing and standards issues, and other government-related matters. The SSINA committees meet quarterly, normally alternating between Washington, D.C. and Pittsburgh.

Steel Manufacturers Association (SMA)
1730 Rhode Island Avenue, NW
Suite 907
Washington, DC 20036-3101
Phone: 202-296-1515
Fax: 202-296-2506
email: steelnet@aol.com
World Wide Web home page:
http://www.steelnet.org
Members: 55

The SMA is the primary trade association of electric arc furnace steelmakers. Last year, EAF steelmakers recycled 38.2 million metric tons of iron and steel scrap. Purchased scrap accounts for almost 100% of the feedstocks used in an EAF to make new steel. Other SMA companies are reconstituted integrated (ore-based) steelmakers, with management practices similar to those of the EAF companies. The SMA Environment Committee meets frequently to address issues affecting the steel industry and works with the EPA and other government agencies to implement effective environmental programs. The SMA also has technical and human resources committees which meet to exchange information and develop public policy positions, as well as ad-hoc task forces to handle specific matters such as radioactive scrap detection, development of emission monitoring protocols, and the EPA's Common Sense Initiative. With 44 U.S., 8 Canadian, and 3 Mexican member companies geographically dispersed across the continent, the SMA is the largest steel trade association in North America in terms of membership. In 1994, the SMA membership accounted for approximately 40% of all steel shipments in the U.S., and as a growing segment of the industry, the SMA share of total U.S. steel production is expected to account for 50% within one decade.

International Iron and Steel Institute
Institut International du Fer et de l'Acier
120, rue Colonel Bourg, B-1140
Brussels, Belgium 32 2 726 50 95
Members: 165
Staff: 20
Budget:
Contact: Ian Christmas, Deputy Secretary General

The International Iron and Steel Institute (IISI) is comprised of steel-producing companies, affiliated federations, and technical societies in 48 countries. The IISI seeks to contribute to the steel industry worldwide. Major functions are: to provide a forum for free and open discussions of the industry's problems and opportunities; to undertake research in scientific, technological, economic, financial, governmental, sociological, legal, environmental, and other aspects of the industry; to collect, evaluate, and disseminate statistics and information concerning matters affecting the steel industry; to establish and maintain liaisons with other organizations related to steel; to promote the use of steel. Some IISI committees include Economic Studies, Environmental Affairs, and Industrial Relations. The IISI publishes the monthly *Iron and Crude Steel Production* (in English) and the annuals *Steel Statistical Yearbook* (in English) and *World Steel in Figures* (in English). IISI also publishes conference proceedings and reports on the following issues: environment, economics, raw materials, technology, market promotion, and public relations. The IISI holds an annual world conference.

Association of Iron and Steel Engineers
3 Gateway Center, Suite 2350
Pittsburgh, PA 15222
Phone: (412) 281-6323
Fax: (412) 281-4657

Members: 10,000
Staff: 19
Budget: $2,500,000

The Association of Iron and Steel Engineers (AISE) consists of engineers, operators, and suppliers in the steel industry. Founded in 1907, this association works to improve the technical phases of the production and processing of iron and steel via technical reports and industry awards. Divisions include Environmental Engineering, Steel Producing, and Continuous Casting. AISE publications include a monthly, *Iron and Steel Engineer* and a *Directory of Iron and Steel Plants*. Conferences are semi-annual.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies: environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

Superintendent of Documents, Mail Stop: SSOP, Washington, DC 20402-9328
ISBN 0-16-048273-9

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

LUMBER AND WOOD PRODUCTS (SIC 24)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a

manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE LUMBER AND WOOD PRODUCTS INDUSTRY

II.A. Introduction, Background, and Scope of the Notebook

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the lumber and wood products industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

The lumber and wood products industry includes establishments engaged in cutting timber and pulpwood; sawmills, lath mills, shingle mills, cooperage stock mills (wooden casks or tubs), planing mills, plywood mills; and establishments engaged in manufacturing finished articles made entirely or mainly of wood or related materials such as reconstituted wood panel products manufacturers. The categorization corresponds to the Standard Industrial Classification (SIC) code 24 established by Department of Commerce's Bureau of the Census to track the flow of goods and services within the economy. It should be noted that silviculture (development and care of forests) and the preparation of forested areas for logging is covered by SIC 08 (forestry) and is not addressed in this industry profile.

In this profile, the industry's processes are divided into four general groups: logging timber; producing lumber; panel products and wood preserving. The Bureau of the Census estimates that in 1992, employment in these principal categories totaled approximately 306,700 (See Exhibit 1 for facility employment size distribution). This does not include the additional employment generated by the wood container, structure wood member, wood kitchen cabinet, and wood building/mobile home sectors. Shipments increased less than one percent in 1993, to an estimated $78.1 billion. Sawmills and planing mills (SIC 242) accounted for $24.8 billion (31 percent) of industry shipments in 1993. Logging (SIC 241) added an additional $15.6 billion (17.8 percent).

The Department of Commerce provides the following three-digit breakout for lumber and wood products industries in SIC 24:

- SIC 241 - Logging
- SIC 242 - Sawmills and Planing Mills
- SIC 243 - Millwork, Veneer, Plywood, and Structural Wood Members
- SIC 244 - Wood Containers
- SIC 245 - Wood Buildings and Mobile Homes

SIC 249 - Miscellaneous Wood Products.

The main end use market for the industry's products is the new construction and remodeling sectors.

This profile covers logging, sawn lumber production, panel products including veneer and plywood manufacture and reconstituted wood panel manufacture (which includes particleboard (PB), hardboard (HB), medium density fiberboard (MDF), and oriented strand board(OSB)), engineered lumber, and wood preserving. Each of these are discussed in greater detail later in the profile. This profile does not address production processes, pollution outputs, or regulatory information for the following three-digit industries contained in SIC 24: Wood Containers (SIC 244), Wood Buildings and Mobile Homes (SIC 245), and some areas of Miscellaneous Wood Products (SIC 249).

II.B. Characterization of the Lumber and Wood Products Industry

The discussion of the characterization of the lumber and wood products industry is divided into the following topics: industry size and geographic distribution; identification of the largest U.S. facilities in the industry by capacity; and industry economic trends.

II.B.1. Industry Size and Distribution

Variation in facility counts occur across data sources due to many factors, including reporting and definition differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

Geographic Distribution

Most of the wood products industry is concentrated in the Pacific Northwest and the Southeast. However, concentrations are also found across the Midwest, the Northeast, and in Appalachia (See Exhibits 2 and 3). Approximately 1/3 of the U.S. is forested. Of this forested area, two-thirds (480 million acres) contain at least 20 cubic feet of commercially usable wood per year per acre, the threshold for determining whether timberland could be commercially productive. The area east of the Mississippi still contains a significant amount of forested acreage; 155 million acres are in the Northern States and 195 million acres are in the South. About 130 million acres of forested land is in Western States. Exhibit 4 illustrates the largest lumber and wood products facilities in the U.S. by capacity.

Exhibit 1
Industry Facility Size Distribution - 1992

Type of Facility	Facilities with 1 to 19 employees	Facilities with 20 to 99 employees	Facilities with 100 or more employees	Total
SIC 2411 - Logging	12,283	691	36	13,010
SIC 2421 - Lumber	4,400	1,283	321	6,004
SICs 2435 & 2436 - Hardwood, Softwood Plywood, Veneer	147	208	164	519
SIC 2491 - Wood Preserving	307	168	11	486
SIC 2493 - Reconstituted Wood Products	108	80	100	288

II.B.2. Economic Trends

The lumber and wood products industry is heavily dependent upon the health of the U.S. residential construction and household furniture industries. Lumber and wood product shipments increased less than one percent in 1993 and this low level of growth is expected to continue in 1994. Domestic wood products shipments over the next five years are expected to remain constant.

Since the mid-1980's, timber harvests from publicly-owned lands have declined by more than 50 percent. The decline is due to new land management policies by the Federal government that have reduced the amount of land available for harvesting.

According to the Hardwood Plywood and Veneer Association, there has been a substantial decline in the use of hardwood plywood prefinished wall paneling due to shifts in consumer preference, a decline in promotion and advertising by major manufacturers, changes in the cost of plywood paneling related to gypsum wallboard, and the public's concern about real or perceived formaldehyde releases from wall paneling. With respect to reconstituted wood panel products shipments of PB, OSB, and MDF are all increasing rapidly. U.S. shipments of MDF were at record levels in 1993.

The engineered lumber sector of the industry (reconstituted wood substitutes for sawn lumber), is currently seeing a rapid rise in production. The production of glulam beams and laminated veneer lumber (LVL), two types of engineered lumber, is increasing rapidly and this increased growth is expected to continue. By 2003, the North American output of LVL is expected to reach 98 million ft^3 (the American Plywood Association's production estimate for LVL in 1995 is 33 million ft^3).

III. INDUSTRIAL PROCESS DESCRIPTION

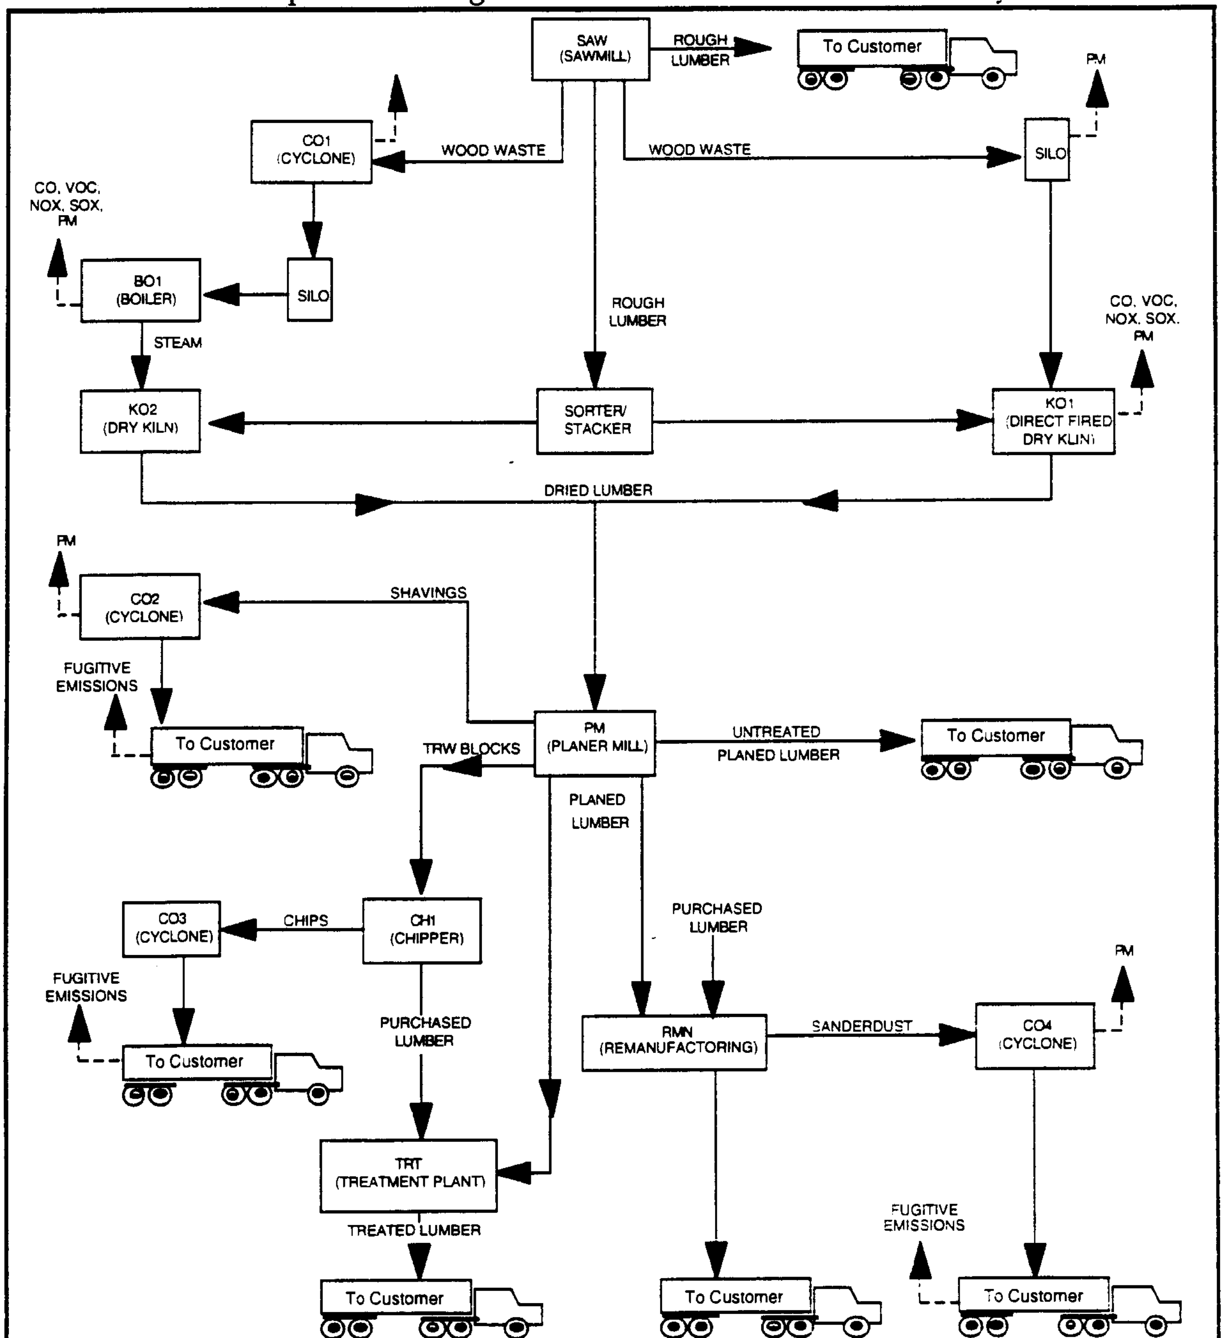
This section describes the major industrial processes within the lumber and wood products industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the by-products produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Lumber and Wood Industry

This section describes the major processes used by the lumber and wood products industry. It is divided into the following sections: logging, sawn lumber, paneling (including veneer and plywood and reconstituted wood panel products), engineered lumber, and wood preserving. Information for these descriptions was obtained from a variety of sources including *Characterization of Manufacturing Processes, Emissions, and Pollution Prevention Options for the Composite Wood Industry* (Martin and Northeim, 1995), *Forest Products and Wood Science* (Haygreen and Bowyer, 1989), and *Guide to Pollution Prevention: Wood Preserving Industry* (U.S. EPA, 1993).

Exhibit 5
Example Flow Diagram For a Lumber Production Facility



Source: Southern Lumber Manufacturing Association, 1995.

Logging

Timber harvesting may be accomplished by either manual or mechanical means. However, the traditional methods of hand sawing or ax use are almost never used. Chain saws powered by gasoline engines or large felling machines are currently used to cut down

R0075663

standing trees. The felling machines use hydraulically-activated shears that cut the tree at its base and transport it to a collection point. The logs are transported by motorized cable or by tractor to larger collection areas for transportation (usually by motor trucks or water) to the sawmill.

Sawn Lumber

Sawn lumber is softwood or hardwood trimmed at a sawmill and destined for a future use such as construction, industrial, or furniture products. Most of the commercially important softwood species such as Southern Yellow Pine, Western Pines, Western Hemlock, Spruce, and Douglas Fir grow in the South or West. Softwood boards are used primarily for framing light construction such as homes, schools, churches, and farm buildings. Hardwood species such as Maple and Oak, are grown and processed mainly in the Eastern portion of the U.S. and are used for flooring, furniture, and crating.

Exhibit 5 illustrates the lumber production process. Logs are delivered to sawmills from the forest and stored in ponds or on land. Most wood is stored on land. Logs are sometimes stored at intermediate points between the forest and the sawmill. If stored on land, the logs are usually sprayed with water to keep them moist and prevent cracking. The raw logs are debarked and then cut into cants (partially cut lumber), which are trimmed into raw lumber. As the logs are debarked, bark is used as hog fuel for boilers or sold as mulch. Shavings, sawdust, and chips can also be used at paper mills and reconstituted wood panel manufacturing plants.

The cants are cut to specific lengths or finished further depending on the final destination of the lumber product. Most lumber is dried to a specific moisture content (conditioned) through air or kiln drying. Air drying, which entails stickering (spacing) and stacking the cut lumber in open storage areas, usually requires several months to a few years. Kiln drying is more time efficient because it uses controlled air flow within a vented closed chamber to quickly dry the lumber to a specified moisture content. Whether lumber is air- or kiln-dried depends upon variables such as the moisture content of the species and the humidity of the region.

Sawmills frequently perform surface protection operations to protect lumber against sapstaining that may occur during temporary storage. Sapstains do not attack the structural components of the wood but do affect the surface, coloring it with dark blue or black stains. This discoloration is often objectionable to the buyer and may decrease the value of the wood and its acceptance of finishes.

Surface protection is typically conducted at mills that process hardwoods; however, softwoods cut for export may also be surface protected. Plants typically treat their lumber with surface protectants only during humid months, depending on the region of the country in which they operate. Wood that is kiln-dried is not normally surface-protected. All green wood to be exported is protected. The most popular surface protectant currently used by approximately 85% of all major U.S. mills who treat lumber is a solution composed of 3-iodo-z-propynyl butyl carbamate (IPBC), didecyl dimethyl ammonium chloride (DDAC), and inert ingredients. The solution is diluted with water to a ratio of 35-1 for spray box application and 100-1 for dip tank applications.

Three major processes are used by sawmills to apply surface protectant to wood: the dip process, the spray process, and the green chain process. Typically the sawmill will use only one process to surface protect; however, some plants use a combination of processes to protect lumber at different locations throughout a mill. Dipping is a batch process; green chain and spray operations are continuous processes. The process used influences the amount of control a plant has over the waste it generates during the surface protection process.

Dip operations offer the best opportunity to control drippage since an owner or operator has the ability to keep the wood over the tank until it stops dripping. Dipping operations can lead to uncontrolled drippage when mills do not allow the treated loads to stop dripping before the next load is dipped. Lumber is dipped in horizontal bundles, and as a result, liquid is often trapped between pieces of wood. When forklifts remove the lumber, large quantities of protectant can drip from the wood onto the ground if the lumber is tipped.

Unlike dipping, the spray operation is a continuous process. Individual pieces of lumber are fed end-to-end by chain, roller, or conveyor belt through a spray box. The spray box is often equipped with flexible brushes or curtains at both ends to isolate the formulation spray and minimize drippage. A drip pan is usually incorporated into the design of the spray box allowing formulation to return to the work tank.

Green-chain systems represent another type of continuous operation. The green-chain is so-named because chains drag fresh cut (or "green") lumber through a tank of protectant formulation and back out again for sorting and grading. A dip vat containing anti-stain formulation is typically located at the head of the green chain and the wood falls into this vat from the cutting operations. Some systems utilize wheels or

R0075665

rollers just above the formulation surface to force the wood pieces into the solution. As the wood is drawn from the vat and along the green chain, excess formulation is released from the wood onto the return drip pan. Green-chain operations are typically the least controllable with respect to drippage.

Panel Products

This section describes two classes of panel products: (1) hardwood veneer, softwood veneer, and plywood; and (2) reconstituted wood products.

Hardwood Veneer and Softwood Veneer and Plywood

Veneer is a thin sheet of wood peeled or sliced from blocks of lumber called flitches or logs. Veneer is glued together to form plywood. Hardwood found in the Western and Southern U.S. is generally used to manufacture hardwood plywood. Softwood logs from the Northwest and Eastern U.S. are used to make softwood plywood. Softwood plywood is primarily used for construction. Softwood veneer and plywood is typically used for structural and industrial applications and represents over 90 percent, by volume, of U.S. production. Hardwood veneer and plywood is used typically for decorative applications and for making interior paneling, components for furniture and cabinets, and specialty products. There are several other important differences between softwood plywood and hardwood plywood: softwood plywood is generally made with relatively thick faces (1/10" and thicker) and with exterior or intermediate glue (for protected construction and industrial uses where moderate delays in providing protection might be expected or conditions of high humidity and water leakage may exist). Hardwood plywood is made with face veneers generally 1/32" and thinner. Because of its nature and the use of decorative thin face veneers, the glues used for hardwood plywood tend to be colorless or light in color so as not to discolor the surfaces if the adhesive bleeds into and through the thin faces. While most hardwood plywood is all veneer, some is made with particleboard and medium density fiberboard core.

The general processes for making softwood and hardwood plywood are the same: log debarking, log steaming and or soaking, veneer cutting, veneer drying, veneer preparation, glue application, pressing, panel trimming, and panel sanding. These basic processes are illustrated in Exhibit 7. Nevertheless, there are differences in details in these softwood and hardwood plywood processes. Because of its greater volume, this section primarily describes softwood veneer and plywood manufacturing. However, it is noted where details of the

R0075666

manufacturing process are substantially different for hardwood plywood.

Most softwood plywood plants also produce veneer. Most hardwood plywood plants purchase components for making plywood from outside sources. Logs received at the plant are debarked and cut into lengths appropriate for the plant's processing equipment. Almost all hardwood and many softwood blocks are heated prior to cutting or peeling the veneer to soften the wood. The cut logs are heated by steaming, soaking in hot water, spraying with hot water, or combinations of these methods. The heating time required depends on the diameter of the log, specific gravity, moisture content, and the temperature needed to properly peel that particular species of wood.

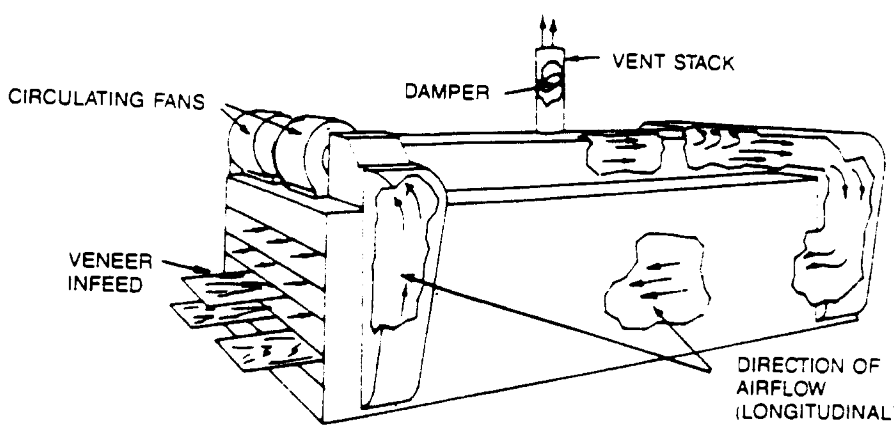
The major methods for producing veneer are slicing and peeling. The majority of veneer is produced by peeling (rotary cutting) on a veneer lathe into sheets of uniform thickness. Slicing is used to produce hardwood decorative veneers from a flitch generally in thicknesses of 1/24" and thinner, and is seldom used with softwood. In either case, the wood is forced under a pressure bar that slightly compresses the wood as it hits the cutting edge of a knife. On a rotary lathe, the block, or log section, continuously rotates against the knife and the pressure bar and peels a sheet of veneer from the heated block.

The veneer is peeled at a rate of 300 to 800 lineal feet/min. A series of 120-foot long trays is used in many softwood plywood plants to gently handle these long sheets of wood as they are peeled from the chuck. In softwood mills and some hardwood mills, high-speed clippers automatically chop the veneer ribbons to usable widths at speeds of 1500 lineal feet/min. In hardwood mills, clipping may be done manually to obtain the maximum amount of clear material from the flitch.

After the veneer is peeled and clipped, it must be dried. Two types of dryers are used in softwood veneer mills: roller resistant dryers, heated by forced air; and platen dryers, heated by steam. In older roller dryers, also still widely used for hardwood veneer, air is circulated through a zone parallel to the veneer (see Exhibit 6). Most plants built in recent years use jet dryers (also called impingement dryers) that direct a current of air, at a velocity of 2,000 to 4,000 feet/min., through small tubes on the surface of the veneer.

Veneer dryers may be heated indirectly with steam, generated by a separate boiler, which is circulated through internal coils in contact with dryer air. Dryers may also be heated directly by the combustion gases of a gas- or wood-fired burner. The gas-fired burner is located inside the dryer, whereas combustion gases from a wood-fired burner are mixed with recirculating dryer air in a blend box outside the dryer and then transported into the dryer. Veneer dryers tend to release organic aerosols, gaseous organic compounds, and small amounts of wood fiber into the atmosphere.

Exhibit 6
Veneer Dryer (Longitudinal)



Source: *Basic Plywood Processing.*

From the dryer, the sheets of veneer travel to a glue application station. Narrow pieces of hardwood veneers are often joined with an adhesive and/or string to maximize recovery. In the gluing process, also known as layup, adhesive is applied to the individual sheets of veneer which are later assembled into plywood. Various adhesive application systems are used including hard rolls, sponge rolls, curtain coaters, sprayers, and foam extruders. The most common application for softwood plywood is an air or airless spray system, which generally uses a fixed-head applicator capable of a 10-foot wide spray at a nozzle pressure of 300 pounds per square inch (psi). Roller applications are most common in the manufacture of hardwood plywood.

With spray systems, control of glue spreads is achieved by adjusting the veneer conveyor speed, or by changing the size of the spray nozzle orifice. Wastes generated in the layup process include adhesive waste (typically overspray), and off-spec plywood.

R0075668

The phenol-formaldehyde (PF) typical in softwood plywood manufacturing and urea-formaldehyde (UF) adhesions typically used in hardwood plywood are made from resins synthesized in regional plants and shipped to individual plywood mills. At the mills, the resins are combined with extenders, fillers, catalysts, and caustic to make a glue mixture. The addition of these ingredients modifies the viscosity of the adhesive and allows it to be compatible with the glue application method (curtain, roll, spray, foam); allows for better adhesive distribution; increases the cure rate; and lowers cost.

Following the application of glue, the panels must be pressed. The purpose of the press is to bring the veneers into close contact so that the glue layer is very thin. At this point, resin is heated to the temperature required for the glue to bond. Most plywood plants prepress the panels in a cold press at lower pressure prior to final pressing in the hot press. This allows the wet adhesive to "tack" the veneers together, permits easier loading of the hot-press, and prevents shifting of the veneers during loading. Pressing is usually performed in multiopening presses, which can produce 20 to 40 4x8-foot panels in each two to seven minute pressing cycle.

One of the goals of the pressing process is to use enough pressure to bring the veneer surfaces together without overcompressing the wood. Less pressure is required if the lathe has cut smooth veneer of a uniform thickness.

After pressing, stationary circular saws trim up to one inch from each side of the pressed plywood to produce square-edged sheets. Approximately 20 percent of annual softwood plywood production is then sanded. Over 90 percent of the hardwood plywood production is sanded. As sheets move through enclosed automatic sanders, pneumatic collectors above and below the plywood continuously remove the sanderdust. Sawdust in trimming operations is also removed by pneumatic collectors. The plywood trim and sawdust are burned as fuel or sold to reconstituted panel plants. Exhibit 7 illustrates the veneer and plywood manufacturing process.

Exhibit 7
Flow Diagram of Veneer and Plywood Production

Note: Many veneer and plywood plants are dry.

R0075670

Reconstituted Wood Products

Reconstituted wood products, such as particleboard (PB), medium density fiberboard (MDF), hardboard (HB), and oriented strand board (OSB), is composed of furnish, or raw wood, that is combined with resins and other additives and formed into a mat, which is then pressed into a board. The manufacturing processes of these boards differ, as do the raw materials used. For example, the furnish (raw materials) used for particleboard consists of finely ground wood particles of various sizes, while OSB is manufactured using specially-prepared strands of wood. In general, the manufacturing processes involve wood size reduction followed by drying (except for wet process boards), adhesive application, pressing at elevated temperatures. Because these products are based on use of all parts of the sawn log, very little solid waste is generated. Instead, air emissions from dryers and presses tend to be the principal environmental concern stemming from the production of these products. Exhibit 8 compares the process flows for some reconstituted wood product manufacturing processes.

Particleboard (PB)

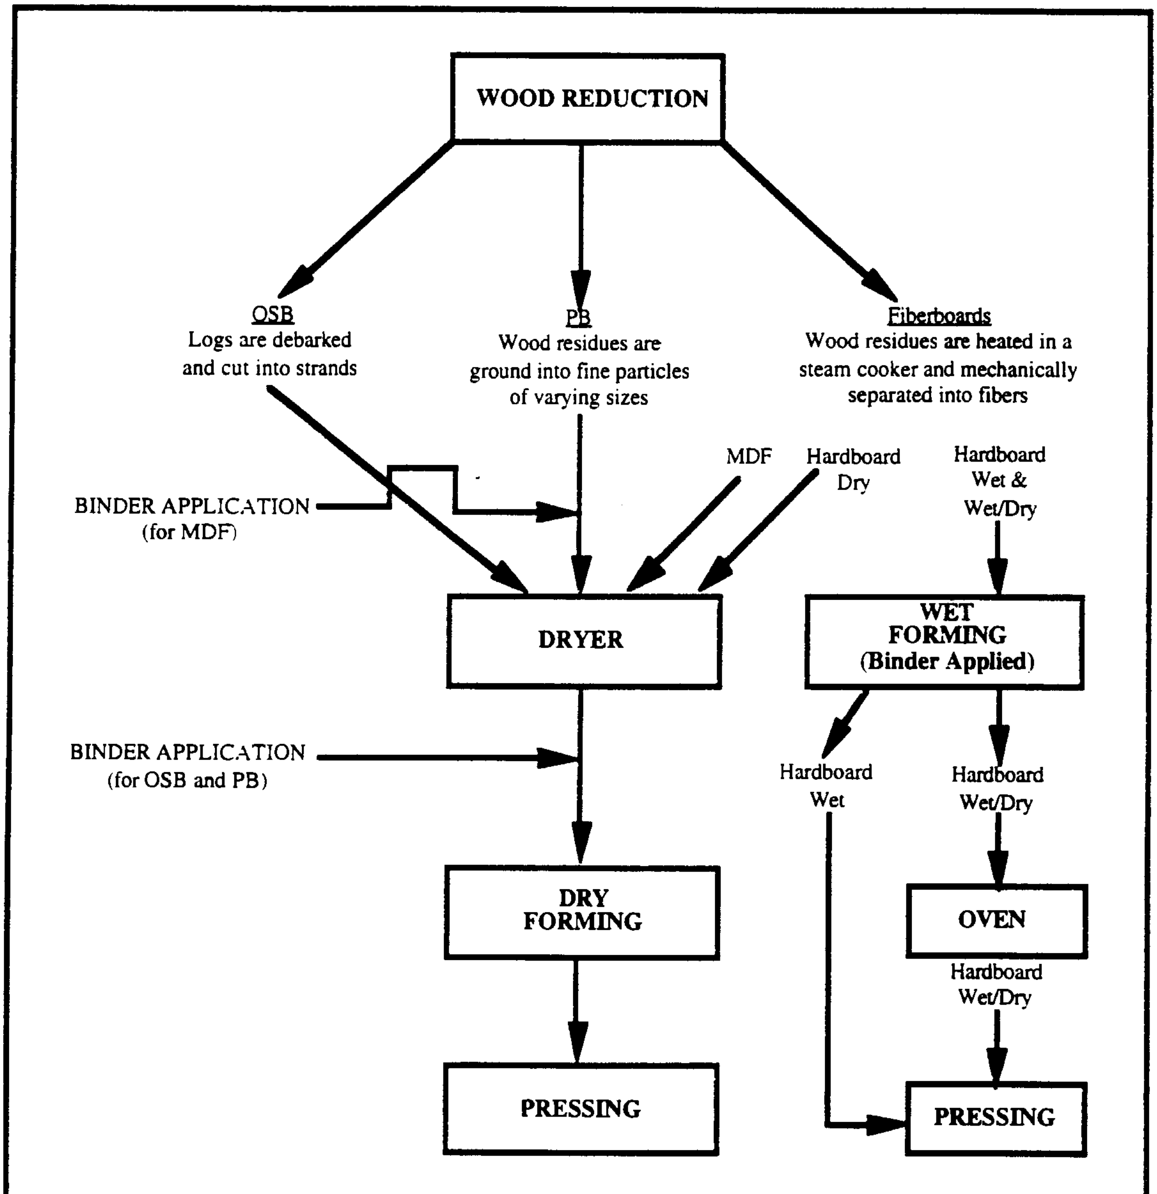
Particleboard is a panel product made from wood particles of various sizes that are bonded together with a synthetic resin such as urea-formaldehyde (UF). The raw materials, or "furnish," that are used to manufacture PB can be either green or dry wood residues. Green residues include planer shavings from green lumber, and green sawdust. Dry process residues include shavings from planing kiln-dried lumber, sawdust, sanderdust and plywood trim. The wood residues are ground into particles of varying sizes using flakers, mechanical refiners, and hammermills. The material may be screened prior to refining.

The furnish is dried to a low moisture content (two to six percent) to allow for moisture that will be gained by the adding of resins and other additives during "blending." Furnishes are generally no warmer than 100°F when blended to avoid precuring and the drying out of the resin.

Most dryers currently in operation in PB and other reconstituted wood panel manufacturing plants use large volumes of air to convey material of varied size through one or more passes within the dryer. Rotating drum dryers requiring one to three passes of the furnish are most common. The use of triple-pass dryers predominates in the United States (see Exhibit 9). Dryer temperatures may be as high as 1100 - 1200°F with a wet furnish. However, dry planer shavings require that dryer temperatures be no higher than 500°F because the ignition point

R0075671

Exhibit 8
Reconstituted Wood Panel Process Flow

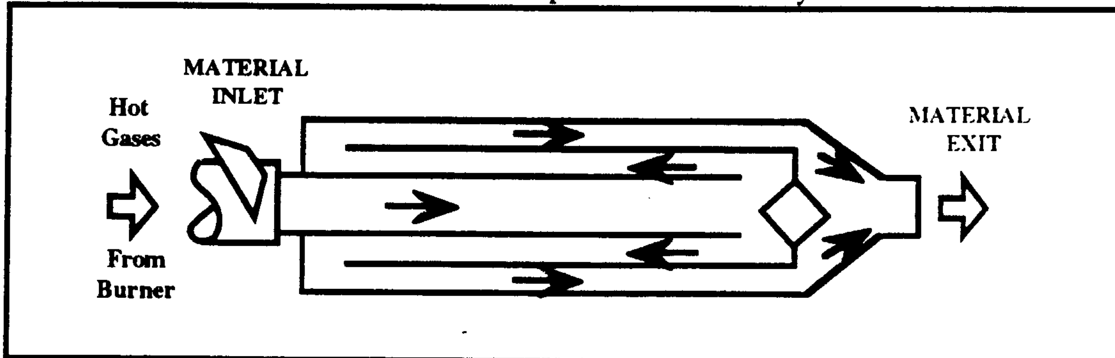


Source: Characterization of Manufacturing Processes, Emissions, and Pollution Prevention - Options for the Composite Wood Industry; Martin and Northeim, Research Triangle Institute Center for Environmental Analysis, 1995.

R0075672

of dry wood is 446°F. Dry material is the predominant furnish in particleboard. Many dryers are directly heated by dry fuel suspension burners. Others are heated by burning oil or natural gas.

Exhibit 9
Schematic of a Triple Pass Drum Dryer



Source: Characterization of Manufacturing Processes, Emissions, and Pollution Prevention - Options for the Composite Wood Industry; Martin and Northeim, Research Triangle Institute Center for Environmental Analysis, 1995.

Direct-fired rotary drum dryers release emissions such as wood dust, combustion products, fly ash, and organic compounds evaporated from the extractable portion of the wood. Steam-heated and natural gas-filled dryers will have no fly ash.

Air classifiers, which separate particles by surface area and weight, may be used alone or in conjunction with screening equipment. Air classifiers perform best if the feed is limited to particles with uniform widths and lengths. The classifier can then efficiently separate particles of different thicknesses due to the weight difference among particles of approximately equal surface area. Undesired material is usually used as fuel for the dryer burner. The screened particles are stored in dry bins until they are conveyed to the blender. Air classifiers have limited use in the industry. Screening systems are typically used to separate fine from coarse material.

The furnish is then blended with a synthetic adhesives, wax, and other additives distributed via spray nozzles, simple tubes, or atomizers. Resin may be added as received (usually an aqueous solution); mixed with water, wax emulsion, catalyst, or other additives. Waxes are added to impart water repellency and dimensional stability to the boards upon wetting.

Particles for PB are mixed with the additive in short retention time blenders in through which the furnish passes in seconds. The blenders consist of a small horizontal drum with high-speed, high shear impellers and glue injection tubes. As the furnish enters the drum,

R0075673

resin is injected, and the impellers hurl the furnish at high speeds to mix it with the resin.

The furnish and resin mixture is then formed into mats using a dry process. This procedure uses air or a mechanical system to distribute the furnish onto a moving caul (tray), belt, or screen. Particleboard mats are often formed of layers of different sized particles, with the larger particles in the core, and the finer particles on the outside of the board.

The mats are hot pressed to increase their density and to cure the resin. Most plants use multiopening platen presses, which typically have 14 to 18 openings (see Exhibit 10). The last ten years has seen the introduction of the continuous press. Though more popular in Europe, the continuous press is currently being used in two PB plants in the United States. Steam generated by a boiler that burns plant residuals runs through a platen passageway to provide the heat in most hot presses. Hot oil and hot water can also be used to heat the platens.

Primary finishing steps for all reconstituted wood panels include cooling or hot stacking, grading, trimming/cutting, and sanding. Cooling is important for UF-resin-cured boards since the resin degrades at high temperatures after curing. Boards bonded using PF resins may be hot-stacked to provide additional curing time. Secondary finishing steps include filling, painting, laminating, and edge finishing. The vast majority of reconstituted panel manufacturers do not apply secondary finishes to their panels; panels are finished primarily by end-users such as cabinet and furniture manufacturers. Panels are also finished by laminators who then sell the finished panels to furniture and cabinet manufacturers.

Exhibit 10
Schematic of a Multi-Opening Board Press

R0075675

Medium Density Fiberboard (MDF)

The uses for this type of composite wood product are similar to those of PB. The furnish used to manufacture MDF consists of the same type of green or dry wood residues used to manufacture PB and hardboard. Fibers and fiber bundels are generated by first steam-heating the wood, then passing it through a refiner. During this step the wood changes both chemically and physically; becoming less susceptible to the influences of moisture and less brittle as the lignin in the wood softens. This semi-plastic wood is then "rubbed" apart into fibers and fiber bundles in a refiner instead of being mechanically "broken" apart as in the PB manufacturing process.

The furnish is dried to a very low moisture content to allow for moisture to be gained by the addition of resins and other additives. Most MDF furnish is dried in tube dryers.

The blending process for MDF differs from that of PB in that it typically occurs before drying. After refining, the fibers are discharged through a valve known as the blowvalve into the blowline, a larger continuous chamber where the UF resins are mixed with the wood fiber. In the blowline, the fibers are sprayed with a resin which is injected from a line located either immediately after the blowvalve or anywhere along the blowline. Material is dried to an acceptable moisture content in a flash tube dryer at low temperatures after the blowline. If the blending is done mechanically, as in PB, it is done after the flash tube dryer.

MDF is formed using a dry process which uses air to distribute the furnish in a random orientation onto a moving caul (tray), belt, or screen. The mats are then pressed using a multi-opening platen press or a continuous press is currently used in three MDF plants in the United States. The boards are then cooled and finished like other reconstituted wood panels.

Hardboard

Hardboard is a higher-density version of MDF. It is typically used for siding, furniture drawer bottoms, dust stops, sliding doors, and cabinet doors and tops. There are three types of hardboard: wet, wet/dry, and dry process hardboard, each classified by their manufacturing processes. The furnish used to manufacture hardboard consists of the same green or dry process wood residues used to manufacture PB and MDF. The cooked semi-plastic furnish is "rubbed" apart into fiber bundles as in the MDF process. The fibers are all the same size, therefore, they need no screening.

In the manufacture of wet, and wet/dry process hardboard, the furnish is not dried because the forming process uses water. Wet and wet/dry process hardboard mats are formed using a wet process in which fibers are mixed with water and Phenol Formaldehyde adhesive and then metered onto a wire screen. Water is drained away with the aid of suction applied to the underside of the wire. The fiber mat, along with the supporting wire, is moved to a prepress where excess water is squeezed out. Wet/dry process hardboard is dried in an oven before being hot pressed.

In the manufacture of dry process hardboard, the furnish is dried using dryers typical of the reconstituted wood panel industry. As with MDF, the hardboard fibers are discharged through a blowvalve into a blowline after refining. Dry process hardboard mats are formed using a process similar to that of MDF and PB in which air is used to distribute the furnish in a random orientation onto a moving caul (tray), belt, or screen. All reconstituted wood panels are hot pressed to increase their density and to cure the resin.

Oriented Strandboard

The furnish used to manufacture OSB is specially flaked from roundwood. Logs entering OSB plants may be either tree length or cut to 100 inch lengths by a slasher saw. The logs are then debarked and sent to a strander which slices them into strands approximately 0.028 inch thick. The strands are then conveyed to a storage bin to await processing through the dryers. (Note: Some older mills cut the logs into 33 inch blocks before sending them to the strander.)

The strands are dried to a low moisture content to allow for moisture gained by adding resins and other additives. The strands are then blended with additives in long retention time blenders in which the furnish passes through in several minutes. The blenders are very large rotating drums (several feet in diameter and many feet in length) that are tilted on their axes. As the strands are fed into the drums, they are sprayed with either PF or MDI (Methylenediphenyl diisocyanate) resin and either liquid or emulsified paraffin wax. The tumbling action of the strands through the drums allows the strands to mix thoroughly with the resin and wax.

OSB is formed by a dry process, which uses air to distribute the furnish. OSB is produced by deliberate mechanical lining-up of the strands. In the mechanical orientation processes, mats are produced by dropping long slender flakes between parallel plates or disks onto a moving caul (tray), belt, or screen. The boards are then hot pressed and finished.

strand lumber, made from long strands of veneer, is extruded with PF resin into various cross sections and widths. Parallel laminated veneer, or laminated veneer lumber (LVL), is constructed of veneers that are bonded together with phenol-formaldehyde (PF) adhesive resin to form a laminate. The veneers are layered with the wood grain along the long axis of the beam. Laminated veneer lumber is manufactured to typical lumber sizes (2 x 4, 2 x 6, etc.). The length of the beams that can be manufactured is varied using end joints or finger joints. Another application of LVL is in the construction of wood "I" joists (a small beam that resembles the letter "I"). LVL is used to construct the top and bottom (flanges) of the joist and OSB or plywood is used to construct the center (web).

Glulam beams are also emerging as a substitute for lumber. Glulam is short for glued-laminated structural timber – large beams fabricated by bonding layers of specially-selected lumber with Resorcinol or Resorcinol/PF adhesives and timber. End and edge jointing permit production of longer and wider structural wood members than are available naturally. Glulam timbers are used with structural wood panels for many types of heavy timber construction.

Most of the engineered lumber products are used as substitutes for structural softwood lumber of large sizes and in applications where uniform strength is essential. I-beams, however, are finding wide application, with extensive use as floor joists and beams for various structures. There are several advantages of composite lumber when compared with sawn softwood lumber. First, these products allow production of large sizes of lumber from small, low-grade logs. Normally, relatively large and high-grade sawlogs are needed for production of lumber of this size. Second, composite lumber compares advantageously to solid sawn lumber in terms of both uniformity of quality and straightness. While the quality of lumber is determined to a great extent by the raw material, the quality of the reconstituted product is dependent upon the manufacturing process. It is likely, however, that use of composite lumber will increase in the future.

Wood Preserving

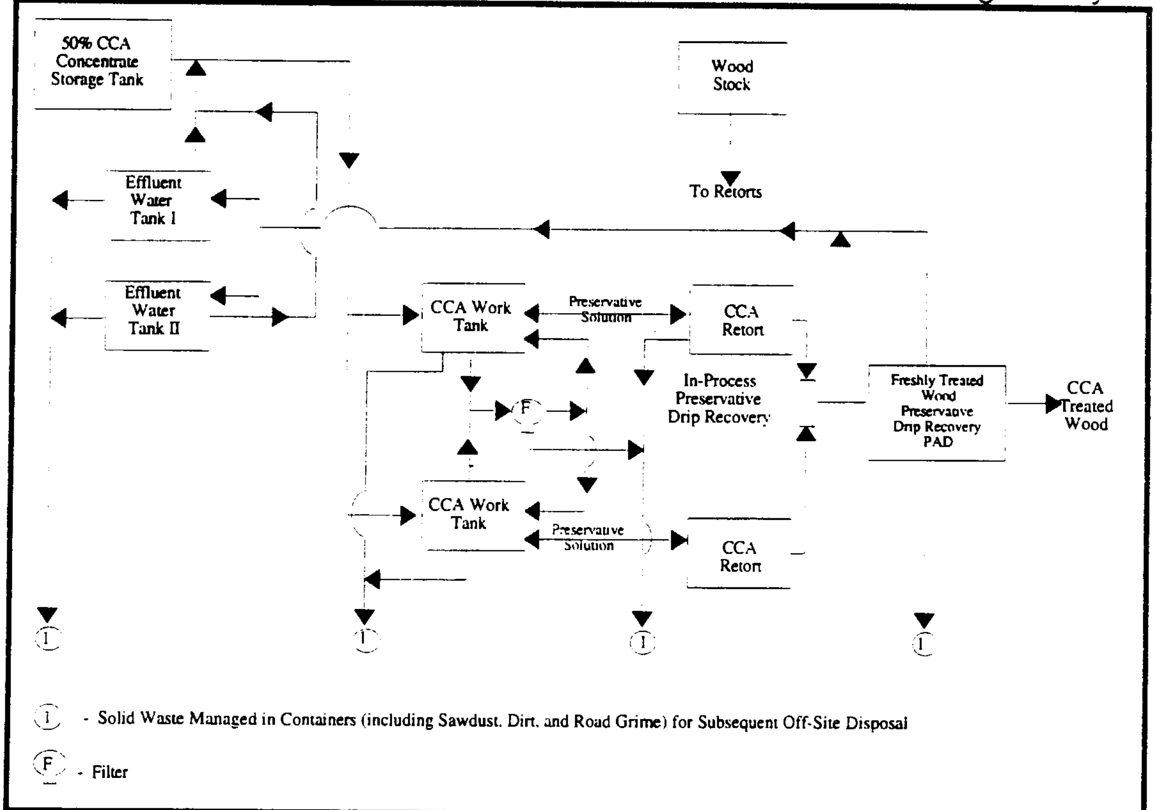
Wood is treated with preservatives to protect it from mechanical, physical, and chemical influences. Preserved wood is used primarily in the construction, railroad, and utilities industries to prevent rotting when wood is exposed to damp soil, standing water, or rain, and as protection against termites and marine borers. The most common preservatives include water-borne inorganics like chromated copper arsenate (CCA) and ammoniacal copper zinc arsenate (ACZA), and oil-borne organics like pentachlorophenol (PCP) and creosote. Generally, protection against termites and marine borers. The most common preservatives include water-borne inorganics like chromated copper arsenate (CCA) and ammoniacal copper zinc arsenate (ACZA), and oil-borne organics like pentachlorophenol (PCP) and creosote. Generally, water-borne inorganic solutions constitute approximately 78 percent of all preservatives used, while oil-borne creosote and PCP comprise 15 percent and 6 percent, respectively.

Creosote, PCP, and inorganic wood preservatives are all applied using similar processes. More than 90 percent of the wood preservation in the U.S. is performed using pressure treatment processes. Exhibit 10 illustrates a two-cylinder pressure treatment process for CCA. A limited quantity of wood is preserved using non-pressure treatment processes in which the preservative is allowed to diffuse into the wood. This process is used with some oil-borne preservatives, but not with waterborne inorganics.

The penetration required to adequately preserve wood can be achieved only if the wood has been conditioned properly; that is, if the moisture content of the freshly-cut wood is reduced to a point where the preservative can penetrate and be retained by the wood. Wood is usually conditioned in the open air or conditioned in the cylinder (retort) in which the pressure treatment is performed. The sawn lumber is sometimes incised to increase preservative penetration. Open air drying is typically used to prepare large stock for treatment with oil-borne preservatives. Other methods for conditioning wood prior to treatment with oil-borne preservatives include steaming, heating, and vapor drying. Kiln drying is used primarily for water-borne treatment. Conditioning is a major source of wastewater in the wood preserving industry.

After the moisture content of the wood has been reduced, the wood is preserved using either non-pressure or pressure methods. Non-pressure processes include brushing, spraying, dipping, soaking, and thermal processes. These processes involve the repeated use of preservative in a treatment tank with fresh preservative solution added to replace consumptive loss. The continual reuse of preservative leads to the accumulation of wood chips, sand, stones, and other debris contaminated with various hazardous constituents in the bottom of the treating tanks. This contaminated debris is a major source of process waste for non-pressure processes.

Exhibit 11
Example Flow Diagram For a Two-Cylinder CCA Pressure-Treating Facility



Source: *Title III, Section 313 Release Reporting Guidance; Office of Pesticides and Toxic Substances; March 1983.*

There are two basic types of pressure treatment processes, distinguished by the sequence in which vacuum and pressure are applied. These are "empty-cell" and "full-cell" or "modified full cell" processes. The terms "empty" and "full" are measures of the level of preservative retained by the wood cells.

"Empty-cell" processes obtain relatively deep penetration with limited absorption of preservative. In the Reuping empty-cell process, air pressure is applied to the wood as preservative is pumped into the treating cylinder. Once the desired level of retention has been achieved, the unused preservative is drained off and the excess preservative is vacuum pumped away from the wood. The process is the same in the Lowry empty-cell process, except no initial pressure is applied. In both processes, air compressed in the wood drives out part of the preservative absorbed during the pressure period when pressure is released.

R0075680

The second method, know as the "full-cell" (Bethel) process, results in higher retention of preservative but limited penetration compared to the empty-cell process. The full-cell or modified full cell procedures are used with both oil- and water-borne preservatives. A vacuum is created in the treating cylinder and preservative is pumped in without breaking the vacuum. Once full, hydrostatic or pneumatic pressure is applied until the wood will retain no more preservative. A final vacuum may then be applied to remove excess preservative, which is returned to the work tank for reuse. The treated wood is removed from the cylinder and placed on a drip pad where it remains until dripping has ceased (see Exhibit 12). Preservative solution, washdown water, and rainwater are collected on the drip pad and maintained in the process. At waterborne plants, these materials are transferred to a dilution water tank where they are blended with additional concentrate to make fresh treating solution. At oil-borne plants, these materials are processed to recover preservative and usable process water. Excess waste water is treated either on-site in a wastewater treatment unit or off-site at a publicly owned treatment works.

III.B. Raw Material Inputs and Pollution Outputs

Exhibit 13 provides an overview of the material inputs and pollution outputs for different processes in the lumber and wood products industry.

Logging

With the exception of concerns for species and ecosystem preservation, harvesting practices have minimal environmental impacts. Harvesting practices often cause discharges of materials into surrounding waters, threatening water quality standards. The Federal Water Protection Control Act regulates these discharges. In addition, road construction for access to timber areas is of concern, due to impacts on surrounding ecosystems.

R0075682

Exhibit 13
Process Materials Inputs and Pollution Outputs

Process	Material Input	Air Emissions	Process Waste	Other Waste
Logging	Trees, diesel, gasoline	PM-10, VOCs, CO, NOx	Not applicable	Waste wood particles
Sawing	Wood logs, diesel, gasoline	PM-10, VOCs, CO, NOx	Not applicable	Waste wood particles
Surface Protection	Wood, 3-Iodo-2-Propynyl Butyl Carbamate (IPBC), Didecyl Dimethyl Ammonium Chloride (DDAC)	IPBC, DDAC, ethyl alcohol, petroleum naphtha	Dripped formulation mixed with rainwater and facility washdown water	Sawdust, wood chips, sand, dirt, stones, tar, emulsified or polymerized oils
Plywood and Veneer	Veneer, phenol-formaldehyde resins, urea-formaldehyde resins, melamine-formaldehyde resins, sodium hydroxide, ammonium sulfate, acids, ammonia	PM-10, VOCs, CO, CO_2, NOx, formaldehyde, phenol, wood dust, condensable hydrocarbons, terpenes, methanol, acetic acid, ethanol, furfural	Not applicable	Waste wood particles, adhesive residues
Reconstituted Wood Products	Wood particles, strands, fiber, same resins as plywood and veneer, methylenediphenyl diisocyanate resins	PM-10, VOCs, CO, CO_2, NOx, formaldehyde, phenol, wood dust, condensable hydrocarbons, terpenes, methanol, acetic acid, ethanol, furfural	Not applicable	Waste wood particles, adhesive residues
Wood Preserving	Wood, pentachlorophenol, creosote, borates, ammonium compounds, inorganic formulations of chromium, copper, and arsenic, carrier oils	Pentachlorophenol, polycyclic organics, creosote, ammonia, boiler emissions, air-borne arsenics, VOCs	Dripped formulation mixed with rainwater and facility washdown water, kiln condensate, contact cooling water	Bottom sediment sludges, process residuals

Sawn Lumber

Most of the residual wood from sawn lumber production is reused as mulch, pulp, and furnish for some types of reconstituted wood panels; some is burned to produce steam or electricity. Studies cited by the Western Wood Products Association indicate that approximately 70 percent of a sawn log is utilized for lumber and other parts are used for co-products. Some of the small residuals are gathered with pneumatic systems for combination with larger amounts destined for use in other products. While there is virtually no waste from the manufacturing process because all parts of the log are used for one product or another, wood residuals are high in organic matter and can threaten aquifers if improperly handled.

A major emission of concern from wood boilers is particulate matter (PM), although other pollutants, particularly CO and organic compounds, may be emitted in significant quantities under poor operating conditions. Boilers that burn wood waste produce: fly ash, carbon monoxide, and volatile organic compounds (VOCs). New boilers must meet new source performance standards (NSPS) for air pollutants. In addition, mills are potential sources of toxic manganese air emissions.

Two types of primary waste streams are typically generated during the surface protection phase of sawn lumber production operations: process residuals and drippage. Secondary waste streams include spent formulations and wastewaters.

Typical process residuals from surface protection are tank sludges that accumulate in the dip tank and/or mix tank as a result of continuous reuse of the protectant. Some plants use spray systems that generate a sludge when recovered formulation is filtered. Periodically, the accumulated sludge must be removed, and is typically placed on sawdust or wood chip piles on-site. The ultimate destination of the sludge is dependent upon the management of the sawdust piles. Plants have reported burning sawdust on-site or shipping it off-site for use as boiler feed for energy recovery. Depending upon the particle size, some wood chips may be shipped to a pulp or paper mill.

Some plants generate little or no tank sludge as a result of certain process variations. Dip tank operations sometimes utilize an internal circulation system to enhance mixing and promote penetration into the packed bundles. The agitation does not allow any particulates to settle, and when the bundles are removed, some of the suspended solids are also removed. Green-chain operations sometimes use a system of rollers that are partially submerged into the dip tank. These rollers force the pieces of lumber under the surface of the formulation to ensure thorough coverage of the exposed surfaces. Forcing the lumber deeper into the tank physically drags the lumber through any sludge that has settled in the tank and this sludge leaves the tank with the treated lumber.

Another wastestream results from the excess formulation drippage from freshly surface protected lumber. In the absence of a drip pad, excess drippage can fall on the ground when the wood is transported from the dip tank or green chain to stacking and packaging areas. Spray operations tend to result in less excess formulation on the wood than either the dipping or green-chain operations. Some plants utilize simple recovery systems to minimize the loss of formulation. For example, pack dip operations hold the wood over the dip tank at an angle to collect excess formulation prior to transfer to storage. Green chain and spray operations may utilize a collection pan under the conveyor to collect formulation as the freshly treated lumber runs along the green chain.

Panel Products

In mills where chips or other furnish is generated on-site, operations such as debarking, sanding, chipping, grinding, and fiber separation generate PM emissions in the form of sawdust and wood particulate matter. The following discussion of pollution outputs from panel production is not divided along product lines. Instead, due to similarities in manufacturing process, this section describes pollution outputs during the drying and pressing stages, where most emissions occur.

Dryers

Organic aerosols and gaseous organic compounds, along with a small amount of wood fiber are found in the emissions from veneer impingement dryers. A mixture of organic compounds is driven from the green wood veneer as its water content is converted to steam in the drying process. Aerosols begin to form as the gaseous emissions are cooled below 302°F. These aerosols form visible emissions called blue haze.

Emissions from the rotating drum wood chip dryers used in reconstituted wood panel plants are composed of wood dust, condensable hydrocarbons, fly ash, organic compounds evaporated from the extractable portion of the wood, and may include products of combustion such as CO, CO_2, and NO_x if direct-fired units are used. The organic portion of industry emissions includes terpenes, resin and fatty acids, and combustion and pyrolysis products such as methanol, acetic acid, ethanol, formaldehyde, and furfural. The condensable hydrocarbons and a portion of the VOCs leave the dryer stack as vapor but condense at normal atmospheric temperatures to form liquid particles that create the blue haze. Both the VOCs and the liquid organic mist are combustion products and compounds evaporated from the wood. Quantities emitted are dependent on wood species, dryer temperature, and fuel used.

R0075685

One significant cause of blue haze is overloading a dryer by attempting to remove too much moisture within a given time. Overloading results in the introduction of green material to a high-temperature flame or gas stream causing a thermal shock that results in a rapid and excessive volatilizing of hydrocarbons that condense upon release to ambient air, causing the characteristic blue haze.

Another factor affecting the composition of the effluent from rotary drum dryers is inlet dryer temperatures. A study conducted in 1986 by The National Council of the Paper Industry for Air and Stream Improvement (NCASI) with data from five different mills using rotary drum dryers concluded that at inlet gas temperatures greater than 600°F, the emission rate of the total condensable portion of total gaseous nonmethane organics (TGNMO) increased as a function of temperature. The report concluded that the concentration of formaldehyde in the dryer exhaust was also directly related to dryer inlet temperature.

The type of wood species ~~burned~~ being dried also affects the composition of the effluent from rotary drum dryers. A second NCASI study concluded that high TGNMO emission rates from the dryers occurred when the wood species processed had high turpentine contents, such as Southern Pine. In a separate study on formaldehyde emissions, NCASI showed that dryers processing hardwood or a mixture of hardwood and softwood species had a moderate to dramatic increase in formaldehyde emissions at dryer inlet gas temperatures greater than 800°F, but dryers processing only softwood species had only a slight increase in formaldehyde emissions with increasing temperatures.

Presses

Emissions from board presses are dependent upon the type of resin used to bind the wood furnish together. Emissions from hot presses consist primarily of condensable organics. When the press opens, vapors that may include resin ingredients such as formaldehyde, phenol, MDI, and other organic compounds are released to the atmosphere through vents in the roof above the press. Formaldehyde emitted through press vents during pressing and board cooling operations is dependent upon the amount of excess formaldehyde in the resin as well as press temperature and cycle time.

Mole ratios are used to measure the number of moles of one compound to another in an adhesive. For example, the F:U (formaldehyde to urea) mole ratio measures the number of moles of formaldehyde to the number of moles of urea in the principal adhesive used for PB and MDF. The nature of the product and the process dictates the mole ratio of resin used. The ratio directly impacts the ultimate strength the resin will produce in the board, i.e., certain products require higher mole ratio resins to attain an adequate level of bond strength. The higher the mole ratio, the higher the board emissions of formaldehyde. Thus lowering the F:U mole ratio is one way of lowering press and board emissions of formaldehyde. However, mole ratio is only one of several variables that can effect formaldehyde emissions. Other variables include application rates, process rates, and the nature of the specific resin formations.

Higher press temperatures generally result in higher formaldehyde emissions. In an NCASI study, emissions of formaldehyde and phenol from PF resins (used mainly for OSB) and structural plywood were not found to be related to any operating procedures, but were affected by different resin compositions. The types of resins used can effect the amount of emissions. There was little information on emissions from the curing of MDI resins (used for OSB along with PF resins).

Wood Preserving

The chemicals used in the wood preserving process and the drip pads used to collect preservative drippage after treatment of wood have been the subject of considerable regulatory action. EPA has issued final regulations regarding wood preserving wastewater, process residuals, preservative drippage, and spent preservatives from wood preserving processes at facilities that use chlorophenolic formulations, creosote formulations, and inorganic preservatives containing arsenic or chromium.

There are six EPA-classified hazardous wastes from wood preserving operations. These are: U051, discarded unused creosote, F027, discarded unused pentachlorophenol-formulation; K001, bottom sediment sludge from the treatment of wastewaters from wood preserving processes that use creosote or PCP; F032, wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that currently use or have previously used chlorophenolic formulations; F034, wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that use creosote formulations; and F035, wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that use inorganic preservatives containing arsenic or chromium.

Drips and spills during the oilborne preservative process may occur during chemical delivery, chemical storage and mixing, freshly-treated wood storage on bare ground (if RCRA guidelines are not followed), and dry-treated wood storage on ground. Aerosols and vapors may be released to ambient air during chemical storage and mixing, solution storage, and during pressure treatment (once the cylinder is opened). Sludges result if filters are used prior to solution reuse from wastewater treatment, and from the collection sumps at the facility.

During the inorganic treatment process, additional vapors such as arsenic, may be released to ambient air during the pressure treating process, such as from the process tank or work vent during the initial vacuum stage, the flooding via vacuum, pressure relief and blow back, and the final vacuum. Aerosols and vapor may also be released from the cylinder door area during pressure treating and door opening.

Wood preserving facilities generate wastewater during the conditioning of the wood prior to its treatment and as a result of the condensation removed from the treatment cylinder. Rainwater, spills collected from the area around the treatment cylinder, and drip pad wash down water also contribute to wastewater volume. Typical air emissions sources are volatilization of organic chemicals during wastewater evaporation, vapors released from the treating cylinder during unloading and charging operations, and emissions from the vacuum vent during the treating cycle.

After both pressure and non-pressure treatment, some unabsorbed preservative formulation adheres to the treated wood surface. Eventually, this liquid drips from the wood or is washed off by precipitation. If the wood has been pressure treated, excess preservative will also exude slowly from the wood as it gradually returns to atmospheric pressure. This is known as "kickback." Current regulations specify that all wood must be drip-free prior to transfer from a drip pad to a storage yard. Also, storage-yard drippage resulting from "kickback" must be cleaned up within 72 hours of the occurrence. Preservative formulation may continue to exude from pressure and non-pressure treated wood for long periods, even after the wood is shipped off-site and installed for its intended end use. (See Exhibit 11 for schematic of wood preserving process and waste generation)

R0075688

III.C. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (EPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R. beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention and compliance assistance activities.

While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The EPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 14 shows that the lumber and wood products industry managed about 69 million pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, 17 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 84 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E and F, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production-related wastes (13.2 percent), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has increased and the portions treated or managed through energy recovery on-site have decreased between 1992 and 1995 (projected).

R0075689

R0075690

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7% between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount, and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds.

Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) - encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of waste to on-site landfills, waste that is land treated or incorporated into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Lumber and Wood Products Industry

TRI Release amounts listed below are not associated with non-compliance with environmental laws. These facilities appear based on self-reported data submitted to the Toxic Release Inventory program.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear in Exhibit 15. Exhibit 16 contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, Exhibit 16 includes facilities that conduct multiple operations — some that are under the scope of this notebook, and some that are not. Operations in Exhibit 16 include: 2621 - paper mills, 2611 - pulp mills, 2631 - paper mills, and 2812 - industrial inorganic chemicals. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibits 17-19 illustrate the TRI releases and transfers for the lumber and wood products industry (SIC 24). For the industry as a whole, VOCs (such as formaldehyde, xylene, toluene, and methanol) comprise the largest number of TRI releases. A large amount of VOC releases, both fugitive and point source emissions, result in part from the extensive use of glues and resins in this industry. VOCs are primarily released during the drying and pressing phases of most wood panel product manufacturing processes. VOC emissions are also associated with solvents used to coat cabinets, decorative panels, and toys.

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET[1]. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB.

---

1 TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

The top TRI releases for the lumber and wood products industry (SIC 24) as whole include:

Acetone
Ammonia
Creosote
Formaldehyde
Methanol
Methyl ethyl ketone
Methyl isobutyl ketone
Phenol
Toluene
Xylenes (mixed isomers).

Acetone

Toxicity. Acetone is irritating to the eyes, nose, and throat. Symptoms of exposure to large quantities of acetone may include headache, unsteadiness, confusion, lassitude, drowsiness, vomiting, and respiratory depression.

Reactions of acetone (see environmental fate) in the lower atmosphere contribute to the formation of ground-level ozone. Ozone (a major component of urban smog) can affect the respiratory system, especially in sensitive individuals such as asthmatics or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released into water, acetone will be degraded by microorganisms or will evaporate into the atmosphere. Degradation by microorganisms will be the primary removal mechanism.

Acetone is highly volatile, and once it reaches the troposphere (lower atmosphere), it will react with other gases, contributing to the formation of ground-level ozone and other air pollutants. EPA is reevaluating acetone's reactivity in the lower atmosphere to determine whether this contribution is significant.

Physical Properties. Acetone is a volatile and flammable organic chemical.

Note: Acetone was removed from the list of TRI chemicals on June 16, 1995 (60 FR 31643) and will not be reported for 1994 or subsequent years.

Ammonia

Toxicity. Anhydrous ammonia is irritating to the skin, eyes, nose, throat, and upper respiratory system.

Ecologically, ammonia is a source of nitrogen (an essential element for aquatic plant growth), and may therefore contribute to eutrophication of standing or slow-moving surface water, particularly in nitrogen-limited waters such as the Chesapeake Bay. In addition, aqueous ammonia is moderately toxic to aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Ammonia combines with sulfate ions in the atmosphere and is washed out by rainfall, resulting in rapid return of ammonia to the soil and surface waters.

Ammonia is a central compound in the environmental cycling of nitrogen. Ammonia in lakes, rivers, and streams is converted to nitrate.

Physical Properties. Ammonia is a corrosive and severely irritating gas with a pungent odor.

Formaldehyde

Toxicity. Ingestion of formaldehyde leads to damage to the mucous membranes of mouth, throat, and intestinal tract; severe pain, vomiting, and diarrhea result. Inhalation of low concentrations can lead to irritation of the eyes, nose, and respiratory tract. Inhalation of high concentrations of formaldehyde causes severe damage to the respiratory system and to the heart, and may even lead to death. Other symptoms from exposure to formaldehyde include: headache, weakness, rapid heartbeat, symptoms of shock, gastroenteritis, central nervous system depression, vertigo, stupor, reduced body temperature, and coma. Repeated contact with skin promotes allergic reactions, dermatitis, irritation, and hardening. Contact with eyes causes injuries ranging from minor, transient injury to permanent blindness, depending on the concentration of the formaldehyde solution. In addition, menstrual disorders and secondary sterility have been reported in women exposed to formaldehyde.

R0075701

Carcinogenicity. Formaldehyde is a probable human carcinogen via both inhalation and oral exposure, based on limited evidence in humans and sufficient evidence in animals.

Environmental Fate. Most formaldehyde is released to the environment as a gas, and is rapidly broken down by sunlight and reactions with atmospheric ions. Its initial oxidation product, formic acid, is a component of acid rain. The rest of the atmospheric formaldehyde is removed via dry deposition, rain or dissolution into surface waters. Biodegradation of formaldehyde in water takes place in a few days. Volatilization of formaldehyde dissolved in water is low. Bioaccumulation of formaldehyde does not occur.

When released onto the soil, aqueous solutions containing formaldehyde will leach through the soil. While formaldehyde is biodegradable under both aerobic and anaerobic conditions, its fate in soil and groundwater is unknown.

Although formaldehyde is found in remote areas, it is probably not transported there, but rather is likely a result of the local generation of formaldehyde from longer-lived precursors which have been transported there.

Methanol

Toxicity. Methanol is readily absorbed from the gastrointestinal tract and the respiratory tract, and is toxic to humans in moderate to high doses. In the body, methanol is converted into formaldehyde and formic acid. Methanol is excreted as formic acid. Observed toxic effects at high dose levels generally include central nervous system damage and blindness. Long-term exposure to high levels of methanol via inhalation cause liver and blood damage in animals.

Ecologically, methanol is expected to have low toxicity to aquatic organisms. Concentrations lethal to half the organisms of a test population are expected to exceed 1 mg methanol per liter water. Methanol is not likely to persist in water or to bioaccumulate in aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Liquid methanol is likely to evaporate when left exposed. Methanol reacts in air to produce formaldehyde which contributes to the formation of air pollutants. In the atmosphere it can react with other atmospheric chemicals or be washed out by rain.

Methanol is readily degraded by microorganisms in soils and surface waters.

Physical Properties. Methanol is highly flammable.

Methyl Ethyl Ketone

Toxicity. Breathing moderate amounts of methyl ethyl ketone (MEK) for short periods of time can cause adverse effects on the nervous system ranging from headaches, dizziness, nausea, and numbness in the fingers and toes to unconsciousness. Its vapors are irritating to the skin, eyes, nose, and throat and can damage the eyes. Repeated exposure to moderate to high amounts may cause liver and kidney effects.

Carcinogenicity. No agreement exists over the carcinogenicity of MEK. One source believes MEK is a possible carcinogen in humans based on limited animal evidence. Other sources believe that there is insufficient evidence to make any statements about possible carcinogenicity.

Environmental Fate. Most of the MEK released to the environment will end up in the atmosphere. MEK can contribute to the formation of air pollutants in the lower atmosphere. It can be degraded by microorganisms living in water and soil.

Physical Properties. Methyl ethyl ketone is a flammable liquid.

Toluene

Toxicity. Inhalation or ingestion of toluene can cause headaches, confusion, weakness, and memory loss. Toluene may also affect the way the kidneys and liver function.

Reactions of toluene (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Some studies have shown that unborn animals were harmed when high levels of toluene were inhaled by their mothers, although the same effects were not seen when the mothers were fed large quantities of toluene. Note that these results may reflect similar difficulties in humans.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases of toluene to land and water will evaporate. Toluene may also be degraded by microorganisms. Once volatized, toluene in the lower atmosphere will react with other atmospheric components contributing to the formation of ground-level ozone and other air pollutants.

Physical Properties. Toluene is a volatile organic chemical.

Xylene (Mixed Isomers)

Toxicity. Xylenes are rapidly absorbed into the body after inhalation, ingestion, or skin contact. Short-term exposure of humans to high levels of xylenes can cause irritation of the skin, eyes, nose, and throat, difficulty in breathing, impaired lung function, impaired memory, and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations can cause effects such as headaches, dizziness, confusion, and lack of muscle coordination. Reactions of xylenes (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases to land and water will quickly evaporate, although some degradation by microorganisms will occur.

Xylenes are moderately mobile in soils and may leach into groundwater, where they may persist for several years.

Xylenes are volatile organic chemicals. As such, xylenes in the lower atmosphere will react with other atmospheric components, contributing to the formation of ground-level ozone and other air pollutants.

IV.C. Other Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 20 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 20
Pollutant Releases (Short Tons/Years)

Industry	CO	NO_2	PM_{10}	PT	SO_2	VOC

IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following table does not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release book.

Exhibit 21 is a graphical representation of a summary of the 1993 TRI data for the Lumber and Wood Products Industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 22 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of Lumber and Wood Products Industry, the 1993 TRI data presented here covers 491 facilities. These facilities listed SIC 24 Lumber and Wood Products as a primary SIC code.

R0075706

V. Pollution Prevention Opportunities

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the lumber and wood products industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

Surface Protection

Several alternative manufacturing methods are part of the industry's pollution prevention efforts. One common alternative is to replace chemical treatment with another type of treatment to achieve surface protection. For example, the need for surface treatment would be decreased if efforts were made to dry the wood to reduce water content (high water content leads to sapstain). Due to economies of scale, this option may not be economically viable for a smaller mill.

Another pollution prevention option is the use of high velocity spray systems that generate fewer process residuals and less drippage. However, a small production volume may not favor this option since spray systems require a larger flow of wood through the systems to be economically or technically feasible.

Other pollution prevention strategies relating to surface protection include: 1) local and general ventilation within the cutting process area to reduce dust which would accumulate on wood; 2) blowing wood with air to further reduce sawdust on wood prior to surface protection; and 3) the use of drainage collection devices on roof tops to keep rainwater away from process wastes. For wastes that cannot be reduced at the source, generators may consider used surface protectant recycling as the next best option.

Panel Products

Air emissions from panel manufacturing are significantly greater than releases to water or land. The following information on pollution prevention options for the wood panel products industry (including veneer/plywood and reconstituted wood products) is from Martin and Northeim's summary.

Alternative Fiber Sources

One pollution prevention opportunity for the reconstituted wood panel industry is to search for alternative sources of wood fiber. This can be done in two ways: utilizing recycled wood waste and using existing agricultural fibers.

Increasing prices for raw wood furnish have led some firms to develop programs to recycle wood waste into chips for PB production. These firms collect construction site debris, discarded household items, crates, and used pallets for eventual use as PB furnish. Beyond finding sources, an ideal fiber recycling program includes extensive training and research on what materials are suitable, careful quality control of the recycled materials, and cleaning materials to remove foreign matter. There are many hurdles to properly cleaning the material because it is difficult to process different kinds of material and maintain a quality product.

A second alternative source for fiber is agricultural fiber, which can come from two sources: agricultural crops grown expressly for fiber (e.g., kenaf and bagasse) and residues of crops grown for other purposes (e.g., corn stalks/cobs and cotton stalks). Currently, two plants are being built in the U.S. that will use agricultural fiber to manufacture composite panels. In terms of potential availability, the amount of residual fiber generated by U.S. agriculture far exceeds present and future fiber requirements for composite panel manufacture. The feasibility of such a substitution, however, depends on many factors such as product quality, cost, and current uses of agriculture residues.

Alternative Adhesives

Other pollution prevention options in the panel products industry involve adhesive substitution. This involves replacing existing adhesives with less toxic formulations. There are a number of innovative adhesive options currently available for use in the panel products industry.

MDI Substitution

Based on price alone, there seems to be little incentive for manufacturers to switch from PF or UF to MDI adhesives. However, since the early 80's, one third of the OSB industry has switched from PF to MDI adhesives. According to their manufacturers, there are several environmental advantages to using these adhesives. Because MDI adhesives are capable of bonding wood flakes with a higher moisture content, less dryer energy is required to dry flakes suitable for MDI bonding. Other advantages to using MDI adhesives are lower press temperatures and shorter press cycles, both of which may lead to reduced press emissions. However, there are other concerns with respect to the use of MDI adhesives. Some companies are opposed to MDI substitution for reasons such as worker toxics exposure, potential acute impacts of possible spills, and inconsistency with toxic use reduction objectives. Manufacturers of MDI state that safe exposure levels are obtainable through good engineering controls which include making sure that blenders are well sealed, and that the blending and forming areas are well ventilated.

High Moisture Adhesives

Switching to an adhesive that is capable of bonding a high moisture furnish eliminates the need to dry wood to a low moisture content. Dryer energy and temperature can be reduced because less water must be removed from the wood. Press temperature can also be lowered since heat transfer is more efficient in high moisture furnish, reducing VOC emissions.

The gluing of high moisture content wood has become an established practice in plywood manufacture. Many OSB plants are switching to high moisture bonding adhesives with the primary goals of reducing dryer emissions and possibly reducing wood drying costs. Efforts have been made to improve phenolic resin technology to allow better bonding in the presence of water. The primary incentive for bonding high moisture veneer is a reduction in adhesive consumption. In the Southern plywood industry; where dryout is a problem, a dramatic reduction in adhesive use has been achieved by gluing high moisture veneer.

Naturally-derived Adhesives

Spurred by rapid price increases of petroleum-derived chemicals in adhesives such as PF and UF, chemical material suppliers, forest products companies, and wood adhesive/binder suppliers are expending research and development funds to search for renewable raw material sources. Substitutes could replace entirely, or at least partially, petroleum-derived chemicals now used in the manufacture of wood adhesives. Naturally-derived adhesives are included in this profile as a pollution prevention opportunity because of the potential to use renewable resources, which in many cases are by-products of other processes.

Furfuryl Alcohol Resins

Resins manufactured from furfuryl alcohol are being evaluated as an alternative low-VOC binder to substitute for PF resins. Unlike PF resins, furfuryl alcohol resins are stored stable at ambient temperatures, without refrigeration. As delivered, furfuryl alcohol resin contains very low amounts of volatile components. Upon curing, it reduces 80 to 90 percent of total VOC emissions, and reduces Hazardous Air Pollutants (HAPs) by the same amount. The furfuryl alcohol system offers the same relative speed of cure as the PF resin systems.

Furfuryl alcohol resin is currently in the experimental stage of development. The industry has shown little interest in the resin because of its high cost; which is twice that of a PF resin. However, cost analyses performed for the insulation industry show that using the resin to meet future HAP standards is cheaper than purchasing and operating control devices such as scrubbers. The same is likely true for the wood products industry.

Lignin Adhesives

Lignin is an aromatic polymer that makes up one of the three major components of wood (cellulose and hemicellulose are the others). The abundance of lignin as a waste product in pulp mills has made it a desirable raw material alternative to nonrenewable petroleum-derived chemicals in the production of wood adhesives.

Until recently, no more than 20 to 30 percent of lignin could be substituted into PF resins because cure times increased as the amount of lignin increased. Another drawback is that lignin adhesives have low cross-linking and strength. However, a new approach has recently been developed that can substitute large amounts of kraft lignin for PF adhesives while actually increasing cure speed and board strength.

Currently, Westvaco is the only company in the U.S. that operates a commercial lignin extraction facility. The capital cost of a new commercial lignin extraction facility compared to the capital cost of a new phenol plant is estimated to be almost equal per pound of product produced. However, because the selling price of lignin is only $0.32-0.34, compared to the selling price of phenol which is $.45/solid pound and rising, there is more of an economic incentive to build a new phenol plant than a lignin extraction facility.

Polyvinyl acetate (PVA)

There have been some mill trials and some small quantities of hardwood plywood made with cross-linked polyvinyl acetate (PVA) adhesives. Blends of PVA and UF are also sometimes used in the manufacture of hardwood plywood. Cross-linked PVAs are light in color, are compatible with the hardwood plywood manufacturing process, and don't require additional equipment. Concerns have been expressed about the potential of airborne release of vinyl monomers. PVA adhesives are considerably higher in cost than UF adhesives.

Alternative Manufacturing Processes

Veneer and Plywood Adhesive Reduction

In the softwood plywood industry, a common waste generated by the typical spray-line layup system is over-spray. A more efficient way of applying adhesive to veneer is by foam extrusion, a process in which foamed adhesive is forced under pressure to the extrusion head. This process better concentrates the glue stream onto the veneer, resulting in less wasted adhesive and less chance of adhesive dryout before pressing. In terms of economics, the combination of less waste and lower spread rates when using foam extruders can add up to savings in the 20 to 31 percent range, depending on the type of equipment used.

Another pollution prevention option in the softwood plywood industry is the variable application rate strategy (VARS). The amount of adhesive required to bond veneer varies with moisture content. For example, high moisture veneer requires less glue than low moisture veneer because there is less migration of water from the glue into the veneer. Although the moisture content of veneer varies at a typical plywood mill, glue is applied at a constant rate to prevent dryout of low moisture veneer. A 1992 study by Faust and Borders outlined in Forest

Products Journal, investigated the use of the glue application rate with respect to improved bond quality and reduced resin consumption. The variable application rate strategy (VARS) they developed adjusted the glue spread rate for each individual plywood panel according to its moisture content. Process-sensing and control technology has been developed for the practical application of VARS. Sensor technology is currently available for on-line adjustment and measurement of veneer moisture content and temperature. In addition to compensating for problem bonding conditions that occur unexpectedly during production, the greatest benefit of VARS from a pollution prevention standpoint is a reduction in adhesive consumption and, consequently a reduction in plant emissions.

Alternative Dryers

There are other process modifications that may be implemented to reduce emissions while drying green furnish for reconstituted wood panel manufacture. Researchers are currently investigating the use of alternative drying methods for raw wood furnish.

Rotary drum dryers are used in the OSB industry. These are typically characterized by high-temperature drying air, aggressive handling of strands, and short product-retention times. The adverse affects of these characteristics include VOC emissions and strand degradation. Research has shown that low-temperature drying reduces VOC emissions. However, this requires that the furnish be retained in the dryer for a longer period of time which is difficult to achieve in a rotary dryer. It has been found that conveyor belt dryers generate less VOC emissions than rotary dryers. Temperatures of less than 400°F and very low volumes of exhaust gases are possible with conveyor dryers, resulting in low emission levels of VOC, while virtually eliminating strand damage within the dryer. Conveyor dryers can also be used to dry PB furnish.

The three pass high velocity (3PHV) rotary drum dryer is a major breakthrough in rotary drum drying technology that has the potential to reduce VOC emissions significantly (see Exhibit 9). The 3PHV is a rotating cylindrical drum consisting of three, concentric, interlocking cylinders. Hot gases enter the outermost cylinder with the wood chips and progress through the intermediate and then the inner drum shells in a serpentine flow path. This flow path direction is the opposite of that in the conventional three-pass dryer. This reverse air flow may reduce VOC emissions.

In the first pass, the 3PHV dryer allows smaller, dried particles to pass through the slower moving mass of larger, wetter particles in an area bounded by the outer and intermediate drum cylinders. This area is much larger than the area of the inner drum of conventional triple pass dryers. As the larger particles are dried, they will "catch up" with the smaller faster moving particles in an area bounded by the intermediate (second pass) drum cylinder. Here, airflow velocities become high enough to convey the entire mass of particles out of the drying portion of the drum and into the inner (third pass) drum cylinder where they will be conveyed out of the dryer. This action prevents the product from reaching temperatures in excess of the wet bulb temperature, thus reducing carbon monoxide and hydrocarbon emissions associated with pyrolysis and combustion of the wood chips.

Wood Preserving

Water-borne preservatives produce less waste than oil-borne preservatives because process wastewater is reused rather than discharged. In addition, well designed treatment plants, good treatment practices, effective housekeeping, and employee training also help reduce waste at the source.

Well designed treatment plants may have enclosed treatment buildings, covered drip pads with liners, automatic lumber handling systems, centralized tank farms with spill containment, and air ventilation systems. The RCRA standards in 40 CFR 264 and 265 require that drip pads must contain drippage, be free of cracks and gaps, and be cleaned and inspected. Plants can also be designed to minimize mist or droplet emissions from cylinders and work tanks through the use of air exchange systems and cylinder and tank venting.

Treatment practices are also important for preventing pollution. Ensuring that wood stock is clean prior to treatment will prevent dirt, sawdust, and other debris from accumulating in the treatment system. To prevent debris buildup, wood can be covered during shipment and/or power-washed when necessary before it enters the treatment plant. Strip pumps may be installed to continuously return residual chemical solutions to the work tank, resulting in less dripping when the cylinder doors are opened. If treating cylinders are tilted slightly away from the drip pad, there is also less spillage when opening the cylinder doors.

Housekeeping is an integral part of waste minimization efforts. All tanks, mixing systems, treating cylinders, drip pads, and spill containments should be inspected regularly for leaks. Drip pads and collection areas should be kept clean. Storage yards should be inspected daily, and any drippage detected should be cleaned up within 24 hours.

Several other preservatives have been proposed as alternatives to traditional preservatives. For example, wood can be treated with borates using both pressure and non-pressure processes. However, because they are highly susceptible to leaching, borates cannot be used to preserve wood that will be in contact with the ground or exposed to the weather (e.g., decking).

Ammoniacal copper/quarternary ammonium (ACQ) is another proposed alternative. Initial above-ground field test data show that ACQ is effective for softwood and hardwood protection. Other alternative preservatives may include copper-8-quinolinolate (Cu_8), copper naphthanate, zinc naphthanate, quarternary NH_4 compounds (QAC), and zinc sulfate.

Treatment processes may vary in their ability to minimize waste. For example, the empty-cell process uses less carrier oil than the full-cell process for oil-borne preservatives. The modified full-cell treatment reduces the uptake of treating solution and minimizes the amount of dripping for water-borne preservatives.

Pollution Prevention Case Studies

Reconstituted Wood Products

By late 1995, CanFibre hopes to start up its first plant to produce MDF using 100 percent post-consumer waste and PF adhesives. The plant (the first of its kind in North America) will be located near Toronto, Ontario. Approximately 1.2 million ft^3 per year of structural MDF will be produced from recycled urban waste such as waste wood, cardboard, drink containers, newspaper, etc. The plant will have two significant cost advantages over conventional MDF plants: (1) the costs of post-consumer waste is currently negative, and (2) savings in freight costs due to the plant's location near an urban site (most existing MDF plants are remotely located and the cost of hauling wood waste back to these mills is high). The net mill cost for the process used by the firm's Toronto plant is estimated to be $183/million square feet (MSF) versus $228/MSF for a conventional plant. The company plans to build a total of nine plants in North America: six in the U.S. and three in Canada. All plants will use 100 percent post-consumer waste and PF adhesives.

Wood Preserving

Perry Builders, Inc. employs 20 people at its Henderson pressure wood preserving manufacturing facility. Perry Builders recognizes that each wood treater has an important responsibility in properly handling and disposing of the wastes it produces and is committed to meeting this challenge. Perry uses a water-borne chemical preservative; chromated copper arsenate, to treat lumber, plywood, timbers, and other wood products for decks, fences, and other outdoor uses. Hazardous waste results from contact of sawdust, wood chips, and dirt with the preservative. It has successfully minimized its hazardous waste generation by 80 percent in two years with the implementation of a low-cost waste minimization program. In 1987, Perry Builders generated 15 drums of hazardous waste with a disposal cost of $2,380. By 1989 Perry Builders reduced its disposal cost to $310 by generating only two drums.

This reduction was achieved by changing both equipment and processes to achieve a fully integrated closed system in which the application, receipt, transfer, and storage of the preservation takes place in a contained area.

The goal is to apply the preservative to the wood while minimizing the loss of the preservative as a waste. By holding the lumber in the treatment chamber longer to allow drippage, and by using a vacuum pump to further dry the lumber, the treatment solution remains in the chamber and does not come into contact with scrap material and dirt. As an incentive to employees to assure adequate drying time, management instituted pay based on hourly wages rather than an amount of lumber treated. A roof over the area housing the treated lumber prevents runoff during rainfall.

Perry Builders estimates that the cost of the vacuum pump, the roof, and the increased drying time will be recovered in five years through reduced disposal costs. There is also another economic benefit-since the drier lumber weighs less, more footage of lumber can be shipped on each truck, thereby reducing freight costs.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

R0075718

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.
- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.
- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.
- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.
- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.
- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund

Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.
- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.
- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.
- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The

Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Requirements

Clean Air Act (CAA)

Under the Clean Air Act, PM_{10}, (particulate matter with an aerodynamic diameter of 10 microns or less) and volatile organic compounds (VOCs) are regulated to ensure attainment with the National Ambient Air Quality Standards for PM_{10} and ground level ozone (VOCs contribute to the formation of ground level ozone). Wood products have the potential to emit PM_{10} and VOCs in significant quantities.

As required by §110 of the CAA, State Implementation Plans (SIPs) must be developed to identify sources of air pollution and determine what reductions are required to meet Federal standards. An important compliance component of these SIPs are generic opacity limits, which dictate that no stack shall have emissions above a certain percent opacity. Within the wood products industry, these regulations apply to hog fuel boilers and veneer dryers. The standard limit for emissions of all kinds is 20 percent opacity, meaning that only 80 percent of light is able to pass through the plume. However, some States provide exceptions to the opacity limits for certain industries or manufacturing processes depending on the state's SIP.

Also written into each SIP are provisions that require all new stationary sources constructed in a National Ambient Air Quality Standards (NAAQ) attainment area and that have the potential to emit above a specified tonnage per year to install best available control technology (BACT). In addition, these facilities need to obtain a Prevention of Significant Deterioration (PSD) permit (40 CFR 52.21).

Standards of Performance for Fossil Fuel Fired Steam Generating Units (40 CFR 60.40, subpart D), apply to any fossil fuel-fired and wood residue fired steam generating unit that commences construction modification or reconstruction after August 17, 1971, and that has a heat input capacity derived from fossil fuels of greater than 73 megawatts (250 mm BTU/hr). Unlike subparts Db and Dc, descriptions of which follow, the contribution of heat from wood fuels is not considered in determining the heat input capacity since it is not a fossil fuel. The regulation addresses emission standards, compliance and performance test methods, monitoring requirements (including continuous opacity monitoring systems), and reporting requirements for particulate matter, nitrogen oxides, and sulfur dioxide.

Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units (40 CFR 60.40b, subpart Db), apply to any steam generating unit that commences construction, modification, or reconstruction after June 19, 1984 and that has a heat input (heat derived from combustion of fuel only, not exhaust gases, etc.) capacity of at least 29 MW. This includes steam generating units that use wood as a source of fuel. The regulation addresses emission standards, compliance and performance test methods, monitoring requirements, and reporting requirements for particulate matter, nitrogen oxides, and sulfur dioxide. Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units (40 CFR 60.40c, Subpart Dc), apply to any small steam generating unit (2.9 MW to 29 MW) that commences construction, modification, or reconstruction, after June 9, 1989. The regulation addresses requirements for particulate matter and sulfur dioxide emissions.

In addition to applying to steam generating units in general (including wood-fueled plants), the subparts make several specific references to wood-fueled plants. With regard to small units, the regulation provides:

- A formula for allowable sulfur dioxide emissions (based on the amount of fuel used) that excludes wood from the calculation of fuel used
- Particulate matter standards for facilities that combust wood
- Opacity standards for facilities that combust wood
- Nitrogen oxide standards for facilities that combust combinations of wood and other fuels
- Compliance procedures for facilities that combust combinations of wood and other fuels.

Clean Water Act (CWA)

Facilities in the lumber and wood products industry that discharge treated wastewaters from point sources to surface waters of the U.S. must obtain a National Pollutant Discharge Elimination System (NPDES) permit. The NPDES permit program is authorized by Section 402 of the CWA and is implemented through 40 CFR Parts 122 through 124. Other parts of the CFR affecting the NPDES program include Part 125 (technology-based standards), Part 129 (toxic pollutant standards), and Part 130 (water quality-based standards). Discharges to publicly-owned treatment works (POTWs) are subject to the pretreatment standards in 40 CFR Part 403.

Technology-based permit limits are derived from effluent limitation guidelines and standards (ELG); 40 CFR Part 429 for this industry. These limitations incorporate both technology-based and water quality-based limits, depending on which is more protective. Effluent guidelines subdivide the industry based on the following production operations:

- Veneer
- Plywood
- Dry process hardboard
- Wet process hardboard
- Wood preserving—water-borne or nonpressure
- Wood preserving—steam
- Wood preserving—Boulton.

The guidelines set limitations for the pollutants of concern (i.e., BOD_5, TSS, pH, COD, phenols, and oil and grease for those facilities in the wood preserving subcategory).

Resource Conservation and Recovery Act (RCRA)

Wood Preserving Final Rule

EPA amended regulations under RCRA (57 Federal Register 61502, December 30, 1992) by listing as hazardous three categories of wastes generated by wood preserving operations that use chlorophenolic, creosote, and/or inorganic (arsenical and chromium) preservatives.

The listed wastes include wastewaters, process residuals, preservative drippage, and spent preservatives from wood preserving processes at facilities that use or have previously used chlorophenolic formulations, facilities that use creosote formulations, and facilities that use inorganic preservatives containing arsenic or chromium.

Specifically, the following RCRA-regulated hazardous wastes are related to wood preserving operations:

- K001 (bottom sediment sludge from the treatment of wastewaters from wood preserving processes that use creosote or PCP),
- F032 (wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that currently use or have previously used chlorophenolic formulations),
- F034 (wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that use creosote formulations), and
- F035 (wastewaters, process residuals, preservative drippage, and spent formulations from wood preserving processes generated at plants that use inorganic preservatives containing arsenic or chromium).

The rule includes permitting and interim status standards for the drip pads used to assist in the collection of treated wood drippage. These standards include requirements for drip pad design, operation, inspection, and closure.

Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), of 1947 (7 U.S.C. 136) requires registration of pesticides to protect consumers from mislabeled, defective, and ineffective pesticides and to identify products that might be harmful to public health or the environment even when used properly. FIFRA has been amended several times: in 1972, 1975, 1978, 1980, 1988, and 1991. The primary purpose of the 1972 amendments was to ensure that pesticide use would be subject to a thorough review of environmental and human health hazards. The 1988 amendments established schedules and duties for re-registration of pesticides.

Under FIFRA, a registered pesticide must be used in a manner consistent with its label. A registered pesticide may be used in a manner inconsistent with its label in the following situations, unless specifically prohibited by the label:

- Applying a pesticide at a dosage, concentration, or frequency less than that specified on the label
- Applying a pesticide against a pest not specified on the label if the application is to a crop, animal, or site that is specified on the label
- Employing a method of application not specifically prohibited by the label
- Mixing a pesticide with a fertilizer
- Applying a pesticide in conformance with an experimental use permit, or a specific exemption of a Federal or State agency
- Applying a pesticide in a manner that the Administrator determines is consistent with the purposes of FIFRA.

Use of a registered pesticide in a manner inconsistent with its label is unlawful in all other situations.

In addition, the Administrator has the authority to classify pesticides as being for general use or for restricted use only. Pesticides classified as for restricted use only include creosote, pentachlorophenol, and inorganic salts such as chromated copper arsenate, all of which are used in wood-preserving solutions. Such pesticides must be applied only by a certified applicator or under the direct supervision of a certified applicator (section 136j(a)(1)(F)). Standards for certification are established by the Federal government or by State governments with Federal approval.

In a notice published in the Federal Register on January 10, 1986 (Vol. 51, No. 7, January 10, 1986, p. 1334-1348), the EPA established several conditions for registering creosote, pentachlorophenol, and inorganic arsenicals for use in wood preserving, to ensure that such use would not endanger human health standards. EPA and the wood preserving industry agreed that the industry would establish a voluntary Consumer Awareness Program to educate consumers in the proper use of and precautionary practices regarding wood treated with creosote, pentachlorophenol, and inorganic arsenicals, to ensure that such uses would not endanger health standards. Through the program, information about treated wood is disseminated in an information sheet provided to end-users at the time of sale or delivery. An earlier Federal Register notice of July 13, 1984 established terms of registration under which the wood preserving industry agreed to establish air monitoring systems at facilities using formulations containing arsenic.

VI.C. Pending and Proposed Regulatory Requirements

RCRA

As part of EPA's groundwater protection strategy, RCRA prohibits the land disposal of most hazardous wastes until they meet a waste specific treatment standard. While most hazardous wastes have already been assigned treatment standards, EPA must still promulgate two additional rule makings to address newly listed wastes and to make changes to the land disposal restrictions (LDR) program.

When finalized, the Phase III LDR rulemaking will establish treatment standards for some newly listed wastes and will mandate RCRA equivalent treatment be performed upon certain characteristically hazardous wastes that are injected into UIC wells under the Safe Drinking Water Act (SDWA) or managed in Subtitle D surface impoundments prior to discharge pursuant to the Clean Water Act (CWA). By consent decree, EPA must promulgate the final rule for Phase III by January 1996.

Phase IV will similarly restrict other newly listed or identified wastes from land disposal and create influent treatment standards to mitigate the impact of sludges, leaks, and air emissions from surface impoundments that manage decharacterized wastes. Of particular significance to wood preserving industries, Phase IV will restrict the land disposal of F032, F034, and F035. Once the prohibitions for these wastes become effective, they will need to meet numeric treatment levels for specific hazardous constituents commonly found in F032, F034, and F035. Phase IV will also restrict the land disposal of the previously exempt Bevill wastes and adjust the treatment standards applicable to wastes that exhibit the toxicity characteristic for a metal

R0075734

constituent. Subject to the same consent decree, Phase IV has been assigned a final judicial deadline of June 1996.

Clean Air Act

Many of the chemicals used for wood preserving are listed as hazardous air pollutants (HAPs) in Section 112 of the Clean Air Act Amendments of 1990. Treatment processes have been identified as potentially significant sources of these HAPs and, as such, are source categories for which national emission standards may be necessary.

Three emissions standards based on "maximum achievable control technology" (MACT) will be developed for products covered by SIC 24: a wood treatment MACT standard is due by November 15, 1997; a plywood/PB manufacturing MACT standard is due by November 15, 2000; and a flat wood paneling (surface coating) MACT standard is due by November 15, 2000. The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

R0075736

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[2] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS

2 EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

R0075737

identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

R0075738

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Lumber and Wood Products Industry Compliance History

Exhibit 23 provides a Regional breakdown of the five-year enforcement and compliance activities for the lumber and wood products industry. Region IV conducted almost 50 percent of the inspections of lumber and wood product manufacturing facilities performed in the U.S. This large percentage is due to the concentration of lumber and wood product manufacturers in the Southeastern U.S. The exhibit also indicates that 100 percent of the enforcement actions in Regions II and VII were lead by the State while 100 percent of the enforcement actions in Region VIII were lead by EPA.

R0075741

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 24-27 contain summaries of the one and five year enforcement and compliance activities for the lumber and wood products industry, as well as for other selected industries. As indicated in Exhibits 24 and 25, the lumber and wood products industry has an average enforcement to inspection rate compared to other industries. Exhibits 26 and 27 provide a breakdown of inspection and enforcement activities by statute. Of all inspections of lumber and wood products industry facilities, approximately 59 percent were performed under the Resource Conservation and Recovery Act, while approximately 31 percent were conducted under the Clean Air Act. The large percentages of RCRA and CAA inspections for this industry are due in part to facility construction requirements for wood preserving facilities under RCRA, and emissions standards under CAA.

VII.C. Review of Major Legal Actions

VII.C.1. Review of Major Cases

This section provides summary information about major cases that have affected this sector. As indicated in EPA's *Enforcement Accomplishments Report, FY 1991, FY 1992, FY 1993* publications, nine significant enforcement cases were resolved between 1991 and 1993 for the lumber and wood products industry. CAA violations comprised four of these cases, the most of any statute. The remaining cases were distributed fairly evenly, with CERCLA cited twice, RCRA cited twice, and FIFRA cited once.

Three of the CAA violations involved excessive hog fuel (waste wood) boiler emissions. Each of these settlements include Supplemental Environmental Projects (SEPs), such as the installation of boiler precipitators, and penalties were usually under $100,000. A notable exception, however, is *U.S. v. Louisiana-Pacific Corporation and Kirby Forest Industries* (1993). The case involved numerous violations of State Implementation Plans, Prevention of Significant Deterioration requirements, New Source Review requirements, and State permit requirements at its Louisiana-Pacific facilities. The penalty assessed in this case represents the largest CAA civil penalty ever collected by EPA, and the second largest penalty recovered under any environmental statute. Under the terms of a consent decree, Louisiana-Pacific was required to pay $11.1 million in civil penalties and was required to install state-of-the-art pollution control equipment valued at $70 million.

The remaining enforcement actions (under CERCLA, RCRA, and FIFRA) involved sites with contamination caused by wood treatment processes. Penalties assessed against responsible parties at these sites ranged from $68,000 to $350,000. In addition, a CERCLA settlement at the Koppers NPL site required Beazer East, Inc. to perform design, construction, operation, and maintenance of an operable unit valued at approximately $77 million.

VII.C.2. Supplemental Environmental Projects (SEPs)

Supplementary Environmental Projects (SEPs) are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement to provide information on the number and type of SEPs entered into by the Regions. Exhibit 28 contains a representative sample of the Regional responses addressing the lumber and wood products industry. The information contained in the chart is not comprehensive and provides only a sample of the types of SEPs developed for the lumber and wood products industry.

R0075748

Exhibit 28
Supplemental Environmental Projects
Lumber/Wood (SIC 24)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Louisiana-Pacific Corporation Moyie Springs, ID	10	CAA-SIP	Pollution Reduction	$ 102,950	Installation of electrified filter bed to reduce particulate emissions.	$ 67,972	$ 33,986
Merritt Brothers Lumber Company Priest River, ID	10	CAA-SIP	Pollution Reduction	$ 213,881	Installation of electrostatic precipitator to reduce particualte emissions.	$ 20,208	$ 10,104
Rosboro Lumber Company Springfield, OR	10	TSCA	Pollution Reduction	$ 37,230	Early disposal of PCB and PCB-contaminated electrical equipment.	$ 37,230	$ 18,615
JD Lumber, Inc. Priest River, ID	10	CAA-SIP	Pollution Prevention	$ 58,000	Purchase and installation of "hog" machine to reduce particulate emissions.	$ 17,500	$ 8,750
Riley Creek Lumber Company Laclede, ID	10	CAA-SIP	Pollution Reduction	$ 254,000	Purchase and installation of electrostatic precipitator to reduce particulate emissions.	$ 20,000	$ 10,000
Georgia Pacific Zachary, LA	6	CERCLA	Equipment Donation	$ 6,000	Donate emergency and/or computer equipment to the Local Emergency Planning Committee (LEPC) to respond to and/or plan for chemical emergencies. Participate in LEPC activities.	$ 25,000	$ 5,000

VIII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Initiatives

EPA Region X conducted the "Idaho Rule Effectiveness Study" from March 1991 through October 1992 in the Idaho Panhandle. The study focused on sources of PM and was designed to evaluate the effectiveness of Idaho rules regulating particulate emissions: the sources selected for the study, which included many wood products facilities, were located in or near suspected PM10 non-attainment areas. Inspections evaluated the compliance status of 26 sources with respect to Idaho rules concerning emissions limitations, visible emissions limitations for wigwam burners, permits to construct, operating permits, and particulate standards for combustion sources.

EPA's impression following completion of the study was that existing controls were not adequate to comply with applicable regulations. A majority of sources used multiclones as their primary control device. Equipment was not routinely maintained; sources did not appear to have a routine operation and maintenance program (O&M); and many mill managers had little knowledge of the air quality regulations that applied to their facility.

A second conclusion reached by EPA was that environmental responsibilities were secondary to those related to the operation of the mill. Even at the largest facilities, the manager of the mill was also responsible for environmental compliance and reported to a production-oriented management structure.

The study resulted in the following actions and lessons learned:

- Five facilities installed air pollution control equipment that will permanently reduce PM10 emissions by 415 tons/year. These installations were in response to enforcement actions issued by the Region during the study. Two additional facilities eliminated wood waste incineration entirely, reducing PM10 emissions by over 250 tons/year;

R0075750

- General industry awareness of environmental regulations has been improved substantially as a result of the initiated inspections, subsequent enforcement actions, and meetings with EPA;
- It is important for a regulatory agency to conduct unannounced inspections;
- After meeting with EPA, an industry group sponsored an opacity certification school in October 1991 which was attended by numerous industry representatives. Additional certifications have been held each April and October since then;
- The problem of wood waste disposal is not only an air quality problem. Resolution of the enforcement cases developed in this study showed that recognition should be given to multimedia environmental impacts;
- Most of the sources will need to obtain operating permits.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of 17 chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given to participants who met their 1992 goals. The list of chemicals includes 17 high-use chemicals reported in the Toxics Release Inventory.

Twenty-four companies and 43 facilities listed under SIC 24 (lumber and wood products) are currently participating in the 33/50 program. They account for approximately nine percent of the 491 companies under SIC 24. This is lower than the average for all industries of 14 percent participation. (Contact: Mike Burns 202-260-6394 or the 33/50 Program 202-260-6907)

Exhibit 29 lists those companies participating in the 33/50 program that reported under SIC code 24 to TRI. Many of the participating companies listed multiple SIC codes (in no particular order), and are therefore likely to conduct operations in addition to Lumber and Wood Products manufacturing. The table shows the number of facilities within each company that are participating in the 33/50 program; each company's total 1993 releases and transfers of 33/50 chemicals; and the percent reduction in these chemicals since 1988.

Exhibit 29

***** = no numerical goal.**

R0075752

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at 202-233-9065 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn, 202-260-0700 or the WasteWi$e Hotline at 1-800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, 202-260-4407)

NICE³

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE³). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, 303-275-4729)

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Environmental Programs

A consortium of Universities, DOE National Laboratories, Forest Service Researchers, and Industrial partners have submitted a coordinated package of proposals for funding under EPA's "Environmental Technology Initiative" (ETI) program aimed at reducing pollution in wood products production. A total of five proposals were submitted, including: "Diffusion of Pollution Prevention Technology for the Lumber and Wood Products Industry," "Process Control Technology to Mitigate VOC Air Emissions in the Production of Oriented Strand Board," "Improved Wood Adhesives for Reduction of Pollutants for the Wood Panel Manufacturing Industry," "Identification and Quantification of Volatile Organic Compounds Emitted from Lumber Dry Kilns," and "Development of Coupled Biological/Chemical Systems to Reduce VOCs in Lumber and Composite Board Facilities." These projects are currently underway at the Forest Products Laboratory in Madison, Wisconsin.

To explore questions related to potential technologies which might be applicable for control of wood panel plant VOC emissions, the American Forest & Paper Association (AF&PA) Solid Wood Committee and NCASI hosted a workshop in October 1993. It was attended by approximately 100 individuals from industry, State regulatory agencies, EPA, and EPA consultants. At the workshop, the following five control technologies were discussed: ultraviolet oxidation, chemical scrubbing with brominated compounds, furnish dryer exhaust gas recirculation to a wood-fired fuel cell for oxidation of organic compounds, biofiltration, and regenerative thermal oxidation. Topics discussed included: current status of development, performance, problems encountered, potential limitations, energy requirements, and estimated costs. In addition, an EPA representative updated the workshop attendees on the Agency's current efforts to develop a common definition of VOCs and to adopt a standard VOC test method for emissions from solid wood manufacturing plants.

According to the American Forest and Paper Association, wood recycling is on the rise. An estimated 400,000 tons of wood waste were recovered in 1990. This waste included barrels, boxes, brush, Christmas trees, construction and demolition waste, crates, pallets, posts, poles, prunings, railroad ties, sawdust, slab wood, and yard trimmings. The management of wood residue as a component of construction and demolition waste and from urban tree removals is becoming a larger issue as landfill tipping fees rise. Wood residue management is also an increasingly important issue for wood products producers, retailers, and the general public. As virgin wood fiber prices rise, incentives and cost-avoidance pressures are motivating wood users and producers to find ways to fully and most profitably utilize this resource.

The American Forest and Paper Association's American Wood Council is producing a Wood Recycling Reference Handbook to encourage and facilitate wood recycling in the United States. The book will list by state and county where wood residue can be bought for reuse and recycling. The first edition is due out in October, 1995.

VIII.C.2. Summary of Trade Associations

There are numerous trade and professional organizations affiliated with the forest products industry. The largest organization is the American Forest and Paper Association. The smaller associations generally focus on specific types of timber (i.e., hardwoods, pine), or specific types of product (i.e., plywood, particleboard). In addition, there are a number of trade organizations which focus their efforts on specific regions of the country.

General

American Forest and Paper Association 1111 19th Street, NW, Suite 800 Washington, DC 20036 Phone: (202) 463-2700 Fax: (202) 463-2785	Members: 425 Contact: Josephine Cooper

The American Forest and Paper Association (AF&PA) is the national trade association of the forest, pulp, paper, paperboard, and wood products industry. AF&PA represents approximately 500 member companies and related trade associations (whose memberships are in the thousands) which grow, harvest, and process wood and wood fiber; manufacture pulp, paper and paperboard products from both virgin and recovered fiber; and produce solid wood products.

National Council of the Paper Industry for Air and Stream Improvement 260 Madison Avenue New York, NY 10016 Phone: (212) 532-9000 Fax: (212) 779-2849	Members: 100 Staff: 90 Budget: $10,000,000 Contact: Dr. Ronald Yeske, President

Founded in 1943, the National Council of the Paper Industry for Air and Stream Improvement (NCASI) presently conducts research on environmental problems related to industrial forestry and the manufacture of pulp, paper, and wood products. NCASI produces technical documents on environmental issues facing the pulp and paper industry and conducts industry conferences. Publications include: a biweekly bulletin on general issues and a variety of technical bulletins (40/year). NCASI also holds and annual March convention in New York City.

Hardwood

Hardwood Manufactures Association 400 Penn Center Blvd. Pittsburgh, PA 15235 Phone: (412) 346-2222 Fax: (412) 346-2233	Members: 145 Staff: 5 Contact: Susan Regan

Manufacturers of hardwood lumber and hardwood products. Conducts promotion programs; compiles statistics.

National Hardwood Lumber Association PO Box 34518 Memphis, TN 38184-0518 Phone: (901) 377-1818 Fax: (901) 382-6419	Members: 1300 Staff: 40 Contact: Ernest J. Stebbins

United States and Canadian hardwood lumber and veneer manufacturers, distributors, and consumers. Inspects, measures, and certifies hardwood lumber. Maintains inspection training school and conducts short courses at members' lumber yards; conducts management and marketing seminars for the hardwood industry. The organization publishes the National Hardwood Lumber Association-Annual Report and the National Hardwood News, an annual newsletter.

Plywood

Hardwood Plywood & Veneer Association 1825 Michael Faraday Dr. PO Box 2789 Reston, VA 22090 Phone: (703) 435-2537	Members: 150 Staff: 12 Budget: $1,000,000 Contact: E.T. Altman

Manufactures and prefinishers of hardwood plywood; manufacturers of veneer; suppliers of glue, machinery, and other products related to the industry. Conducts laboratory testing of plywood, adhesives, finishes, flamespread, formaldehyde emissions, structural, and smoke density. The association provides public relations, advertising, marketing, and technical services to members. It represents the industry in legislative matters and keep members informed on tariff and trade actions. Publications include the annual *Hardwood Plywood and Veneer News* and *The Executive Brief.*

American Plywood Association PO Box 11700 Tacoma, WA 98411 Phone: (206) 565-6600 Fax: (206) 565-7265	Members: 136 Staff: 180 Budget: $14,000,000 Contact: Gene Zellner

Manufacturers of plywood, oriented strand board and composites. Conducts trade promotion through advertising, publicity, merchandising, and field promotion. The Association provides quality oversight and conducts research to improve products, applications, and manufacturing techniques. Publications include the *Management Report*, and periodic *Plywood Statistics*.

Hardboard

American Hardboard Association 1210 W. Northwest Highway Palatine, IL 60067 Phone: (708) 934-8800 Fax: (708) 934-8803	Members: 4 Staff: Budget: Contact: C. Curtis Peterson

Manufacturers representing major U.S. producers of hardboard.

Particleboard

National Particleboard Association 18928 Premiere Court Gaithersburg, MD 20879 Phone: (301) 670-0604 Fax: (301) 840-1252	Members: 19 Staff: 10 Budget: Contact: Richard Margosian

Mat-formed wood particleboard and medium-density fiberboard manufacturers interested in establishing industry product standards with the American National Standards Institute and quality standards for performance. Sponsors educational programs and publishes promotional and technical bulletins on topics including laminating and veneering.

Wood Preserving

American Wood-Preservers' Association P.O. Box 286 Woodstock, MD 21163-0286 Phone: (410) 465-3169 Fax: (410) 465-3195	Members: 2000 Staff: Budget: Contact: John F. Hall

The association includes processors and users of chemically treated wood and is affiliated with the American Wood Preservers Institute. Publications include the annual *AWPA Book of Standards,* which is a technical handbook covering preservatives and treatments.

American Wood Preservers Institute 1945 Old Gallows Road, Ste. 150 Vienna, VA 22182-3931 Phone: (703) 893-4005 Fax: (703) 893-8492	Members: 150 Staff: 8 Budget: $1,100,000 Contact: Gene Bartlow

The American Wood Preservers Institute is the national trade association representing the wood preserving industry. Its members include manufacturers of treated wood products, manufacturers and distributors of wood preservatives, and providers of allied services. AWPI provides technical forums for the industry, publishes a bi-monthly newsletter, and produces annual Industry Statistical Reports.

Regional

Northeastern Lumber Manufacturers Association 272 Tuttle Rd., Box 87A Cumberland Center, ME 04021 Phone: (207) 829-6901 Fax: (207) 829-4293	Members: 200 Staff: 7 Budget: Contact: Stephen Clark

Northeastern Lumber Manufacturers is an association of hardwood and softwood lumber and timber products manufacturers in New England. The group promotes the interests of the Northeastern lumber manufacturing industry and presents the views of the industry to other organizations, the government, and the public. Publications include the monthly *Northeastern Lumber Manufacturers Association.*

Southeastern Lumber Manufacturers Association PO Box 1788 Forest Park, GA 30051 Phone: (404) 361-1445 Fax: (404) 361-5963	Members: 390 Staff: 10 Budget: $2,000,000 Contact: Ed C. Cone, Jr.

Represents Southeastern hardwood and softwood lumber manufacturers and coordinates efforts of membership to alleviate local, regional, and national problems that affect the regional lumber industry. Publishes a quarterly newsletter, Silva Magazine, and Management Update. SLMA also conducts technical workshops.

R0075760

Southern Forest Products Association PO Box 52468 New Orleans, LA 70152 Phone: (504) 443-4464 Fax: (504) 443-6612	Members: 220 Staff: 31 Budget: $2,856,000 Contact: Karl Lindberg

The Southern Forest Products Association (SFPA) represents Southern pine lumber manufacturers and conducts market development and product promotional programs and government support activities. SFPA publishes a weekly newsletter covering a variety of industry activities.

Western Wood Preservers Institute 601 Main Street, Suite 405 Vancouver, WA 98660 Phone: (360) 693-9958 Fax: (360) 693-9958	Members: 50 Staff: 3 Budget: Contact: Dennis Hayward

WWPI represents the treated wood industry in Western North America. WWPI provides educational information to assist consumers in the selection and proper, safe, and environmentally appropriate use of treated wood products.

Western Wood Products Association Yeon Building 522 SW 5th Ave. Portland, OR 97204-2122 Phone: (503) 224-3930 Fax: (503) 224-3934	Members: 250 Staff: 63 Budget: Contact: Robert Hunt

WWPA is a rules-writing agency (for lumber grades), approved under the American Lumber Standard Committee under the jurisdiction of the Department of Commerce. The Association also provides economic and statistical information on the Western lumber industry, conducts research in wood technology, engineering and performance; provides technical and educational services both domestically and internationally; and published technical and consumer information for Western Lumber end-use.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROSENSE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Integrated environmental policies based upon comprehensive analysis of air, water and land pollution are a logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was originally initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded to its current form. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing this system. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks for sectors not already covered, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE METAL CASTING INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the metal casting industry. Facilities described within this document are described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

The metal casting industry makes parts from molten metal according to an end-user's specifications. Facilities are typically categorized as casting either ferrous or nonferrous products. The metal casting industry described in this notebook is categorized by the Office of Management and Budget (OMB) under Standard Industrial Classification (SIC) codes 332 Iron and Steel Foundries and 336 Nonferrous Foundries (Castings). The die casting industry is contained within the SIC 336 category since die casting establishments primarily cast nonferrous metals. OMB is in the process of changing the SIC code system to a system based on similar production processes called the North American Industrial Classification System (NAICS). (In the NAIC system, iron and steel foundries, nonferrous foundries, and die casters are all classified as NAIC 3315.)

Although both foundries and die casters are included in this notebook, there are significant differences in the industrial processes, products, facility size and environmental impacts between die casters and foundries. Die casting operations, therefore, are often considered separately throughout this notebook.

In addition to metal casting, some foundries and die casters carry out further operations on their cast parts that are not the primary focus of this notebook. Examples include heat treating (e.g. annealing), case hardening, quenching, descaling, cleaning, painting, masking, and plating. Such operations can contribute significantly to a facility's total waste generation. Typical wastes generated during such operations include spent cyanide baths, salt baths, quenchents, abrasive media, solvents and plating wastes. For more information on these processes, refer to the Fabricated Metal Products Industry Sector Notebook.

II.B. Characterization of the Metal Casting Industry

Foundries and die casters that produce ferrous and nonferrous castings generally operate on a job or order basis, manufacturing castings for sale to others companies. Some foundries, termed captive foundries, produce castings as a subdivision of a corporation that uses the castings to produce larger products such as machinery, motor vehicles, appliances or plumbing fixtures.

R0075782

In addition, many facilities do further work on castings such as machining, assembling, and coating.

II.B.1. Product Characterization

About 13 million tons of castings are produced every year in the U.S. (U.S. DOE, 1996). Most of these castings are produced from recycled metals. There are thousands of cast metal products, many of which are incorporated into other products. Almost 90 percent of all manufactured products contain one or more metal castings (LaRue, 1989). It is estimated that on average, every home contains over a ton of castings in the form of pipe fittings, plumbing fixtures, hardware, and furnace and air conditioner parts. Automobiles and other transportation equipment use 50 to 60 percent of all castings produced - in engine blocks, crankshafts, camshafts, cylinder heads, brake drums or calipers, transmission housings, differential casings, U-joints, suspension parts, flywheels, engine mount brackets, front-wheel steering knuckles, hubs, ship propellers, hydraulic valves, locomotive undercarriages, and railroad car wheels. The defense industry also uses a large portion of the castings produced in the U.S. Typical cast parts used by the military include tank tracks and turrets and the tail structure of the F-16 fighter (Walden, 1995). Some of other common castings include: pipes and pipe fittings, valves, pumps, pressure tanks, manhole covers, and cooking utensils. Figure 1 shows the proportion of various types of castings produced in the U.S.

Figure 1: Uses of Cast Metal Products

R0075783

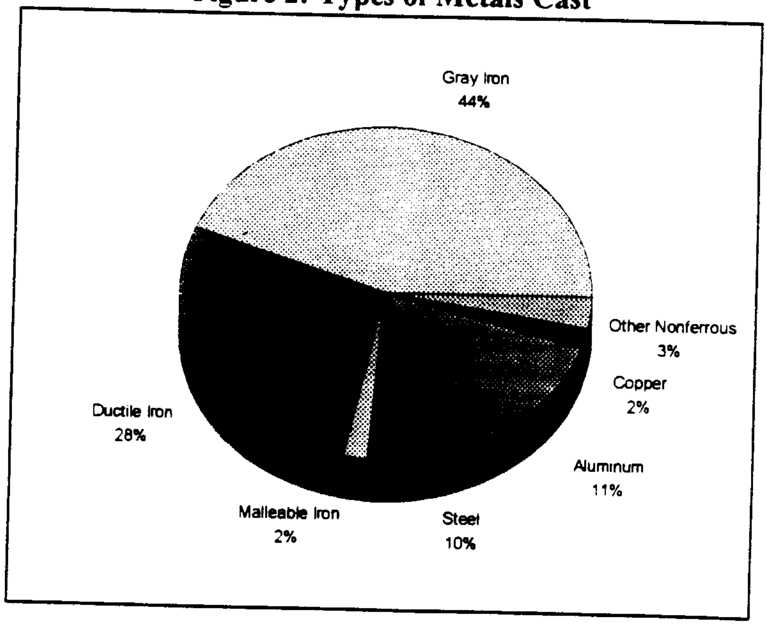
Iron and Steel (Ferrous) Castings

Depending on the desired properties of the product, castings can be formed from many types of metals and metal alloys. Iron and steel (ferrous) castings are categorized by four-digit SIC code by the Bureau of Census according to the type of iron or steel as follows:

SIC 3321 - Gray and Ductile Iron Foundries
SIC 3322 - Malleable Iron Foundries
SIC 3324 - Steel Investment Foundries
SIC 3325 - Steel Foundries, Not Elsewhere Classified

Gray and Ductile Iron make up almost 75 percent of all castings (ferrous and nonferrous) by weight (see Figure 2). Gray iron contains a higher percentage of carbon in the form of flake graphite and has a lower ductility than other types of iron. It is used extensively in the agricultural, heavy equipment, engine, pump, and power transmission industries. Ductile iron has magnesium or cerium added to change the form of the graphite from flake to nodular. This results in increased ductility, stiffness, and tensile strength (Loper, 1985).

Figure 2: Types of Metals Cast



Source: U.S. Department of Energy, 1996.

Malleable iron foundries produce only about two percent of all castings (ferrous and nonferrous). Malleable iron contains small amounts of carbon, silicon, manganese, phosphorus, sulfur and metal alloys to increase strength

R0075784

and endurance. Malleable iron has excellent machinability and a high resistance to atmospheric corrosion. It is often used in the electrical power, conveyor and handling equipment, and railroad industries.

Compared to steel, gray, ductile, and malleable iron are all relatively inexpensive to produce, easy to machine, and are widely used where the superior mechanical properties of steel are not required (Loper, 1985).

Steel castings make up about 10 percent of all castings (ferrous and nonferrous). In general, steel castings have better strength, ductility, heat resistance, durability and weldability than iron castings. There are a number of different classes of steel castings based on the carbon or alloy content, with different mechanical properties. A large number of different alloying metals can be added to steel to increase its strength, heat resistance, or corrosion resistance (Loper, 1985). The steel investment casting method produces high-precision castings, usually smaller castings. Examples of steel investment castings range from machine tools and dies to golf club heads.

Nonferrous Castings

Nonferrous castings are categorized by four-digit SIC code by the Bureau of Census according to the type of metal as follows:

SIC 3363 - Aluminum Die-Castings
SIC 3364 - Nonferrous Die-Castings, Except Aluminum
SIC 3365 - Aluminum Foundries
SIC 3366 - Copper Foundries
SIC 3369 - Nonferrous Foundries, Except Aluminum and Copper

Nonferrous foundries often use the same basic molding and casting techniques as ferrous foundries. Many foundries cast both ferrous and nonferrous metals. Aluminum, copper, zinc, lead, tin, nickel, magnesium and titanium are the nonferrous metals of primary commercial importance. Usually, these metals are cast in combinations with each other or with some of about 40 other elements to make many different nonferrous alloys. A few of the more common nonferrous alloys are: brass, bronze, nickel-copper alloys (Monel), nickel-chromium-iron alloys, aluminum-copper alloys, aluminum-silicon alloys, aluminum-magnesium alloys, and titanium alloys.

Nonferrous metals are used in castings that require specific mechanical properties, machinability, and/or corrosion resistance (Kunsman, 1985). Aluminum and aluminum alloy castings are produced in the largest volumes; 11 percent of all castings (ferrous and nonferrous) by weight are aluminum. Copper and copper alloy castings make up about two percent of all castings by weight (DOE, 1996). Figure 2 shows the proportions of raw material types used in castings in the U.S.

About 9 percent by weight of all cast metal products are produced using die casting techniques (DOE, 1996). Die casting is cost effective for producing large numbers of a casting and can achieve a wide variety of sizes and shapes with a high degree of accuracy. Holes, threads, and gears can be cast, reducing the amount of metal to be machined from the casting. Most die castings are aluminum; however, lead, tin, zinc, copper, nickel, magnesium, titanium, and beryllium alloys are also die cast. Die casts are usually limited to nonferrous metals and are often under ten pounds. A wide variety of products are produced using the die casting process, ranging from tiny wrist watch parts to one-piece automobile engine blocks (Street, 1977). Other typical die castings include: aluminum transmission cases, bearings, bushings, valves, aircraft parts, tableware, jewelry and household appliance parts.

II.B.2. Industry Size and Geographic Distribution

According to the *1992 Census of Manufacturers* data, there are approximately 2,813 metal casting facilities under SIC codes 332 and 336. The payroll for 1992 totaled $5.7 billion for a workforce of 158,000 employees, and value of shipments totaled $18.8 billion. The industry's own estimates of the number of facilities and employment are somewhat higher at 3,100 facilities employing 250,000 in 1994 (Cast Metals Coalition, 1995). Based on the Census of Manufacturers data, the industry is labor intensive. The value of shipments per employee, a measure of labor intensity, is $119,000 that is less than half of the steel manufacturing industry value ($245,000 per employee) and less than seven percent of the petroleum refining industry value ($1.8 million per employee).

Most metal casting facilities in the U.S. are small. About seventy percent of the facilities employ fewer than 50 people (see Table 1). Most metal casting facilities manufacture castings for sale to other companies (U.S. Census of Manufacturers, 1992). An important exception are the relatively few (but large) "captive" foundries operated by large original equipment manufacturers (OEM's) including General Motors, Ford, Chrysler, John Deere, and Caterpillar. OEM's account for a large portion of the castings produced and employ a significant number of the industry's workforce.

Although die casting establishments account for only about 9 percent of cast products by weight, they make up about 20 percent of metal casting establishments and value of sales (U.S. Census of Manufacturers, 1992). In proportion to the industry size, there is very little difference between the size distribution of foundries and die casters.

Table 1: Facility Size Distribution for the Metal Casting Industry

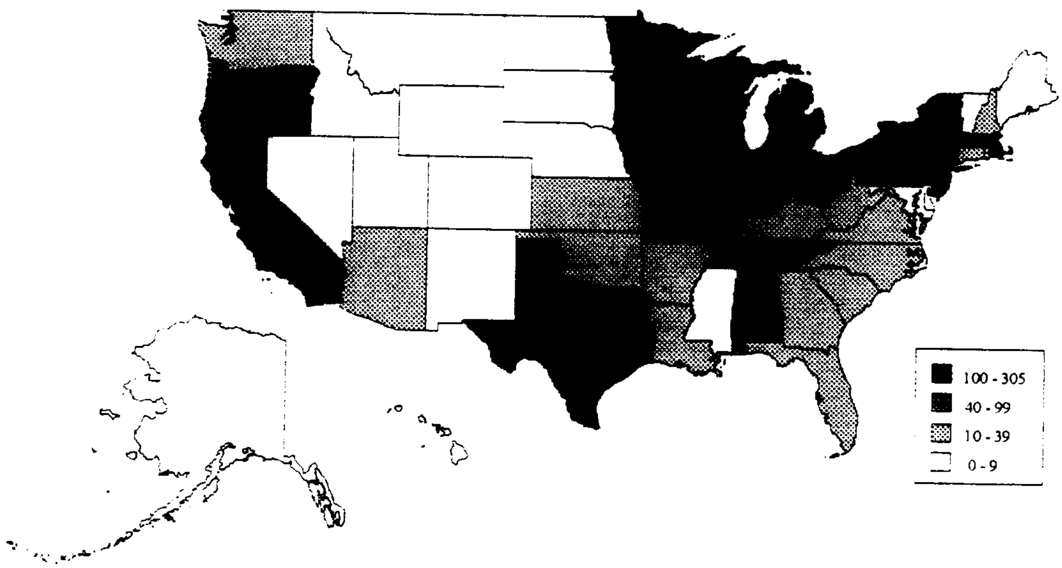
Employees per Facility	Ferrous and Nonferrous Foundries (SIC 332, 3365, 3366, and 3369)		Die Casting Establishments (SIC 3363 and 3364)	
	Number of Facilities	Percentage of Facilities	Number of Facilities	Percentage of Facilities
1-9	742	33%	167	28%
10-49	843	38%	214	36%
50-249	494	22%	186	31%
250-499	90	4%	25	4%
500-2499	43	2%	4	1%
2500 or more	4	0%	0	0%
Total	2216	100%	596	100%

Source: U.S. Department of Commerce, Census of Manufacturers, 1992.

Geographic Distribution

The geographic distribution of the metal casting industry resembles that of the iron and steel industry. The highest geographic concentration of facilities is in the Great Lakes, midwest, southeast regions and California. The top states by number of facilities in order are: California, Ohio, Pennsylvania, Michigan, Illinois, Wisconsin, and Indiana. Figure 3 shows the U.S. distribution of facilities based on 1992 data from the U.S. Census of Manufacturers. Historically, locations for metal casting establishments were selected for their proximity to raw materials (iron, steel, and other metals), coal, and water for cooling, processing, and transportation. Traditional metal casting regions included the Monongahela River valley near Pittsburgh and along the Mahoning River near Youngstown, Ohio. The geographic concentration of the industry is changing as facilities are built where scrap metal and electricity are available at a reasonable cost and there is a local market for the cast products.

Figure 3: Geographic Distribution of Metal Casting Establishments



Source: U.S. Census of Manufacturers, 1992.

Dun & Bradstreet's *Million Dollar Directory,* compiles financial data on U.S. companies including those operating within the metal casting industry. Dun & Bradstreet ranks U.S. companies, whether they are a parent company, subsidiary or division, by sales volume within their assigned 4-digit SIC code. Readers should note that: (1) companies are assigned a 4-digit SIC that resembles their principal industry most closely; and (2) sales figures include total company sales, including subsidiaries and operations (possibly not related to metal casting). Additional sources of company specific financial information include Standard & Poor's *Stock Report Services*, *Ward's Business Directory of U.S. Private and Public Companies*, Moody's Manuals, and annual reports.

II.B.3. Economic Trends

The U.S. metal casting industry experienced an unprecedented drop in production during the 1970's and 1980's. Production of cast metal products declined from 19.6 million tons in 1972 to 11.3 million tons in 1990. During this period over 1,000 metal casting facilities closed (DOE, 1996). A number of reasons have been given for this decline including: decreased U.S. demand for cast metal resulting from decreases in automobile production and smaller, lighter weight vehicles for increased fuel efficiency; increased foreign competition; increased use of substitute materials such as plastics, ceramics, and composites; and increased costs to comply with new environmental and health and safety regulations.

The metal casting industry began to recover in the early 1990's; however, it still produces less than in the early 1970's. The recovery has been attributed to increases in domestic demand in part due to increases in automobile production. In addition, exports of castings have increased and imports have decreased. Between 1993 and 1994 alone the U.S. increased its share of world metal casting production from 18 percent to 20 percent. The increases in production came primarily from increases in capacity utilization at existing facilities rather than an increase in facilities. In fact, the American Foundrymen's Society estimates that the number of metal casting facilities decreased by over 200 between 1990 and 1994 (DOE, 1996).

In 1972, only five percent of all castings were aluminum. Today aluminum accounts for over 11 percent of the market (DOE, 1996). Aluminum castings are steadily comprising a larger share of the castings market as their use in motor vehicle and engine applications continues to grow. To produce lighter weight, more fuel efficient vehicles, the automobile industry is in the process redesigning the engine blocks, heads and other parts of passenger cars and light trucks for aluminum. Cast aluminum is expected to increase from 140 pounds per vehicle in 1995 to 180 pounds per vehicle in 2004. This is primarily at the expense of gray iron which will decrease from 358 pounds per vehicle in 1995 to 215 pounds in 2004 (*Modern Casting*, September, 1995).

The U.S. metal casting industry that emerged from the two decades of decline in the 1970's and 1980's is stronger and more competitive. The industry is developing new markets and recapturing old markets. Research and development has resulted in technological advances that have improved product quality, overall productivity and energy efficiency. Important recent technological advances have included Computer Aided Design (CAD) of molds and castings, the use of sensors and computers to regulate critical parameters within the processes, and the use of programmable robots to perform dangerous, time consuming or repetitive tasks.

To stay competative, the industry has identified the following priority areas for research and development to improve its processes and products:

- improving casting technologies
- developing new casting materials (alloys) and die materials
- developing higher strength and lower weight castings
- improving process controls
- improving dimensional control
- improving the quality of casting material
- reducing casting defects (DOE, March 1996)
- developing environmentally improved materials to meet today's regulations (AFS, 1997)

Research into new casting methods and improvements in the current methods are resulting in improved casting quality, process efficiency, and environmental benefits.

Page 12 intentionally left blank.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the metal casting industry, including the materials and equipment used and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of resource materials and contacts that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the by-products produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A. Industrial Processes in the Metal Casting Industry

Many different metal casting techniques are in use today. They all have in common the construction of a mold with a cavity in the external shape of the desired cast part followed by the introduction of molten metal into the mold.

For the purposes of this profile, the metal casting process has been divided into the following five major operations:

- Pattern Making
- Mold and Core Preparation and Pouring
- Furnace Charge Preparation and Metal Melting
- Shakeout, Cooling and Sand Handling
- Quenching, Finishing, Cleaning and Coating

All five operations may not apply to each casting method. Since the major variations between processes occur in the different types of molds used, Section III.A.2 - Mold and Core Preparation is divided into subsections describing the major casting processes. In addition to the casting techniques described below, there are numerous special processes and variations of those processes that cannot be discussed here. Nevertheless, such processes may play an important role in a facility's efforts to comply with environmental requirements. Refer to Section IX for a list of references providing more detail on casting processes.

R0075792

Note that die casting operations have been presented separately in Section III.A.6. The different processes, equipment, and environmental impacts of die casting do not fit easily into operations outlined above.

III.A.1. Pattern Making

Pattern making, or foundry tooling, requires a high level of skill to achieve the close tolerances required of the patterns and coreboxes. This step is critical in the casting process since the castings produced can be no better than the patterns used to make them. In some pattern making shops, computer-aided drafting (CAD) is used in the design of patterns. Cutter tool paths are designed with computer-aided manufacturing (CAM). Numerical output from these computers is conveyed to computer-numerical-controlled (CNC) machine tools, which then cut the production patterns to shape. Such computer-aided systems have better dimensional accuracy and consistency than hand methods (LaRue, 1989).

Patterns and corebox materials are typically metal, plastic, wood or plaster. Wax and polystyrene are used in the investment and lost foam casting processes, respectively. Pattern makers have a wide range of tools available including wood working and metal machining tools. Mechanical connectors and glues are used to join pattern pieces. Wax, plastic or polyester putty are used as "fillet" to fill or round the inside of square corners (LaRue, 1989).

<u>Wastes Generated</u>
Very little waste is generated during pattern making compared to other foundry operations. Typical pattern shop wastes include scrap pattern materials (wood, plastics, metals, waxes, adhesives, etc.) and particulate emissions from cutting, grinding and sanding operations. Waste solvents and cleaners may be generated from equipment cleaning.

Table 3: Comparison of Several Casting Methods
(approximate and depending upon the metal)

	Green Sand Casting	Permanent Mold Cast	Die Casting	Sand-Shell CO_2-Core Casting	Investment Casting
Relative cost in quantity	low	low	lowest	medium high	highest
Relative cost for small number	lowest	high	highest	medium high	medium
Permissible weight of casting	up to about 1 ton	100 lbs.	60 lbs.	Shell: ozs. - 250 lbs. CO_2: 1/2 lbs. - tons	Ozs. - 100 lbs.
Thinnest section castable, inches	1/10	1/8	1/32	1/10	1/16
Typical dimensional tolerance, inches (not including parting lines)	.012	0.03	0.01	.010	0.01
Relative surface finish	fair to good	good	best	Shell: good CO_2: fair	very good
Relative mechanical properties	good	good	very good	good	fair
Relative ease of casting complex design	fair to good	fair	good	good	best
Relative ease of changing design in production	best	poor	poorest	fair	fair
Range of alloys that can be cast	unlimited	copper base and lower melting point metals preferable	aluminum base and lower melting preferable	unlimited	limited

Source: American Foundrymen's Society, 1981.

III.A.2. Mold and Core Preparation and Pouring

The various processes used to cast metals are largely defined by the procedures and materials used to make the molds and cores. Table 3 summarizes the major casting methods and their applications. A mold and cores (if required) are usually made for each casting. These molds and cores are destroyed and separated from the casting during shakeout (see Section III.A.4 - Shakeout, Cooling and Sand Handling). (Exceptions include the permanent mold process and die casting process in which the molds are used over and over again.) Most sand is reused over and over in other molds; however, a portion of sand becomes spent after a number of uses and must be removed as waste. Mold and core making are, therefore, a large source of foundry wastes.

Sand Molds and Cores

For most sand casting techniques, the following summary of the process applies (see Figure 4). First, engineers design the casting and specify the metal or alloy to be cast. Next, a pattern (replica of the finished piece) is constructed from either plastic, wood, metal, plaster or wax. Usually, the pattern is comprised of two halves. The molding sand is shaped around the pattern halves in a metal box (flask) and then removed, leaving the two mold halves. The top half of the mold (the cope) is assembled with the bottom half (the drag) which sits on a molding board. The interface between the two mold halves is called a parting line. Weights may be places on the cope to help secure the two halves together. The molten metal is poured or injected into a hole in the cope called a sprue or sprue basin which is connected to the mold cavity by runners. The runners, sprue, gates, and risers comprise the mold's gating system, which is designed to carry molten metal smoothly to all parts of the mold. The metal is then allowed to solidify within the space defined by the mold.

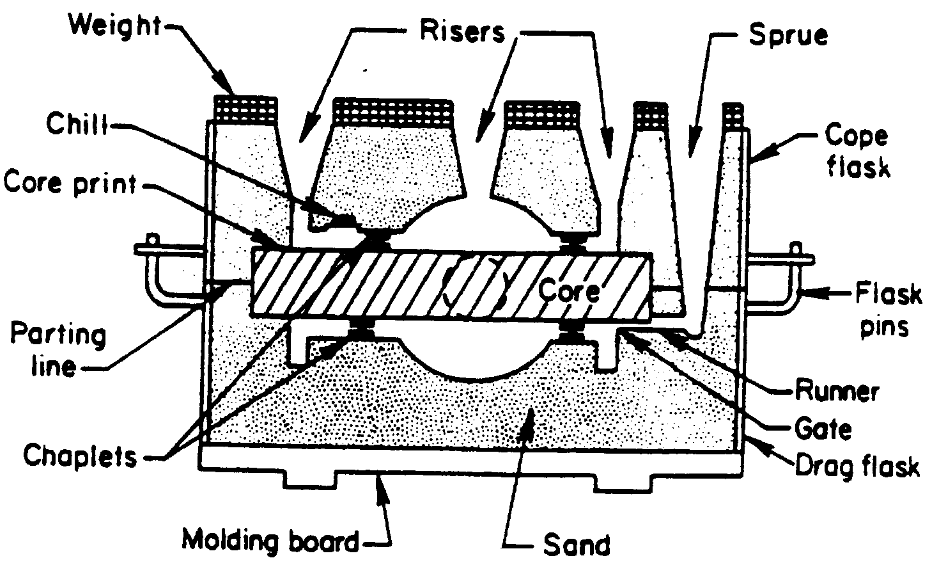
Since the molds themselves only replicate the external shape of the pattern, cores are placed inside the mold to form any internal cavities. Cores are produced in a core box, which is essentially a permanent mold that is developed in conjunction with the pattern. So that molten metal can flow around all sides of the cores, they are supported on core prints (specific locations shaved into the mold) or on by metal supports called chaplets.

Foundry molds and cores are most commonly constructed of sand grains bonded together to form the desired shape of the casting. Sand is used because it is inexpensive, is capable of holding detail, and resists deformation when heated. Sand casting affords a great variety of casting sizes and complexities. Sand also offers the advantage of reuse of a large portion of the sand in future molds. Depending on the quantity of castings, however, the process can be slower and require more man-hours than processes not requiring a separate mold for each casting. In addition, castings from sand molds are dimensionally less accurate than those produced from some other techniques and often require a certain amount of machining (USITC, 1984). The pattern making, melting, cleaning, and finishing operations are essentially the same whether or not sand molds are used. Sand molds and cores will.

however, require the additional operational steps involved with handling quantities of used mold and core sand (see Section III.A.5 - Sand Handling).

In general, the various binding systems can be classified as either clay bonded sand (green sand) or chemically bonded sand. The type of binding system used depends on a number of production variables, including the temperature of the molten metal, the casting size, the types of sand used, and the alloys to be cast. The differences in binding systems can have an impact on the amounts and toxicity of wastes generated and potential releases to the environment.

Figure 4: Sand Mold and Core Cross Section



Source: American Foundrymen's Society, 1981.

Some sand molding techniques utilize chemical binders which then require that the mold halves be heat treated or baked in order to activate the binders. In order to pour molten metal into the mold when the cope and drag are latched together, runners are cut or molded into each half. Runners are connected to the mold cavity with a gate which is usually cut into the cope. A sprue is cut or molded through the cope to the runners such that when molten metal is poured into the hole through the cope, it travels through the runners and gate into the mold. Often risers are also cut into the mold halves. After pouring, risers provide a reservoir of molten metal to areas of the casting that solidify last. If metal is not supplied to these areas, the casting will have shrinkage defects.

Cores require different physical characteristics than molds; therefore, the binding systems used to make cores may be different from those used for molds. Cores must be able to withstand the strong forces of molten metal filling the mold, and often must be removed from small passages in the solidified casting. This means that the binding system used must produce strong, hard cores that will collapse for removal after the casting has hardened. Therefore, cores are typically formed from silica sand (and occasionally olivine or zircon sand), and strong chemical binders (U.S. EPA, 1992). The sand and binder mix is placed in a core box where it hardens into the desired shape and is removed. Hardening, or curing, is accomplished with heat, a chemical reaction, or a catalytic reaction. The major binding systems in use for molds and cores are discussed below.

Green Sand

Green sand is the most common molding process, making about 90% of castings produced in the U.S. Green sand is not used to form cores. Cores are formed using one of the chemical binding systems. Green sand is the only process that uses a moist sand mix. The mixture is made up of about 85 to 95 percent silica (or olivine or zircon) sand, 4 to 10 percent bentonite clay, 2 to 10 percent carbonaceous materials such as powdered (sea) coal, petroleum products, corn starch or wood flour, and 2 to 5 percent water (AFS, 1996). The clay and water act as the binder, holding the sand grains together. The carbonaceous materials burn off when the molten metal is poured into the mold, creating a reducing atmosphere which prevents the metal from oxidizing while it solidifies (U.S. EPA, 1992).

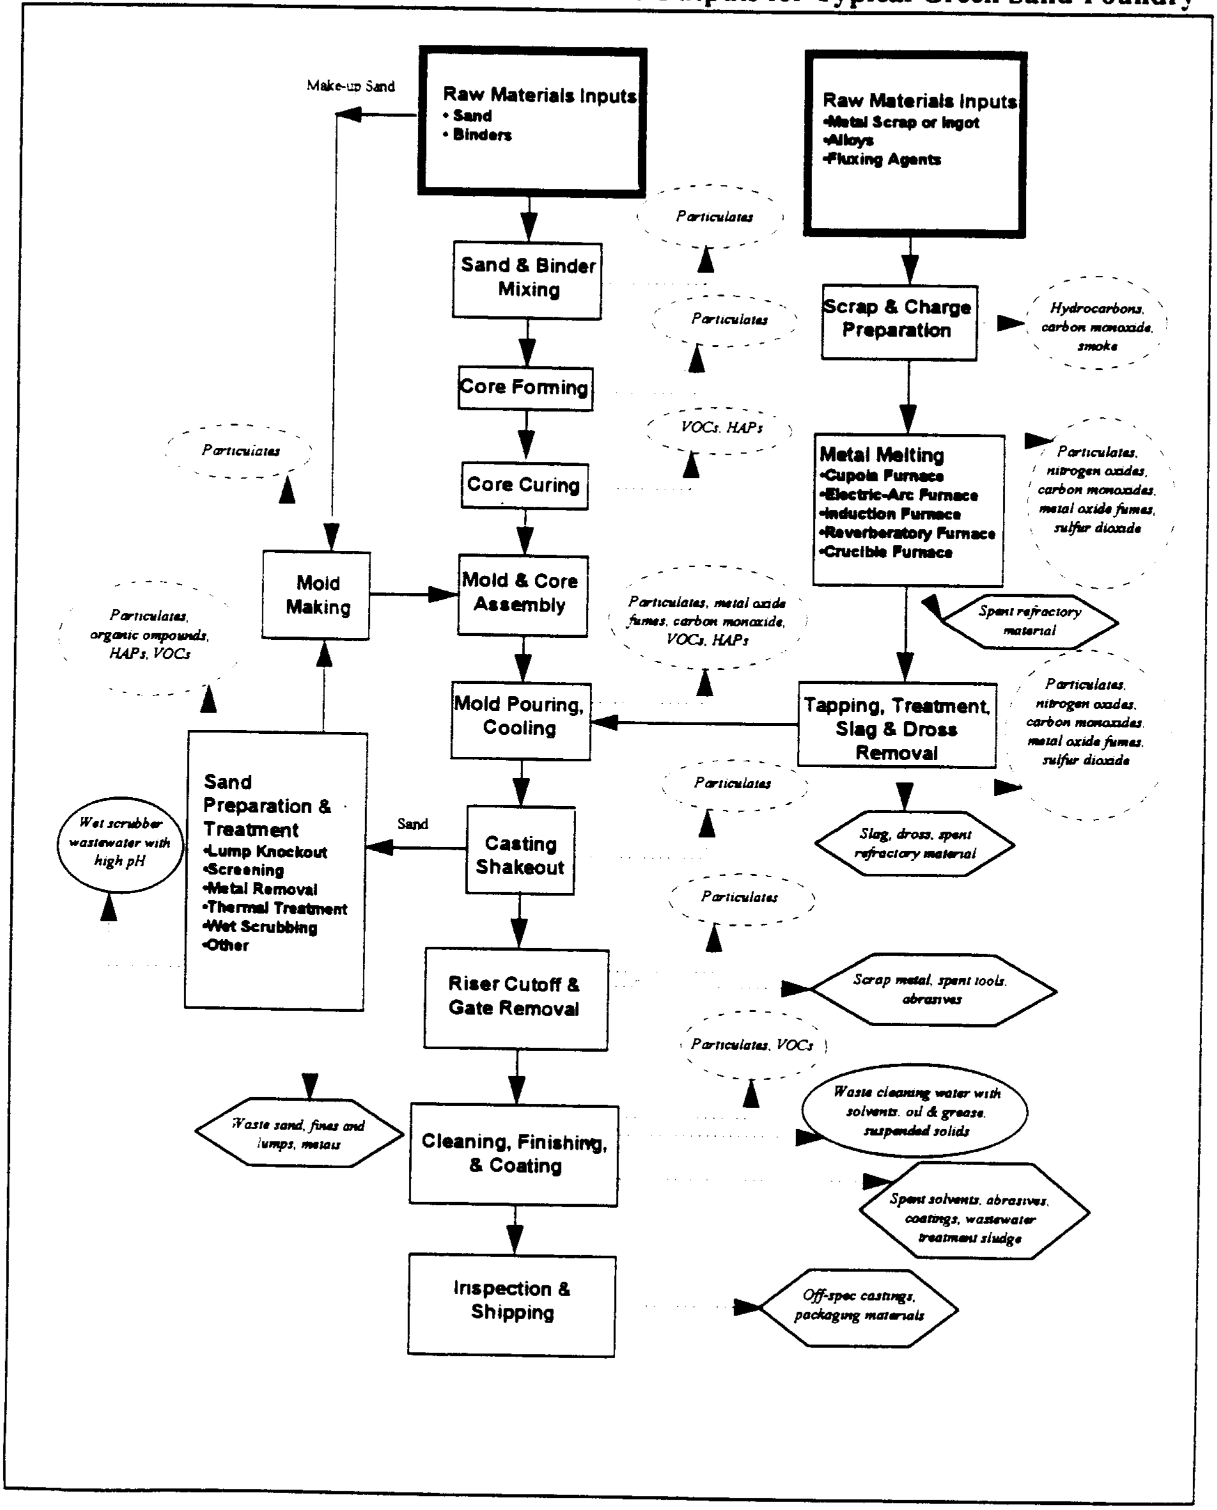
Advantages and Disadvantages

Green sand, as exemplified by its widespread use, has a number of advantages over other casting methods. The process can be used for both ferrous and non-ferrous metal casting and it can handle a more diverse range of products than any other casting method. For example, green sand is used to produce both small precision castings and large castings of up to a ton. If uniform sand compaction and accurate control of sand properties are maintained, very close tolerances can be obtained. The process also has the advantage of requiring a relatively short time to produce a mold compared to many other processes. In addition, the relative simplicity of the process makes it ideally suited to a mechanized process (AFS, 1989).

Wastes Generated

Sand cores that are used in molds break down and become part of the mold sand. Foundries using green sand molds generate waste sand that becomes spent after it has been reused in the process a number of times, as a portion must be disposed of to prevent the build up of grains that are too fine. Waste chemically bonded core sands are also generated. Typically, damaged cores are not reusable and must be disposed as waste.

Figure 5: Process Flow and Potential Pollutant Outputs for Typical Green Sand Foundry



Source: Adapted from Kotzin, Air Pollution Engineering Manual: Steel Foundries, 1992.

R0075798

Particulate emissions are generated during mixing, molding and core making operations. In addition, gaseous and metal fume emissions develop when molten metal is poured into the molds and a portion of the metal volatilizes and condenses. When green sand additives and core sand binders come into contact with the molten metal, they produce gaseous emissions such as carbon monoxide, organic compounds, hydrogen sulfide, sulfur dioxide, nitrous oxide, benzene, phenols, and other hazardous air pollutants (HAPs) (Twarog, 1993). Wastewater containing metals and suspended solids may be generated if the mold is cooled with water.

Chemical Binding Systems

Chemical binding systems are primarily used for core making. Green sand is not used for cores because, chemically bound sand is stronger, harder, and can be more easily removed from the cavity after the metal has solidified. Almost every foundry using sand molds uses one or more of the chemical binding systems described below in constructing sand cores. Although some foundries also use chemical binding systems to construct molds, the much more simple, quick and inexpensive green sand molds described previously dominate the industry in terms of tons of castings produced. When chemical binding systems are used for mold making, the "shell-mold" system is most often used. Chemical bonding systems work through either thermal setting, chemical or catalytic reactions. The major thermal setting systems include: oil-bake, shell core/mold, hot box, and warm box. The major catalytic systems are the no-bake and cold box systems (U.S. EPA, 1993).

Oil-Bake

The traditional method used to produce cores is the oil-bake, or core-oil system. The oil-bake system uses oil and cereal binders mixed with sand. The core is shaped in a core box and then baked in an oven to harden it. Oils used can be natural, such as linseed oil, or synthetic resins, such as phenolic resins. The oil-bake system was used almost exclusively before 1950, but has now been largely replaced by other chemical binding systems (U.S. EPA, 1981).

Shell Core

The shell core system uses sand mixed with synthetic resins and a catalyst. The resins are typically phenolic or furan resins, or mixtures of the two. Often the shell core sand is purchased as dry coated sand. The catalyst is a weak aqueous acid such as ammonium chloride. The sand mixture is shaped in a heated metal core box. Starting from the outside edge of the core box and moving through the sand towards the center of the core box, the heat begins to cure the sand mix into a hard mass. When the outside 1/8 to 3/16 inches of sand has been cured, the core box is inverted. The uncured sand pours out of the core box leaving a hard sand core shell behind. The shell core is then removed from the core box, allowed to cure for an addition few minutes and is then ready for placement in the mold (LaRue, 1989). The system has the advantage of using less sand and binders than other systems; however, shell sand may be more expensive than sand used in other sand processes.

Shell Mold

The shell mold system is similar to the shell core system, but is used to construct molds instead of cores. In this process, metal pattern halves are preheated, coated with a silicone emulsion release agent, and then covered by the resin-coated sand mixture. The heat from the patterns cures the sand mix and the mold is removed after the desired thickness of sand is obtained. The silicone emulsion acts as a mold release allowing the shell mold to be removed from the pattern after curing (LaRue, 1989).

Hot Box Core

The hot box process uses a phenolic or furan resin and a weak acid catalyst that are mixed with sand to coat the surface of the grains. The major difference between this system and the shell core system is that the core box is heated to about 450 to 550 °F until the entire core has become solidified (Twarog, 1993). The system has the advantage of very fast curing times and a sand mix consistency allowing the core boxes to be filled and packed quickly. Therefore, the system is ideal for automation and the mass production of cores. The disadvantage is that more sand and binder is used in this system than in the shell core system.

Warm Box Core

The warm box system is essentially the same as the hot box system, but uses a different catalyst. The catalysts used allow the resin binders to cure at a lower temperature (300 to 400 °F). As with the hot box, the resins used are phenolic and furan resins. Either copper salts or sulfonic acids are used as a catalyst. The advantage over hot box is reduced energy costs for heating (Twarog, 1993).

Cold Box

The cold box process is relatively new to the foundry industry. The system uses a catalytic gas to cure the binders at room temperature. A number of different systems are available including phenolic urethane binder with carbon dioxide gas as the catalyst. Other systems involve different binders (e.g., sodium silicate) and gases, such as sulfur dioxide and dimethylethylamine (DMEA), many of which are flammable or irritants. Compared to other chemical systems, the cold box systems have a short curing time (lower than ten seconds) and therefore are well suited to mass production techniques (AFS, 1981). In addition, the absence of costly oven heating can result in substantial energy savings.

No-Bake

The no-bake or air set binder systems allow curing at room temperature without the use of reactive gases. The no-bake system uses either acid catalysts or esters to cure the binder. The acid catalysts are typically benzene, toluene, sulfonic or phosphoric acids. Binders are either phenolic resins, furan resins, sodium silicate solution or alkyd urethane. The system has the advantage of substantial savings in energy costs (Twarog, 1993).

Advantages and Disadvantages

Cores are necessarily constructed using chemical binders. Molds, however, may be constructed with chemical binders or green sand. The advantages to using chemically bonded molds over green sand molds may include: a longer storage life for the molds, a potentially lower metal pouring temperature, and molds having better dimensional stability and surface finish. Disadvantages include the added costs of chemical binders, the energy costs for curing the binders, added difficulties to reclaim used sand, and environmental and worker safety concerns for air emissions associated with binder chemicals during curing and metal pouring.

Wastes Generated

Solid wastes generated include broken cores and sand that has set up prematurely or inadequately. Waste resins and binders can be generated from spills, residuals in containers, and outdated materials. In addition to fugitive dust from the handling of sand, mold and core making using chemical binding systems may generate gaseous emissions such as carbon monoxide, VOCs and a number of gasses listed as hazardous air pollutants (HAPs) under the Clean Air Act. Emissions occur primarily during heating or curing of the molds and cores, removal of the cores from core boxes, cooling, and pouring of metal into molds (Twarog, 1993). The specific pollutants generated depends on the type of binding system being used. Section III.B Table 4 lists typical air emissions that may be expected from each major type of chemical binding system. Wastewater containing metals, suspended solids, and phenols may be generated if molds are cooled with water.

Permanent Mold Casting

In permanent mold casting, metal molds are used repeatedly. Although the molds deteriorate over time, they can be used to make thousands of castings before being replaced. The process is similar to die casting (see Section III.A.6 on Die Casting) with the exception being that gravity is used to fill the mold rather than external pressure. Permanent molds are designed to be opened, usually on a hinge, so that the castings can be removed. Permanent molds can be used for casting both ferrous and nonferrous metals as long as the mold metal has a higher melting point than the casting metal. Cores from permanent molds can be sand, plaster, collapsible metal or, soluble salts.

When cores are not reusable, the process is often referred to as semipermanent mold casting (AFS, 1981).

Since the process is relatively simple after the mold has been fabricated, and since large numbers of castings are usually produced, permanent mold casting is typically an automated process. The sequence of operations includes an initial cleaning of the mold followed by preheating and the spraying or brushing on of a mold coating. The coating serves the purpose of insulating the molten metal from the relatively cool, heat conducting mold metal. This allows the mold to be filled completely before the metal begins to solidify. The coatings also help produce good surface finish, act as a lubricant to facilitate casting removal, and allow any air in the mold to escape via space between the mold and coating. After coating, cores are then inserted and the mold is closed. The metal is poured and allowed to solidify before opening and ejecting the casting (LaRue, 1989).

Materials

Mold metals are typically made of cast iron. The molds can be very simple or can have a number of sophisticated features, such as ejector pins to remove castings, water cooling channels and sliding core pins. Coatings are typically mixtures of sodium silicate and either vermiculite, talc, clay or bentonite (AFS, 1981).

Advantages and Disadvantages

Permanent molds have the obvious advantage of not requiring the making of a new mold (and the associated time and expenses) for every casting. The elimination of the mold making process results in a more simple overall casting process, a cleaner work environment, and far less waste generation. Because molten metal cools and solidifies much faster in a permanent mold than in a sand mold, a more dense casting with better mechanical properties is obtained. The process can also produce castings with a high level of dimensional accuracy and good surface finish (AFS, 1981). One disadvantage is the high cost of tooling, which includes the initial cost of casting and machining the permanent mold. In addition, the shapes and sizes of castings are limited due to the impossibility of removing certain shapes from the molds (USITC, 1984).

Wastes Generated

Compared to sand casting operations, relatively little waste is generated in the permanent mold process. Some foundries force cool the hot permanent molds with water sprayed or flushed over the mold. The waste cooling water may pick up contaminants from the mold such as metals and mold coatings. Fugitive dust and waste sand or plaster are generated if cores are fabricated of sand or plaster, respectively. Waste coating material may also be generated during cleaning of the mold.

R0075802

Plaster Mold Casting

The conventional plaster molding process is similar to the sand molding processes. In cope and drag flasks, a plaster slurry mix is poured over the pattern halves. When the plaster has set, the patterns are removed and the mold halves are baked to remove any water (USITC, 1984). Since even small amounts of water will, when quickly heated during pouring, expand to steam and adversely affect the casting, drying is a critical step in plaster mold casting. Oven temperatures may be as high as 800°F for as long as 16 to 36 hours. As in the sand mold processes, the cores are inserted, and the dried mold halves are attached prior to pouring the molten metal. The plaster molds are destroyed during the shakeout process. Plaster or sand cores may be used in the process.

The conventional plaster molding process described here is the most common of a number of plaster mold casting processes in use. Other processes include the foamed plaster casting process, the Antioch casting process and the match plate pattern casting process (AFS, 1981).

Materials
The plasters used in plaster mold casting are very strong, hard gypsum (calcium sulfate) cements mixed with either fibrous talcs, finely ground silica, pumice stone, clay or graphite. Plaster mixtures may also be comprised of up to 50 percent sand (AFS, 1981).

Advantages and Disadvantages
The plaster mold process can produce castings with excellent surface detail, complex and intricate configurations, and high dimensional accuracy. Plaster mold castings are also light, typically under 20 pounds (USITC, 1994). The process is limited to nonferrous metals because ferrous metals will react with the sulfur in the gypsum, creating defects on the casting surface (AFS, 1981). Plaster mold casting is more expensive than sand casting, and has a longer process time from mold construction to metal pouring. The process is only used, therefore, when the desired results cannot be obtained through sand casting or when the finer detail and surface finish will result in substantial savings in machining costs.

Wastes Generated
Waste mold plaster and fugitive dust can be generated using this process. Waste sand can also be generated, depending on the type of cores used.

Investment/Lost Wax Casting

Investment casting processes use a pattern or replica that is consumed, or lost, from the mold material when heated. The mold-making process results in a

R0075803

one-piece destroyable mold. The most common type of investment casting, the lost wax process, uses patterns fabricated from wax. Plastic patterns, however, are also fairly common in investment casting.

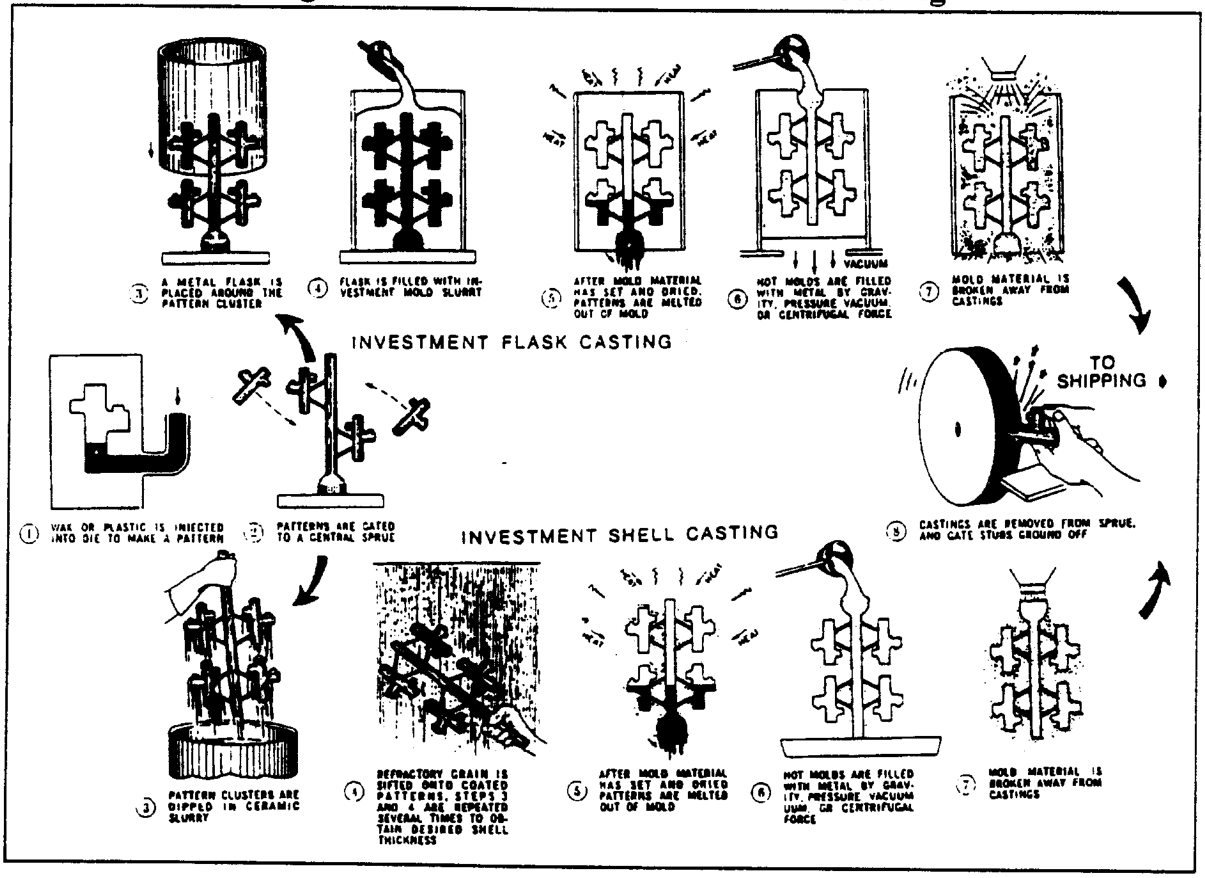
The process begins with the production of a wax or plastic replica of the part. Replicas are usually mass produced by injecting the wax or plastic into a die (metal mold) in a liquid or semi-liquid state. Replicas are attached to a gating system (sprue and runners) constructed of the same material to form a tree assembly (see Figure 6). The assembly is coated with a specially formulated heat resistant refractory slurry mixture which is allowed to harden around the wax or plastic assembly forming the mold (USITC, 1984).

In the investment *flask* casting method, the assembly is placed in a flask and then covered with a refractory slurry which is allowed to harden (see Figure 6). In the more common investment *shell* casting method, the assembly is dipped in a refractory slurry and sand is sifted onto the coated pattern assembly and allowed to harden. This process is repeated until the desired shell thickness is reached (LaRue, 1989). In both methods, the assembly is then melted out of the mold. Some investment casting foundries are able to recover the melted wax and reuse a portion in the pattern making process. The resulting mold assemblies are then heated to remove any residual pattern material and to further cure the binder system. The mold is then ready for the pouring of molten metal into the central sprue which will travel through the individual sprues and runners filling the mold.

Although normally not necessary, cores can be used in investment casting for complex interior shapes. The cores are inserted during the pattern making step. The cores are placed in the pattern die and pattern wax or plastic is injected around the core. After the pattern is removed from the die, the cores are removed. Cores used in investment casting are typically collapsible metal assemblies or soluble salt materials which can be leached out with water or a dilute hydrochloric acid solution.

In addition to the investment flask and shell mold casting methods described above, a number of methods have been developed which use reusable master patterns. These processes were developed to eliminate production of expendable patterns, one of the most costly and time-consuming steps in the casting process. One process, called the Shaw Process, uses a refractory slurry containing ethyl silicate. The slurry cures initially to a flexible gel which can be removed from the pattern in two halves. The flexible mold halves can then be further cured at high temperatures until a hard mold is formed ready for assembly and pouring (AFS, 1981).

Figure 6: Investment Flask and Shell Casting



Source: American Foundrymen's Society, 1981.

Materials

The refractory slurries used in both investment flask and shell casting are comprised of binders and refractory materials. Refractory materials include silica, aluminum silicates, zircon, and alumina. Binders include silica sols (very small silica particles suspended in water), hydrolyzed ethyl silicate, sodium and potassium silicate, and gypsum type plasters. Ethyl silicate is typically hydrolyzed at the foundry by adding alcohol, water, and hydrochloric acid to the ethyl silicate as a catalyst (AFS, 1981).

Pattern materials are most commonly wax or polystyrene. Wax materials can be synthetic, natural, or a combination. Many different formulations are available with varying strengths, hardness, melting points, setting times, and compatibilities, depending on the specific casting requirements.

R0075805

Advantages and Disadvantages

The investment casting process produces castings with a higher degree of dimensional accuracy than any other casting process. The process can also produce castings with a high level of detail and complexity and excellent surface finish. Investment casting is used to create both ferrous and nonferrous precision pieces such as dental crowns, fillings and dentures, jewelry, and scientific instruments. The costs of investment casting are generally higher than for other casting processes due in part to the high initial costs of pattern die-making (USITC, 1984). In addition, the relatively large number of steps in the process is less amenable to automation than many other casting methods.

Wastes Generated

Waste refractory material, waxes, and plastic are the largest volume wastes generated. Air emissions are primarily particulates. Wastewater with suspended and dissolved solids and low pH may also be generated if soluble salt cores are used.

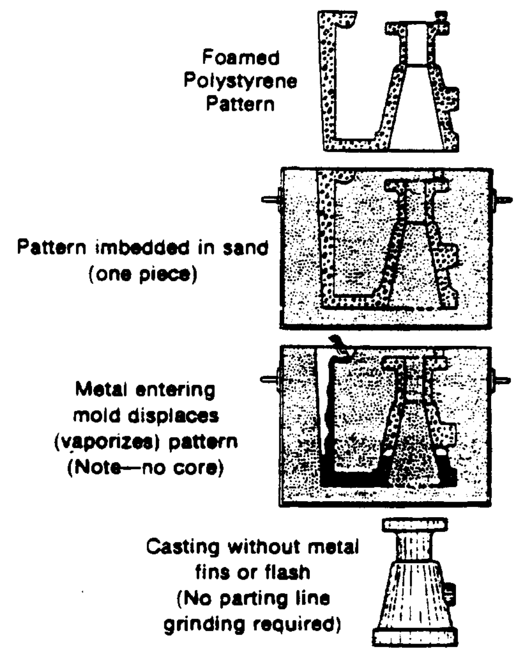
Lost Foam Casting

The lost foam casting process, also known as Expanded Polystyrene (EPS) casting, and cavityless casting, is a relatively new process that is gaining increased use. The process is similar to investment casting in that an expendable polystyrene pattern is used to make a one-piece expendable mold. As in investment casting, gating systems are attached to the patterns, and the assembly is coated with a specially formulated gas permeable refractory slurry. When the refractory slurry has hardened, the assembly is positioned in a flask, and unbonded sand is poured around the mold and compacted into any internal cavities. Molten metal is then poured into the polystyrene pattern which vaporizes and is replaced by the metal (see Figure 7). When the metal has solidified, the flask is emptied onto a steel grate for shakeout. The loose sand falls through the grate and can be reused without treatment. The refractory material is broken away from the casting in the usual manner (AFS, 1981).

Materials

Refractory slurries for lost foam casting must produce a coating strong enough to prevent the loose sand around the coated assembly from collapsing into the cavity as the pattern vaporizes. Coatings must also be permeable to allow the polystyrene vapors to escape from the mold cavity, through the coating, into the sand and out of the flask. Flasks for this process have side vents which allow the vapors to escape (AFS, 1981).

Figure 7: Lost Foam Casting Cross Sections



Source: American Foundrymen's Society, 1981.

Polystyrene patterns can be fabricated from polystyrene boards or by molding polystyrene beads. Patterns from boards are fabricated using normal pattern forming tools (see Section III.A.1). The boards are available in various sizes and thicknesses, and can be glued together to increase thickness if needed. Molded polystyrene patterns begin as small beads of expandable polystyrene product. The beads are pre-expanded to the required density using a vacuum, steam, or hot air processes. In general, the aim is to reduce the bead density as much as possible in order to minimize the volume of vapors to be vented during casting. If vapors are generated faster than can be vented, casting defects will result. The expanded polystyrene beads are blown into a cast aluminum mold. Steam is used to heat the beads causing them to expand further, fill void areas, and bond together. The mold and pattern are allowed to cool, and the pattern is ejected (AFS, 1981).

Advantages and Disadvantages

The lost foam process can be used for precision castings of ferrous and nonferrous metals of any size. In addition to being capable of producing highly accurate, complex castings with thin walls, good surface finish, and no parting lines, there are numerous practical advantages to the process. For example, there are far fewer steps involved in lost foam casting compared to sand casting. Core making and setting is not necessary, nor is the mixing of

R0075807

large amounts of sand and binders. Shakeout and sand handling is a matter of pouring out the sand which is mostly reusable without any treatment since binders are not used. Some portion of sand may need to be removed to avoid the buildup of styrene in the sand. The flasks used are less expensive and easier to use since there are no cope and drag halves to be fastened together. The reduced labor and material costs make lost foam casting an economical alternative to many traditional casting methods. Although the potential exists for other metals to be cast, currently only aluminum and gray and ductile iron are cast using this method (AFS, 1981). In addition there are some limitations in using the technique to cast low carbon alloys (SFSA, 1997).

Wastes Generated

The large quantities of polystyrene vapors produced during lost foam casting can be flammable and may contain hazardous air pollutants (HAPs). Other possible air emissions are particulates related to the use of sand. Waste sand and refractory materials containing styrene may also be generated.

III.A.3. Furnace Charge Preparation and Metal Melting

Foundries typically use recycled scrap metals as their primary source of metal. and use metal ingot as a secondary source when scrap is not available. The first step in metal melting is preparation of the scrap materials. Preparation. which also may be done by the foundry's metal supplier, consists of cutting the materials to the proper size for the furnace and cleaning and degreasing the materials. Cleaning and degreasing can be accomplished with solvents or by a precombustion step to burn off any organic contaminants (Kotzin, 1992). Prepared scrap metal is weighed and additional metal, alloys, and flux may be added prior to adding the metal to the furnace. Adding metal to a furnace is called "charging." (Alloys may also be added at various stages of the melt or as the ladle is filled.)

Flux is a material added to the furnace charge or to the molten metal to remove impurities. Flux unites with impurities to form dross or slag, which rises to the surface of the molten metal where it is removed before pouring (LaRue, 1989). The slag material on the molten metal surface helps to prevent oxidation of the metal. Flux is often chloride or fluoride salts that have an affinity to bind with certain contaminants. The use of salt fluxes may result in emissions of acid gasses.

Five types of furnaces are commonly used to melt metal in foundries: cupola, electric arc, reverberatory, induction and crucible (see Figure 8). Some foundries operate more than one type of furnace and may even transfer molten metal between furnace types in order to make best use of the best features of each.

Cupola Furnaces

The cupola furnace is primarily used to melt gray, malleable, or ductile iron. The furnace is a hollow vertical cylinder on legs and lined with refractory material. Hinged doors at the bottom allow the furnace to be emptied when not in use. When charging the furnace, the doors are closed and a bed of sand is placed at the bottom of the furnace, covering the doors. Alternating layers of coke for fuel and scrap metal, alloys and flux are placed over the sand. Although air, or oxygen enriched air, is forced through the layers with a blower, cupolas require a reducing atmosphere to maintain the coke bed. Heat from the burning coke melts the scrap metal and flux, which drip to the bottom sand layer. In addition, the burning of coke under reducing conditions raises the carbon content of the metal charge to the casting specifications. A hole level with the top of the sand allows molten metal to be drained off, or "tapped." A higher hole allows slag to be drawn off. Additional charges can be added to the furnace as needed (LaRue, 1989).

Electric Arc Furnaces

Electric arc furnaces are used for melting cast iron or steel. The furnace consists of a saucer-shaped hearth of refractory material for collecting the molten metal with refractory material lining the sides and top of the furnace. Two or three carbon electrodes penetrate the furnace from the top or sides. The scrap metal charge is placed on the hearth and melted by the heat from an electric arc formed between the electrodes. When the electric arc comes into contact with the metal, it is a direct-arc furnace and when the electric arc does not actually touch the metal it is an indirect-arc furnace. Molten metal is typically drawn off through a spout by tipping the furnace. Alloying metal can be added, and slag can be removed, through doors in the walls of the furnace (LaRue, 1989). Electric arc furnaces have the advantage of not requiring incoming scrap to be clean. One disadvantage is that they do not allow precise metallurgical adjustments to the molten metal.

Reverberatory Furnaces

Reverberatory furnaces are primarily used to melt large quantities of nonferrous metals. Metal is placed on a saucer-shaped hearth lined with refractory material on all sides. Hot air and combustion gasses from oil or gas burners are blown over the metal and exhausted out of the furnace. The heat melts the metal and more charge is added until the level of molten metal is high enough to run out of a spout in the hearth and into a well from which it can be ladled out (LaRue, 1989).

Induction Furnaces

Induction furnaces are used to melt both ferrous and non-ferrous metals. There are several types of induction furnaces, but all create a strong magnetic field by passing an electric current through a coil wrapped around the furnace. The magnetic field in turn creates a voltage across and subsequently an electric current through the metal to be melted. The electrical resistance of the metal produces heat which melts the metal. Induction furnaces are very efficient and are made in a wide range of sizes (LaRue, 1989). Induction furnaces require cleaner scrap than electric arc furnaces, however, they do allow precise metallurgical adjustments.

Crucible Furnaces

Crucible furnaces are primarily used to melt smaller amounts of nonferrous metals than other furnace types. The crucible or refractory container is heated in a furnace fired with natural gas or liquid propane. The metal in the crucible melts, and can be ladled from the crucible or poured directly by tipping the crucible (LaRue, 1989).

Wastes Generated

Cupola, reverberatory and electric arc furnaces may emit particulate matter, carbon monoxide, hydrocarbons, sulfur dioxide, nitrogen oxides, small quantities of chloride and fluoride compounds, and metallic fumes from the condensation of volatilized metal and metal oxides. Induction furnaces and crucible furnaces emit relatively small amounts of particulates, hydrocarbons, and carbon monoxide emissions. The highest concentration of furnace emissions occur when furnaces are opened for charging, alloying, slag removal, and tapping (Kotzin, 1992). Particulate emissions can be especially high during alloying and the introduction of additives. For example, if magnesium is added to molten metal to produce ductile iron, a strong reaction ensues, with the potential to release magnesium oxides and metallic fumes (NADCA, 1996).

Furnace emissions are often controlled with wet scrubbers. Wet scrubber wastewater can be generated in large quantities (up to 3,000 gallons per minute) in facilities using large cupola furnaces. This water may contain metals and phenols, and is typically highly alkaline or acidic and is neutralized before being discharged to the POTW (AFS Air Quality Committee, 1992). Non-contact cooling water with little or no contamination may also be generated.

Scrap preparation using thermal treatment will emit smoke, organic compounds and carbon monoxide. Other wastes may include waste solvents if solvents are used to prepare metal for charging. Slag is also generated during metal melting operations. Hazardous slag can be generated if the charge materials contain enough toxic metals such as lead and chromium or if calcium carbide is used in the metal to remove sulfur compounds (see Section III.B.1) (U.S. EPA, 1992).

III.A.4. Shakeout, Cooling and Sand Handling

For those foundries using sand molding and core making techniques, castings need to be cooled and separated from the sand mold. After molten metal has been ladled into the mold and begins to solidify, it is transported to a cooling area where the casting solidifies before being separated from the mold. Larger, more mechanized foundries use automatic conveyor systems to transfer the casting and mold through a cooling tunnel on the way to the shakeout area. Less mechanized foundries allow the castings to cool on the shop floor. In the shakeout area, molds are typically placed on vibrating grids or conveyors to shake the sand loose from the casting. In some foundries, the mold may be separated from the casting manually (EPA, 1986).

Sand casting techniques can generate substantial volumes of waste sand. Many foundries reuse a large portion of this sand and only remove a small portion as waste. Waste sand removed from the foundry is primarily made up of fine grains that build up as the sand is reused over and over. Most foundries, therefore, have a large multi-step sand handling operation for capturing and conditioning the reusable sand. Larger foundries often have conveyorized sand-handling systems working continuously. Smaller, less mechanized foundries often use heavy equipment (e.g., front-end loaders) in a batch process (U.S. EPA, 1992). Increasingly, foundry waste sand is being sent off-site for use as a construction material (see Section V).

Sand handling operations receive sand directly from the shakeout step or from an intermediate sand storage area. A typical first step in sand handling is lump knockout. Sand lumps occur when the binders used in sand cores only partially degrade after exposure to the heat of molten metal. The lumps, or core butts, may be crushed and recycled into molding sand during this step. They can also be disposed as waste material. A magnetic separation operation is often used in ferrous foundries to remove pieces of metal from the sand. Other steps involve screening to remove fines that build up over time, and cooling by aeration. In addition, some foundries treat mold and core sand thermally to remove binders and organic impurities (U.S. EPA, 1992).

Wastes Generated
Shakeout, cooling, and sand handling operations generate waste sand and fines possibly containing metals. In addition, particulate emissions are generated during these operations. If thermal treatment units are used to reclaim chemically bonded sands, emissions such as carbon monoxide, organic compounds, and other gasses can be expected.

R0075812

III.A.5. Quenching, Finishing, Cleaning and Coating

Rapid cooling of hot castings by quenching in a water bath is practiced by some foundries and die casters to cool and solidify the casting rapidly (to speed the process) and to achieve certain metallurgical properties. The water bath may be plain water or may contain chemical additives to prevent oxidation.

Some amount of finishing and cleaning is required for all castings; however, the degree and specific types of operations will depend largely on the casting specifications and the casting process used. Finishing and cleaning operations can be a significant portion of the overall cost to produce a casting. Foundries, therefore, often search for casting techniques and mold designs that will reduce the finishing needed.

Finishing operations begin once the casting is shaken out and cooled. Hammers, band saws, abrasive cutting wheels, flame cut-off devices, and air-carbon arc devices may be used to remove the risers, runners, and sprues of the gating system. Metal fins at the parting lines (lines on a casting corresponding to the interface between the cope and drag of a mold) are removed with chipping hammers and grinders. Residual refractory material and oxides are typically removed by sand blasting or steel shot blasting, which can also be used to give the casting a uniform and more attractive surface appearance (U.S. EPA, 1992).

The cleaning of castings precedes any coating operations to ensure that the coating will adhere to the metal. Chemical cleaning and coating operations are often contracted out to off-site firms, but are sometimes carried out at the foundries. Scale, rust, oxides, oil, grease, and dirt can be chemically removed from the surface using organic solvents (typically chlorinated solvents, although naphtha, methanol, and toluene are also used), emulsifiers, pressurized water, abrasives, alkaline agents (caustic soda, soda ash, alkaline silicates, and phosphates), or acid pickling. The pickling process involves the cleaning of the metal surface with inorganic acids such as hydrochloric acid, sulfuric acid, or nitric acid. Castings generally pass from the pickling bath through a series of rinses. Molten salt baths are also used to clean complex interior passages in castings (U.S. EPA, 1992).

Castings are often given a coating to inhibit oxidation, resist deterioration, or improve appearance. Common coating operations include: painting, electroplating, electroless nickel plating, hard facing, hot dipping, thermal spraying, diffusion, conversion, porcelain enameling, and organic or fused dry-resin coating (U.S. EPA, 1992).

Wastes Generated
Casting quench water may contain phenols, oil and grease, suspended solids, and metals (e.g., copper, lead, zinc). Metal-bearing sludges may be generated when quench baths are cleaned out (EPA, 1995).

Finishing operations may generate particulate air emissions. Wastewater may contain cutting oils, ethylene glycol, and metals. Solid wastes include metal chips and spent cutting oils (EPA, 1995).

Cleaning and coating may generate air emissions of VOCs from painting, coating and solvent cleaning; acid mists and metal ion mists from anodizing, plating, polishing, hot dip coating, etching, and chemical conversion coating. Wastewater may contain solvents, metals, metal salts, cyanides, and high or low pH. Solid wastes include cyanide and metal-bearing sludges, spent solvents and paints, and spent plating baths (EPA, 1995).

III.A.6. Die Casting

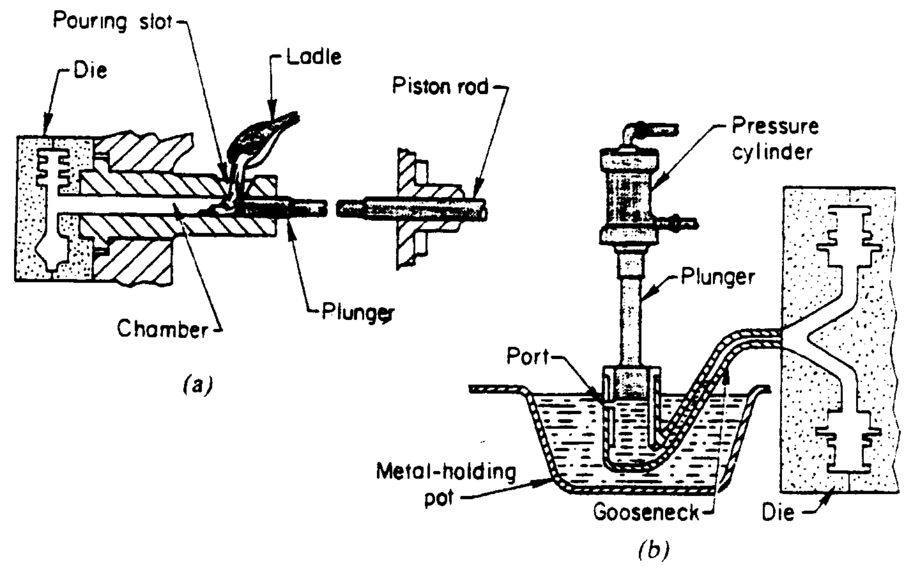
The term "die casting" usually implies "pressure die casting." The process utilizes a permanent die (metal mold) in which molten metal is forced under high pressure. Dies are usually made from two blocks of steel, each containing part of the cavity, which are locked together while the casting is being made. Retractable and removable cores are used to form internal surfaces. The metal is held under pressure until it cools and solidifies. The die halves are then opened and the casting is removed, usually by means of an automatic ejection system. Dies are preheated and lubricated before being used, and are either air- or water-cooled to maintain the desired operating temperature (Loper, 1985). Metal is typically melted on site from prealloyed ingot, or by blending the alloying constituents (or occasionally metal scrap). Some aluminum die casters, however, purchase molten aluminum and store it on site in a holding furnace (NADCA, 1996). Two basic types of die casting machines are used: hot chamber and cold-chamber (see Figure 9).

Die casting machines
Hot-chamber die casting machines are comprised of a molten metal reservoir, the die, and a metal-transferring device which automatically withdraws molten metal from the reservoir and forces it under pressure into the die. A steel piston and cylinder system is often used to create the necessary pressure within the die. Pressures can range from a few hundred to over 5,000 psi. Certain metals, such as aluminum alloys, zinc alloys, and pure zinc cannot be used in hot-chamber die casting because they rapidly attack the iron in the piston and cylinder. These metals, therefore, require a different type of casting machine, called a gooseneck. A gooseneck machine utilizes a cast-iron channel to transfer the molten metal from the reservoir to the die (see Figure 9(b)). After the gooseneck is brought into contact with the die.

compressed air is applied to the molten metal. Pressures are typically in the range of 350 to 500 psi (Loper, 1985).

Cold chamber machines have molten metal reservoirs separate from the casting machine. Just enough metal for one casting is ladled by hand or mechanically into a small chamber, from which it is forced into the die under high pressure (see Figure 9(a)). Pressure is produced through a hydraulic system connected to a piston, and is typically in the range of a few thousand psi to 10,000 psi. In cold chamber machines, the metal is just above the melting point and is in a slush-like state. Since the metal is in contact with the piston and cylinder for only a short period of time, the process is applicable to aluminum alloys, magnesium alloys, zinc alloys, and even high melting-point alloys such as brasses and bronzes (Loper, 1985).

Figure 9: Cold (a), and Hot Chamber (b), Die Casting Machines



Source: American Foundrymen's Society, 1981.

Die Lubrication

Proper lubrication of dies and plungers is essential for successful die casting. Die lubrication affects the casting quality, density, and surface finish, the ease of cavity fill, and the ease of casting ejection. Proper lubrication can also speed the casting rate, reduce maintenance, and reduce build up of material on the die face (Street, 1977).

Die lubrication can be manual or automatic. In manual systems, the die casting machine operator uses a hand held spray gun to apply lubricant to the

R0075815

die surface just before the die is closed. Automatic systems use either fixed or reciprocating spray systems to apply lubricant (Allsop, 1983).

There are many types and formulations of lubricants on the market. No one lubricant meets the requirements for all die casters. The specific lubricant formulation used depends on a number of factors, including: the metal being cast, the temperatures of casting, the lubricant application method, the surface finish requirements, the complexity of the casting, and the type of ejection system. Although specific formulations are proprietary, in general, lubricants are a mixture of a lubricant and a carrier material. Formulations may also include additives to inhibit corrosion, increase stability during storage, and resist bacterial degradation (Kaye, 1982).

Lubricants are mostly carrier material which evaporates upon contact with the hot die surface, depositing a thin uniform coating of die lubricant on the die face. Typical ratios of carrier to lubricant are about 40 to 1 (Kaye, 1982).

Both water-based lubricants and solvent-based lubricants are in use today. Solvents, however, are largely being phased out due to health and fire concerns associated with the large amounts of solvent vapors released. Water-based lubricants are now used almost exclusively in the U.S. Lubricating materials are typically mineral oils and waxes in water emulsions. Silicone oils and synthetic waxes are finding increased use. In addition, research is under way to develop a permanent release coating for die surfaces which will eliminate the need for repeated lubricant application (Kaye, 1982).

Advantages and Disadvantages

Die casting is not applicable to steel and high melting point alloys. Pressure dies are very expensive to design and produce, and the die casting machines themselves are major capital investments (LaRue, 1989). Therefore, to compete with other casting methods, it must be more economical to produce a component by virtue of higher production rates, or the finished components must be superior to those produced using other methods -- often, it is a combination of both factors (USITC, 1984).

Once the reusable die has been prepared, the die casting process can sustain very high production rates. Castings can be made at rates of more than 400 per hour. There is a limit, however, to the number of castings produced in a single die depending on the die design, the alloys being casted, and the dimensional tolerances required. The useable life span of a die can range from under 1,000 to over 5,000,000 castings or "shots." (Allsop, 1983) Therefore, the design of the die itself is critical not only for producing high quality castings but also in ensuring the economic viability of the production process. Die design is a very complex exercise. In addition to the design of the component geometry and constituent materials, numerous factors related to the die itself must be considered, including: the type of alloys, the temperature gradients within the die, the pressure and velocity of the molten metal when it enters the die, the technique for ejecting the casting from the die, and the lubrication system used (Street, 1977). Computer-aided design and modeling of die designs is now commonplace and has played an important role in advancing the technology.

One major advantage of die casting over other casting methods is that the produced castings can have very complex shapes. The ability to cast complex shapes often makes it possible to manufacture a product from a single casting instead of from an assembly of cast components. This can greatly reduce casting costs as well as costs associated with fabrication and machining. Furthermore, die casting produces castings having a high degree of dimensional accuracy and surface definition compared to other casting methods, which may also reduce or eliminate costly machining steps. Finally, castings with relatively thin wall sections can be produced using the die casting method. This can result in substantial savings in material costs and reductions in component weight (Allsop, 1983).

Wastes Generated

Wastes generated during metal melting will be similar to those of metal melting in foundries, depending on the particular furnace used. Relatively little waste is generated in the actual die casting process compared to other metal casting processes. However, some gaseous and fume emissions occur during metal injection. Metal oxide fumes are released as some of the metal vaporizes and condenses. Gaseous emissions can originate from: the molten metal itself; the evolution of chemicals from the lubricant as it is sprayed onto the hot metal die; and as the molten metal contacts the lubricant (NADCA, 1996).

III.B. Raw Materials Inputs and Pollution Outputs

Raw material inputs and pollutant outputs differ for foundries and die casters. The major difference lies in the use of permanent molds by die casting facilities which eliminates any need for large mold making operations and the handling, treatment and disposal of sand and other refractory materials. For this reason, the material inputs and pollutant outputs of permanent mold casting foundries will likely be more similar to those of die casting facilities. Table 4 summarizes the material inputs and pollution outputs discussed in this section.

III.B.1. Foundries

The main raw material inputs for foundries are sand and other core and mold refractory materials (depending of the particular processes used), metals in the form of scrap and ingot, alloys, and fuel for metal melting. Other raw material inputs include binders, fluxing agents, and pattern making materials.

Air Emissions

Air emissions at foundries primarily arise from metal melting, mold and core making, shakeout and sand handling, and the cleaning and finishing of cast parts (Kotzin, 1992).

<u>Furnaces and Metal Melting</u>
Furnace air emissions consist of the products of combustion from the fuel and particulate matter in the form of dusts, metallics, and metal oxide fumes. Carbon monoxide and organic vapors may also arise if oily scrap is charged to the furnace or preheat system (AP-42, 1993). Particulates will vary according to the type of furnace, fuel (if used), metal melted, melting temperature, and a number of operating practices. Air emissions from furnaces and molten metal can often be reduced by applying a number of good operating practices (see Section V.A). Particulates can include fly ash, carbon, metallic dusts, and fumes from the volatilization and condensation of molten metal oxides. In steel foundries, these particulates may contain varying amounts of zinc, lead, nickel, cadmium, and chromium (Kotzin, 1992). Carbon-steel dust can be high in zinc as a result of the use of galvanized scrap, while stainless steel dust is high in nickel and chromium. Painted scrap can result in particulates high in lead. Particulates associated with nonferrous metal production may contain copper, aluminum, lead, tin, and zinc. The particulate sizes of the oxide fumes are often very small (submicron) and, therefore, require high efficiency control devises (Licht, 1992).

Furnace air emissions are typically captured in ventilation systems comprised of hoods and duct work. Hoods and ducts are usually placed over and/or near the tapping spouts, and metal charging, slag removal, and pouring areas. Hoods can be permanently fixed at pouring stations or attached to the pouring ladle or crane through flexible duct work. Depending on the type of furnace and metals melted, these ventilation systems may be ducted to coolers to cool the hot combustion gases, followed by baghouses, electrostatic precipitators and/or wet scrubbers to collect particulates. Afterburners may also be used to control carbon monoxide and oil vapors (Licht, 1992).

Mold and Core Making

The major air pollutants generated during mold and core making are particulates from the handling of sand and other refractory materials, and VOCs from the core and mold curing and drying operations. VOCs, particulates, carbon monoxide, and other organic compounds are also emitted when the mold and core come into contact with the molten metal and while the filled molds are cooled (AP-42, 1993).

The use of organic chemical binding systems (e.g., cold box, hot box, no bake, etc.) may generate sulfur dioxide, ammonia, hydrogen sulfide, hydrogen cyanide, nitrogen oxides and large number of different organic compounds. Emissions occur primarily during heating and curing, removal of the cores from core boxes, cooling, and pouring the metal into molds and may include a number of gases listed as hazardous air pollutants (HAPs) under the Clean Air Act. Potential HAPs emitted when using chemical binding systems include: formaldehyde, methylene diphenyl diisocyanate (MDI), phenol, triethylamine, methanol, benzene, toluene, cresol/cresylic acid, napthalene, polycyclic-organics, and cyanide compounds (Twarog, 1993).

Some core-making processes use strongly acidic or basic substances for scrubbing the off gasses from the core making process. In the free radical cure process, acrylic-epoxy binders are cured using an organic hydroperoxide and SO_2 gas. Gasses are typically scrubbed to remove sulfur dioxide before release through the stack to the atmosphere. A wet scrubbing unit absorbs the SO_2 gas. A 5 to 10 percent solution of sodium hydroxide at a pH of 8 to 14 neutralizes the SO_2 and prevents the by-product (sodium sulfite) from precipitating out of solution (U.S. EPA, 1992).

Amine scrubbers may be used for sulfur dioxide control by foundries. In amine scrubbing the gas containing sulfur dioxide is first passed through a catalyst bed, where the sulfur compounds are converted to hydrogen sulfide. The gas stream then enters a packed or trayed tower (scrubber) where it is contacted with a solution of water and an organic amine. The amine solution is alkaline and the weakly acidic hydrogen sulfide in the gas stream dissolves in it. The amine solution with hydrogen sulfide is then sent to a stripping tower, where it is boiled and the acid gases stripped out. The amine solution is cooled and returned to the scrubbing tower for reuse. Acid gases are cooled and treated through neutralization. A number of amines are used including diethanolamine (DEA), monoethanolamine (MEA), and methyldiethanolamine (MDEA). Air emissions from the amine scrubbers may include some H_2S and other sulfur compounds. (Scott, 1992).

Shakeout, Finishing, and Sand Handling

Shakeout and sand handling operations generate dust and metallic particulates. Finishing and cleaning operations will generate metallic particulates from deburring, grinding, sanding and brushing, and volatile organic compounds from the application of rust inhibitors or organic coatings such as paint. Control systems involve hoods and ducts at key dust generating points followed by baghouses, electrostatic precipitators, or wet scrubbers (AFS Air Quality Committee, 1992).

Wastewater

Wastewater mainly consists of noncontact cooling water and wet scrubber effluent (Leidel, 1995). Noncontact cooling water can typically be discharged to the POTW or to surface waters under an NPDES permit. Wet scrubber wastewater in facilities using large cupola furnaces can be generated in large quantities (up to 3,000 gallons per minute). This water is typically highly alkaline or acidic and is neutralized before being discharged to the POTW (AFS Air Quality Committee, 1992). If amine scrubbers are used, amine scrubbing solution can be released to the plant effluent system through leaks and spills. Some foundries using cupola furnaces also generate wastewater containing metals from cooling slag with water. Wastewater may also be generated in certain finishing operations such as quenching and deburring. Such wastewater can be high in oil and suspended solids (NADCA, 1996).

Residual Wastes

Residual wastes originate from many different points within foundries. Waste sand is by far the largest volume waste for the industry. Other residual wastes may include dust from dust collection systems, slag, spent investment casting refractory material, off-spec products, resins, spent solvents and cleaners, paints, and other miscellaneous wastes.

Furnaces and Metal Melting

The percentage of metal from each charge that is converted to dust or fumes and collected by baghouses, electrostatic precipitators, or wet scrubbers can vary significantly from facility to facility depending on the type of furnace used and the type of metal cast. In steel foundries, this dust contains varying amounts of zinc, lead, nickel, cadmium, and chromium. Carbon-steel dust tends to be high in zinc as a result of the use of galvanized scrap, while stainless steel dust is high in nickel and chromium. Dust high in lead may result from the use of scrap painted with leaded paint. Dust associated with nonferrous metal production may contain copper, aluminum, lead, tin, and zinc. Steel dust may be encapsulated and disposed of in a permitted landfill, while nonferrous dust is often sent to a recycler for metal recovery.

Slag is a glassy mass with a complex chemical structure. It can constitute about 25 percent of a foundry's solid waste stream (Kotzin, 1995). Slag is composed of metal oxides from the melting process, melted refractories, sand, coke ash (if coke is used), and other materials. Large quantities of slag are generated in particular from iron foundries that melt in cupola furnaces. Fluxes are used to facilitate removal of contaminants from the molten metal into the slag so that it can be removed from the molten metal surface. Hazardous slag may be produced in melting operations if the charge materials contain toxic metals such as lead, cadmium, or chromium. To produce ductile iron by reducing the sulfur content of iron, some foundries use calcium carbide desulfurization and the slag generated by this process may be classified as a reactive waste (U.S. EPA, 1992).

Mold and Core Making

Those core-making processes that use strongly acidic or basic substances for scrubbing the off gasses from the core making process may generate sludges or liquors. These sludges or liquors are typically pH controlled prior to discharge to the sewer system as nonhazardous waste. If not properly treated, the waste may be classified as hazardous corrosive waste and thus subjected to numerous federal, state and local mandates (U.S. EPA, 1992).

Shakeout and Sand Handling

Foundries using sand molds and cores generate large volumes of waste sands. Waste foundry sand can account for 65 to 90 percent of the total waste generated by foundries. In many foundries, casting sands are recycled internally until they can no longer be used. Some foundries reclaim waste sands so that they can be recycled to the process or recycled off-site for another use (see Section V.A.1). Sand that can no longer be used by iron or steel foundries, is often landfilled as nonhazardous waste. Casting sands used in the production of brass or bronze castings may exhibit toxicity characteristic for lead or cadmium. The hazardous sand may be reclaimed in a thermal treatment unit which may be subject to RCRA requirements for hazardous waste incinerators (see Section VI.B) (U.S. EPA, 1992). Approximately two percent of all foundry spent sand is hazardous (Kotzin, 1995).

Investment casting shells can be used only once and are disposed in landfills as a nonhazardous waste unless condensates from heavy metal alloy constituents are present in the shells.

Most foundries generate miscellaneous residual waste that varies greatly in composition, but makes up only a small percentage of the total waste. This waste includes welding materials, waste oil from heavy equipment and hydraulics, empty binder drums, and scrubber lime (U.S. EPA, 1992).

III.B.2. Die Casters

The main raw material inputs for die casters include: metal in the form of ingot, molten metal, metal scrap, alloys, and fuel for metal melting. Other raw material inputs include: fluxing agents, die lubricants, refractory materials, hydraulic fluid, and finishing and cleaning materials.

Air Emissions

Furnace air emissions consist of the products of combustion from the fuel and particulate matter in the form of dusts, metallics, and metal oxide fumes. Carbon monoxide and oil vapors may also arise if oily scrap is charged to the furnace or preheat system. Metallic particulates arise mainly from the volatilization and condensation of molten metal oxides. These will vary according to the type of furnace, fuel, metal, melting temperature, and a number of operating practices. The particulate sizes of the oxide fumes are often very small (submicron) and may contain copper, aluminum, lead, tin, and zinc (Licht, 1992).

Fluxing and dross removal operations to remove impurities from the molten metal can also be the source of air emissions. Die casters can use a number of different fluxing agents to remove different impurities, including: sulfur hexafluoride, solvent fluxes, aluminum fluoride, or chlorine. Metallic particulates, the fluxing agents themselves, and products of chemical reactions with impurities can be emitted from the molten metal surface or from the subsequently removed dross as it cools. For example, if chlorine is used, it may react with aluminum and water in the atmosphere to form aluminum oxide fumes and hydrochloric acid. Although not always necessary, particulate emissions control equipment, such as fabric bag filters, are sometimes used to control furnace emissions at die casting facilities (NADCA, 1996).

Die lubrication and plunger tip lubrication can also be a significant source of air releases from die casting facilities. Both oil- and water-based die lubricants are used. Oil-based lubricants typically contain naphtha and result in much higher emissions of volatile organic compounds than water-based lubricants. The air emissions will depend on the specific formulation of the lubricant product and may contain hazardous air pollutants (NADCA, 1996).

Other air emissions arise from finishing and cleaning operations which generate metallic particulates from deburring, grinding, sanding and brushing, and volatile organic compounds from the application of rust inhibitors or paint. Casting quench tanks for the cooling of zinc castings can contain volatile organic compounds and water treatment chemicals resulting in potential emissions of volatile organic compounds and hazardous air pollutants (NADCA, 1996).

Wastewater

Both process wastewater and waste noncontact cooling water may be generated at die casting facilities. Noncontact cooling water will likey have elevated temperature and very little or no chemical contamination. Process wastewater from die casting facilities can be contaminated with spent die lubricants, hydraulic fluid and coolants. Contaminants in such wastewater are typically oil and phenols. As with foundries, die casters may also generate wastewater in certain finishing operations such as in-process cleaning, quenching and deburring. Such wastewater can be high in oil and suspended solids. Typical wastewater treatment at die casting facilities consists of oil/water separation and/or filtration before discharge to a POTW. Facilities generating large volumes of wastewater may also utilize biological treatment (NADCA, 1996).

Residual Wastes

Residual waste streams from die casting facilities are relatively small compared to most sand casting foundries. Typical residual wastes include: slag or dross generated from molten metal surfaces; refractory materials from furnaces and ladles; metallic fines, spent shot (plunger) tips, tools, heating coils, hydraulic fluid, floor absorbent, abrasive cutting belts and wheels, quench sludge, and steel shot. Most residual wastes from die casting facilities are sent off-site for disposal as a non-hazardous waste. Waste dross is usually sent to secondary smelters for metal recovery. Waste oils, lubricants and hydraulic fluids may be sent off-site for recycling or energy recovery (NADCA, 1996).

Table 4: Summary of Material Inputs and Potential Pollutant Outputs for the Metal Casting Industry

Industrial Process	Material Inputs	Air Emissions	Wastewater	Residual Wastes
Pattern Making	Wood, plastic, metal, wax, polystyrene	VOCs from glues, epoxies, and paints.	Little or no wastewater generated	Scrap pattern materials
Mold and Core Preparation and Pouring				
Green Sand	Green sand and chemically-bonded sand cores	Particulates, metal oxide fumes, carbon monoxide, organic compounds, hydrogen sulfide, sulfur dioxide, and nitrous oxide. Also, benzene, phenols, and other hazardous air pollutants (HAPs) if chemically bonded cores are used.	Wastewater containing metals, elevated temperature, phenols and other organics from wet dust collection systems and mold cooling water	Waste green sand and core sand potentially containing metals
Chemical Binding Systems	Sand and chemical binders	Particulates, metallic oxide fumes, carbon monoxide, ammonia, hydrogen sulfide, hydrogen cyanide, sulfur dioxide, nitrogen oxides, and other HAPs	Scrubber wastewater with amines or high or low pH; and wastewater containing metals, elevated temperature, phenols and other organics from wet dust collection systems and mold cooling water	Waste mold and core sand potentially containing metals and residual chemical binders
Permanent Mold	Steel mold, permanent, sand, plaster, or salt cores	Particulates, metallic oxide fumes	Waste cooling water with elevated temperature and wastewater with low pH and high in dissolved salts if soluble salt cores are used	Waste core sand or plaster potentially containing metals
Plaster Mold	Plaster mold material	Particulates, metallic oxide fumes	Little or no wastewater generated	Spent plaster
Investment/Lost Wax	Refractory slurry, and wax or plastic	Particulates, metallic oxide fumes	Wastewater with low pH and high in dissolved salts if soluble salt cores are used	Waste refractory material, waxes and plastics
Lost Foam	Refractory slurry, polystyrene	Particulates, metallic oxide fumes, polystyrene vapors and HAPs	Little or no wastewater generated	Waste sand and refractory material potentially containing metals and styrene

R0075824

Industrial Process	Material Inputs	Air Emissions	Wastewater	Residual Wastes
Furnace Charge Preparation and Metal Melting				
Charging and Melting	Metal scrap, ingot and returned castings	Products of combustion, oil vapors, particulates, metallic oxide fumes	Scrubber wastewater with high pH, slag cooling water with metals, and non-contact cooling water	Spent refractory material potentially containing metals and alloys
Fluxing and Slag and Dross Removal	Fluxing agents	Particulates, metallic oxide fumes, solvents, hydrochloric acid	Wastewater containing metals if slag quench is utilized	Dross and slag potentially containing metals
Pouring	Ladles and other refractory materials	Particulates, metallic oxide fumes	Little or no wastewater generated	Spent ladles and refractory materials potentially containing metals
Quenching, Finishing, Cleaning and Coating				
Painting and rust inhibitor application	Paint and rust inhibitor	VOCs	Little or no wastewater generated	Spent containers and applicators
Cleaning , quenching, grinding, cutting	Unfinished castings, water, steel shot, solvents	VOCs, dust and metallic particulates	Waste cleaning and cooling water with elevated temperature, solvents, oil and grease, and suspended solids	Spent solvents, steel shot, metallic particulates, cutting wheels, metallic filings, dust from collection systems, and wastewater treatment sludge
Shakeout, Cooling and Sand Handling	Water and caustic for wet scrubbers	Dust and metallic particulates; VOC and organic compounds from thermal sand treatment systems	Wet scrubber wastewater with high or low pH or amines, permanent mold contact cooling water with elevated temperature, metals and mold coating	Waste foundry sand and dust from collection systems, metal
Die Casting[1]	Metal, fuel, lubricants, fluxing agents, hydraulic fluid	VOCs from die and plunger tip lubrication	Waste cooling water with elevated temperature and wastewater contaminated with oil, and phenols	Waste hydraulic fluid, lubricants, floor absorbent, and plunger tips

[1] Furnaces, metal melting, finishing, cleaning, and coating operations also apply to die casting.

R0075825

III.C. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (PPA) requires facilities to report information about the management of Toxic Release Inventory (TRI) chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1993-1996 and are meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

While the quantities reported for 1994 and 1995 are estimates of quantities already managed, the quantities listed by facilities for 1996 and 1997 are projections only. The PPA requires these projections to encourage facilities to consider future source reduction, not to establish any mandatory limits. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Foundries

Table 5 shows that the TRI reporting foundries managed about 272 million pounds of production related wastes (total quantity of TRI chemicals in the waste from routine production operations in column B) in 1995. From the yearly data presented in column B, the total quantity of production related TRI wastes increased between 1994 and 1995. This is likely in part because the number of chemicals on the TRI list nearly doubled between those years. Production related wastes were projected to decrease in 1996 and 1997. The effects of production increases and decreases on the amount of wastes generated are not evaluated here.

Values in Column C are intended to reveal the percent of production-related waste (about 40 percent) either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. Column C shows a decrease in the amount of wastes either transferred off-site or released to the environment from 43 percent in 1994 to 40 percent in 1995. In other words, about 60 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E, and F, respectively. Most of these on-site managed wastes were recycled on-site, typically in a metals recovery process. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production related wastes (32 percent in 1994 and 1995), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or is transferred off-site for disposal.

Table 5: Source Reduction and Recycling Activity for Foundries (SIC 332, 3365, 3366, and 3369) as Reported within TRI

[b] Total TRI transfers and releases as reported in Section 5 and 6 of Form R as a percentage of production related wastes.

[c] Percentage of production related waste released to the environment and transferred off-site for disposal.

Die Casters

Table 6 shows that the TRI reporting foundries managed about 63 million pounds of production related wastes (total quantity of TRI chemicals in the waste from routine production operations) in 1995 (column B). Column C reveals that of this production-related waste, about 21 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 79% of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E, and F, respectively. Most of these on-site managed wastes were recycled on-site, typically in a metals recovery process. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production related wastes (2 percent in 1994), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20 through 39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1995) TRI reporting year (which includes over 600 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries. TRI data provide the type, amount and media receptor of each chemical released or transferred.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1995 Toxic Release Inventory Public Data Release, reported onsite releases of toxic chemicals to the environment decreased by 5 percent (85.4 million pounds) between 1994 and 1995 (not including chemicals added and removed from the TRI chemical list during this period). Reported releases dropped by 46 percent between 1988 and 1995. Reported transfers of TRI chemicals to off-site locations increased by 0.4 percent (11.6 million pounds) between 1994 and 1995. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

Certain limitations exist regarding TRI data. Release and transfer reporting are limited to the approximately 600 chemicals on the TRI list. Therefore, a large portion of the emissions from industrial facilities are not captured by TRI. Within some sectors, (e.g. dry cleaning, printing and transportation equipment cleaning) the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. For these sectors, release information from other sources has been included. In addition, many facilities report more than one SIC code reflecting the multiple operations carried out onsite. Therefore, reported releases and transfers may or may not all be associated with the industrial operations described in this notebook.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, vents, ducts, or pipes. Fugitive emissions include equipment leaks, evaporative losses from surface impoundments and spills, and releases from building ventilation systems.

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Releases due to runoff, including storm water runoff, are also reportable to TRI.

Releases to Land -- occur within the boundaries of the reporting facility. Releases to land include disposal of toxic chemicals in landfills, land treatment/application farming, surface impoundments, and other land disposal methods (such as spills, leaks, or waste piles).

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal. Wastes containing TRI chemicals are injected into either Class I wells or Class V wells. Class I wells are used to inject liquid hazardous wastes or dispose of industrial and municipal wastewater beneath the lowermost underground source of drinking water. Class V wells are generally used to inject non-hazardous fluid into or above an underground source of drinking water. TRI reporting does not currently distinguish between these two types of wells, although there are important differences in environmental impact between these two methods of injection.

TRANSFERS-- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. Chemicals reported to TRI as transferred are sent to off-site facilities for the purpose of recycling, energy recovery, treatment, or disposal. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, the reported quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewater transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment or removal of a chemical from the wastewater depend on the nature of the chemical, as well as the treatment methods present at the POTW. Not all TRI chemicals can be treated or removed by a POTW. Some chemicals, such as metals, may be removed, but are not destroyed and may be disposed of in landfills or discharged to receiving waters.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovery by a variety of recycling methods, including solvent recovery, metals recovery, and acid regeneration. Once these chemicals have been

R0075832

recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site to be treated through a variety of methods, including neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Metal Casting Industry

This section summarizes TRI data of ferrous and nonferrous foundries reporting SIC codes 332, 3365, 3366, and 3369, and ferrous and nonferrous die casting facilities reporting SIC codes 3363 and 3364 as the primary SIC code for the facility. Of the 2,813 metal casting establishments reported by the *1992 Census of Manufacturers*, 654 reported to TRI in 1995.

Ferrous and nonferrous foundries made up 85 percent (554 facilities) of metal casting facilities reporting to TRI and accounted for about 89 percent of the total metal casting TRI releases and transfers for metal casting facilities in 1995. Die casters made up 15 percent (100 facilities) of metal casting facilities and reported the remaining 11 percent of the total releases and transfers. Because the TRI information differs for foundries and die casters, the releases and transfers for these two industry segments are presented separately below.

IV.A.1. Toxic Release Inventory for Ferrous and Nonferrous Foundries

According to the 1995 TRI data, the reporting ferrous and nonferrous foundries released and transferred a total of approximately 109 million pounds of pollutants during calendar year 1995. These releases and transfers are dominated by large volumes of metallic wastes. Evidence of the diversity of processes at foundries reporting to TRI is found in the fact that the most frequently reported chemical (copper) is reported by only 45 percent of the facilities and over half of the TRI chemicals were reported by fewer than ten facilities. The variability in facilities' pollutant profiles may be attributable to the large number of different types of foundry processes and products. For example, foundries casting only ferrous parts will have different pollutant profiles than those foundries casting both ferrous and nonferrous products.

Releases

Releases to the air, water, and land accounted for 33 percent (36 million pounds) of foundries' total reportable chemicals. Of these releases, 70 percent go to onsite land disposal, and about 75 percent are fugitive or point source air emissions (See Table 7). Metallic wastes accounted for over 95 percent of the industry's releases. Manganese, zinc, chromium, and lead account for over 95 percent of the on-site land disposal. The industry's air releases are associated with volatilization, fume or aerosol formation in the furnaces and byproduct processing. Lighter weight organics, such as methanol, acids and metal contaminants found in scrap metal are the principal types of TRI chemicals released to the air. In addition to air releases of chemicals reported to TRI, foundries are often a source of particulates, carbon monoxide, nitrogen oxides and sulfur compounds due to sand handling operations, curing of chemical binders, and combustion of fossil fuels. Methanol, trichloroethylene and other solvent releases account for most of the fugitive releases (approximately 61 percent).

Transfers

Off-site transfers of TRI chemicals account for 69 percent of foundries' total TRI-reportable chemicals (74 million pounds). Almost 57 percent of the industry's total TRI wastes (42 million pounds) are metallic wastes that were transferred off-site for recycling, typically for recovery of the metal content. Metallic wastes account for approximately 95 percent of the industry's transfers. About 61 percent of off-site transfers reported by foundries are sent off-site for recycling. Copper, manganese, zinc, chromium, nickel, and lead are the six metals transferred in the greatest amounts and number of facilities (See Table 8). TRI chemicals sent off-site for disposal (primarily manganese, zinc, chromium, and copper) account for 31 percent of transfers. Less than three percent of the remaining transfers from foundries go to treatment off-site, discharge to POTWs, and energy recovery.

After metals, the next largest volume of chemicals transferred are acids including: sulfuric acid, nitric acid, phosphoric acid, and hydrochloric acid. Spent acids can be generated in wet scrubber systems. In addition, acids are often used to clean and finish the surfaces of the metal castings before plating or coating. The spent acids are often sent off-site for recycling or for treatment. Solvents and other light weight organic compounds are frequently reported but account for a relatively small amount of total transfers. Solvents are used frequently for cleaning equipment and cast parts. The primary solvents and light weight organics include: phenol, xylene, 1,2,4-trimethylbenzene, 1,1,1-trichloroethane, trichloroethylene, methanol, and toluene. Transferred solvents are mostly sent off-site for disposal or recycling. Phenols and phenoisocyanates are frequently reported but amount to less than one percent of the total TRI pounds transferred. Phenols are often found in chemical binding systems and may be present in waste sand containing chemical binders (AFS and CISA, 1992).

IV.A.2. Toxic Release Inventory for Die Casting Facilities

According to the 1995 TRI data, the reporting die casting facilities released and transferred a total of approximately 13 million pounds of TRI chemicals during calendar year 1995. As with foundries, the releases and transfers for die casters are dominated by large volumes of metallic wastes. Evidence of the diversity of processes at die casting facilities reporting to TRI is found in the fact that all but three of the TRI reported chemicals (copper, nickel, and aluminum) are reported by fewer than ten percent of the facilities. The variability in facilities' pollutant profiles may be attributed primarily to the different types of metals cast.

Releases

Releases make up only four percent of die casters' total TRI-reportable chemicals (518,000 pounds). Almost all of these releases (99 percent) are released to the air through point source and fugitive emissions (see Table 9). Metallic wastes (primarily aluminum, zinc, and copper) account for over 67 percent of the releases. The remainder of the industry's releases are primarily solvents and other volatile organic compounds including, trichloroethylene, tetrachloroethylene, glycol ethers, hexochloroethane, and toluene, which account for 32 percent of the releases. In addition to air releases of chemicals reported to TRI, die casting facilities can be a source of particulates, carbon monoxide, nitrogen oxides and sulfur compounds due to the combustion of fossil fuels for metal melting, from the molten metal itself, and from die cleaning and lubricating operations.

Transfers

Off-site transfers of TRI chemicals account for 96 percent of die casters' total TRI-reportable chemicals (13 million pounds). Almost all off-site transfers (97 percent) reported by die casting facilities are sent off-site for recycling. Copper, aluminum, zinc, and nickel make up 98 percent of all transfers and are reported by the largest number of facilities (see Table 10). Chemicals sent off-site for disposal (primarily aluminum and copper) account for less than three percent of transfers. After metals, the next class of chemicals transferred are solvents. These chemicals account for only about one percent of total transfers.

Table 9: 1995 TRI Releases for Die Casting Facilities, by Number of Facilities Reporting (Releases reported in pounds/year)

R0075842

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for the metal casting industry are listed below in Tables 11 and 12. Facilities that have reported only the primary SIC codes covered under this notebook appear on Table 11. Table 12 contains additional facilities that have reported the SIC codes covered within this notebook, or SIC codes covered within this notebook report and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list may include facilities that conduct multiple operations -- some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Table 11: Top 10 TRI Releasing Metal Casting Facilities[1]

R0075844

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1995 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reduction over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult these sources for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the Hazardous Substances Data Bank (HSDB) and the Integrated Risk Information System (IRIS). The discussions of toxicity describe the range of possible adverse health effects that have been found to be associated with exposure to these chemicals. These adverse effects may or may not occur at the levels released to the environment. Individuals interested in a more detailed picture of the chemical concentrations associated with these adverse effects should consult a toxicologist or the toxicity literature for the chemical to obtain more information. The effects listed below must be taken in context of these exposure assumptions that are explained more fully within the full chemical profiles in HSDB. For more information on TOXNET[3], contact the TOXNET help line at 1-800-231-3766.

Manganese and Manganese Compounds (CAS: 7439-96-5; 20-12-2)

Sources. Manganese is found in iron charge materials and is used as an addition agent for alloy steel to obtain desired properties in the final product. In carbon steel, manganese is used to combine with sulfur to improve the ductility of the steel. An alloy steel with manganese is used for applications

[3] TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

involving small sections which are subject to severe service conditions, or in larger sections where the weight saving derived from the higher strength of the alloy steels is needed (U.S. EPA, 1995).

Toxicity. There is currently no evidence that human exposure to manganese at levels commonly observed in ambient atmosphere results in adverse health effects.

Chronic manganese poisoning, however, bears some similarity to chronic lead poisoning. Occurring via inhalation of manganese dust or fumes, it primarily involves the central nervous system. Early symptoms include languor, speech disturbances, sleepiness, and cramping and weakness in legs. A stolid mask-like appearance of face, emotional disturbances such as absolute detachment broken by uncontrollable laughter, euphoria, and a spastic gait with a tendency to fall while walking are seen in more advanced cases. Chronic manganese poisoning is reversible if treated early and exposure stopped. Populations at greatest risk of manganese toxicity are the very young and those with iron deficiencies.

Ecologically, although manganese is an essential nutrient for both plants and animals, in excessive concentrations manganese inhibits plant growth.

Carcinogenicity. There is currently no evidence to suggest that manganese is carcinogenic.

Environmental Fate. Manganese is an essential nutrient for plants and animals. As such, manganese accumulates in the top layers of soil or surface water sediments and cycles between the soil and living organisms. It occurs mainly as a solid under environmental conditions, though may also be transported in the atmosphere as a vapor or dust.

Zinc and Zinc Compounds (CAS: 7440-66-6; 20-19-9)

Sources. To protect metal from oxidizing, it is often coated with a material that will protect it from moisture and air. In the galvanizing process, steel is coated with zinc. Galvanized iron and steel is often found in furnace charge materials (USITC, 1984).

Toxicity. Zinc is a trace element; toxicity from ingestion is low. Severe exposure to zinc might give rise to gastritis with vomiting due to swallowing of zinc dusts. Short-term exposure to very high levels of zinc is linked to lethargy, dizziness, nausea, fever, diarrhea, and reversible pancreatic and neurological damage. Long-term zinc poisoning causes irritability, muscular stiffness and pain, loss of appetite, and nausea.

Zinc chloride fumes cause injury to mucous membranes and to the skin. Ingestion of soluble zinc salts may cause nausea, vomiting, and purging.

Carcinogenicity. There is currently no evidence to suggest that zinc is carcinogenic.

Environmental Fate. Significant zinc contamination of soil is only seen in the vicinity of industrial point sources. Zinc is a stable soft metal, though it burns in air. Zinc bioconcentrates in aquatic organisms.

Methanol (CAS: 67-56-1)

Sources. Methanol is used as a cleaning solvent and can be emitted during the production of cores using the hot box and no-bake systems.

Toxicity. Methanol is readily absorbed from the gastrointestinal tract and the respiratory tract, and is toxic to humans in moderate to high doses. In the body, methanol is converted into formaldehyde and formic acid. Methanol is excreted as formic acid. Observed toxic effects at high dose levels generally include central nervous system damage and blindness. Long-term exposure to high levels of methanol via inhalation cause liver and blood damage in animals.

Ecologically, methanol is expected to have low toxicity to aquatic organisms. Concentrations lethal to half the organisms of a test population are expected to exceed one mg methanol per liter water. Methanol is not likely to persist in water or to bioaccumulate in aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that methanol is carcinogenic.

Environmental Fate. Methanol is highly volatile and flammable. Liquid methanol is likely to evaporate when left exposed. Methanol reacts in air to produce formaldehyde which contributes to the formation of air pollutants. In the atmosphere it can react with other atmospheric chemicals or be washed out by rain. Methanol is readily degraded by microorganisms in soils and surface waters.

Trichloroethylene (CAS:79-01-6)

Sources. Trichloroethylene is used extensively as a cleaning solvent.

Toxicity. Trichloroethylene was once used as an anesthetic, though its use caused several fatalities due to liver failure. Short term inhalation exposure to high levels of trichloroethylene may cause rapid coma followed by eventual death from liver, kidney, or heart failure. Short-term exposure to lower concentrations of trichloroethylene causes eye, skin, and respiratory tract irritation. Ingestion causes a burning sensation in the mouth, nausea, vomiting and abdominal pain. Delayed effects from short-term trichloroethylene poisoning include liver and kidney lesions, reversible nerve degeneration, and psychic disturbances. Long-term exposure can produce headache, dizziness, weight loss, nerve damage, heart damage, nausea, fatigue, insomnia, visual impairment, mood perturbation, sexual problems, dermatitis, and rarely jaundice. Degradation products of trichloroethylene (particularly phosgene) may cause rapid death due to respiratory collapse.

Carcinogenicity. Trichloroethylene is considered by EPA to be a probable human carcinogen via both oral and inhalation exposure, based on limited human evidence and sufficient animal evidence.

Environmental Fate. Trichloroethylene breaks down slowly in water in the presence of sunlight and bioconcentrates moderately in aquatic organisms. The main removal of trichloroethylene from water is via rapid evaporation. Trichloroethylene does not photodegrade in the atmosphere, though it breaks down quickly under smog conditions, forming other pollutants such as phosgene, dichloroacetyl chloride, and formyl chloride. In addition, trichloroethylene vapors may be decomposed to toxic levels of phosgene in the presence of an intense heat source such as an open arc welder. When spilled on land, trichloroethylene rapidly volatilizes from surface soils. Some of the remaining chemical may leach through the soil to groundwater.

Xylenes (Mixed Isomers) (CAS: 1330-20-7)

Sources. Xylenes are used extensively as cleaning solvents and paint solvents and may be formed as a decomposition product of binders.

Toxicity. Xylenes are rapidly absorbed into the body after inhalation, ingestion, or skin contact. Short-term exposure of humans to high levels of xylene can cause irritation of the skin, eyes, nose, and throat, difficulty in breathing, impaired lung function, impaired memory, and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations can cause effects such as headaches, dizziness, confusion, and lack of muscle coordination. Reactions of xylenes (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that xylenes are carcinogenic.

Environmental Fate. A portion of releases to land and water will quickly evaporate, although some degradation by microorganisms will occur. Xylenes are moderately mobile in soils and may leach into groundwater, where they may persist for several years. Xylenes are volatile organic chemicals. As such, xylene in the lower atmosphere will react with other atmospheric components, contributing to the formation of ground-level ozone and other air pollutants.

Chromium and Chromium Compounds (CAS: 7440-47-3; 20-06-4)

Sources. Chromium is used as a plating element for metal to prevent corrosion and is sometimes found on charge materials. Chromium is also a constituent of stainless steel.

Toxicity. Although the naturally-occurring form of chromium metal has very low toxicity, chromium from industrial emissions is highly toxic due to strong oxidation characteristics and cell membrane permeability. The majority of the effects detailed below are based on Chromium VI (an isomer that is more toxic than Cr III). Exposure to chromium metal and insoluble chromium salts affects the respiratory system. Inhalation exposure to chromium and chromium salts may cause severe irritation of the upper respiratory tract and scarring of lung tissue. Dermal exposure to chromium and chromium salts can also cause sensitive dermatitis and skin ulcers.

Ecologically, although chromium is present in small quantities in all soils and plants, it is toxic to plants at higher soil concentrations (i.e., 0.2 to 0.4 percent in soil).

Carcinogenicity. Different sources disagree on the carcinogenicity of chromium. Although an increased incidence in lung cancer among workers in the chromate-producing industry has been reported, data are inadequate to confirm that chromium is a human carcinogen. Other sources consider chromium VI to be a known human carcinogen based on inhalation exposure.

Environmental Fate. Chromium is a non-volatile metal with very low solubility in water. If applied to land, most chromium remains in the upper five centimeters of soil. Most chromium in surface waters is present in particulate form as sediment. Airborne chromium particles are relatively unreactive and are removed from the air through wet and dry deposition. The precipitated chromium from the air enters surface water or soil. Chromium bioaccumulates in plants and animals, with an observed bioaccumulation factor of 1,000,000 in snails.

IV.C. Other Data Sources

The toxic chemical release data obtained from TRI captures only about one quarter of the facilities in the metal casting industry. However, it allows for a comparison across years and industry sectors. Reported chemicals are limited to the approximately 600 TRI chemicals. A large portion of the emissions from metal casting facilities, therefore, are not captured by TRI. The EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., total hydrocarbons, SOx, NOx, CO, particulates, etc.) from many metal casting sources.

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Table 13 summarizes annual releases (from the industries for which a Sector Notebook Profile was prepared) of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of TRI releases and transfers within each sector profiled under this project. Please note that the following figure and table do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release Book.

Figure 10 is a graphical representation of a summary of the 1995 TRI data for the metal casting industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the vertical axis. The graph is based on the data shown in Table 14 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the metal casting industry, the 1995 TRI data presented here covers 654 facilities. These facilities listed SIC 332 (Iron and Steel Foundries) and 336 (Nonferrous Foundries) as primary SIC codes.

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasibly. In the waste management hierarchy, if source reduction is not feasible the next alternative is recycling of wastes, followed by energy recovery, and waste treatment as a last alternative.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the metal casting industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be used effectively. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

Most of the pollution prevention activities in the metal casting industry have concentrated on reducing waste sand, waste electric arc furnace (EAF) dust and desulfurization slag, and increasing the overall energy efficiency of the processes. This section describes some of the pollution prevention opportunities for foundries within each of these areas.

V.A. Waste Sand and Chemical Binder Reduction and Reuse

Disposal of waste foundry sand in off-site landfills has become less appealing to foundry operators in recent years. Landfill disposal fees have increased considerably, especially in areas that suffer from shortages of landfill capacity.

Landfill disposal can be a long-term CERCLA liability as well (see Section VI.A. for a discussion of CERCLA). Currently, about 2 percent of foundry waste sands generated is considered hazardous waste under RCRA requiring expensive special treatment, handling and disposal in hazardous waste landfills. Therefore, there are strong financial incentives for applying pollution prevention techniques that reduce waste foundry sand generation. In fact, for years many foundries have been implementing programs to reduce the amounts of waste sand they generate. Also, the industry is conducting a significant amount of research in this area (AFS, 1996).

V.A.1. Casting Techniques Reducing Waste Foundry Sand Generation

The preferable approach to reducing disposal of waste sands is through source reduction rather than waste management and pollution control or treatment techniques. Foundry operators aiming to reduce waste sand may want to examine the feasibility and economic incentives of new casting methods for all or part of their production. A number of the casting techniques described in Section III.A such as investment casting, permanent mold casting, die casting, and lost foam casting generate less sand waste than other techniques.

Adopting different casting methods, however, may not always be feasible depending on the physical characteristics of the parts to be cast (e.g., type of metal, casting size and configuration, tolerances and surface finish required, etc.), the capabilities of the alternative methods, and the economic feasibility. When considering the economic feasibility of implementing these alternative methods, the savings in waste sand handling and disposal and raw material costs should be examined.

In addition to the more common methods listed above and described in Section III.A, there are a number of lesser known and/or new casting methods that also have the potential to reduce the volume of foundry waste sand generated. One promising method, vacuum molding, is described below. For additional information on new, alternative casting techniques, see the references in Section IX.

Vacuum Molding

Vacuum molding, or the V-Process, uses a strong vacuum applied to free-flowing, dry, unbonded sand around patterns in air tight flasks. The vacuum inside the mold results in a net pressure outside pushing in, holding the sand rigidly in the shape of the pattern even after the pattern is removed. The process uses a specially designed plastic film to seal the open ends of the sand mold and the mold cavity. After the pattern is removed, the mold halves are placed together and the metal is poured. The plastic film inside the mold cavity melts and diffuses into the sand as it contacts the molten metal. When the metal has cooled, the vacuum is removed, allowing the sand to fall away from the casting. Shakeout equipment is not needed and virtually no waste sand is generated. The V-Process can be used on almost all metal types, for all sizes and shapes. Although the process has not gained widespread use, it can be economical, uses very little energy and can produce castings with high dimensional accuracy and consistency (La Rue, 1989).

V.A.2. Reclamation and Reuse of Waste Foundry Sand and Metal

Although less preferable than source reduction, the more immediate shift in industry practices is towards waste reclamation and reuse. A number of techniques are being used to reclaim waste sand and return it to the mold and core making processes. In addition, markets for off-site reuse of waste foundry sand have also been found. (Unless otherwise noted, this section is based on the 1992 EPA Office of Research and Development report, *Guides to Pollution Prevention, The Metal Casting and Heat Treating Industry*.)

Waste Segregation

A substantial amount of sand contamination comes from mixing the various foundry waste streams with waste sand. The overall amount of sand being discarded can be reduced by implementing the following waste segregation steps:

- Replumbing the dust collector ducting on the casting metal gate cutoff saws to collect metal chips for easier recycling
- Installing a new baghouse on the sand system to separate the sand system dust from the furnace dust
- Installing a new screening system or magnetic separator on the main molding sand system surge hopper to continuously clean metal from the sand system
- Separate nonferrous foundry shot blast dust (often a hazardous waste stream) from other nonhazardous foundry and sand waste streams.
- Installing a magnetic separation system on the shotblast system to allow the metal dust to be recycled
- Changing the core sand knockout procedure to keep this sand from being mixed in with system sand prior to disposal

Screen and Separate Metal from Sand

Most foundries screen used sand before reusing it. Some employ several different screen types and vibrating mechanisms to break down large masses of sand mixed with metal chips. Coarse screens are used to remove large chunks of metal and core butts. The larger metal pieces collected in the screen are usually remelted in the furnace or sold to a secondary smelter. Increasingly fine screens remove additional metal particles and help classify the sand by size before it is molded. Some foundries remelt these smaller metal particles; other foundries sell this portion to metal reclaimers. The metal recovered during the screening process is often mixed with coarser sand components or has sand adhering to it. Therefore, remelting these pieces in the furnace generates large amounts of slag, especially when the smaller particles are remelted.

Reclaim Sand by Dry Scrubbing/Attrition

Reclaiming sand by dry scrubbing is widely used, and a large variety of equipment is available with capacities adaptable to most binder systems and foundry operations. Dry scrubbing may be divided into pneumatic or mechanical systems.

In pneumatic scrubbing, grains of sand are agitated in streams of air normally confined in vertical steel tubes called cells. The grains of sand are propelled upward; they impact each other and/or are thrust against a steel target to remove some of the binder. In some systems, grains are impacted against a steel target. Banks of tubes may be used depending on the capacity and degree of cleanliness desired. Retention time can be regulated, and fines are removed through dust collectors. In mechanical scrubbing, a variety of available equipment offers foundries a number of options. An impeller may be used to accelerate the sand grains at a controlled velocity in a horizontal or vertical plane against a metal plate. The sand grains impact each other and metal targets, thereby removing some of the binder. The speed of rotation has some control over impact energy. The binder and fines are removed by exhaust systems, and screen analysis is controlled by air gates or air wash separators. Additional equipment options include:

- A variety of drum types with internal baffles, impactors, and disintegrators that reduce lumps to grains and remove binder
- Vibrating screens with a series of decks for reducing lumps to grains, with recirculating features and removal of dust and fines

- Shot-blast cleaning equipment that may be incorporated into other specially designed units to form a complete casting cleaning/sand reclamation unit

- Vibro-energy systems that use synchronous and diametric vibration, where frictional and compressive forces separate binder from sand grains.

> Southern Aluminum is a high-production automotive foundry in Bay Minette, Alabama. The company recently installed a rotating drum attrition/scrubber sand reclaimer unit to remove lumps and tramp aluminum from its spent green sand and core butts so that it could be used by an asphalt company. Spent sand is fed into one end of the rotating drum where the lumps are reduced and binder is scrubbed off the grains. The sand then enters a screening and classifying section, binder and fines are removed by a dust collector, and clean tramp metal is removed. The company is removing far more aluminum from the sand than expected (about 6,000 pounds per day) resulting in substantial cost savings. The equipment paid for itself before it finished treating three-months worth of spent sand stockpiled at the facility (Philbin, 1996).

Reclaim Sand with Thermal Systems

Most foundries recycle core and mold sands; however, these materials eventually lose their basic characteristics, and the portions no longer suitable for use are disposed of in a landfill. In the reclamation of chemically bonded sands, the system employed must be able to break the bond between the resin and sand and remove the fines that are generated. The systems employed most commonly are scrubbing/attrition and thermal (rotary reclamation) systems for resin-bonded sands.

Reclamation of green sand for reuse in a green sand system is practiced on a limited basis in the United States. However, reclamation of core sand and chemically bonded molding sand is widespread. Wet reclamation systems employed in the 1950s for handling green sands are no longer used. Specific thermal reclamation case studies are summarized in AFS (1989) and Modern Casting August (1996). A typical system to reclaim chemically bonded sand for reuse in core room and molding operations consists of a lump reduction and metal removal system, a particle classifier, a sand cooler, a dust collection system, and a thermal scrubber (two-bed reactor). A number of thermal sand reclamation techniques are described below. Note that EPA may classify some types of thermal sand reclamation as incineration. As of June 1996, EPA was taking comments on the regulatory status of thermal recovery units. Contact Mary Cunningham at (703) 308-8453.

Thermal Calcining/Thermal Dry Scrubbing. These systems are useful for reclamation of organic and clay-bonded systems. Sand grain surfaces are not smooth; they have numerous crevices and indentations. The application of heat with sufficient oxygen calcines the binders or burns off organic binders. Separate mechanical attrition units may be required to remove calcined inorganic binders. Heat offers a simple method of reducing the encrusted grains of molding sand to pure grains. Both horizontal and vertical rotary kiln and fluidized bed systems are available. Foundries should examine the regulatory requirements of using thermal systems to treat waste sand. The use of these systems may need to be permitted as waste incineration.

Carondelet Foundry Company in Pevely, Missouri installed a fluidized bed thermal sand reclamation unit and a mechanical reclaimer in 1994 to treat its phenolic urethane no-bake and phenolic urethane Isocure sand. The steel jobbing shop was sending on average 150 tons per day of waste sand off-site for landfill disposal at a cost of about $29 per cubic yard. In addition, new sand was costing approximately $22 per ton. The thermal system processes 125 tons per day and the mechanical system processes the remaining 25 tons. Only 5 percent of the foundry's sand is not reclaimed. The reclamations system is estimated to save the foundry over $1 million per year and payed for itself in under a year. In addition, the foundry feels that the reclaimed sand is better than new sand and results in better castings (Philbin, 1996).

Rotary Drum. This system has been used since the 1950s for reclaiming shell and chemically bonded sands. The direct-fired rotary drum is a refractory-lined steel drum that is mounted on casters. The feed end is elevated to allow the sand to flow freely through the unit. The burners can be at either end of the unit with direct flame impingement on the cascading sand; flow can be either with the flow of solids or counter to it.

In indirect-fired units, the drum is mounted on casters in the horizontal position and is surrounded by refractory insulation. Burners line the side of the drum, with the flames in direct contact with the metal drum. The feed end is elevated to allow the sand to flow freely through the unit, and in some cases flights (paddles connected by chains) are welded to the inside to assist material flow.

Multiple-Hearth Vertical Shaft Furnace. This furnace consists of circular refractory hearths placed one above the other and enclosed in a refractory-lined steel shell. A vertical rotating shaft through the center of the furnace is equipped with air-cooled alloy arms containing rabble blades (plows) that stir the sand and move it in a spiral path across each hearth.

Sand is repeatedly moved outward from the center of a given hearth to the periphery, where it drops through holes to the next hearth. This action gives excellent contact between sand grains and the heated gases. Material is fed into the top of the furnace. It makes its way to the bottom in a zigzag fashion, while the hot gases rise counter-currently, burning the organic material and calcining clay, if one or both are present. Discharge of reclaimed sand can be directly from the bottom hearth into a tube cooler, or other cooling methods may be used. The units are best suited to large tonnages (five tons or more).

New approaches and equipment designed for sand reclamation units are continuing to evolve, and foundries must evaluate each system carefully with regard to the suitability for a particular foundry operation.

In 1988, R.H. Sheppard Company, Inc. in Hanover, Pennsylvania installed a thermal sand reclamation system to recover its 2,200 tons per year of waste green sand. Between the sand purchase price and disposal costs, the foundry was spending over $180,000 per year. Even considering the $428,500 capital investment and regular operation and maintenance costs, over the 20 year useful life of the equipment, the company estimates it will save about $2 million. This does not include the intangible savings of reduced liability of waste sand disposal (Pennsylvania DEP, 1996).

Use Sand as a Construction Material

Depending on its physical and chemical characteristics, non-hazardous waste foundry sand can be used as construction material assuming a market can be found and federal, state, and local regulations relating to handling, storage, and disposal allow it. Many foundries currently recycle foundry waste sand for construction purposes. Industry research, however, indicates that only a small portion of the potential market for waste sand is being utilized. Some potential construction uses for waste sand include: feed stock for portland cement production; fine aggregate for concrete; fine construction aggregate for fill; and bituminous concrete (asphalt) fine aggregate.

Since late 1993, Viking Pump, Inc., of Cedar Falls, Iowa has been shipping spent sand to a portland cement manufacturer for use as a raw material. This reuse reduces the costs for the cement company because the need for mining virgin sand is reduced. Landfill costs for the foundry have been reduced creating a win-win situation for both companies. When Viking began testing foundry sand for use in cement manufacturing, the sand was loaded with an endloader into grain trucks for hauling to the cement plant. Completing a loading took almost an hour. Once the cement company decided that the waste sand was compatible with its process, Viking invested in a sand silo for storage. The sand is now conveyed to the silo and gravity fed into trucks for transportation, significantly reducing handling time to six minutes. Viking expects to send at least half of the spent foundry sand to the portland cement manufacturer and is continuing to look for alternative uses to achieve its pollution prevention goals (U.S. EPA Enviroene Website, 1996).

Not all foundry sand will be ideal for all construction uses. For example, although many foundry sands actually increase compression strengths of concrete when used as a fine aggregate, green molding sands have been shown to decrease compression strengths. In addition, foundries will probably not be able to find markets for their waste sand in its "as-generated" condition. Some processing is typically required in order to match the customers' product specifications. Waste sand may first need to be dried, crushed, screened and separated from metals.

Waste sand streams from certain foundry processes could render a foundry's entire waste sand stream worthless if mixed together. A material flow diagram detailing the flow of sand and its characteristics (particle size distribution, mineralogical composition, moisture content, and chemical and contaminant concentration) through the production processes will help foundry operators identify those spent sand generation points that must be separated out for either processing and sale to a customer or for disposal in a landfill.

V.B. Metal Melting Furnaces

The metal casting industry is highly energy intensive and therefore has opportunities to prevent pollution through increasing energy efficiency. The majority of the energy is consumed by the furnaces used to melt metal; however, energy used in heat curing of sand molds can also be significant depending on the process used (DOE, 1996). Increases in energy efficiency in metal casting operations may have the dual pollution prevention effect of reducing fossil fuel consumption (and the associated environmental impacts) and reducing the amounts of wastes generated from furnaces and curing ovens (e.g., hazardous desulfurization slag, dust, VOCs, etc.). Since energy costs can be a large portion of a metal caster's overall operating costs, increases in energy efficiency can also result in significant cost savings.

Improve Furnace Efficiency

Currently, many foundry furnaces are less than 35 percent energy efficient. Facilities using reverberatory or crucible furnaces may have opportunities to improve their furnace efficiency and stack emissions by upgrading their combustion system (DOE, 1996). New oxygen burners and computerized gas flow metering systems have helped a number of facilities to comply with Clean Air Act regulations for NO_x and CO emissions while reducing energy costs. Some foundries are utilizing regenerative ceramic burner systems. The systems are comprised of two burners which function alternately as a burner and an exhaust port. When one burner fires, the other collects the exhaust gases, recouping the heat from the waste gases. In the next cycle, this burner then fires, recombusting the gases. The recombustion of the waste gases ensures complete combustion and has been shown to reduce NO_x formation. One firm implementing this system reported a 33 percent reduction in energy use and a better melting rate, improving production capacity (Binczewski, 1993).

Install Induction Furnaces

Induction furnaces may offer advantages over electric arc or cupola furnaces for some applications. Induction furnaces are about 75 to 80 percent energy efficient and emit about 75 percent less dust and fumes because of the absence of combustion gases or excessive metal temperatures. When clean scrap material is used, the need for emission control equipment may be minimized. Of course, production operations and process economics must be considered carefully when planning new or retrofit melting equipment (U.S. EPA, 1992).

Minimize Metal Melting

Depending on the casting, between reject castings and gating systems, over half of the metal poured into molds may not become a useful part of the casting. This metal needs to be separated from the castings and remelted, usually at a significant cost. Any increases in yield (reductions in the amount of scrap) will result in energy cost savings from eliminating the need for melting the excess metal. In addition, costs of separating scrap from the castings and waste sand, and the time and expense in machining of gating systems may be reduced. Gating system design that increases yield and reduces the need for machining can reduce a foundry's costs. Optimally designed systems will not use any more metal than is necessary while ensuring that the metal flows into the mold cavity properly to minimize casting defects. A number of computer software products are available to optimize casting design. These products simulate mold filling and casting solidification for various designs and can reduce costs by improving quality and reducing scrap.

A number of casting methods use a central sprue gated to a number of individual casting patterns. Such assemblies termed "trees" or pattern clusters, can generate less excess metal than single pattern mold designs. This technique is most commonly used in the investment and lost foam casting methods. A variation of the investment casting method termed, hollow sprue casting, or counter gravity casting, employs a vacuum to fill the mold with molten metal. A mold or mold cluster assembly fabricated using the investment casting technique is placed in a closed mold chamber with only the open end protruding from the bottom. The mold and mold chamber are lowered to the surface of a ladle or crucible of molten metal until the mold opening is below the surface. A vacuum is then applied to the mold chamber and mold, forcing the molten metal to rise and fill the mold and gating system. The vacuum is maintained until the casting and gates have solidified and is released before the sprue has solidified. The sprue metal then drains back into the molten metal for reuse. If the gating system is designed properly, over 90 percent of the metal becomes part of the useful casting.

Use Alternative Fuels for Melting

Some melt furnaces can utilize natural gas or fuel-oil as a fuel source. Particulate emissions from fuel oils tend to be much greater than emissions from natural gas combustion. If fuel oil must be used, particulate emissions can be reduced by using a lower grade of fuel oil. Petroleum distillates (Numbers 1 and 2 fuel oil) will result in lower particulate emissions than heavier grade fuels (Nos. 4,5,6). Sulfur dioxide emissions can be reduced by choosing a fuel with a low sulfur content. Emissions of nitrogen oxides result from the oxidation of nitrogen bound in the fuel. Selection of a low nitrogen fuel oil will reduce NOx emissions (NADCA, 1996).

Air emissions from the operation of furnaces can be further reduced by using natural gas as a fuel source. Natural gas is considered a clean fuel which, when combusted, emits relatively small amounts of SOx and particulate matter. The primary emission resulting from the combustion of natural gas is nitrogen oxides. NOx emissions can be reduced by applying alternative firing techniques, including the recirculation of flue-gas, staged combustion, and the installation of low NOx burners (NADCA, 1996).

Proper maintenance of furnaces will also help to reduce air emissions. Inefficient fuel/air mixing may generate excess particulate emissions.

V.C. Furnace Dust Management

Dust generation, especially in the Electric Arc Furnace (EAF), and its disposal, has been recognized as a serious problem, but one with potential for pollution prevention through material recovery and source reduction. EAF dust can have high concentrations of lead and cadmium. Some EAF dust can be shipped off-site for zinc reclamation. Most of the EAF dust recovery options are only economically viable for dust with a zinc content of at least 15 - 20 percent (U.S. EPA, 1995).

In-process recycling of EAF dust may involve pelletizing and then reusing the pellets in the furnace, however, recycling of EAF dust on-site has not proven to be technically or economically competitive for all foundries. Improvements in technologies have made off-site recovery a cost effective alternative to thermal treatment or secure landfill disposal.

Maintain Optimal Operating Parameters

Dust emissions from furnaces can often be minimized through a number of good operating practices. Such practices include: avoiding excessive superheating of the metal; maintaining a sufficient flux or slag cover over the metal to keep the molten metal separated from the atmosphere; preheating the metal charged; avoiding the addition of metals at maximum furnace temperatures; and avoiding the heating of the metal too fast.

Recycle EAF Dust to the Original Process

EAFs generate 1 to 2 percent of their charge into dust or fumes. If the zinc and lead levels of the metal dust are low, return of the dust to the furnace for recovery of base metals (iron, chromium, or nickel) may be feasible. This method may be employed with dusts generated by the production of stainless or alloy steels. However, this method is usually impractical for handling dust associated with carbon steel production because galvanized metal scrap is often used and the recovered dust tends to be high in zinc (U.S. EPA, 1992).

Many methods have been proposed for flue-dust recycling, including direct zinc recovery. Zinc content can be increased to the required 15 to 20 percent by returning the dust to the furnace from which it is generated. If the dust is injected into the furnace after the charge of scrap metal is melted, temperatures are high enough for most of the heavy metals to fume off. This technique results in an increased zinc concentration in the dust collected by the scrubbers, electrostatic precipitation systems, or baghouses (U.S. EPA, 1992).

Recycle Dust Outside the Original Process

Silica-based baghouse dust from sand systems and cupola furnaces may be used as a raw material by cement companies. The dust is preblended with other components and transferred to a kiln operation. It is envisioned that baghouse dusts may constitute 5 to 10 percent of the raw material used by cement manufacturers in the future. The use of higher levels may be limited by adverse effects of the baghouse dust on the setting characteristics of the cement (U.S. EPA, 1992).

Waste EAF dust can be reused outside the original process by reclaiming the zinc, lead, and cadmium concentrated in emission control residuals. The feasibility of such reclamation depends on the cost of dust treatment and disposal, the concentration of metals within the residual, the cost of recovering the metals, and the market price for the metals. While this approach is useful in the nonferrous foundry industry (i.e., brass foundries), its application within gray iron foundries is extremely limited. Some foundries market furnace dust as input to brick manufacturing and other consumer product applications, but product liability limits this option. Recovery methods include: pyrometallurgical, rotary kiln, electrothermic shaft furnace, and zinc oxide enrichment (U.S. EPA, 1992).

Pyrometallurgical methods for metals recovery are based on the reduction and volatilization of zinc, lead, cadmium, and other components of EAF dust. Lead is removed preferentially through roasting in an oxidizing environment, while zinc, cadmium and other metals are removed through roasting under reducing conditions. The rotary (or Waelz) kiln method can simultaneously reduce ferrous iron oxide to solid iron and lead and zinc oxide to their metallic forms, using a reducing atmosphere such as carbon monoxide and hydrogen. However, rotary kilns must be fairly large and must process large volumes of dust to be economically and thermally efficient. The electrothermic shaft furnace can extract metallic zinc from a feed containing at least 40 percent of the metal. Typically, agglomerated EAF dust is mixed with other feed to attain this percentage. To recycle dust by direct reduction of oxides, iron oxide is reduced to iron and water using pure hydrogen at a temperature range of 1000 to 1100°C. The reduction of zinc oxide produces zinc vapors and steam at 1000 to 1100°C that are removed from the furnace and subjected to an oxidation step. The zinc reacts with water to produce zinc oxide, and hydrogen is removed and recycled. The zinc oxide produced is separated in a baghouse. The hydrogen containing the steam is further treated for steam condensation, and then the hydrogen is ready for recycling into the furnace (U.S. EPA, 1992).

Alter Raw Materials

The predominant source of lead, zinc, and cadmium in ferrous foundry baghouse dust or scrubber sludge is galvanized scrap metal used as a charge material. To reduce the level of these contaminants, their source must be identified and charge material containing lower concentrations of the contaminants must be acquired. A charge modification program at a large foundry can successfully reduce the lead and cadmium levels in dust collector waste to below EP-toxicity values. Foundries need to work closely with steel scrap suppliers to develop reliable sources of high-grade scrap.

V.D. Slag and Dross Management

Minimize Hazardous Desulfurizing Slag

In the production of ductile iron, it is often necessary to add a desulfurizing agent in the melt to produce the desired casting microstructure. One desulfurization agent used commonly is solid calcium carbide (CaC_2). Calcium carbide is thought to decompose to calcium and graphite. The calcium carbide desulfurization slag is generally removed from the molten iron in the ladle and placed into a hopper. For adequate sulfur removal, CaC_2 must be added in slight excess. Since an excess of CaC_2 is employed to ensure removal of the sulfur, the resulting slag contains both CaS and CaC_2 and must be handled as a reactive waste. The slag might also be hazardous due to high concentrations of heavy metals (U.S. EPA, 1992).

Treatment of this material consists normally of converting the carbide to acetylene and calcium hydroxide by reacting with water. Problems with this method include handling a potentially explosive waste material; generating a waste stream that contains sulfides (due to calcium sulfide in the slag) and many other toxic compounds; and liberating arsine, phosphine, and other toxic materials in the off gas (U.S. EPA, 1992).

One way to reduce the need for calcium carbide is to reduce the amount of high sulfur scrap used as furnace charge materials. While this method is effective, the ability to obtain a steady supply of high-grade scrap varies considerably and may be uneconomical (U.S. EPA, 1992).

To eliminate entirely the use of calcium carbide, several major foundries have investigated the use of alternative desulfurization agents. One proprietary process employs calcium oxide, calcium fluoride, and two other materials. The process can be more economical than carbide desulfurization and results in a satisfactory iron quality (U.S. EPA, 1992).

Often, the amount of sulfur removal for a product is based not on the requirements of that product but on what is achievable in practice. When total sulfur removal is required, it is not uncommon that 20 to 30 percent excess carbide is employed resulting in the generation of larger amounts of slag. If the iron were desulfurized only to the extent actually needed, much of this waste could be reduced or eliminated (U.S. EPA, 1992).

Recycle Hazardous Desulfurizing Slag

Because calcium carbide slag is often removed from the metal by skimming, it is not uncommon to find large amounts of iron mixed in with the slag. Depending on the means of removal, this metal will either be in the form of large blocks or small granules. To reduce metal losses, some foundries crush the slag and remove pieces of metal by hand or with a magnet for remelting. Other foundries have investigated recharging the entire mass to the remelting furnace. Inside the furnace, calcium hydroxide forms in the slag as the recycled calcium carbide either removes additional sulfur or is oxidized directly. While this method has been successful, more research is necessary. For example, it is not known to what extent the calcium sulfide stays with the slag or how much sulfur is carried in the flue gas and the scrubber system. Initial tests indicate that the sulfur does not concentrate in the metal, so that product quality is not affected (U.S. EPA, 1992).

Slag from stainless steel melting operations (where Ni, Mo, and Cr metals are used as alloy additions) is hazardous as a result of high chromium concentrations. Such slag can be recycled as a feed to cupola furnaces (gray iron production line). The cupola furnace slag scavenges trace metals from the induction furnace slag. The resulting cupola slag may be rendered a nonhazardous waste (U.S. EPA, 1992).

Minimize Air Emissions During Dross and Slag Removal

Emissions resulting from the removal of dross and slag can be reduced by decreasing the time in which the dross is exposed to the air. This is true for dross and slag removal processes throughout the facility (e.g., melting, laundering, die casting). Dross and slag pots should be covered as soon as possible to eliminate emissions to the atmosphere. Alternative dross and slag handling techniques can also be practical to reduce emissions. Dross and slag pots can be positioned under or near exhaust hoods in order to divert the emissions to a filter or other emission control device (NADCA, 1996).

R0075869

V.E. Wastewater

Reduce Phenols in Die Casting Wastewater Streams

The major pollutants in the wastewater streams from die casting operations are oils and phenols, with the phenols being the regulated pollutant in most wastewater discharge situations. Common sources of phenols in die casting are the various oils used in the process, such as phosphate ester-based hydraulic oil, die lube, way lube, die cast coolant, etc. Cast salts, degreasers, and heat transfer oils may also contain phenols as an impurity (NADCA, 1996).

An effective method for source control of phenols would be to check each individual raw material used in die casting for phenols, and use or substitute with materials which have little or no phenols. For example, petroleum oils which often contain phenols as contaminants may be substituted with synthetic oils or water-based materials that contain no phenols. Although the alternative materials can be more costly than petroleum-based oils, the annual incremental cost increase may not be significant depending on the volume of material used. In addition, anticipated reductions in environmental control costs may outweigh potential raw material cost increases (NADCA, 1996).

Another effective method of reducing or eliminating phenols in wastewater consists of segregating the various waste streams at the point of generation by collecting the materials in catch pans and handling them separately. For example, die lube overspray can be collected in a metal pan installed below the die, screened to remove debris, filtered (if necessary) to remove fine particulate matter, treated (if necessary) for bacteria contamination, and recycled for reuse in the plant. Plunger lubricants and other drippings may also be collected in pans and recycled off-site as used oil (NADCA, 1996).

Reduce Wastewater and Sludge Generation

Water used to cool parts can be reduced by implementing cooling water recycling systems. Further wastewater reductions may be accomplished by optimizing deburring operations to minimize the total suspended solids in wastewater. This, in turn, will reduce the sludge generation from subsequent treatment. Sludge dewatering can also be optimized through the use of pH controls and filter aids (such as diatomaceous earth) to produce a drier filter cake prior to land disposal.

R.H. Sheppard Company, Inc. in Hanover, Pennsylvania used large quantities of fresh water for cooling metal parts as they were ground to fine tolerances. The company installed a 16,000 gallon closed loop cooling system with temperature and bacteria controls which improved the grinding process and saves 3.4 million gallons of water per year. From its reduced coolant disposal costs and savings in water costs, R.H. Sheppard Company expects a two- to three-year payback period on its $540,000 investment (Pennsylvania DEP, 1996).

Reduce VOC Emissions from Cooling and Quench Water

The primary cause of air emissions from non-contact cooling water cooling towers and quench baths is the use of additives, such as biocides, which contain volatile organic compounds that are eventually emitted to the atmosphere. The best method for reducing air emissions from cooling towers and quench baths is to use fewer additives or to use additives containing no VOCs or Hazardous Air Pollutants (HAPs) (NADCA, 1996).

V.F. Die Casting Lubrication

The majority of emissions generated during the die casting process come from the application of die lubes. These emissions consist of VOC, particulate matter, and HAPs. VOC emissions from die lube application can be reduced by the use of water-based die lubricants or solid lubricants. Eliminating the volatile components of petroleum-based lubricants will also reduce VOC emissions when wet milling finishing techniques are used. However, it is important to note that lubricants which reduce VOC emissions may not necessarily reduce HAP emissions and, in some cases, HAP emissions may be greater from water-based die lubes. Apparently, some of the solvent replacement additives in water-based lubricants may result in increased HAP emissions. It is important to thoroughly evaluate the potential implications for air emissions before alternative lubricant products are used (NADCA, 1996).

In the same manner as VOC emissions, alternative lubricants can be used to reduce particulate emissions from the application of die lubes. However, lubricant-specific evaluations should be performed to determine the particulate emission reduction potential of individual lubricant changes (NADCA, 1996).

V.G. Miscellaneous Residual Wastes

The generation of solid wastes from shipping and receiving processes can be minimized through the use of reusable packaging materials. Metal casters can seek suppliers that use these materials, and work with customers to initiate their use of reusable shipping materials. Many of the common packaging materials in use today, including shrink wrap, strapping materials, cardboard, totes, and drums, can be recycled off-site using commercial recycling services. (NADCA, 1996)

Dross from melting operations is commonly sold to secondary smelters for recovery of the valuable metals. Die casting shot-tip turnings can be re-sized on-site and re-used in the original process (NADCA, 1996).

Leaking hydraulic fluid from die cast machines can be segregated from other die cast fluids using drip pans and/or containment curbing. Leaking and spent hydraulic fluids may be collected and recycled as used oil. Used oil recycling options include re-refining and burning the material for energy recovery in space heaters, boilers, or industrial furnaces (NADCA, 1996).

Refractory, coils, and servicing tools must be periodically replaced in the melting and conveyance operations due to wear. Although the generation of these materials cannot be eliminated, their generation rates can be minimized by raising the pollution prevention awareness of maintenance personnel and optimizing maintenance and servicing schedules (NADCA, 1996).

The generation of floor absorbent solid waste at die cast machines can be minimized through the use of drip pans and containment berming. Hydraulic fluids, die release agents, way lubricants, and other leaking fluids can be collected in this manner. If floor absorbents are to be used, launderable absorbents should be considered. These absorbents are becoming available increasingly from industrial suppliers and laundry services, and can be reused over and over. The use of launderable absorbents results in reduced landfill disposal for both the absorbents and the recovered fluids (NADCA, 1996).

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section VI.A. contains a general overview of major statutes
- Section VI.B. contains a list of regulations specific to this industry
- Section VI.C. contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation and Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities must obtain a permit either from EPA or from a State agency which EPA has authorized to implement the permitting program if they store hazardous wastes for more than 90 days before treatment or disposal. Facilities may treat hazardous wastes stored in less-than-ninety-day tanks or containers without a permit. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 States and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator must follow to determine whether the material in question is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet LDR treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities that store such waste, including large quantity generators accumulating waste prior to shipment off-site.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that must be met by December 22, 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA, Superfund and EPCRA Hotline, *at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.*

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law known commonly as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the

Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as removals. EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance (the list of such substances is in 40 CFR Part 355. Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release equaling or exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, known commonly as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., ET, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The National Pollutant Discharge Elimination System (NPDES) program (CWA §502) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized 42 States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set the conditions and effluent limitations on the facility discharges.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated the NPDES storm water permit application regulations. These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, consult the regulation.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing, 32 (except 323)-stone, clay, glass, and concrete, 33-primary metals, 3441-fabricated structural metal, and 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national pretreatment program (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

Spill Prevention, Control and Countermeasure Plans

The 1990 Oil Pollution Act requires that facilities that could reasonably be expected to discharge oil in harmful quantities prepare and implement more rigorous Spill Prevention Control and Countermeasure (SPCC) Plan required under the CWA (40 CFR §112.7). There are also criminal and civil penalties for deliberate or negligent spills of oil. Regulations covering response to oil discharges and contingency plans (40 CFR Part 300), and Facility Response Plans to oil discharges (40 CFR §112.20) and for PCB transformers and PCB-containing items were revised and finalized in 1995.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA Underground Injection Control (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, volatile organic compounds (VOCs), ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under section 110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and may go into effect as early as late 1997.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title I, section 112(c) of the CAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV of the CAA establishes a sulfur dioxide nitrous oxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI of the CAA is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs) and chloroform, were phased out (except for essential uses) in 1996.

EPA's Clean Air Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities (www.epa.gov ttn then select Directory and then CATC).

VI.B. Industry Specific Requirements

Resource Conservation and Recovery Act (RCRA)

Under the authority of RCRA, EPA created a regulatory framework that addresses the management of hazardous waste. The regulations address the generation, transport, storage, treatment, and disposal of hazardous waste.

The metal casting industry generates waste during molding and core making, melting operations, casting operations, and finishing and cleaning operations. The wastes that are produced during these processes which meet the RCRA hazardous waste criteria must be handled accordingly.

Molding and core making operations produce large quantities of spent foundry sand. Although most of the spent sand is non-hazardous, sand that results from the production of brass or bronze may exhibit the toxicity characteristic for lead or cadmium. The hazardous sand may be reclaimed in a thermal treatment unit which may be subject to RCRA requirements for hazardous waste incinerators. EPA is currently taking public comment on the regulatory status of these units. Wastewaters that are produced during molding and core making may exhibit the corrosivity characteristic but are generally discharged to a POTW after being neutralized, in which case they are not subject to RCRA. Sludges resulting from mold and core making may also be corrosive hazardous wastes.

The wastes associated with metal casting melting operations include fugitive dust and slag. Lead and chromium contamination may cause the waste slag to be subject to RCRA as a hazardous waste. Additionally, calcium carbide desulfurization slag generated during metal melting could be a reactive hazardous waste. Spent solvents used in the cleaning and degreasing of scrap metal prior to melting may also be a hazardous waste. The inorganic acids and chlorinated solvents used in the cleaning operations could be subject to RCRA as well, if they are spilled or disposed of prior to use.

Casting facilities that use electric arc furnaces (EAF) for metal melting produce dust and sludge that may be characteristically hazardous. However, the emission control dust and sludge from foundry operations that use EAFs is not within the K061 hazardous waste listing. Also, this dust and sludge is not considered to be a solid waste under RCRA when reclaimed.

Finishing operations produce wastes similar to those resulting from the cleaning and degreasing of scrap metal prior to melting, including spent solvents and alkaline cleaners. Additionally, any sludge from spent pickle liquor recovery generated by metal casting facilities (SIC code 332) would be a listed hazardous waste (K062).

Clean Air Act

The CAA New Source Review (NSR) requirements apply to new facilities, expansions of existing facilities, or process modifications. New sources of the NAAQS "criteria" pollutants in excess of "major" levels defined by EPA are subject to NSR requirements (40 CFR §52.21(b)(1)(i)(a)-(b)). NSRs are typically conducted by the state agency under standards set by EPA and adopted by the state as part of its state implementation plan (SIP). There are two types of NSRs: Prevention of Significant Deterioration (PSD) reviews for those areas that are meeting the NAAQS; and nonattainment (NA) reviews for areas that are violating the NAAQS. Permits are required to construct or operate the new source for PSD and NA areas.

For NA areas, permits require the new source to meet lowest achievable emission rate (LAER) standards and the operator of the new source must procure reductions in emissions of the same pollutants from other sources in the NA area in equal or greater amounts to the new source. These emission offsets may be banked and traded through state agencies.

For PSD areas, permits require the best available control technology (BACT), and the operator or owner of the new source must conduct continuous on-site air quality monitoring for one year prior to the new source addition to determine the effects that the new emissions may have on air quality.

EPA has not established New Source Performance Standards (NSPSs) for the metal casting industrial category.

Under Title V of the CAAA 1990 (40 CFR Parts 70-72) all of the applicable requirements of the Amendments are integrated into one federal renewable operating permit. Facilities defined as major sources under the Act must apply for permits within one year from when EPA approves the state permit programs. Since most state programs were not approved until after November 1994, Title V permits, for the most part, began to be due in late 1995. Due dates for filing complete applications vary from state to state, based on the status of review and approval of the state's Title V program by EPA.

A facility is designated as a major source if it includes sources subject to the NSPS acid rain provisions or NESHAPS, or if it releases a certain amount of any one of the CAAA regulated pollutants (SO_x, NO_x, CO, VOC, PM_{10}, hazardous air pollutants, extremely hazardous substances, ozone depleting substances, and pollutants covered by NSPSs) depending on the region's air quality category. Title V permits may set limits on the amounts of pollutant emissions and require emissions monitoring, recordkeeping, and reporting.

Many large and some medium-sized foundries are likely to be major sources and therefore must apply for a Title V permit. Selected small foundries may also be classified as major sources, depending on their location and operational factors.

Clean Water Act

Foundry and die casting facility wastewater released to surface waters is regulated under the CWA (40 CFR Part 464). National Pollutant Discharge Elimination System (NPDES) permits must be obtained to discharge wastewater into navigable waters (40 Part 122). Effluent limitation guidelines, new source performance standards, pretreatment standards for new sources, and pretreatment standards for existing sources for the Metal Molding and Casting Point Source Category apply to ferrous and non-ferrous foundries and die casters and are listed under 40 CFR Part 464 and are divided into subparts according to the metal cast:

Subpart A	Applies to aluminum casting operations
Subpart B	Applies to copper casting operations
Subpart C	Applies to ferrous casting operations
Subpart D	Applies to zinc casting operations

In addition to the effluent guidelines, facilities that discharge to a POTW may be required to meet National Pretreatment Standards for some contaminants. General pretreatment standards applying to most industries discharging to a POTW are described in 40 CFR Part 403 (Contact Pat Bradley, EPA Office of Water, 202-260-6963). As shown above, pretreatment standards applying specifically to the metal casting point source category are listed in the subparts of 40 CFR Part 464 (Contact: George Jett, EPA Office of Water, 202-260-7151).

Stormwater rules require that metal casting facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. The rules require that certain facilities with storm water discharge from from industrial activity apply for storm water permit applications (see Section VI.A).

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the Superfund Amendments and Reauthorization Act of 1986 (SARA) provide the basic legal framework for the federal "Superfund" program to clean up abandoned hazardous waste sites (40 CFR Part 305). The metals and metal compounds used in metal casting, are often found in casting facilities' air emissions, water discharges, or waste shipments for off-site disposal. These include chromium, manganese, aluminum, nickel, copper, zinc, and lead. Metals are frequently found at CERCLA's problem sites. In 1989, when Congress ordered EPA and the Public Health Service's Agency for Toxic Substances and Disease Registry (ATSDR) to list the hazardous substances found most commonly at problem sites and that pose the greatest threat to human health, lead, nickel, and aluminum all made the list (Breen and Campbell-Mohn, 1993). A number of sites containing foundry wastes are on the National Priorities (Superfund) List. Compliance with the requirements of RCRA lessens the chances that CERCLA compliance will be an issue in the future.

VI.C. Pending and Proposed Regulatory Requirements

Resource Conservation and Recovery Act (RCRA)

Currently, the practice of adding iron dust or filings to spent foundry sand as a form of stabilization is subject to case-specific interpretation by EPA regarding whether this activity effectively treats the waste. However, EPA has proposed to regulate this activity as impermissible dilution, which is strictly prohibited under the land disposal restrictions program, and intends to examine the issue further.

Thermal processing or reclamation units (TRUs) remove contaminants from spent foundry sand primarily by combusting the organic binder materials in the sand. These units are identified as foundry furnaces under the definition of industrial furnace and are subject to regulation under 40 CFR Part 266, Subpart H when they burn hazardous waste. However, EPA did not consider whether TRUs would be appropriately controlled under these standards. EPA has proposed two approaches to ensure controls for TRUs. The first option is a deferral from regulation under 40 CFR Part 266, Subpart H. This would allow development of the foundry maximum achievable control technology under the Clean Air Act and potentially the application of these controls to TRUs that process hazardous waste sand. The second option is to provide a variance from the RCRA definition of solid waste. Under the variance provisions, EPA may grant a variance from the definition of solid waste for materials that are reclaimed and used as a feedstock within the original production process if the reclamation process is an essential part of the production process. Under this option, TRUs would not be subject to RCRA regulation, but could be regulated under the Clean Air Act or state or local air pollution laws (EPA, RCRA Hotline, 1997).

Clean Air Act

In addition to the CAA requirements discussed above, EPA is currently working on or will be working on additional regulations that will directly affect the metal casting industry. Under Title III, EPA is required to develop national standards for 189 hazardous air pollutants (HAPs) some of which are emitted from foundries. NESHAP standards may limit the air emissions from foundries through Maximum Achievable Control Technology (MACT) based on performance standards that will set limits based upon concentrations of HAPs in the waste stream. NESHAP standards for ferrous foundries are scheduled to be promulgated by EPA in November of 2000 (James Maysilles, U.S. EPA, Office of Air, (919) 541-3265). Non-ferrous foundries and die casting facilities will not be subject to NESHAP standards.

R0075890

EPA is also developing the Compliance Assurance Monitoring Rule. The rule may require monitoring of certain emissions from certain facilities. Facilities are required to pay a fee for filing for a permit and are required to pay an annual fee based on the magnitude of the facility's potential emissions.

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small

businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (April 1, 1992 to March 31, 1997) and the other for the most recent twelve-month period (April 1, 1996 to March 31, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across EPA Regions for certain sectors.[4] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data

[4] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of records for that facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times, e.g., a facility with 3 enforcement actions counts as 3.

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and FIFRA/TSCA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Metal Casting Industry Compliance History

Table 15 provides an overview of the reported compliance and enforcement data for the metal casting industry over the past five years (April 1992 to April 1997). These data are also broken out by EPA Regions thereby permitting geographical comparisons. A few points evident from the data are listed below.

- Almost 80 percent of metal casting facility inspections and 63 percent of enforcement actions occurred in Regions III, IV, and V, where most facilities (68 percent) are located.

- Region X had a high ratio of enforcement to inspections (0.40) compared to other Regions.

- Region IX had a significantly higher average time between inspections (70 months), which means that fewer inspections were carried out in relation to the number of facilities in the Region (54 facilities and 40 inspections).

- Region IV had the shortest average time between inspections (9 months), but also had the lowest rate of enforcement actions to inspections of any Region (0.05).

Table 15: Five-Year Enforcement and Compliance Summary for the Metal Casting Industry

A	B	C	D	E	F	G	H	I	J
Region	Facilities in Search	Facilities Inspected	Number of Inspections	Average Months Between Inspections	Facilities with 1 or More Enforcement Actions	Total Enforcement Actions	Percent State Lead Actions	Percent Federal Lead Actions	Enforcement to Inspection Rate
I	15	8	44	20	2	3	67%	33%	0.07
II	26	16	128	12	10	19	68%	32%	0.15

TOTAL	669	424	2,535	16	113	191	71%	29%	0.08

VII.B. Comparison of Enforcement Activity Between Selected Industries

Tables 16 and 17 allow the compliance history of the metal casting sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Tables 16 and 17 permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering the last five years (April 1992 to April 1997) to that of the past year (April 1996 to April 1997). Some points evident from the data are listed below.

- Over the past year, the industry has had one of the highest proportions of facilities inspected with violations (103 percent) and enforcement actions (10 percent).

- Over the past year, the average enforcement to inspection rate for the metal casting industry has decreased to 0.06 compared to 0.08 over the past five years.

- Of the sectors listed, facilities in the metal casting sector had one of the highest proportions of federal-lead enforcement actions (29 percent).

Tables 18 and 19 provide a more in-depth comparison between the metal casting industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Tables (Tables 16 and 17), the data cover the last five years (Table 18) and the last one year (Table 19) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- The percentage of inspections carried out under each environmental statute has changed little over the past five years compared to the past year. Inspections under CAA account for the majority (about 60 percent) followed by RCRA and CWA.

- The percentage of CAA enforcement actions increased from 44 percent over the past five years to 58 percent over the past year. In addition, the percentage of enforcement actions carried under FIFRA/TSCA/EPCRA/Other decreased from 14 percent to 0 percent while CWA and RCRA remained about the same.

VII.C. Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VII.C.1. Review of Major Cases

As indicated in EPA's *Enforcement Accomplishments Report, FY1995 and FY1996* publications, 8 significant enforcement actions were resolved between 1995 and 1996 for the metal casting industry.

EMI Company (Pennsylvania): On May 29, 1996, EPA executed a consent agreement and order settling an administrative action against EMI Company for payment of $20,000 and agreement to perform a Supplemental Environmental Project (SEP). The SEP requires respondent to install and operate (for one (1) year) baghouse emissions control technology for four (4) electric induction furnaces presently not subject to Best Available Control Technology (BAT) control requirements. The total SEP capital costs and operating expenditure costs for one year are estimated to be at least $786,664. Those particulates include some of the regulated materials (copper and manganese) that are the subject of this action. Region III filed the administrative complaint against EMI Company of Erie, Pennsylvania for EPCRA reporting violations.

Leggett and Platt (Grafton, Wisconsin): On Monday, April 1, 1996, a consent decree was entered in the Milwaukee Federal court with Leggett & Platt, concerning their Grafton, WI, facilities (2). A penalty of $450,000 was stipulated in the decree based on four years of reporting failures and exceeding the Federal Pretreatment standards for the Metal Molding and Casting industry. Also, the company agreed in the consent decree not to discharge process wastes to the Grafton POTW. As a result of this stipulation the company started a water recycle system in April, 1995, with several levels of plant water cleanliness. After several months of experimentation the company observed that the recycle system had a two-year payout due to the reduction of the use of plant lubricants. The yearly savings were in excess of $50,000/year. Therefore, there was no economic benefit available for recovery.

Cooper Cameron (Richmond, Texas): This enforcement action arose out of the Region VI Foundry Initiative. EPA conducted an inspection of the Cooper Industries, Inc., Oil Tool Division in Richmond, Texas on September 21-23, 1994. At that facility, the Cooper Oil Tool Division manufactured a variety of low and high carbon steel and stainless steel oil tool castings for valves and other equipment. During the inspection, EPA discovered a waste pile which contained Electric Arc Furnace (EAF) baghouse dust. This material was sampled using the TCLP method and was found to contain chromium (D007) above the 5.0 mg/L regulatory level. Therefore, the EAF baghouse dust is a hazardous waste. Cooper Oil Tool Division was acquired by Cooper Cameron Corporation which was spun off from Cooper Industries, Inc. in 1995. As the corporate successor to the Oil Tool Division, Cooper Cameron became responsible for the cited violations. Region VI simultaneously filed the consent agreement/consent order on September 30, 1996, assessing a civil penalty of $45,000 plus injunctive relief. Additionally, Cooper Cameron has agreed to remediate, under the Texas Natural Resource Conservation Commision (TNRCC) Voluntary Cleanup Program, approximately 30 acres of waste materials stored in piles on their site. It is estimated that this action will reduce the risk of releasing more than 100 tons of chromium contaminated soil. The agreement to remediate the waste pile is a result of concern over environmental justice. The surrounding community is approximately 51% minority while Texas' average is 39%.

HICA Steel Foundry and Upgrade Co. (Shreveport, Louisiana): On November 7, 1995, EPA issued HICA Steel Foundry and Upgrade Company an administrative order (complaint). The order proposed a $472,000 fine and required closure of several unauthorized hazardous waste management units. This action required the removal and proper disposal of 2,600 gallons on corrosive and ignitable hazardous waste and 255 tons of lead and chromium contaminated waste from the facility.

NIBCO, Inc. (Blytheville, Arkansas): A final consent agreement/consent order was signed by both Region VI and NIBCO on September 30, 1996. NIBCO agreed to pay $750,000 in cash to satisfy the approximately $2.5 million in civil penalties assessed by Region VI in this Foundry Initiative enforcement action. The enforcement action against NIBCO originated because the facility was treating sand used in the casting of metal valves (casting sand) with metallic iron dust, without a permit, and disposing of the material in the Nacogdoches municipal landfill. The casting sand absorbs lead during the casting process, making it a hazardous waste. In order to offset the civil penalty, NIBCO agreed to work with Texas Natural Resource Conservation Commision (TNRCC) and the City of Nacogdoches to characterize the foundry sand waste disposed of in the Nacogdoches municipal landfill, and ensure closure and post-closure measures are performed in accordance with all applicable requirements and schedules established by TNRCC.

Lynchburg Foundry Company (Lynchburg, VA): On August 24, 1995, the Region III Administrator signed a consent order which requires Lynchburg Foundry Company to perform tasks set out in the compliance section of the consent agreement, and to pay $330,000 to EPA. Lynchburg, located in Lynchburg, Virginia, operates two facilities: Radford and Archer Creek, both of which manufacture metal automotive parts. Under the terms of the consent agreement and order, Lynchburg must: 1) list all hazardous wastes handled at both facilities within its hazardous waste notification filed with the Virginia Department of Hazardous Waste; 2) amend or supplement its emergency contingency plans for both facilities to reflect the arrangements agreed to by local emergency services; and 3) permanently cease illegally storing or treating D006 and D008 hazardous wastes in waste piles at either facility.

Great Lakes Casting Corporation (Ludington, MI): On November 15, 1994, a consent decree was entered in the U.S. District Court for the Western District of Michigan in the *U.S. v. Great Lakes Casting Corporation* case requiring Great Lakes to pay a civil penalty of $350,000 for illegal hazardous waste disposal under RCRA.

CMI-Cast Parts, Inc. (Cadillac, MI): A consent agreement and final order was signed on December 22, 1994, which settled an administrative complaint against CMI-Cast Parts, Inc. CMI-Cast Parts, Inc. is a Michigan corporation which owns and operates an iron foundry in Cadillac, Michigan. CMI-Cast Parts, Inc. failed to obtain interim status or a proper operating permit to treat, store or dispose of hazardous waste at its Cadillac facility. From September 1990 to January 1994, the facility failed to comply with the hazardous waste management standards. On January 26, 1995, CMI-Cast Parts, Inc., submitted a certified check in the amount of $454,600.00, payable to the Treasurer of the United States of America, for final settlement of the enforcement action.

VII.C.2. Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the Internet at EPA's Enviroene Website: http://es.inel.gov/sep.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

VIII.A.1. Federal Activities

Metalcasting Competitiveness Research (MCR) Program

The U.S. Department of Energy (DOE) Metalcasting Competitiveness Research Act (Public Law 101-425) was signed in 1990 and established the U.S. DOE, Office of Industrial Technology Metalcasting Competitiveness Research (MCR) Program. The program provides assistance to the metalcasting industry by fostering R&D in technology areas that were identified as priority in nature by the industry including technology competitiveness and energy efficiency. In this program, industry and the DOE provide cost-share funding to metalcasting research institutions that conduct the R&D. Projects are chosen based on a set of research priorities developed by the Metalcasting Industrial Advisory Board (IAB). The IAB meets once a year to revise these priorities. As of 1996, 24 projects have been funded through the MCR Program, a number of them having direct and indirect benefits to the environment.

Casting Emission Reduction Program

The Casting Emission Reduction Program (CERP) is primarily focused on developing new materials, processes or equipment for metalcasting manufacturing which will achieve a near-zero effect on the environment while producing high quality components for the U.S. military and other users. The program also has the objective of bridging the critical gap between laboratory and full scale casting production. The result will be a platform for proofing and validating the next generation of light weight weapon system components using near net shape metal castings.

The program was initiated by the Department of Defense (DoD) in response to the rapid reduction in domestic foundries capable of producing the critical components of military hardware. These parts range from tank tracks and turrets to the tail structure of the F-16 fighter. The DoD sees an immediate threat to sand casting foundries and their ability to withstand the changes resulting from the Titles III and V Amendments to the 1990 Clean Air Act.

In addition, DoD realizes that the needs of the military for post year 2000 hardware will depend on manufacturing technologies which do not exist today or are unable to make the transition from the lab bench to the shop floor. CERP aims to provide the country with the ability to launch lighter weight castings more quickly and at the same time meet the more demanding environmental regulations of the 1990 Clean Air Act Amendments. Although the program was initiated to address military needs, it is anticipated that it will benefit the entire industry.

The specific activities of CERP will include obtaining a baseline of emissions from foundries across the U.S., developing a pilot foundry at McClellan AFB in California for the testing and prototyping of new casting processes and materials, and developing the real-time emission instrumentation for foundries. The five-year program receives Congressional appropriations under the Research, Development, Test & Defense Wide category. Other technical partners directly supporting the project include the American Foundrymen's Society, the U.S. Environmental Protection Agency (EPA), the California Air Resources Board (CARB), and the U.S. Council for Automotive Research (USCAR). Contact: Bill Walden, (916) 643-1090.

EPA Region VI Foundry Initiative

EPA's Region VI (Oklahoma, Texas, Louisiana, Arkansas, New Mexico) began a Foundry Initiative in 1993 to improve compliance rates among the 600 foundries in the region. An initial inspection of 27 foundries in the Region indicated that a large percentage had potential RCRA violations. Region VI formed a partnership with the States and the American Foundrymen's Society to develop an initiative for environmental compliance which would be beneficial to foundries. EPA, the States and foundry representatives established a workgroup that provides an open forum for discussion, identifies relevant environmental issues facing foundries and develops educational assistance programs.

Through education and compliance assistance, the program aims to improve communication between the industry and the regulatory agencies and increase voluntary compliance with the regulations. The program provides foundries with information to fix problems before active enforcement occurs. For example, in Oklahoma where the initiative has recently been completed, a six month correction period was offered. Workshops and seminars were held in each state and individual compliance assistance and site visits are being offered. Contact: Joel Dougherty, Ph.D., (214) 665-2281.

VIII.A.2. State Activities

Oklahoma

The Oklahoma Department of Environmental Quality (DEQ) Customer Assistance Program recently completed its Foundry Initiative with EPA Region VI (See above). After Region 6 made plans to inspect 12 facilities in Oklahoma, the Oklahoma (DEQ) suggested an alternate strategy. A multi-media workshop was held in April 1995 that focused on pollution issues facing the foundry industry. From that workshop, an entire state-wide compliance achievement program was developed for metal casting facilities.

The Program consisted of the following trade-offs between industry and the regulators.

1) The industry would perform an environmental self-audit and fix any problems identified.
2) The DEQ and the EPA would allow a six month "correction period."
3) During the correction period any regularly scheduled annual inspections were canceled. This allowed the facility to focus on identifying and correcting areas of non-compliance.
4) At the end of the "correction period" there would be a return to normally scheduled inspections.

Of the 45 qualifying facilities in Oklahoma, 23 participated in the program. Each of the 23 facilities performed a self-audit that covered air quality, water quality, and waste management issues. Each facility also completed the program, which included workshops, self-audits, site visits, and "free" inspections. The types of compliance issues that were corrected as a result of the program were:

1) state minor air permits,
2) solid waste disposal approvals,
3) storm water pollution prevention plans,
4) SARA Title III reporting, and
5) air pollution controls.

An important outcome was the new relationship between the foundries and the agency. This new relationship was based on information sharing for the common goal of compliance. The participating foundries were able to obtain permits and disposal approvals without penalty. Several facilities continue to work with the DEQ to solve more complex compliance issues, such as on-site land disposal of foundry sand. Contact: Dave Dillon, Customer Assistance Program, Oklahoma DEQ, (405) 271-1400.

University of Wisconsin - Milwaukee Center for By-Product Utilization

At the University of Wisconsin - Milwaukee Center for By-Product Utilization researchers are examining the feasibility of using spent foundry sand and slag as feed for concrete manufacturing. The center is testing the compression strengths of concrete mixed with 25 percent and 35 percent (by weight) of different types of used foundry sand. Tests are also being carried out substituting foundry sand in asphaltic concrete. Many of the tests have shown that structural grade concrete and asphaltic concrete can be produced successfully and economically using waste foundry sand.

VIII.B. EPA Voluntary Programs

33/50 Program

The 33/50 Program is a groundbreaking program that has focused on reducing pollution from seventeen high-priority chemicals through voluntary partnerships with industry. The program's name stems from its goals: a 33% reduction in toxic releases by 1992, and a 50% reduction by 1995, against a baseline of 1.5 billion pounds of releases and transfers in 1988. The results have been impressive: 1,300 companies have joined the 33/50 Program (representing over 6,000 facilities) and have reached the national targets a year ahead of schedule. The 33% goal was reached in 1991, and the 50% goal -- a reduction of 745 million pounds of toxic wastes -- was reached in 1994. The 33/50 Program can provide case studies on many of the corporate accomplishments in reducing waste (Contact 33/50 Program Director David Sarokin -- 202-260-6396).

Table 19 lists those companies participating in the 33/50 program that reported four-digit SIC codes within 332 and 336 to TRI. Some of the companies shown also listed facilities that are not producing metal castings. The number of facilities within each company that are participating in the 33/50 program and that report metal casting SIC codes is shown. Where available and quantfiable against 1988 releases and transfers, each company's 33/50 goals for 1995 and the actual total releases and transfers and percent reduction between 1988 and 1994 are presented.

Fourteen of the seventeen target chemicals were reported to TRI by metal casting facilities in 1994. Of all TRI chemicals released and transferred by the metal casting industry, nickel and nickel compounds, and chromium and chromium compounds (both 33/50 target chemicals), were released and transferred second and third most frequently (behind copper), and were in the top ten largest volume released and transferred. Other frequently reported 33/50 target chemicals were lead and lead compounds, xylenes and toluene.

Table 20 shows that 55 companies comprised of 129 facilities reporting SIC 332 and 336 are participating in the 33/50 program. For those companies shown with more than one metal casting facility, all facilities may not be participating in 33/50. The 33/50 goals shown for companies with multiple metal casting facilities, however, are company-wide, potentially aggregating more than one facility and facilities not carrying out metal casting operations. In addition to company-wide goals, individual facilities within a company may have their own 33/50 goals or may be specifically listed as not participating in the 33/50 program. Since the actual percent reductions shown in the last column apply to all of the companies' metal casting facilities and only metal casting facilities, direct comparisons to those company goals incorporating non-metal casting facilities or excluding certain facilities may not be possible. For information on specific facilities participating in 33/50, contact David Sarokin (202-260-6907) at the 33/50 Program Office.

Source: U.S. EPA 33/50 Program Office, 1996.

1 Company-Wide Reduction Goals aggregate all company-owned facilities which may include facilities not producing metal castings.

2 Releases and Transfers are from metal casting facilities only.

* = Reduction goal not quantifiable against 1988 TRI data.

** = Use reduction goal only.

*** = No numeric reduction goal.

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative developed by EPA that focuses on improving environmental performance, encouraging voluntary compliance, and building working relationships with stakeholders. EPA initiated a one year pilot program in 1995 by selecting 12 projects at industrial facilities and federal installations which would demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, pollution prevention, community involvement, and mentor programs. In return for participating, pilot participants received public recognition and were given a period of time to correct any violations discovered during these experimental projects.

EPA is making plans to launch its full-scale Environmental Leadership Program in 1997. The full-scale program will be facility-based with a 6-year participation cycle. Facilities that meet certain requirements will be eligible to participate, such as having a community outreach/employee involvement programs and an environmental management system (EMS) in place for 2 years. (Contact: http://es.inel.gov/elp or Debby Thomas, ELP Deputy Director, at 202-564-5041)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline 202-260-8590, Web: http://www.epa.gov/ProjectXL, or Christopher Knopes at EPA's Office of Policy, Planning and Evaluation 202-260-9298)

Climate Wise Program

Climate Wise is helping US industries turn energy efficiency and pollution prevention into a corporate asset. Supported by the technical assistance, financing information and public recognition that Climate Wise offers, participating companies are developing and launching comprehensive industrial energy efficiency and pollution prevention action plans that save money and protect the environment. The nearly 300 Climate Wise companies expect to save more than $300 million and reduce greenhouse gas emissions by 18 million metric tons of carbon dioxide equivalent by the year 2000. Some of the actions companies are undertaking to achieve these results include: process improvements, boiler and steam system optimization, air compressor system improvements, fuel switching, and waste heat recovery measures including cogeneration. Created as part of the President's Climate Change Action Plan, Climate Wise is jointly operated by the Department of Energy and EPA. Under the Plan many other programs were also launched or upgraded including Green Lights, WasteWi$e and DoE's Motor Challenge Program. Climate Wise provides an umbrella for these programs which encourage company participation by providing information on the range of partnership opportunities available. (Contact: Pamela Herman, EPA, 202-260-4407 or Jan Vernet, DoE, 202-586-4755)

Energy Star Buildings Program

EPA's ENERGY STAR Buildings Program is a voluntary, profit-based program designed to improve the energy-efficiency in commercial and industrial buildings. Expanding the successful Green Lights Program, ENERGY STAR Buildings was launched in 1995. This program relies on a 5-stage strategy designed to maximize energy savings thereby lowering energy bills, improving occupant comfort, and preventing pollution -- all at the same time. If implemented in every commercial and industrial building in the United States, ENERGY STAR Buildings could cut the nation's energy bill by up to $25 billion and prevent up to 35% of carbon dioxide emissions. (This is equivalent to taking 60 million cars of the road). ENERGY STAR Buildings participants include corporations; small and medium sized businesses; local, federal and state governments; non-profit groups; schools; universities; and health care facilities. EPA provides technical and non-technical support including software, workshops, manuals, communication tools, and an information hotline. EPA's Office of Air and Radiation manages the operation of the ENERGY STAR Buildings Program. (Contact: Green Light/Energy Star Hotline at 1-888-STAR-YES or Maria Tikoff Vargas, EPA Program Director at 202-233-9178 or visit the ENERGY STAR Buildings Program website at http://www.epa.gov/appdstar/buildings/)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program saves money for businesses and organizations and creates a cleaner environment by reducing pollutants released into the atmosphere. The program has over 2,345 participants which include major corporations, small and medium sized businesses, federal, state and local governments, non-profit groups, schools, universities, and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. As of March 1997, participants had lowered their electric bills by $289 million annually. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and an information hotline. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Green Light/Energy Star Hotline at 1-888-STARYES or Maria Tikoff Vargar, EPA Program Director, at 202-233-9178)

WasteWiSe Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1997, the program had about 500 companies as members, one third of whom are Fortune 1000 corporations. Members agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports. To member companies, EPA, in turn, provides technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at 1-800-372-9473 or Joanne Oxley, EPA Program Manager, 703-308-0199)

NICE^3

The U.S. Department of Energy is administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 45 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, and demonstrate new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the forest products, chemicals, petroleum refining, steel, aluminum, metal casting and glass manufacturing sectors. (Contact: http//www.oit.doe.gov/access/nice3, Chris Sifri, DOE, 303-275-4723 or Eric Hass, DOE, 303-275-4728)

Design for the Environment (DfE)

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202) 260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at http://es.inel.gov/dfe.

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Industry Research Programs

American Metalcasting Consortium (AMC)

The American Metalcasting Consortium (AMC) is a group of six organizations from the metalcasting industry that have joined together to ally the thousands of small and medium sized metalcasters within the market in an effort to re-establish American viability in the metalcasting industry. AMC aims to energize critical facets of the industry which stimulate lead time and cost reductions, quality, and market share/growth. These goals are being implemented through efforts focused on projects in the areas of 1) applied research and development, 2) education, training, and technology transfer, 3) small business, and 4) casting applications development. Many of the projects will result in positive environmental impacts by improving the industry's overall energy efficiency and reducing the quantity of wastes and off-spec castings. The AMC organizations are: The American Foundrymen's Society (AFS); Non-Ferrous Founders' Society (NFFS); North American Die Casting Association (NADCA); and the Steel Founders' Society of America (SFSA).

Cast Metals Coalition (CMC)

In 1995, Chief Executive Officers and Presidents from the foundry, diecasting, and foundry supply industries developed goals for the future of the industry in *Beyond 2000: A Vision for the American Metalcasting Industry*. Representatives from the American Foundrymen's Society, the Steel Founders' Society of America, and the North American Die Casters Association formed the Cast Metals Coalition (CMC). The CMC is working

R0075917

towards developing a technology roadmap for pursuing and achieving these goals. CMC is working with industry and research institutions, including universities and national laboratories to develop this roadmap.

Pennsylvania Foundry Consortia

A consortia of Pennsylvania foundries, the Pennsylvania Foundrymen's Association and Penn State University have been working cooperatively since 1985 on issues associated with solid waste disposal, sand reclamation, and beneficial use of foundry residuals. This group is addressing the impediments to beneficial use of foundry residuals on a comprehensive national level. The goals of the research are to maximize the beneficial reuse of environmentally safe foundry residuals and to streamline the path for their acceptability by other industries. Specific tasks carried out involve establishing a database of technical and environmental information to support reuse applications, developing and administering a comprehensive survey of potential aggregate users, and performing physical and environmental testing to demonstrate the applicability of residual wastes for reuse applications. The program receives funding from a U.S. EPA grant.

VIII.C.2. Trade Associations

American Foundrymen's Society, Inc.
(AFS)
505 State Street
Des Plaines, IL 60016-8399
Phone: (800) 537-4237
Fax: (847) 824-7848

Members: 12,800
Staff: 60
Contact: Gary Mosher,
Vice President, Environmental Health and Safety

The American Foundrymen's Society (AFS) is the primary trade association for the foundry industry. Founded in 1896, the Society has student and local groups throughout the U.S. and internationally. AFS is the technical, trade, and management association of foundrymen, pattern makers, technologists, and educators. The society sponsors foundry training courses through the Cast Metals Institute on all subjects pertaining to the casting industry and sponsors numerous regional and local conferences and meetings. AFS maintains an extensive Technical Information Center, conducts research programs, compiles statistics, and provides marketing information. environmental services, and testing. The monthly trade magazine, *Modern Casting*, covers current technology practices and other factors affecting the production and marketing of metal castings.

North American Die Casting Association
(NADCA)
9701 W. Higgins Rd., Ste. 880
Rosemont, IL 60018
Phone: 847-292-3600
Fax: 847-292-3620

Members: 3,200
Staff: 17
Contact: Dan Twarog

The North American Die Casting Association (NADCA) was founded in 1989 and is made up of producers of die castings and suppliers to industry, product and die designers, metallurgists, and students. There are regional and local groups across the U.S. NADCA develops product standards; compiles trade statistics on metal consumption trends; conducts promotional activities; and provides information on chemistry, mechanics, engineering, and other arts and sciences related to die casting. The association also maintains a library and provides training materials and short, intensive courses in die casting. A trade magazine, *Die Casting Engineer*, is published periodically and contains information on new products and literature, chapter news, and a calendar of events.

Non-Ferrous Founders' Society
455 State St., Suite 100
Des Plaines, IL 60016
Phone: 847-299-0950
Fax: 847-299-3598

Members: 185
Staff: 2
Contact: Jim Mallory or Mark Remlinger, Chair of Environment Committee

The Non-Ferrous Founders' Society (NFFS) is comprised of manufacturers of brass, bronze, aluminum, and other nonferrous castings. Founded in 1943, NFFS conducts research programs and compiles statistics related to the nonferrous castings industry. The Society has committees related to: export government relations; insurance; local management group; management conferences; planning; quality; and technical research. NFFS publishes *The Crucible* bimonthly. This trade magazine contains articles relevant to the day-to-day management of aluminum, brass, bronze, and other nonferrous foundries. NFFS also publishes a biennial *Directory of Nonferrous Foundries* listing member and nonmember foundries producing primarily aluminum, brass, and bronze castings.

Steel Founders' Society of America (SFSA)
Cast Metals Fed. Bldg.
455 State St.
Des Plaines, IL 60016
Phone: 847-299-9160
Fax: 847-299-3105

Members: 75
Staff: 6
Contact: Raymond Monroe

The Steel Founders Society of America (SFSA) is comprised of manufacturers of steel castings. Founded in 1902, the Society conducts research programs and compiles statistics related to the steel casting industry. SFSA periodically publishes *CASTEEL* which contains special articles on specifications and technical aspects of steel castings. SFSA also publishes a biennial *Directory of Steel Foundries* listing steel foundries in the U.S., Canada, and Mexico. Committees include Marketing, Specifications, and Technical Research.

Investment Casting Institute
8350 N. Central Expressway
Suite M 1110
Dallas, TX 75206
Phone: 214-368-8896
Fax: 214-368-8852

Members: 275
Staff: 5
Contact: Henry Bidwell

The Investment Casting Institute is an international trade association comprised of manufacturers of precision castings for industrial use made by the investment (or lost wax) process and suppliers to such manufacturers. The Institute provides training courses and other specialized education programs and publishes the monthly newsletter *Incast*.

Casting Industry Suppliers Association (CISA)
455 State St., Suite 104
Des Plaines, IL 60016
Phone: 708-824-7878
Fax: 708-824-7908

Members: 66
Staff: 1
Contact: Darla Boudjenah

The Casting Industry Suppliers Association (CISA) was founded in 1986 and represents manufacturers of foundry equipment and supplies such as molding machinery, dust control equipment and systems, blast cleaning machines, tumbling equipment, and related products. CISA also aims to foster better trade practices and serve as an industry representative before the government and the public. The Association also compiles industry statistics and disseminates reports of progress in new processes and methods in foundry operation.

The Ferroalloys Association (TFA)
900 2nd St. NE, Suite 201
Washington, DC 20002
Phone: 202-842-0292
Fax: 202-842-4840

Members: 21
Staff: 3
Contact: Edward Kinghorn Jr.

The purpose of The Ferroalloys Association's (TFA) is to promote the general welfare of the producers of chromium, manganese, silicon, vanadium ferroalloys and related basic alloys/metals in the United States and to engage in all lawful activities to that end. Founded in 1971, TFA consistently provides the ferroalloy industry a means to accomplish tasks through a common bond of business interests.

The ferroalloy industry produces high strength metals created by submerged electric arc smelting, induction melting, alumino/silicothermic reduction processes, and vacuum reduction furnaces, as well as by electrolytic processes. More than 50 different alloys and metals in hundreds of compositions and sizes are produced by the ferroalloy industry for use in the manufacturing of stainless steel, iron, and aluminum. The industry also produces vital materials used in the production of chemicals, semi-conductors, solar cells, coatings, and catalysts.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS

For further information on selected topics within the metal casting industry a list of contacts and publications are provided below.

INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.epa.gov/comply/sector/index.html

or use

www.epa.gov/oeca - then select the button labeled Industry and Gov't Sectors and select the appropriate sector from the menu. The Notebook will be listed.

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Superintendent of Documents, Mail Stop: SSOP, Washington, DC 20402-9328
ISBN 0-16-048274-7

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

FABRICATED METAL PRODUCTS (SIC 34)

I. INTRODUCTION OF THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a

manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE FABRICATED METAL PRODUCTS INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Fabricated Metal Products industry. The types of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

The fabricated metal products industry comprises facilities that generally perform two functions: forming metal shapes and performing metal finishing operations, including surface preparation. The Standard Industrial Classification (SIC) code 34 is composed of establishments that fabricate ferrous and nonferrous metal products and those that perform electroplating, plating, polishing, anodizing, coloring, and coating operations on metals. Since the main processes associated with this industry can be divided into three types of operations (i.e., metal fabrication, metal preparation, and metal finishing), this profile is organized by the techniques that fall within these three groups.

II.B. Characterization of the Fabricated Metal Products Industry

To provide a general understanding of this industry, information pertaining to the industry size and distribution, product characterization, and economic health and outlook is presented below. This information should provide a basic understanding of the facilities developing the products, the products themselves, and the economic condition of the industry.

II.B.1. <u>Industry Size and Geographic Distribution</u>

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

The U.S. fabricated metal products industry comprises approximately 34,000 companies. Exhibit 1 lists the largest companies in selected metal fabricating industries. Companies are ranked by sales figures.

Exhibit 1
Metal Fabrication Companies

Company	Sales ($ Millions)	Number of Employees
SIC 3444 -- Sheet Metal Work		
Stolle Corp., Sidnev, OH	480	4,600
Alcan Alum. Corp., Warren, OH	120	1,200
Nytronics, Inc., Pitman, NJ	110	2,000
Hart and Cooley Inc., Holland, MI	100	1,200
Syro Steel Co., Girard, OH	100	400
Consolidated Systems, Inc., Columbia, SC	100	300
SIC 3465 -- Automotive Stampings		
Budd Co., Troy, MI	1,000	9,000
Douglas and Lomason Co., Farmington Hts., MI	391	5,800
Northern Engraving Corp., Sparta, WI	280	3,000

SIC 3469 -- Metal Stampings		
Hexcel Corp., Pleasanton, CA	386	2,900
JSJ Corp., Grand Haven, MI	260	2,500
Mirro-Folev Co., Manitowoc, WI	210	2,000
Tempel Steel Co., Niles, IL	210	1,100
SIC 3499 -- Fabricated Metal Products		
Steel Technologies, Louisville, KY	155	500
R.D. Werner Companv, Inc., Greenville, PA	150	1,600
BW/IP Int., Inc., Seal Div., Long Beach, CA	104	400
LeFebure Corp., Cedar Rapids, IA	100	1,100
Dura Mech. Components, Inc., Troy, MI	100	1,000

Source: Fabricators & Manufacturers Association, Intl.

Exhibits 2 and 3 show the distribution of employees and the total shipments for the metal finishing industry. A typical "job shop" (i.e., small, independently owned metal finishing company) employs 15 to 20 people and generates $800,000 to $1 million in annual gross revenues.

Exhibit 2
Number of Employees in Metal Finishing Industry

	1988	1989	1990	1991	1992
SIC 3471	76,300	76,600	73,200	66,600	65,400
SIC 3479	47,000	44,600	44,300	43,400	43,700
Total	123,300	121,200	117,500	110,000	109,100

Exhibit 5
Organic Coating Job Shops

Company	Sales ($ Millions)	Number of Employees
Metokote Corp., Lima, OH	25+	800
The Crown Group, Warren, MI	25+	659
Industrial Powder Coatings, Inc., Norwalk, OH	25+	620
PreFinish Metals, Chicago, IL	25+	600
E/M Corp., West Lafayette, IN	15-25	300
Chicago Finished Metals, Bridgeview, IL	25+	250
Linetec Co., Wausau, WI	10-15	200
B.L. Downey Co., Inc., Broadview, IL	10-15	175

Source: "Large Coating Job Shops," Beverly A. Greaves, Products Finishing, December 1994.

Between 1982 and 1987, the total number of independent metal finishers employing less than 20 employees declined slightly, while those employing more than 20 employees increased by a corresponding amount. Exhibit 6 shows the number and percent of metal finishers of various sizes.

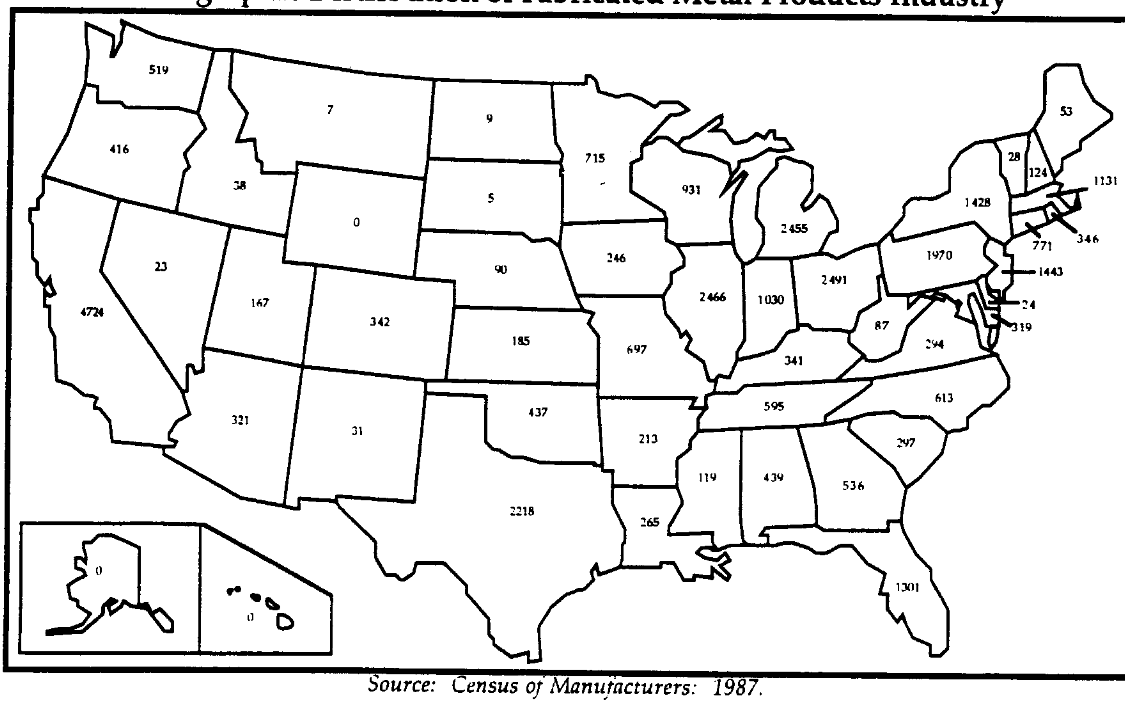
Exhibit 6
Metal Finishing Establishments, by Size

	1987		1992	
Establishments With and Average of :	**Number of Companies**	**Percent Total**	**Number of Companies**	**Percent Total**
1 to 9 Employees	2481	47.1	2553	48.7
10 to 49 Employees	2262	43.0	2186	41.7
50 to 99 Employees	365+	6.9	381	6.8
100 to 249 Employees	137	2.6	356	2.4
250 or more Employees	20	0.4	127	0.4
Total	**5265**	**100.0**	**5603**	**100.0**

Source: Census of Manufacturers: 1992, U. S. Department of Commerce, Bureau of the Census.

Although the metal finishing industry is geographically diverse, the industry is concentrated in what are usually considered the most heavily industrialized regions in the United States (See Exhibit 7). This geographic concentration occurs in part because it is cost-effective for small metal finishing facilities to be located near their customer base.

Exhibit 7
Geographic Distribution of Fabricated Metal Products Industry



Source: Census of Manufacturers: 1987.

California has more establishments that produce metal-related products than any other State. California's establishments

R0075948

constitute 10.2 percent of the total establishments that produce fabricated structural metal (SIC 3441). In addition, California leads in the number of establishments of other related industries: 15.6 percent of the sheet metal work establishments (SIC 3444); 13 percent of the metal doors, sash, and trim establishments (SIC 3442); and 13.7 percent of the architectural metal work establishments (SIC 3446). California also has the majority of plating and polishing (SIC 3471) and metal coating and allied services (SIC 3479) establishments at 17.3 and 16.1 percent, respectively.

Michigan, Illinois, and Ohio have large numbers of various metal-related industries. Michigan has the largest number of companies in the screw machine products (SIC 3451) and automotive stampings (SIC 3465) industries, at 14 and 46.7 percent of the total companies in the United States, respectively. Illinois is home to 14.1 percent of companies that produce bolts, nuts, rivets, and washers (SIC 3452) and Ohio contains 12.6 percent of companies that produce iron and steel forgings (SIC 3462).

Establishments engaged primarily in metal finishing tend to be small, independently owned job shops, also are referred to as independent metal finishers. Establishments that conduct metal finishing operations as part of a larger manufacturing operation are referred to as "captive" metal finishers. Captive metal finishing facilities are approximately three times more numerous than independent metal finishers. Numerous similarities exist between the independent and captive facilities; for the purposes of this profile, they are considered part of one industry. In addition, the two segments have parallel ties with suppliers and customers. Captive operations may be more specialized in their operations, however, because they often work on a limited number of products and/or employ a limited number of processes. Independent metal finishers, on the other hand, tend to be less specialized in their operations because they may have many customers, often with different requirements.

II.B.2. Product Characterization

The Department of Commerce classification codes divide this industry by product and services. SIC code 34 is further divided as follows:

- SIC 341 - Metal Cans and Shipping Containers
- SIC 342 - Cutlery, Handtools, and General Hardware
- SIC 343 - Heating Equipment, Except Electric and Warm Air, and Plumbing Fixtures
- SIC 344 - Fabricated Structural Metal Products
- SIC 345 - Screw Machine Products, and Bolts, Nuts, Screws, Rivets, and Washers
- SIC 346 - Metal Forgings and Stampings
- SIC 347 - Coating, Engraving, and Allied Services
- SIC 348 - Ordnance and Accessories, Except Vehicles and Guided Missiles
- SIC 349 - Miscellaneous Fabricated Metal Products.

II.B.3. Economic Trends

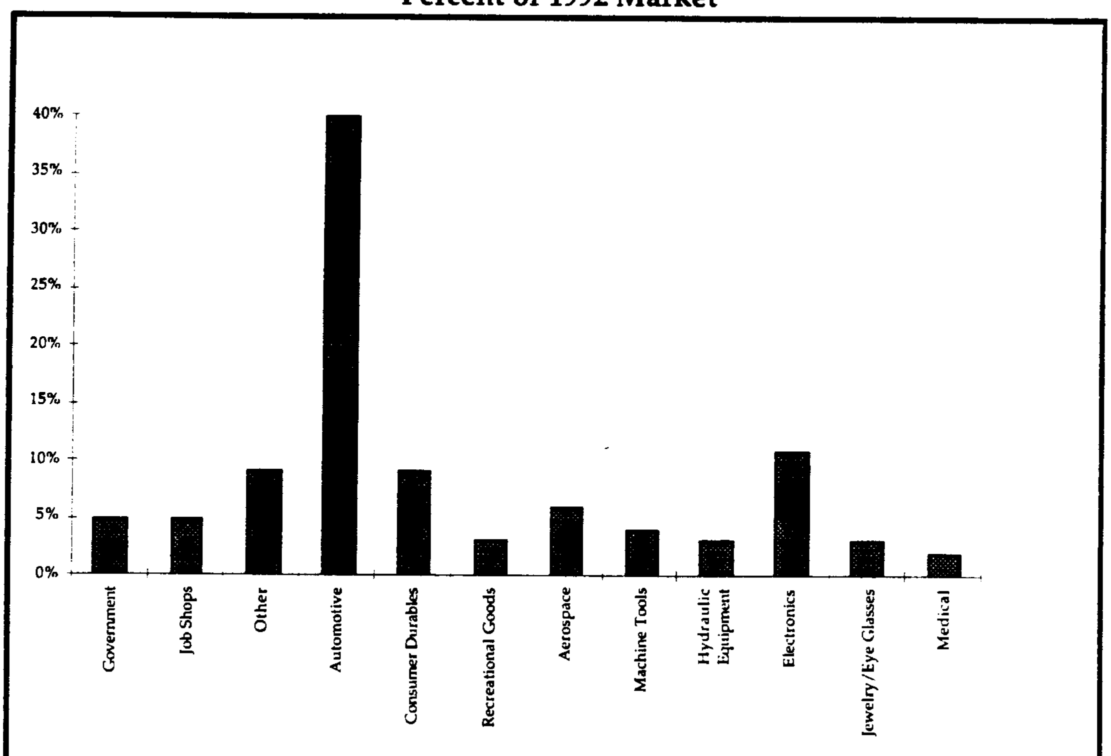
Most industries in SIC 34 are largely dependent upon the demands of other industries. For example, the success of the commercial construction industry is fundamental to the success of the fabricated structural metal industry; 95 percent of the output from the latter is consumed by the former. The general component-producing industries (e.g., screw machine products, industrial fasteners, etc.) display the same demand structure; the demand for such products is directly related to the demand for automobiles and public works construction.

Fabricated structural metal output declined two percent in 1993 due to a decrease in construction of office buildings, commercial structures, manufacturing facilities, and multi-family housing. Ninety-five percent of structural metal output is consumed by the construction industry. Low demand for structural metal is expected to continue, attributable to the recent overbuilding of commercial space and high levels of vacant office space. A slight increase in demand from the public sector (e.g., highway construction) is expected, however, which will positively influence demand for structural metal products. An increased demand for plumbing products is also likely, as the residential construction industry continues to grow.

Total shipments of general components (e.g., screw machine products, industrial fasteners, valves, and pipe fittings) increased by about 3.1 percent in 1993. Strong demand from the automotive sector, combined with increased demand from equipment and machinery manufacturers, were the major factors causing the increased shipments.

The two primary markets for metal finishing services are the automotive and electronics industries. As illustrated in Exhibit 8, consumer durables, aerospace, and the government also are large segments served by metal finishers.

Exhibit 8
Markets Served by Metal Finishers
Percent of 1992 Market



Source: Surface Finishing Market Research Board, Metal Finishing Industry Market Survey 1992-1993.
NOTE: Data includes both job and captive shops.

The sale of metal finishing services is also essentially a derived demand (i.e., sales depend entirely upon the production of other industries). However, sales by the metal finishing industry have not kept up with sales of the industries served.

R0075951

In the last several years, many U.S. fastener (nuts, screws, bolts, rivets) companies have become more competitive in the global market by incorporating new technology into production lines to improve efficiency and quality. In 1993, U.S. exports of industrial fasteners edged up about 0.6 percent; Canada and Mexico were the largest importers. U.S. imports of industrial fasteners also increased 11 percent over the last several years. This is because demand in the U.S. out-paced production. The expansion of the U.S. automotive and residential construction sectors was a major factor in the increase in fastener imports.

Exports of U.S. valve and pipe fittings are also expected to grow. 1993 industry exports increased six percent compared with 1992 figures. Although Canada remains the principal foreign market, exports to Chile and the Philippines almost tripled, and exports to developing countries increased dramatically.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the Fabricated Metal Products industry, including the materials and equipment used and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile: pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

Specifically, this section contains a description of commonly used production processes, the associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provides a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Fabricated Metal Products Industry

In view of the high cost of most new equipment and the relatively long lead time necessary to bring new equipment into operation, changes in production methods and products are made only gradually; even new process technologies that fundamentally change the industry are only adopted over long periods of time. In addition, the recent financial performance of the Fabricated Metal Products industry combined with the difficulty of raising funds in the bond market, have left many establishments with a limited ability to raise the capital necessary to purchase new equipment.

For the purposes of this profile, the industrial processes associated with the Fabricated Metal Products industry will be grouped into three categories: fabricated metal products; surface preparation; and metal finishing. Each category is discussed in greater depth in the following subsections.

III.A.1. Fabricated Metal Products

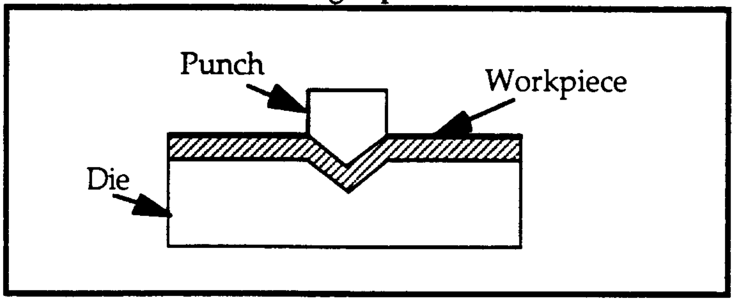
Once molten metal (ferrous or nonferrous) containing the correct metallurgical properties has been produced (see SIC 33, which comprises activities associated with the nonferrous metals industry), it is cast into a form that can enter various shaping processes. Recently, manufacturers have been using continuous casting techniques that allow the molten metal to be formed directly into sheets, eliminating interim forming stages. This section identifies some of the many forming and shaping methods used by the metal fabrication industry. In general, the metal may be heat treated or remain cold. Heat treating is the modification of the physical properties of a workpiece through the application of controlled heating and cooling cycles. Cold metal is formed by applying direct physical pressure to the metal.

Regardless of the forming method used, the metal fabricating process usually employs the use of cutting oils (e.g., ethylene glycol), degreasing and cleaning solvents, acids, alkalis, and heavy metals. The oils are typically used when forming and cutting the metal. The solvents (e.g., trichloroethane, methyl ethyl ketone), alkalines, and acids (e.g., hydrochloric, sulfuric) are used to clean the surface of the metals. The current trend in the industry is to use aqueous non-VOCs to clean the metals, whenever possible. The use of 1,1,1-trichloroethane and methyl ethyl ketone is declining.

Once molten metal is formed into a workable shape, shearing and forming operations are usually performed. Shearing operations cut materials into a desired shape and size, while forming operations bend or conform materials into specific shapes. Cutting or shearing operations include punching, piercing, blanking, cutoff, parting, shearing, and trimming. Basically, these operations produce holes or openings, or produce blanks or parts. The most common hole-making operation is punching. Cutoff, parting, and shearing are similar operations with different applications. The rate of production is highest in hot forging operations and lowest in simple bending and spinning operations.

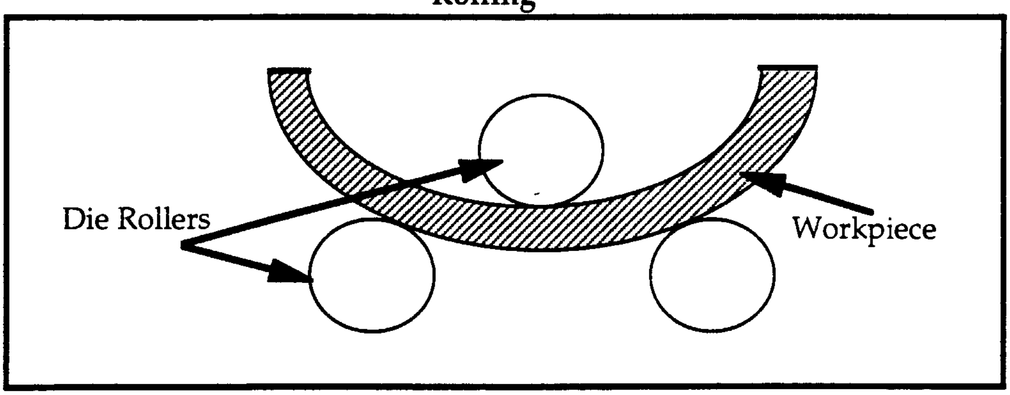
Forming operations, as illustrated in Exhibit 9, shape parts by bending, forming, extruding, drawing, rolling, spinning, coining, and forging the metal into a specific configuration. Bending is the simplest forming operation; the part is simply bent to a specific angle or shape. Other types of forming operations produces both two- and three-dimensional shapes.

Exhibit 9
Forming Operations



Extruding is the process of forming a specific shape from a solid blank by forcing the blank through a die of the desired shape. Extruding can produce complicated and intricate cross-sectional shapes. In rolling the metal passes through a set or series of rollers that bend and form the part into the desired shape (See Exhibit 10). Coining is a process that alters the form of the part by changing its thickness to produce a three-dimensional relief on one or both sides of the part, like a coin.

Exhibit 10
Rolling



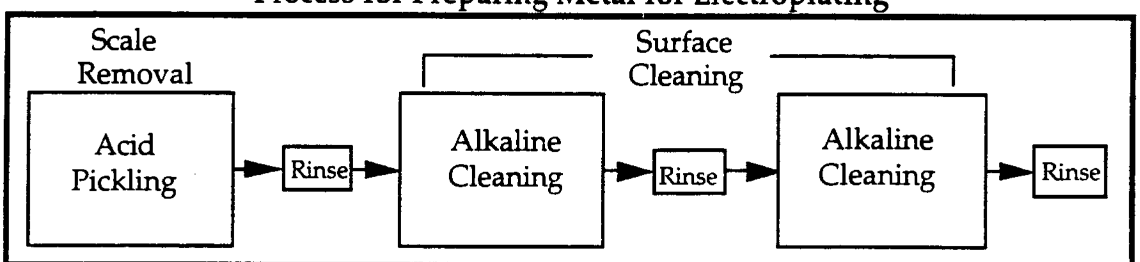
In drawing, a punch forces sheet stock into a die, where the desired shape is formed in the space between the punch and die. In spinning, pressure is applied to the sheet while it spins on a rotating form, forcing the sheet to acquire the shape of the form. Forging operations produce a specific shape by applying external pressure that either strikes or squeezes a heated blank into a die of the desired shape. Forging operations may be conducted on hot or cold metal using either single- or multi-stage dies.

Once shearing and forming activities are complete, the material is machined. Machining refines the shape of a workpiece by removing material from pieces of raw stock with machine tools. The principal processes involved in machining are drilling, milling, turning, shaping/planing, broaching, sawing, and grinding.

III.A.2. Surface Preparation

The surface of the metal may require preparation prior to applying a finish. Surface preparation, cleanliness, and proper chemical conditions are essential to ensuring that finishes perform properly. Without a properly cleaned surface, even the most expensive coatings will fail to adhere or prevent corrosion. Surface preparation techniques range from simple abrasive blasting to acid washes to complex, multi-stage chemical cleaning processes. Exhibit 11 provides a flow chart of a representative process used when preparing metal for electroplating. Various surface preparation methods are discussed below.

Exhibit 11
Process for Preparing Metal for Electroplating



Source: Metals Handbook, Ninth Edition; Volume 5, Surface Cleaning, Finishing, and Coating, 1982, American Society for Metals.

Some cleaning techniques involve the application of organic solvents to degrease the surface of the metal. Other techniques, emulsion cleaning, for example, use common organic solvents (e.g., kerosene, mineral oil, and glycols) dispersed in an aqueous medium with the aid of an emulsifying agent. Emulsion cleaning uses less chemical than solvent degreasing because the concentration of solvent is lower.

Alkaline cleaning may also be utilized for the removal of organic soils. Most alkaline cleaning solutions are comprised of three major types of components: (1) builders, such as alkali hydroxides and carbonates, which make up the largest portion of the cleaner; (2) organic or inorganic additives, which promote better cleaning or act to affect the metal surface in some way; and (3) surfactants.

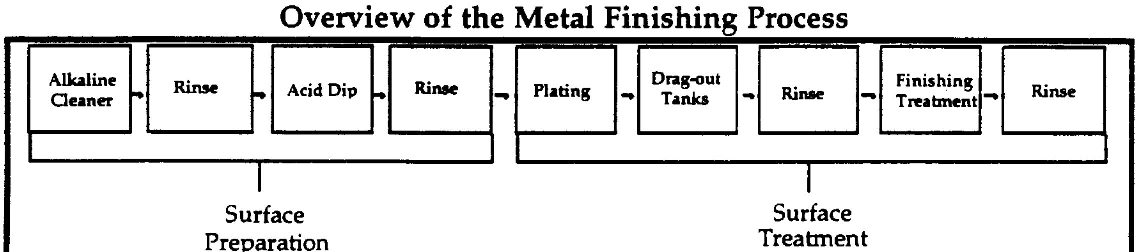
Alkaline cleaning is often assisted by mechanical action, ultrasonics, or by electrical potential (e.g., electrolytic cleaning).

Acid cleaning, or pickling, can also be used to prepare the surface of metal products by chemically removing oxides and scale from the surface of the metal. For instance, most carbon steel is pickled with sulfuric or hydrochloric acid, while stainless steel is pickled with hydrochloric or hydrofluoric acids, although hydrochloric acid may embrittle certain types of steel and is rarely used. The metal generally passes from the pickling bath through a series of rinses. Acid pickling is similar to acid cleaning, but is usually used to remove the scale from semi-finished mill products, whereas acid cleaning is usually used for near-final preparation of metal surfaces before electroplating, painting, and other finishing processes.

III.A.3. Metal Finishing

Surface finishing usually involves a combination of metal deposition operations and numerous finishing operations. A diagram depicting the general metal finishing process, including surface preparation, is provided in Exhibit 12. Wastes typically generated during these operations are associated with the solvents and cleansers applied to the surface and the metal-ion-bearing aqueous solutions used in the plating tanks. Metal-ion-bearing solutions are commonly based on hexavalent chrome, trivalent chrome, copper, gold, silver, cadmium, zinc, and nickel. Many other metals and alloys are also used, although less frequently. The cleaners (e.g., acids) may appear in process wastewater; the solvents may be emitted into the air, released in wastewater, or disposed of in solid form; and other wastes, including paints, metal-bearing sludges, and still bottom wastes, may be generated in solid form. Several of the many metal finishing operations are described below.

Exhibit 12
Overview of the Metal Finishing Process



Source: Sustainable Industry: Promoting Strategic Environmental Protection in the Industrial Sector, Phase 1 Report, U.S. EPA, OERR, June 1995.

Anodizing

Anodizing is an electrolytic process which converts the metal surface to an insoluble oxide coating. Anodized coatings provide corrosion protection, decorative surfaces, a base for painting and other coating processes, and special electrical and mechanical properties. Aluminum is the most frequently anodized material. Common aluminum anodizing processes include: chromic acid anodizing, sulfuric acid anodizing, and boric-sulfuric anodizing. The sulfuric acid process is the most common method.

Following anodizing, parts are typically rinsed, then proceed through a sealing operation that improves the corrosion resistance of the coating. Common sealants include chromic acid, nickel acetate, nickel-cobalt acetate, and hot water.

Chemical Conversion Coating

Chemical conversion coating includes chromating, phosphating, metal coloring, and passivating operations. Chromate conversion coatings are produced on various metals by chemical or electrochemical treatment. Solutions, usually containing hexavalent chromium and other compounds, react with the metal surface to form a layer containing a complex mixture of compounds consisting of chromium, other constituents, and base metal. Phosphate coatings may be formed by the immersion of steel, iron, or zinc-plated steel in a dilute solution of phosphate salts, phosphoric acid, and other reagents to condition the surfaces for further processing. They are used to provide a good base for paints and other organic coatings, to condition the surfaces for cold forming operations by providing a base for drawing compounds and lubricants, and to impart corrosion resistance to the metal surface.

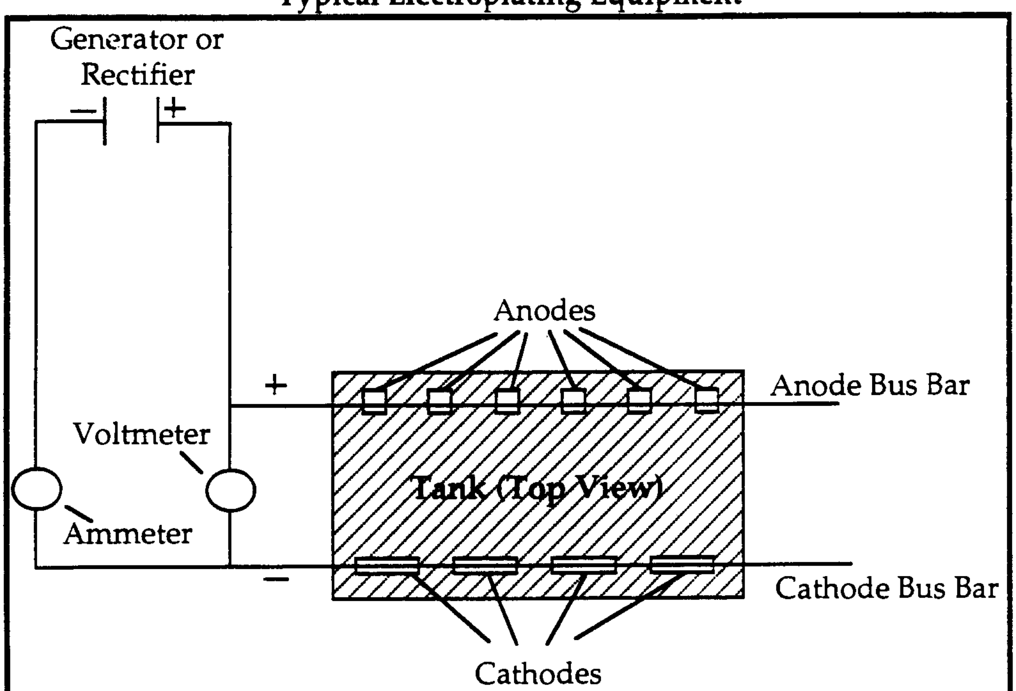
Metal coloring involves chemically converting the metal surface into an oxide or similar metallic compound to produce a decorative finish such as a green or blue patina on copper or steel, respectively. Passivating is the process of forming a protective film on metals by immersion into an acid solution, usually nitric acid or nitric acid with sodium dichromate. Stainless steel products are often passivated to prevent corrosion and extend the life of the product.

Electroplating

Electroplating is the production of a surface coating of one metal upon another by electrodeposition. Electroplating activities involve applying predominantly *inorganic* coatings onto surfaces to provide corrosion resistance, hardness, wear resistance, anti-frictional characteristics, electrical or thermal conductivity, or decoration. Exhibit 13 illustrates the important parts of typical electroplating equipment. The most commonly electroplated metals and alloys include: brass (copper-zinc), cadmium, chromium, copper, gold, nickel, silver, tin, and zinc.

In electroplating, metal ions in either acid, alkaline, or neutral solutions are reduced on the workpieces being plated. The metal ions in the solution are usually replenished by the dissolution of metal from solid metal anodes fabricated of the same metal being plated, or by direct replenishment of the solution with metal salts or oxides. Cyanide, usually in the form of sodium or potassium cyanide, is usually used as a complexing agent for cadmium and precious metals electroplating, and to a lesser degree, for other solutions such as copper and zinc baths.

Exhibit 13
Typical Electroplating Equipment



Source: McGraw Hill Encyclopedia of Science and Technology, Volume 6, 1987.

The sequence of steps in an electroplating includes: cleaning, often using alkaline and acid solutions; stripping of old plating or paint; electroplating; and rinsing between and after each of these operations. Sealing and conversion coating may be employed on the metals after electroplating operations.

Electroless Plating

Electroless plating is the chemical deposition of a metal coating onto a plastic object, by immersion of the object in a plating solution. Copper and nickel electroless plating is commonly used for printed circuit boards. The basic ingredients in an electroless plating solution are: a source of metal (usually a salt); a reducer; a complexing agent to hold the metal in solution; and various buffers and other chemicals designed to maintain bath stability and increase bath life. Immersion plating produces a thin metal deposit, commonly zinc or silver, by chemical displacement. Immersion plating baths are usually formulations of metal salts, alkalis, and complexing agents (e.g., lactic, glycolic, malic acid salts). Electroless plating and immersion plating commonly generate more waste than other plating techniques, but individual facilities vary significantly in efficiency. Exhibit 13 illustrates a typical plating process.

R0075960

Painting

Painting involves the application of predominantly *organic* coatings to a workpiece for protective and/or decorative purposes. It is applied in various forms, including dry powder, solvent-diluted formulations, and water-borne formulations. Various methods of application are used, the most common being spray painting and electrodeposition. Spray painting is a process by which paint is placed into a pressurized cup or pot and is atomized into a spray pattern when it is released from the vessel and forced through an orifice. Electrodeposition is the process of coating a workpiece by either making it anodic or cathodic in a bath that is generally an aqueous emulsion of the coating material. When applying the paint as a dry powder, some form of heating or baking is necessary to ensure that the powder adheres to the metal. These processes may result in solvent waste (and associated still bottom wastes generated during solvent distillation), paint sludge wastes, paint-bearing wastewaters, and paint solvent emissions.

Other Metal Finishing Techniques

Polishing, hot dip coating, and etching are processes that are also used to finish metal. Polishing is an abrading operation used to remove or smooth out surface defects (scratches, pits, or tool marks) that adversely affect the appearance or function of a part. Following polishing operations, area cleaning and washdown can produce metal-bearing wastewaters. Hot dip coating is the coating of a metallic workpiece with another metal to provide a protective film by immersion into a molten bath. Galvanizing (hot dip zinc) is a common form of hot dip coating. Water is used for rinses following precleaning and sometimes for quenching after coating. Wastewaters generated by these operations often contain metals. Etching produces specific designs or surface appearances on parts by controlled dissolution with chemical reagents or etchants. Etching solutions commonly comprise strong acids or bases with spent etchants containing high concentrations of spent metal. The solutions include ferric chloride, nitric acid, ammonium persulfate, chromic acid, cupric chloride, and hydrochloric acid.

III.B. Raw Material Inputs and Pollution Outputs in the Production Line

The material inputs and pollution outputs resulting from metal fabrication, surface preparation, and metal finishing processes are presented by media in Exhibit 15. Exhibit 16 illustrates the general processes associated with this industry, the pollutants generated, and the point in the process at which the pollutants are produced.

Exhibit 15
Process Materials Inputs and Outputs

Process	Material Input	Air Emission	Process Wastewater	Solid Waste
Metal Shaping				
Metal Cutting and/or Forming	Cutting oils, degreasing and cleaning solvents, acids, alkalis, and heavy metals	Solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)	Waste oils (e.g., ethylene glycol) and acid (e.g., hydrochloric, sulfuric, nitric), alkaline, and solvent wastes	Metal chips (e.g., scrap steel and aluminum), metal-bearing cutting fluid sludges, and solvent still-bottom wastes
Surface Preparation				
Solvent Degreasing and Emulsion, Alkaline, and Acid Cleaning	Solvents, emulsifying agents, alkalis, and acids	Solvents (associated with solvent degreasing and emulsion cleaning only)	Solvent, alkaline, and acid wastes	Ignitable wastes, solvent wastes, and still bottoms
Surface Finishing				
Anodizing	Acids	Metal-ion-bearing mists and acid mists	Acid wastes	Spent solutions, wastewater treatment sludges, and base metals
Chemical Conversion Coating	Metals and acids	Metal-ion-bearing mists and acid mists	Metal salts, acid, and base wastes	Spent solutions, wastewater treatment sludges, and base metals
Electroplating	Acid/alkaline solutions, heavy metal bearing solutions, and cyanide bearing solutions	Metal-ion-bearing mists and acid mists	Acid/alkaline, cyanide, and metal wastes	Metal and reactive wastes
Plating	Metals (e.g., salts), complexing agents, and alkalis	Metal-ion-bearing mists	Cyanide and metal wastes	Cyanide and metal wastes
Painting	Solvents and paints	Solvents	Solvent wastes	Still bottoms, sludges, paint solvents, and metals
Other Metal Finishing Techniques (Including Polishing, Hot Dip Coating, and Etching)	Metals and acids	Metal fumes and acid fumes	Metal and acid wastes	Polishing sludges, hot dip tank dross, and etching sludges

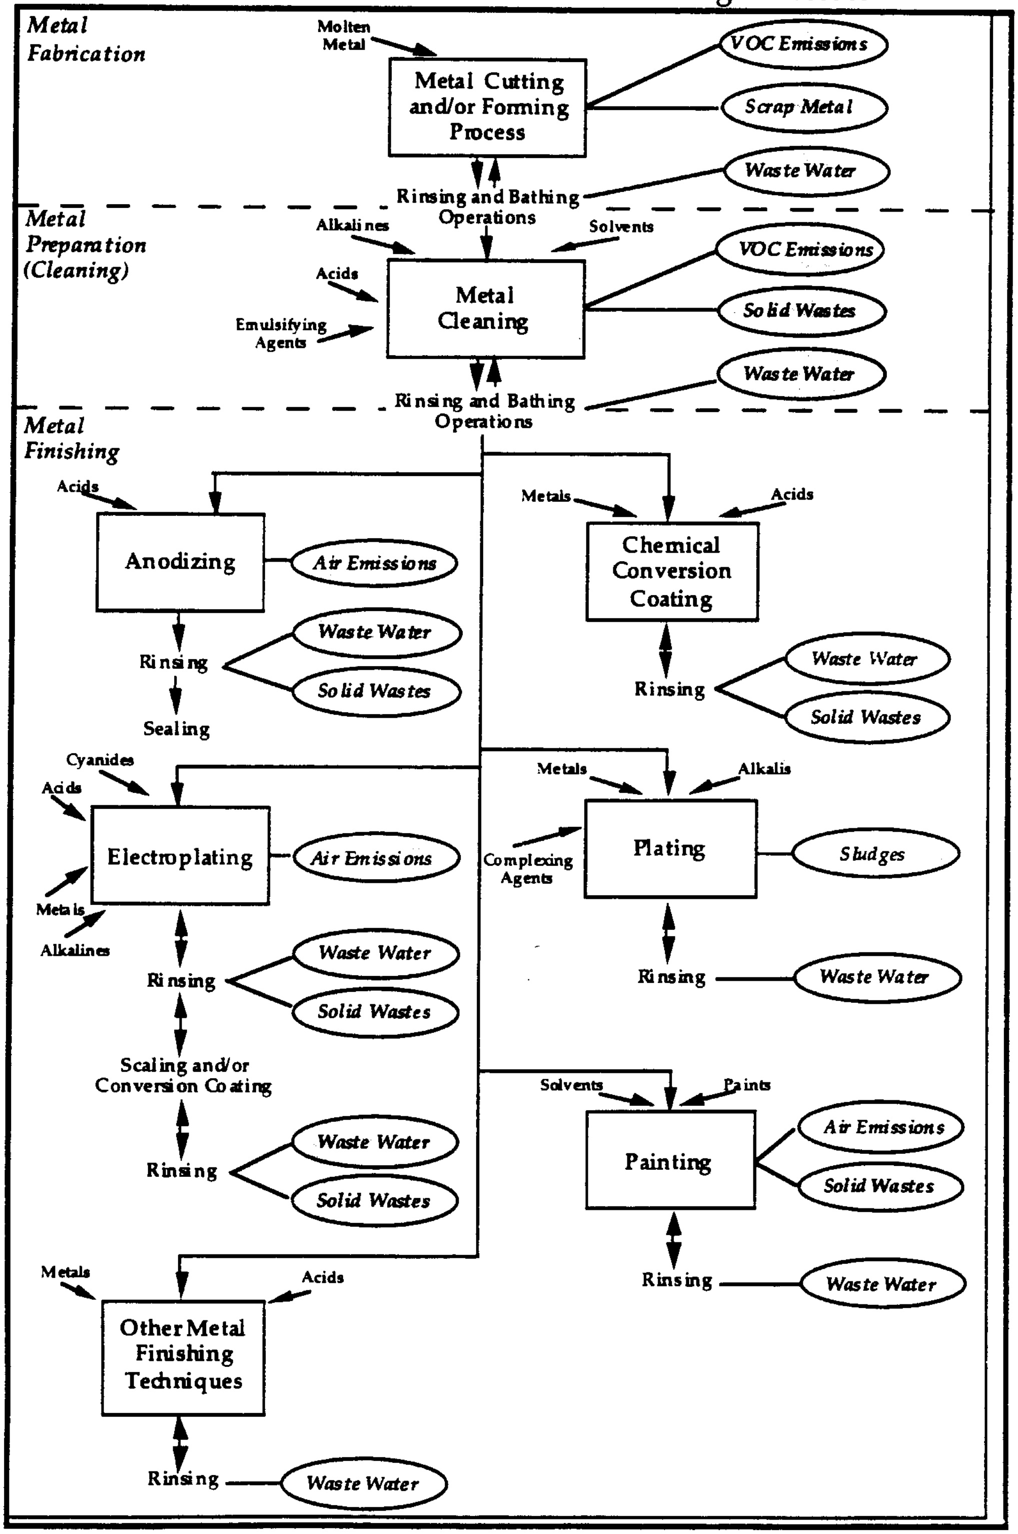
Exhibit 16
Fabricated Metal Products Manufacturing Processes



R0075964

III.B.1. Metal Fabrication

Each of the metal shaping processes can result in wastes containing chemicals of concern. For example, the application of solvents to metal and machinery results in air emissions. Additionally, wastewater containing acidic or alkaline wastes and waste oils, and solid wastes, such as metals and solvents, are usually generated during this process.

Metal fabrication facilities are major users of solvents for degreasing. In cases where solvents are used solely in degreasing (not used in any other plant operations), records of the amount and frequency of purchases provide enough information to estimate emission rates, based on the assumption that all solvent purchased is eventually emitted. Section V.D., Pollution Prevention Options, illustrates techniques that may be used to reduce the loss of solvents to the atmosphere.

Metalworking fluids are applied to either the tool or the metal being tooled to facilitate the shaping operation. Metalworking fluid is used to:

- Control and reduce the temperature of tools and aid lubrication,
- Control and reduce the temperature of workpieces and aid lubrication,
- Provide a good finish,
- Wash away chips and metal debris, and
- Inhibit corrosion or surface oxidation.

Fluids resulting from this process typically become spoiled or contaminated with extended use and reuse. In general, metal working fluids can be petroleum-based, oil-water emulsions, and synthetic emulsions. When disposed, these fluids may contain high levels of metals (e.g., iron, aluminum, and copper). Additional contaminants present in fluids resulting from these processes include acids and alkalis (e.g., hydrochloric, sulfuric, nitric), waste oils, and solvent wastes.

Scrap metal may consist of metal removed from the original piece (e.g., steel), and may be combined with small amounts of metalworking fluids (e.g., solvents) used prior to and during the metal shaping operation that generates the scrap. Quite often, this scrap is reintroduced into the process as a feedstock. The scrap and metalworking fluids, however, should be tracked since they may be regulated as solid wastes.

III.B.2. Surface Preparation

Surface preparation activities usually result in air emissions, contaminated wastewater, and solid wastes. The primary air emissions from cleaning are due to the evaporation of chemicals from solvent degreasing and emulsion cleaning processes. These emissions may result through volatilization of solvents during storage, fugitive losses during use, and direct ventilation of fumes.

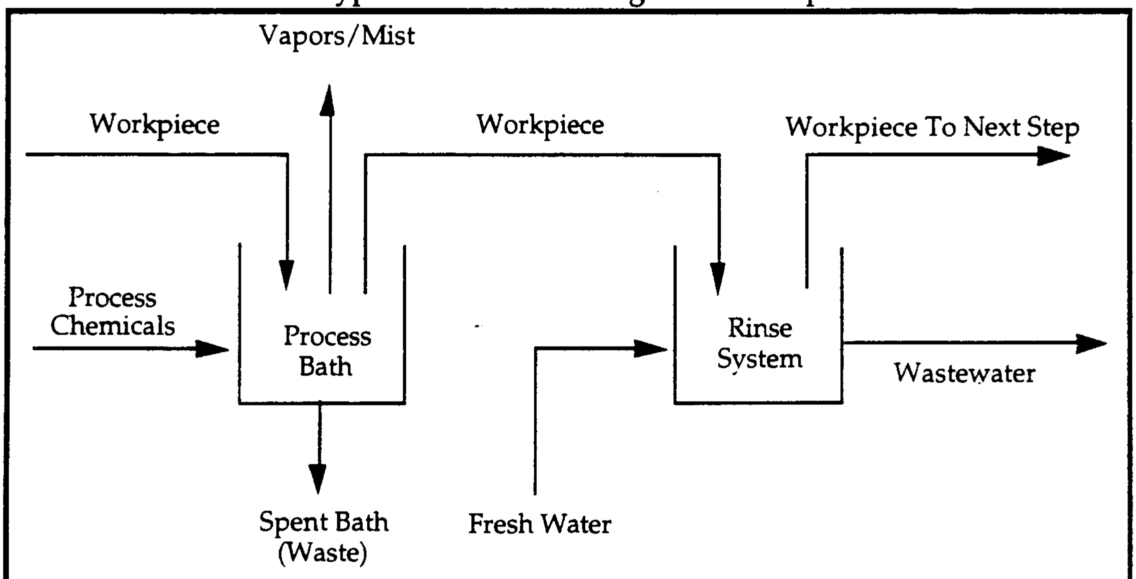
Wastewaters generated from cleaning are primarily rinse waters, which are usually combined with other metal finishing wastewaters (e.g., electroplating) and treated on-site by conventional hydroxide precipitation. Solid wastes (e.g., wastewater treatment sludges, still bottoms, cleaning tank residues, machining fluid residues, etc.) may also be generated by the cleaning operations. For example, solid wastes are generated when cleaning solutions become ineffective and are replaced. Solvent-bearing wastes are typically pre-treated to comply with any applicable National Pollutant Discharge System (NPDES) permits and then sent off-site, while aqueous wastes from alkaline and acid cleaning , which do not contain solvents, are often treated on-site.

III.B.3. Metal Finishing

Many metal finishing operations are typically performed in baths (tanks) and are then followed by rinsing cycles. Exhibit 17 illustrates a typical chemical or electrochemical process step in which a workpiece enters the process bath containing process chemicals that are carried to the rinse water (drag-out). Metal plating and related waste account for the largest volumes of metal- (e.g., cadmium, chromium, copper, lead, and nickel) and cyanide-bearing wastes. Painting operations account for the generation of solvent-bearing wastes and the direct release of solvents (including benzene, methyl ethyl ketone, methyl isobutyl ketone, toluene, and xylene). Paint cleanup operations may contribute to the release of chlorinated solvents (including carbon tetrachloride, methylene chloride, 1,1,1-trichloroethane, and perchloroethylene). Compliance with one law through emission or effluent controls may generate waste regulated under another statute (e.g., effluent controls required by the Clean Water Act may generate sludges which are regulated by the

Resource Conservation and Recovery Act). The nature of the wastes produced by these processes is discussed further below.

Exhibit 17
Typical Metal Finishing Process Step



Source: *Guides to Pollution Prevention: The Metal Finishing Industry, U.S. EPA, ORD, October 1992.*

Anodizing

Anodizing operations produce air emissions, contaminated wastewaters, and solid wastes. Mists and gas bubbles arising from heated fluids are a source of air emissions, which may contain metals or other substances present in the bath. When dyeing of anodized coatings occurs, wastewaters produced may contain nickel acetate, non-nickel sealers, or substitutes from the dye. Other potential pollutants include complexers and metals from dyes and sealers. Wastewaters generated from anodizing are usually combined with other metal finishing wastewaters and treated on-site by conventional hydroxide precipitation. Wastewaters containing chromium must be pretreated to reduce hexavalent chromium to its trivalent state. The conventional treatment process generates a sludge that is usually sent off-site for metals reclamation and/or disposal.

Solid wastes generated from anodizing include spent solutions and wastewater treatment sludges. Anodizing solutions may be contaminated with the base metal being processed due to the anodic nature of the process. These solutions eventually reach an intolerable concentration of dissolved metal and require processing

R0075967

to remove the dissolved metal to a tolerable level or treatment/disposal.

Chemical Conversion Coating

Chemical conversion coating generally produces contaminated wastewaters and solid waste. Pollutants associated with these processes enter the wastestream through rinsing and batch dumping of process baths. The process baths usually contain metal salts, acids, bases, and dissolved basis materials. Wastewaters containing chromium are usually pretreated to reduce hexavalent chromium to its trivalent state. The conventional treatment process generates a sludge that is sent off-site for metals reclamation and/or disposal. Solid wastes generated from these processes include spent solutions and wastewater treatment sludges. Conversion coating solutions may also be contaminated with the base metal being processed. These solutions will eventually reach an intolerable concentration of dissolved metal and require processing to remove the dissolved metal to a tolerable level.

Electroplating

Electroplating operations produce air emissions, contaminated wastewaters and solid wastes. Mists arising from electroplating fluids and process gases can be a source of air emissions, which may contain metals or other substances present in the bath. The industry has recently begun adding fume suppressants to electroplating baths to reduce air emissions of chromium, one of the most frequently electroplated metals. The fume suppressants lower the surface tension of the bath, which prevents hydrogen bubbles in the bath from bursting and producing a chromium-laden mist. The fume suppressants are highly effective when used in decorative plating, but less effective when used in hard-chromium plating. Contaminated wastewaters result from workpiece rinsing and process cleanup waters. Rinse waters from electroplating are usually combined with other metal finishing wastewaters and treated on-site by conventional hydroxide precipitation. Wastewaters containing chromium must be pretreated to reduce hexavalent chromium to its trivalent state. These wastewater treatment techniques can result in solid-phase wastewater treatment sludges. Other wastes generated from electroplating include spent solutions which become contaminated during use, and therefore, diminish performance of the process. In addition to these wastes, spent process solutions and quench bathes may be discarded periodically when the concentrations of contaminants inhibit proper function of the solution or bath.

Electroless Plating

Electroless plating produces contaminated wastewater and solid wastes. The spent plating solution and rinse water are usually treated chemically to precipitate out the toxic metals and to destroy the cyanide. Electroless plating solutions can be difficult to treat; settling and simple chemical precipitation are not effective at removing the chelated metals used in the plating bath. The extent to which plating solution carry-over adds to the wastewater and enters the sludge depends on the type of article being plated and the specific plating method employed. However, most sludges may contain significant concentrations of toxic metals, and may also contain complex cyanides in high concentrations if cyanides are not properly isolated during the treatment process.

Painting

Painting operations result in emissions, contaminated wastewaters, and the generation of liquid and solid wastes. Atmospheric emissions consist primarily of the organic solvents used as carriers for the paint. Emissions also result from paint storage, mixing, application, and drying. In addition, cleanup processes can result in the release of organic solvents used to clean equipment and painting areas. Wastewaters are often generated from painting processes due primarily to the discharge of water from water curtain booths. On-site treatment processes to treat contaminated wastewater generate a sludge that is sent off-site for disposal. Sources of solid- and liquid-phase wastes include:

- Paint application emissions control devices (e.g., paint booth collection systems, ventilation filters, etc.)
- Equipment washing
- Disposal materials used to contain paint and overspray
- Excess paints discarded upon completion of a painting operation or after expiration of the paint shelf-life.

These solid and liquid wastes may contain metals from paint pigments and organic solvents, such as paint solvents and cleaning solvents. Still bottoms also contain solvent wastes. The cleaning solvents used on painting equipment and spray booths may also contribute organic solid waste to the wastes removed from the painting areas.

Other Metal Finishing Techniques

Wastewaters are often generated during other metal finishing processes. For example, following polishing operations, area cleaning and washdown can produce metal-bearing wastewaters. Hot dip coating techniques, such as galvanizing, use water for rinses following pre-cleaning and sometimes for quenching after coating. Hot dip coatings also generate solid waste, anoxide dross, that is periodically skimmed off the heated tank. These operations generate metal-bearing wastewaters. Etching solutions are comprised of strong acids (e.g., ferric chloride, nitric acid, ammonium persulfate) or bases. Resulting spent etchant solutions may contain metals and acids.

III.C. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (EPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The EPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 18 shows that the fabricated metals industry managed about 798 million pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related

R0075970

waste, 34 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 62 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E and F, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production-related wastes (13.2 percent), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site is projected to decrease and the portions treated or managed through energy recovery on-site have increased between 1992 and 1995 (projected).

Exhibit 18
Source Reduction and Recycling Activity for SIC 34

A	B	C	D	E	F	G	H	I	J
Year	Production Related Waste Volume (10^6lbs.)*	% Reported as Released and Transferred	On-Site			Off-Site			Remaining Releases and Disposal
			% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated	
1992	750	38%	23.22%	12.24%	23.11%	26.03%	1.57%	2.02%	12.05%
1993	798	34%	26.48%	11.04%	24.24%	21.31%	1.54%	2.10%	13.28%
1994	735	—	27.91%	8.90%	26.33%	22.18%	1.53%	2.32%	10.84%
1995	697	—	19.20%	13.86%	27.78%	23.94%	1.63%	2.46%	11.13%

R0075971

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7 percent between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount, and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) - encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of waste to on-site landfills, waste that is land treated or incorporated into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Fabricated Metal Products Industry

TRI release amounts listed below are not associated with non-compliance with environmental laws. These facilities appear based on self-reported data submitted to the Toxic Release Inventory program.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear in Exhibit 19. Exhibit 20 contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, Exhibit 20 includes facilities that conduct multiple operations — some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibits 21 - 24 illustrate the TRI releases and transfers for the Fabricated Metal Products industry (SIC 34). For the industry as a whole, solvents comprise the largest number of TRI releases. This reflects the fact that solvents are used during numerous metal shaping, surface preparation, and surface finishing operations. For example, during metal shaping and surface preparation operations, solvents are used primarily to degrease metal. Solvents are also used during painting operations. All of the processes which use solvents generally result in air emissions, contaminated wastewater, and solid wastes.

Between 1988 and 1993, the Fabricated Metals Products industry substantially reduced its TRI transfers and releases (see section V. Pollution Prevention Opportunities). Exhibits 21 and 22 show the differences in transfers and releases over time, categorized by type of transfer or release.

Exhibit 19 lists the ten facilities with the highest total TRI releases, most of which are continuous coil manufacturers (e.g., facilities that manufacture aluminum cans from long strips of metal). The wastes generated by these manufacturers are not necessarily representative of the wastes generated by the metal fabricating and finishing industries as a whole.

Exhibit 19
Top 10 TRI Releasing Fabricated Metal Products Facilities

SIC Codes	Total TRI Releases in Pounds	Facility Name	City	State
3411	946,923	U.S. Can Co., Plant 20 Weirton	Weirton	WV
3411	880,500	Metal Container Corp., NWB	New Windsor	NY

Exhibits 26 - 29 illustrate the TRI releases and transfers for the coating, engraving, and allied services portion (SIC 347) of the fabricated metal products industry. For these activities, solvents, as well as acids, constitute the largest number of TRI releases. Solvents are primarily used during painting operations, while acids are used during most finishing operations (e.g., anodizing, chemical conversion coating, electroplating). The solvents usually produce air emissions, contaminated wastewater, and solid-phase wastes, while the acids generally result in contaminated wastewater. Because NPDES permits do not allow low PH levels, the wastewater is pretreated to reduce the acidity prior to being discharged from the facility.

Exhibit 26
Top 10 TRI Releasing Metal Finishing Facilities (SIC 347)

Rank	Total TRI Releases in Pounds	Facility Name	City	State
1	708,285	Plastene Supply Co.	Portageville	MO
2	619,436	Ken-Koat, Inc.	Huntington	IN
3	492,872	Tennessee Electroplating, Inc.	Ripley	TN
4	430,781	SR of Tennessee	Ripley	TN
5	418,912	Ken-Koat of Tennessee, Inc., Plant 1	Lewisburg	TN
6	408,628	Anomatic Corp.	Newark	OH
7	406,419	Roll Coater, Inc.	Greenfield	IN
8	381,788	Reynolds Metals Co.,.Sheffield Plant	Sheffield	AL
9	368,014	Roll Coater, Inc.	Kingsbury	IN
10	344,572	Mottley Foils, Inc.	Farmville	VA

Source: U.S. EPA, Toxics Release Inventory Database, 1993.

Note: Being included on this list does not mean that the release is associated with non-compliance with environmental laws.

IV.B. Summary of the Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET[1]. The

1 TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR

information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB.

The top ten TRI releases for the Fabricated Metal Products industry (SIC 34) as a whole include: glycol ethers, n-butyl, xylene, methyl ethyl ketone, trichloroethylene, toluene-1, dichloromethane, methyl isobutyl ketone, acetone, and tetrachloroethylene. The top ten TRI releases for the coating, engraving, and allied services portion of the fabricated metal products industry (SIC 347) include: methyl ethyl ketone, toluene, glycol ethers, trichloroethylene, xylene (mixed isomers), 1,1,1-trichloroethane, dichloromethane, tetrachloroethylene, hydrochloric acid, and methyl isobutyl ketone. Summaries of most of these chemicals follow.

Acetone

Toxicity. Acetone is irritating to the eyes, nose, and throat. Symptoms of exposure to large quantities of acetone may include headache, unsteadiness, confusion, lassitude, drowsiness, vomiting, and respiratory depression.

Reactions of acetone (see environmental fate) in the lower atmosphere contribute to the formation of ground-level ozone. Ozone (a major component of urban smog) can affect the respiratory system, especially in sensitive individuals such as asthmatics or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released into water, acetone will be degraded by microorganisms or will evaporate into the atmosphere.

(Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

Degradation by microorganisms will be the primary removal mechanism.

Acetone is highly volatile, and once it reaches the troposphere (lower atmosphere), it will react with other gases, contributing to the formation of ground-level ozone and other air pollutants. EPA is reevaluating acetone's reactivity in the lower atmosphere to determine whether this contribution is significant.

Physical Properties. Acetone is a volatile and flammable organic chemical.

Note: Acetone was removed from the list of TRI chemicals on June 16, 1995 (60 FR 31643) and will not be reported for 1994 or subsequent years.

Glycol Ethers

Due to data limitations, data on diethylene glycol (glycol ether) are used to represent all glycol ethers.

Toxicity. Diethylene glycol is only a hazard to human health if concentrated vapors are generated through heating or vigorous agitation or if appreciable skin contact or ingestion occurs over an extended period of time. Under normal occupational and ambient exposures, diethylene glycol is low in oral toxicity, is not irritating to the eyes or skin, is not readily absorbed through the skin, and has a low vapor pressure so that toxic concentrations of the vapor can not occur in the air at room temperatures.

At high levels of exposure, diethylene glycol causes central nervous depression and liver and kidney damage. Symptoms of moderate diethylene glycol poisoning include nausea, vomiting, headache, diarrhea, abdominal pain, and damage to the pulmonary and cardiovascular systems. Sulfanilamide in diethylene glycol was once used therapeutically against bacterial infection; it was withdrawn from the market after causing over 100 deaths from acute kidney failure.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Diethylene glycol is a water-soluble, volatile organic chemical. It may enter the environment in liquid form via petrochemical plant effluents or as an unburned gas from combustion sources. Diethylene glycol typically does not occur in sufficient concentrations to pose a hazard to human health.

Hydrochloric Acid

Toxicity. Hydrochloric acid is primarily a concern in its aerosol form. Acid aerosols have been implicated in causing and exacerbating a variety of respiratory ailments. Dermal exposure and ingestion of highly concentrated hydrochloric acid can result in corrosivity.

Ecologically, accidental releases of solution forms of hydrochloric acid may adversely affect aquatic life by including a transient lowering of the pH (i.e., increasing the acidity) of surface waters.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of hydrochloric acid to surface waters and soils will be neutralized to an extent due to the buffering capacities of both systems. The extent of these reactions will depend on the characteristics of the specific environment.

Physical Properties. Concentrated hydrochloric acid is highly corrosive.

Methylene Chloride (Dichloromethane)

Toxicity. Short-term exposure to dichloromethane (DCM) is associated with central nervous system effects, including headache, giddiness, stupor, irritability, and numbness and tingling in the limbs. More severe neurological effects are reported from longer-term exposure, apparently due to increased carbon monoxide in the blood from the break down of DCM. Contact with DCM causes irritation of the eyes, skin, and respiratory tract.

Occupational exposure to DCM has also been linked to increased incidence of spontaneous abortions in women. Acute damage to the eyes and upper respiratory tract, unconsciousness, and death were reported in workers exposed to high concentrations of DCM. Phosgene (a degradation product of DCM) poisoning has been reported to occur in several cases where DCM was used in the presence of an open fire.

Populations at special risk from exposure to DCM include obese people (due to accumulation of DCM in fat), and people with impaired cardiovascular systems.

Carcinogenicity. DCM is a probable human carcinogen via both oral and inhalation exposure, based on inadequate human data and sufficient evidence in animals.

Environmental Fate. When spilled on land, DCM is rapidly lost from the soil surface through volatilization. The remainder leaches through the subsoil into the groundwater.

Biodegradation is possible in natural waters but will probably be very slow compared with evaporation. Little is known about bioconcentration in aquatic organisms or adsorption to sediments but these are not likely to be significant processes. Hydrolysis is not an important process under normal environmental conditions.

DCM released into the atmosphere degrades via contact with other gases with a half-life of several months. A small fraction of the chemical diffuses to the stratosphere where it rapidly degrades through exposure to ultraviolet radiation and contact with chlorine ions. Being a moderately soluble chemical, DCM is expected to partially return to earth in rain.

Methyl Ethyl Ketone

Toxicity. Breathing moderate amounts of methyl ethyl ketone (MEK) for short periods of time can cause adverse effects on the nervous system ranging from headaches, dizziness, nausea, and numbness in the fingers and toes to unconsciousness. Its vapors are irritating to the skin, eyes, nose, and throat and can damage the eyes. Repeated exposure to moderate to high amounts may cause liver and kidney effects.

Carcinogenicity. No agreement exists over the carcinogenicity of MEK. One source believes MEK is a possible carcinogen in humans based on limited animal evidence. Other sources believe that there is insufficient evidence to make any statements about possible carcinogenicity.

Environmental Fate. Most of the MEK released to the environment will end up in the atmosphere. MEK can contribute to the formation of air pollutants in the lower atmosphere. It can be degraded by microorganisms living in water and soil.

Physical Properties. Methyl ethyl ketone is a flammable liquid.

Toluene

Toxicity. Inhalation or ingestion of toluene can cause headaches, confusion, weakness, and memory loss. Toluene may also affect the way the kidneys and liver function.

Reactions of toluene (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Some studies have shown that unborn animals were harmed when high levels of toluene were inhaled by their mothers, although the same effects were not seen when the mothers were fed large quantities of toluene. Note that these results may reflect similar difficulties in humans.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases of toluene to land and water will evaporate. Toluene may also be degraded by microorganisms. Once volatized, toluene in the lower atmosphere will react with other atmospheric components contributing to the formation of ground-level ozone and other air pollutants.

Physical Properties. Toluene is a volatile organic chemical.

1,1,1-Trichloroethane

Toxicity. Repeated contact of 1,1,1-trichloroethane (TCE) with skin may cause serious skin cracking and infection. Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations.

Exposure to high concentrations of TCE causes reversible mild liver and kidney dysfunction, central nervous system depression, gait disturbances, stupor, coma, respiratory depression, and even death. Exposure to lower concentrations of TCE leads to light-headedness, throat irritation, headache, disequilibrium, impaired coordination, drowsiness, convulsions and mild changes in perception.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of TCE to surface water or land will almost entirely volatilize. Releases to air may be transported long distances and may partially return to earth in rain. In the lower atmosphere, TCE degrades very slowly by photooxidation and slowly diffuses to the upper atmosphere where photodegradation is rapid.

Any TCE that does not evaporate from soils leaches to groundwater. Degradation in soils and water is slow. TCE does not hydrolyze in water, nor does it significantly bioconcentrate in aquatic organisms.

Trichloroethylene

Toxicity. Trichloroethylene was once used as an anesthetic, though its use caused several fatalities due to liver failure. Short term inhalation exposure to high levels of trichloroethylene may cause rapid coma followed by eventual death from liver, kidney, or heart failure. Short-term exposure to lower concentrations of trichloroethylene causes eye, skin, and respiratory tract irritation. Ingestion causes a burning sensation in the mouth, nausea, vomiting and abdominal pain. Delayed effects from short-term trichloroethylene poisoning include liver and kidney lesions, reversible nerve degeneration, and psychic disturbances. Long-term exposure can produce headache, dizziness, weight loss, nerve damage, heart damage, nausea, fatigue, insomnia, visual impairment, mood perturbation, sexual problems, dermatitis, and rarely jaundice. Degradation products of trichloroethylene (particularly phosgene) may cause rapid death due to respiratory collapse.

Carcinogenicity. Trichloroethylene is a probable human carcinogen via both oral and inhalation exposure, based on limited human evidence and sufficient animal evidence.

Environmental Fate. Trichloroethylene breaks down slowly in water in the presence of sunlight and bioconcentrates moderately in aquatic organisms. The main removal of trichloroethylene from water is via rapid evaporation.

Trichloroethylene does not photodegrade in the atmosphere, though it breaks down quickly under smog conditions, forming other pollutants such as phosgene, dichloroacetyl chloride, and formyl chloride. In addition, trichloroethylene vapors may be decomposed to toxic levels of phosgene in the presence of an intense heat source such as an open arc welder.

When spilled on the land, trichloroethylene rapidly volatilizes from surface soils. The remaining chemical leaches through the soil to groundwater.

Xylene (Mixed Isomers)

Toxicity. Xylenes are rapidly absorbed into the body after inhalation, ingestion, or skin contact. Short-term exposure of humans to high levels of xylenes can cause irritation of the skin, eyes, nose, and throat, difficulty in breathing, impaired lung function, impaired memory, and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations can cause effects such as headaches, dizziness, confusion, and lack of muscle coordination. Reactions of xylenes (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases to land and water will quickly evaporate, although some degradation by microorganisms will occur.

Xylenes are moderately mobile in soils and may leach into groundwater, where they may persist for several years.

Xylenes are volatile organic chemicals. As such, xylenes in the lower atmosphere will react with other atmospheric components, contributing to the formation of ground-level ozone and other air pollutants.

IV.C. Other Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 30 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 30
Pollutant Releases (Short Tons/Years)

Industry	CO	NO_2	PM_{10}	PT	SO_2	VOC

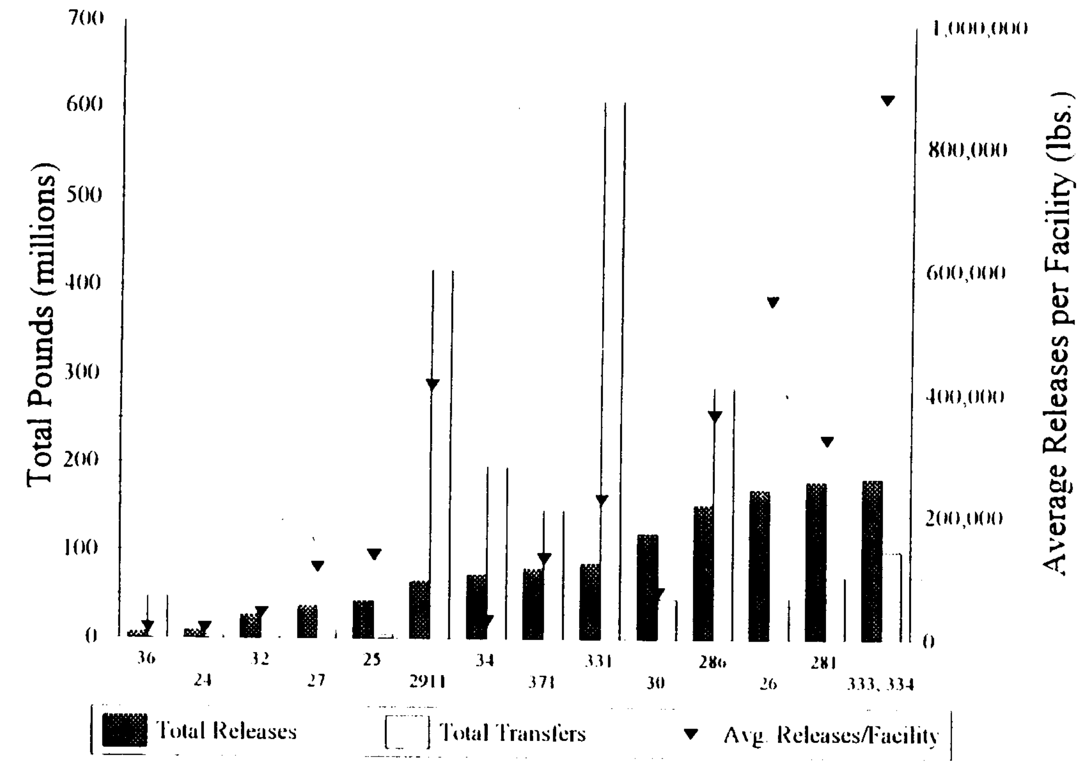
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following table does not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release book.

Exhibit 31 is a graphical representation of a summary of the 1993 TRI data for the Fabricated Metals Products industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 32 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of Fabricated Metal Products industry, the 1993 TRI data presented here covers 2,363 facilities. These facilities listed SIC 34 (Fabricated Metal Products industry) as a primary SIC code.

R0075996

Exhibit 31: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg
24	Lumber and Wood Products	34	Fabricated Metals	26	Pulp and Paper
32	Stone, Clay, and Concrete	371	Motor Vehicles, Bodies, Parts, and Accecessories	281	Inorganic Chemical Mfg

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the Fabricated Metal Products industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

V.A. Identification of Pollution Prevention Activities in Use and Environmental and Economic Benefits of Each Pollution Prevention Activity

Pollution prevention (sometimes referred to as source reduction) is the use of materials, processes, or practices that reduce or eliminate the creation of pollutants or wastes at the source. Pollution prevention includes practices that reduce the use of hazardous materials, energy, water or other resources, and practices that protect natural resources through conservation or more efficient use.

EPA and the Fabricated Metal Products industry are working together to promote pollution prevention because it is often the most cost-effective way to reduce pollution and the associated risks to human health and the environment. Pollution prevention is often cost effective because it may reduce raw material losses; reduce reliance on expensive "end-of-pipe" treatment technologies and disposal practices; conserve energy, water, chemicals, and other inputs; and mitigate the potential liability associated with waste generation and disposal. Pollution prevention often involves complex re-engineering however, and companies must balance the desired savings in materials and benefits to the environment against the cost of changing operating practices.

All companies in the Fabricated Metal Products industry, regardless of their size, must comply with environmental regulations related to metal fabricating and/or metal finishing processes. Therefore, all companies benefit from the knowledge of pollution prevention techniques which, if implemented, may increase a company's ability to meet these requirements. Many large companies have been successful in identifying and implementing pollution prevention and other techniques allowing them to operate in an efficient and environmentally protective manner. This capability may be due in part because large companies often have resources to devote to tracking and implementing pollution prevention techniques, and maintaining an awareness and understanding of regulations that apply to their facilities.

Smaller companies may have limited resources to devote to these activities, which may make monitoring and understanding regulations more difficult and may result in limited pollution prevention participation. Increased awareness and publication of pollution prevention techniques improve the ability of companies to comply with regulations. Pollution prevention techniques also permit industrial processes to be more efficient and less costly, providing all companies with an opportunity to maximize the efficiency of their operations and reduce their costs while protecting the environment.

Pollution Prevention techniques and processes currently used by the metal fabricating and finishing industry can be grouped into seven general categories:

- Production planning and sequencing
- Process or equipment modification
- Raw material substitution or elimination
- Loss prevention and housekeeping

- Waste segregation and separation
- Closed-loop recycling
- Training and supervision.

Each of these categories is discussed briefly below. Refer to Section V.D. for a list of specific pollution prevention techniques and associated costs, savings, and other information. It should be kept in mind that every pollution prevention option may not be available for each facility.

Production planning and sequencing is used to ensure that only necessary operations are performed and that no operation is needlessly reversed or obviated by a following operation. One example is to sort out substandard parts prior to painting or electroplating. A second example is to reduce the frequency with which equipment requires cleaning by painting all products of the same color at the same time. A third example is to schedule batch processing in a manner that allows the wastes or residues from one batch to be used as an input for the subsequent batch (e.g., to schedule paint formulation from lighter shades to darker) so that equipment need not be cleaned between batches.

Process or equipment modification is used to reduce the amount of waste generated. For example, manufacturers can change to a paint application technique that is more efficient than spray painting, reduce overspray by reducing the atomizing air pressure, reduce drag-out by reducing the withdrawal speed of parts from plating tanks, or improve a plating line by incorporating drag-out recovery tanks or reactive rinsing.

Raw material substitution or elimination is the replacement of existing raw materials with other materials that produce less waste, or a non-toxic waste. Examples include substituting alkali washes for solvent degreasers, and replacing oil with lime or borax soap as the drawing agent in cold forming.

Loss prevention and housekeeping is the performance of preventive maintenance and equipment and materials management so as to minimize opportunities for leaks, spills, evaporative losses, and other releases of potentially toxic chemicals. For example, spray guns can be cleaned in a manner that does not damage leather packings and cause the guns to leak; or drip pans can be placed under leaking machinery to allow recovery of the leaking fluid.

Waste segregation and separation involves avoiding the mixture of different types of wastes and avoiding the mixture of hazardous wastes with non-hazardous wastes. This makes the recovery of hazardous wastes easier by minimizing the number of different hazardous constituents in a given waste stream. It also prevents the contamination of non-hazardous wastes. Specific examples include segregating scrap metal by metal type, and segregating different kinds of used oils.

Closed-loop recycling is the on-site use or reuse of a waste as an ingredient or feedstock in the production process. For example, in-plant paper fiber waste can be collected and recycled to make pre-consumer recycled paper products.

Training and supervision provides employees with the information and the incentive to minimize waste generation in their daily duties. This might include ensuring that employees know and practice proper and efficient use of tools and supplies, and that they are aware of, understand, and support the company's pollution prevention goals.

V.B. Possible Pollution Prevention Future Trends

There are numerous pollution prevention trends in the metal fabrication and finishing industry. These include recycling liquids, employing better waste control techniques, using mechanical forms of surface preparation, and/or substituting raw materials. One major trend is the increased recycling (e.g., reuse) of most process liquids (e.g., rinse water, acids, alkali cleaning compounds, solvents, etc.) used during the metal forming and finishing processes. For instance, instead of discarding liquids, companies are containing them and reusing them to cut down on the volume of process liquids that must eventually be disposed of. Also, many companies are replacing aqueous plating with ion vapor deposition.

Another common approach to reducing pollution is to reduce rinse contamination via drag-out by slowing and smoothing the removal of parts (rotating them if necessary), maximizing drip time, using drainage boards to direct dripping solutions back to process tanks, and/or installing drag-out recovery tanks to capture dripping solutions. By slowing down the processes and developing structures to contain the dripping solutions, a facility can better control the potential wastes emitted.

To reduce the use of acids when cleaning parts, the industry is using and encouraging the use of mechanical scraping/scrubbing techniques to clean and prepare the metal surface. Emphasizing mechanical approaches would greatly diminish the need for acids, solvents, and alkalis. In addition to the mechanical technique for cleaning surfaces, companies are encouraged to substitute acids and solvents with less harmful liquids (e.g., alcohol). Section V.D. lists numerous specific pollution prevention techniques that have been employed in the industry.

V.C. Pollution Prevention Case Studies

Numerous pollution prevention case histories have been documented for the metal fabricating and finishing industries. Many of these have dealt primarily with electroplating or general finishing operations. The Eastside Plating case, presented in this section, is a classic example of the numerous pollution prevention techniques that can be implemented at an electroplating company. For other pollution prevention case studies, see section V.D. Pollution Prevention Options, and the list of pollution prevention contacts in section V.E.

Eastside Plating, an Oregon-based company, has made money complying with new environmental regulations. Under the direction of its Maintenance and Water Treatment Manager, the electroplating firm implemented operational changes that save more than $300,000 annually. Eastside Plating management made the commitment to implement a hazardous waste reduction program in 1982. By changing rinsing techniques, substituting materials, and segregating wastes for treatment, the firm has become a more cost-effective operation.

By setting priorities and upgrading in phases, the firm was able to work toward compliance yet meet increased demand for services during a period of rapid growth. The first operational modification addressed counterflow and cascade rinsing systems. The changes decreased water used for rinsing, a process that accounts for 90 percent of all water used in electroplating. In counterflow rinsing, water is used a number of times, thus dramatically reducing volume. Cascade rinsing requires only one tank with a center divider which allows water to spill into the other side. The filling/draining process is continuous and very slow to reduce the amount of water used. Both systems cut water bills and wastewater treatment costs.

Management next searched for waste treatment chemicals that decreased, rather than increased, the production of sludge. Total chromium and cyanide wastes were cut in half simply by changing reducing agents. Chromium acid wastes are now oxidized by using sodium bisulfite and sulfuric acid instead of ferrous sulfate, while cyanide reduction is now accomplished more efficiently with gaseous, instead of liquid, chlorine.

Eastside Plating also upgraded its three major waste treatment components: the cyanide oxidation tank, the chromium reduction tank, and the acid/alkaline neutralizing tank. The goal was to separate tank flow, eliminate contamination of the acid/alkaline neutralizing tank, and increase efficiency. Automated metering equipment reduced the quantity of costly caustic chemicals needed to treat acid wastes by 50 percent. To eliminate the risks associated with pump failure and the equalize flow rate, cyanide and chromic acid oxidation and reduction tanks were redesigned as gravity flow systems. Additionally, plumbing was segregated to prevent cross-contamination. These simple solutions saved Eastside Plating hundreds of thousands of dollars.

Next, management consulted with suppliers when they modified the company's mixing sump (sometimes called a reaction tank) and a flocculent mix tank (sometimes called a neutralizing tank). The modification to each prohibits 'indigestion' in the mixing sump interfering with the neutralization process. The suppliers helped resolve the problems of inadequate mixing by baffling the neutralization tank.

Since employees can make or break the best anti-pollution plan, Eastside Plating offers an extensive employee education program. The company says "it's a matter of changing how we do business." In addition, Eastside Plating's Safety Committee helps all employees work together more safely. Additionally, the company reported that working with regulators helped the company make the move toward compliance: "The City of Portland and the Department of Environmental Quality were more interested in helping us solve our problems than in blaming us."

Industry Pollution Prevention Activities

Several pollution prevention initiatives focus on the fabricated metal products industry. As identified below, some efforts include Georgia's Pollution Prevention Assistance Division (P^2AD) strategy, the Industrial Technology Corporation collaborative effort, and the Merit Partnership.

R0076004

Georgia Department of Natural Resources

A core strategy of the Pollution Prevention Assistance Division (P^2AD) of the Georgia Department of Natural Resources (DNR) is to focus technical assistance efforts on Georgia manufacturers that release chemicals posing the greatest risk to the public and the environment. After reviewing those industries which provide significant opportunities for pollution prevention, various strategies will be developed, including on-site technical assistance, financial assistance, fact sheets, workshops, and other outreach activities that will help manufacturers reduce their generation of toxic chemicals. The first phase is an on-going targeting effort, which evaluates waste generation characteristics of Georgia manufacturers producing toxic and hazardous wastes. The fabricated metal products industry was selected as a high priority manufacturing sector, along with the paper and paper products industry, chemical and allied products industry, transportation equipment industry, rubber and plastic products, and printing and publishing.

ITAC

The Industrial Technology Assistance Corporation (ITAC), in collaboration with the New York Branch of the AESF, the New York Masters Association of Metal Finishers, Utility Metal Research Corporation, and ten electroplating companies applied for and received funding to deliver a program coordinated and written by the Wastewater Technology Center of Canada. This is an industry-specific hands on 24 hour training session that integrates the assessment and incorporation of pollution prevention techniques into all types of electroplating and metal finishing operations. The training also includes an economic evaluation of the benefits of resource recovery on a multi-media basis.

Merit Partnership

The Merit Partnership brings industry and government representatives together to identify pollution prevention needs and accelerate pollution prevention technology diffusion. Merit partners and participants include EPA Region 9, The Metal Finishing Association of Southern California (MFASC), the National Institute of Standards and Testing/California Manufacturing Technology Center, EPA's Office of Research and Development/Risk Reduction Engineering Lab, large companies processing pollution prevention technologies applicable to the metal finishing industry, local regulatory agencies, and participating companies. The Merit Partnership is working closely with its members to develop metal finishing projects that are transferable to small businesses. There is an emphasis on having large companies that are involved with metal finishing share their proven metal finishing methods with smaller companies. The Merit Partnership and MFASC have already begun to identify programmatic areas for metal plating pollution prevention opportunities, from which potential projects will be chosen.

V.D. Pollution Prevention Options

The following sections list numerous pollution prevention techniques that may be useful to companies specializing in metal fabrication and finishing operations. These are options available to facilities, but are not to be construed as requirements. The information is organized by metal shaping, surface preparation, plating, and other finishing operations.

V.D.1. Metal Shaping Operations

Technique - Production Planning and Sequencing

Option 1 - Improve scheduling of processes that require use of varying oil types in order to reduce the number of cleanouts.

Technique - Process or Equipment Modification

Option 1 - Standardize the oil types used for machining, turning, lathing, etc. This reduces the number of equipment cleanouts, and the amount of leftovers and mixed wastes.

Option 2 - Use specific pipes and lines for each set of metals or processes that require a specific oil in order to reduce the amount of cleanouts.

Option 3 - Save on coolant costs by extending machine coolant life through the use of a centrifuge and the addition of biocides. **Costs and Savings:** Waste Savings/Reductions: 25 percent reduction in plant-wide waste coolant generation. Product/Waste Throughput Information: based on handling 20,600 gallons of coolant per year.

Option 4 - Install a second high speed centrifuge on a system already operating with a single centrifuge to improve recovery efficiency even more. **Costs and Savings:** Capital Investment: $126,000. Payback Period: 3.1 years. Product/Waste Throughput Information: based on handling 20,600 gallons of coolant per year.

Option 5 - Install a chip wringer to recover excess coolant on aluminum chips. **Costs and Savings**: Capital Investment: $11,000 to $23,000 (chip wringer and centrifuge system).Payback Period: 0.9 years. Product/Waste Throughput Information: based on handling 20,600 gallons of coolant per year.

Option 6 - Install a coolant recovery system and collection vehicle for machines not on a central coolant sump. **Costs and Savings:** Capital Investment: $104,000. Payback Period: 1.9 years. Product/Waste Throughput Information: based on handling 20,600 gallons of coolant per year.

Option 7 - Use a coolant analyzer to allow better control of coolant quality. **Costs and Savings:** Capital Investment: $5,000. Payback Period: 0.7 years. Product/Waste Throughput Information: based on handling 20,600 gallons of coolant per year.

Option 8 - Use an ultrafiltration system to remove soluble oils from wastewater streams. **Costs and Savings:** Annual Savings: $200,000 (in disposal costs). Product/Waste Throughput Information: based on a wastewater flow rate of 860 to 1,800 gallons per day.

Option 9 - Use disk or belt skimmers to remove oil from machine coolants and prolong coolant life. Also, design sumps for ease of cleaning. **Costs and Savings:** Waste Savings/Reduction: coolant is now disposed once per year rather than 3-6 times per year.

Technique - Raw Material Substitution

Option 1 - In cold forming or other processes where oil is used only as a lubricant, substitute a hot lime bath or borax soap for oil.

Option 2 - Use a stamping lubricant that can remain on the piece until the annealing process, where it is burned off. This eliminates the need for hazardous degreasing solvents and alkali cleaners. **Costs and Savings:** Annual Savings: $12,000 (results from reduced disposal, raw material, and labor costs). Waste Throughput Information: The amount of waste solvents and cleaners was reduced from 30,000 pounds in 1982 to 13,000 pounds in 1986. Employee working conditions were also improved by removing vapors associated with the old cleaners.

Technique - Waste Segregation and Separation

Option 1 - If filtration or reclamation of oil is required before reuse, segregate the used oils in order to prevent mixing wastes.

Option 2 - Segregation of metal dust or scrap by type often increases the value of metal for resale (e.g., sell metallic dust to a zinc smelter instead of disposing of it in a landfill). **Costs and Savings:** Capital Investment: $0. Annual Savings: $130,000. Payback Period: immediate. Waste Savings/Reduction: 2,700 tons per year. (Savings will vary with metal type and market conditions.)

Option 3 - Improve housekeeping techniques and segregate waste streams (e.g., use care when cleaning cutting equipment to prevent the mixture of cutting oil and cleaning solvent). **Costs and Savings:** Capital Investment: $0. Annual Savings: $3,000 in disposal costs. Waste Savings/Reduction: 66 percent (30 tons reduced to 10 tons).

Technique - Recycling

Option 1 - Where possible, recycle oil from cutting/machining operations. Often oils need no treatment before recycling. **Costs and Savings:** Capital Investment: $1,900,000. Annual Savings: $156,000. Waste Throughput Information: 2 million gallons per year. Facility reclaims oil and metal from process water.

Option 2 - Oil scrap mixtures can be centrifuged to recover the bulk of the oil for reuse.

Option 3 - Follow-up magnetic and paper filtration of cutting fluids with ultrafiltration. By so doing, a much larger percentage of cutting fluids can be reused. **Costs and Savings:** Capital Investment: $42,000 (1976). Annual Savings: $33,800 (1980).

Option 4 - Perform on-site purification of hydraulic oils using commercial "off-the-shelf" cartridge filter systems. **Costs and Savings:** Capital Investment: $28,000. Annual Savings: $17,800/year based on operating costs, avoided new oil purchase, and lost resale revenues. Payback Period: less than 2 years. Product/Waste Throughput Information: example facility handles 12,300 gallons/year of waste hydraulic oil.

Option 5 - Use a continuos flow treatment system to regenerate and reuse aluminum chemical milling solutions. **Costs and Savings:** Capital Investment: $465,000. Annual Savings: $342,000. Payback Period: less than 2 years. Waste Savings/Reduction: 90 percent

Option 6 - Use a settling tank (to remove solids) and a coalescing unit (to remove tramp oils) to recover metal-working fluids. **Costs and Savings:** Annual Savings: $26,800 (resulting from reduced material, labor, and disposal costs).

V.D.2. Surface Preparation Operations

SOLVENT CLEANING

Technique - Training and Supervision

Option 1 - Improve solvent management by requiring employees to obtain solvent through their shop foreman. Also, reuse "waste" solvents from cleaner up-stream operations in down-stream, machines shop-type processes. **Costs and Savings:** Capital Investnent: $0. Annual Savings: $7,200. Waste Savings/Reduction 49 percent (310 tons reduced to 152 tons). Product/Waste Throughput Information: original waste stream history: reactive anions (6,100 gallons/year), waste oils (1,250 gallons/year), halogenated solvents (500 gallons/year).

Technique - Production Planning and Sequencing

Option 1 - Pre-cleaning will extent the life of the aqueous or vapor degreasing solvent (wipe, squeeze, or blow part with air, shot, etc.). **Costs and Savings:** Annual Savings: $40,000. Payback Period: 2 years. Waste Savings/Reduction: 48,000 gallons of aqueous waste. Aluminum shot was used to preclean parts.

Option 2 - Use countercurrent solvent cleaning (i.e., rinse initially in previously used solvent and progress to new, clean solvent).

Options 3 - Cold clean with a recycled mineral spirits stream to remove the bulk of oil before final vapor degreasing.

Option 4 - Only degrease parts that must be cleaned. Do not routinely degrease all parts.

Technique - Process or Equipment Modification

Option 1 - The loss of solvent to the atmosphere from vapor degreasing equipment can be reduced by:

- increasing the freeboard height above the vapor level to 100 percent of tank width;
- covering the degreasing unit (automatic covers are available);
- installing refrigerator coils (or additional coils) above the vapor zone;
- rotating parts before removal from the vapor degreaser to allow all condensed solvent to return to degreasing unit;
- controlling the speed at which parts are removed (10 feet or less per minute is desirable) so as not to disturb the vapor line;
- installing thermostatic heating controls on solvent tanks; and
- adding in-line filters to prevent particulate buildup in the degreaser.

Option 2 - Reduce grease accumulation by adding automatic oilers to avoid excess oil applications.

Option 3 - Use plastic blast media for paint stripping rather than conventional solvent stripping techniques. **Costs and Savings:** Waste Savings/Reduction: volume of waste sludge is reduced by as much as 99 percent over chemical solvents; wastewater fees are eliminated.

Technique - Raw Material Substitution

Option 1 - Use less hazardous degreasing agents such as petroleum solvents or alkali washes. For example, replace halogenated solvents (e.g., trichloroethylene) with liquid alkali cleaning compounds. (Note that compatibility of aqueous cleaners with wastewater treatment systems should be ensured.) **Costs and Savings:** Capital Investment: $0. Annual Savings: $12,000. Payback Period: immediate. Waste Savings/Reduction: 30 percent of 1,1,1-trichloroethane replaced with an aqueous cleaner.

Option 2 - Substitute chromic acid cleaner with non-fuming cleaners such as sulfuric acid and hydrogen peroxide. **Costs and Savings:** Annual Savings: $10,000 in treatment equipment costs and $2.50/lb. of chromium in treatment chemical costs. Product/Waste Throughput Information: rinse water flowrate of 2 gallons per minute.

Option 3 - Substitute less polluting cleaners such as trisodium phosphate or ammonia for cyanide cleaners. **Costs and Savings:** Annual Savings: $12,000 in equipment costs and $3.00/lb. of cyanide in treatment chemical costs. Product/Waste Throughput Information: rinse water flowrate of 2 gallons per minute.

Technique - Recycling

Option 1 - Recycle spent degreasing solvents on site using batch stills. **Costs and Savings:** Capital Investment: $2,600-$4,100 and $4,200-$17,000. Product Throughput Information: 35-60 gallons per hour and 0.6-20 gallons per hour, respectively. Two cost and throughput estimates for distillation units from two vendors.

Option 2 - Use simple batch distillation to extend the life of 1,1,1-trichloroethane. **Costs and Savings:** Capital Investment: $3,500 (1978). Annual Savings: $50,400. Product/Waste Throughput Information: facility handles 40,450 gallons 1,1,1-trichloroethane per year.

Option 3 - When on-site recycling is not possible, agreements can be made with supply companies to remove old solvents. **Costs and Savings:** Capital Investment: $3,250 for a temporary storage building. Annual Savings: $8,260. Payback Period: less than 6 months. Waste Savings/Reduction: 38,000 pounds per year of solvent sent off site for recycling.

Option 4 - Arrange a cooperative agreement with other small companies to centrally recycle solvent.

CHEMICAL TREATMENT

Technique - Process or Equipment Modification

Option 1- Increase the number of rinses after each process bath and keep the rinsing counter-current in order to reduce drag-out losses.

Option 2 - Recover unmixed acids in the wastewater by evaporation.

Option 3 - Reduce rinse contamination via drag-out by:

- slowing and smoothing removal of parts, rotating them if necessary;
- using surfactants and other wetting agents;
- maximizing drip time;
- using drainage boards to direct dripping solutions back to process tanks;
- installing drag-out recovery tanks to capture dripping solutions;
- using a fog spray rinsing technique above process tanks;
- using techniques such as air knives or squeegees to wipe bath solutions off of the part; and
- changing bath temperature or concentrations to reduce the solution surface tension.

Option 4 - Instead of pickling brass parts in nitric acid, place them in a vibrating apparatus with abrasive glass marbles or steel balls. A slightly acidic additive is used with the glass marbles, and a slightly basic additive is used with the steel balls. **Costs and Savings:** Capital Investment: $62,300 (1979); 50 percent less than conventional nitric acid pickling.

Option 5 - Use mechanical scraping instead of acid solution to remove oxides of titanium. **Costs and Savings:** Annual Savings: $0; cost of mechanical stripping equals cost of chemical disposal. Waste Savings/Reduction: 100 percent. Waste Throughput Information: previously disposed 15 tons/year of acid with metals.

Option 6 - For cleaning nickel and titanium alloy, replace alkaline etching bath with a mechanical abrasive system that uses a silk and carbide pad and pressure to clean or "brighten" the metal. **Costs and Savings:** Capital Investment: $3,250. Annual Savings: $7,500. Waste Savings/Reduction: 100 percent. Waste Throughput Information: previous etching bath waste total was 12,000 gallons/year.

Option 7 - Clean copper sheeting mechanically with a rotating brush machine that scrubs with pumice, instead of cleaning with ammonium persulfate, phosphoric acid, or sulfuric acid; may generate non-hazardous waste sludge. **Costs and Savings:** Capital Investment: $59,000. Annual Savings: more than $15,000. Payback Period: 3 years. Waste Savings/Reduction: 40,000 pounds of copper etching waste reduced to zero.

Option 8- Reduce molybdenum concentration in wastewaters by using a reverse osmosis/precipitation system. **Costs and Savings:** Capital Investment: $320,000. Waste Throughput Information: permeate capacity of 18,000 gallons per day. Savings Relative to an Evaporative System: installed capital cost savings: $150,000; annual operating cost savings: $90,000.

Option 9 - When refining precious metals, reduce the acid/metals waste stream by maximizing reaction time in the gold and silver extraction process. **Costs and Savings:** Capital Investment: $0. Annual Savings: $9,000. Waste Savings/Reduction: 70 percent (waste total reduced from 50 tons to 15 tons).

Technique - Raw Material Substitution

Option 1 - Change copper bright-dipping process from a cyanide dip and chromic acid dip to a sulfuric acid/hydrogen peroxide dip. The new bath is less toxic and copper can be recovered.

Option 2 - Use alcohol instead of sulfuric acid to clean copper wire. One ton of wire requires 4 liters of alcohol solution, versus 2 kilograms of sulfuric acid. **Costs and Savings:** Capital Investment: $0.

Option 3 - Replace caustic wire cleaner with a biodegradable detergent.

Option 4 - Replace chromated desmutting solutions with nonchromated solutions for alkaline etch cleaning of wrought aluminum. **Costs and Savings:** Annual Savings: $44,541. Waste Savings/Reduction: sludge disposal costs reduced by 50 percent.

Option 5 - Replace barium and cyanide salt heat treating with a carbonate/chloride carbon mixture, or with furnace heat treating.

Option 6 - Replace thermal treatment of metals with condensation of saturated chlorite vapors on the surface to be heated. **Costs and Savings:** Waste Savings/Reduction: this process is fast, nonoxidizing, and uniform; pickling is no longer necessary.

Technique - Recycling

Option 1 - Sell waste pickling acids as feedstock for fertilizer manufacture or neutralization/precipitation.

Option 2 - Recover metals from solutions for resale. **Costs and Savings:** Annual Savings: $22,000. Payback Period: 14 months. Company sells copper recovered from a bright-dip bath regeneration process employing ion exchange and electrolytic recovery.

Option 3 - Send used copper pickling baths to a continuous electrolysis process for regeneration and copper recovery. **Costs and Savings:** Capital Investment: $28,500 (1977). Product Throughput Information: pickling 12,000 tons of copper; copper recovery is at the rate of 200 gallons/ton of processed copper.

Option 4 - Recover copper from brass bright dipping solutions using a commercially available ion exchange system. **Costs and Savings:** Annual Savings: $17,047; based on labor savings, coppers sulfate elimination, sludge reduction, copper metal savings, and bright dip chemicals savings. Product Throughput Information: example facility processes approximately 225,000 pounds of brass per month.

Option 5 - Treat industrial wastewater high in soluble iron and heavy metals by chemical precipitation. **Costs and Savings:** Annual Savings: $28,000; based on reduced water and sewer rates. Waste Throughput Information: wastewater flow from facility's "patening" line is 100 gallons per minute.

Option 6 - Oil quench baths may be recycled on site by filtering out the metals.

Option 7 - Alkaline wash life can be extended by skimming the layer of oil (the skimmed oil may be reclaimed).

V.D.3. Plating Operations

Technique - Training and Supervision

Option 1 - Educate plating shop personnel in the conservation of water during processing and in material segregation.

Technique - Production Planning and Sequencing

Option 1 - Preinspect parts to prevent processing of obvious rejects.

Technique - Process or Equipment Modification

Option 1 - Modify rinsing methods to control drag-out by:
- Increasing bath temperature
- Decreasing withdrawal rate of parts from plating bath
- Increasing drip time over solution tanks; racking parts to avoid cupping solution within part cavities
- Shaking, vibrating, or passing the parts through an air knife, angling drain boards between tanks
- Using wetting agents to decrease surface tension in tank.

Contact: Braun Intertec Environmental, Inc., and MN Office of Waste Management (612) 649-5750.

Option 2 - Utilize water conservation methods including:
- Flow restrictors on flowing rinses
- Counter current rinsing systems
- Fog or spray rinsing
- Reactive rinsing
- Purified or softened water
- Dead rinses
- Conductivity controllers
- Agitation to assure adequate rinsing and homogeneity in rinse tank
- Flow control valves.

Contact: Braun Intertec Environmental, Inc., and MN Office of Waste Management (612) 649-5750.

Option 3 - Implement counter flow rinsing and cascade rinsing systems to conserve consumption of water. **Costs and Savings:** Costs: $75,000 to upgrade existing equipment and purchasing new and used equipment. Waste Savings/Reduction: reduce water use and wastewater treatment costs. **Contact:** Eastside Plating and OR Department of Environmental Quality (800)452-4011.

Option 4 - Use drip bars to reduce drag-out. **Costs and Savings:** Capital Investment: $100 per tank. Savings: $600. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 5 - Use drain boards between tanks to reduce generations of drag-out. **Costs and Savings:** Capital Investment: $25 per tank. Savings: $450. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 6 - Install racking to reduce generations of drag-out. **Costs and Savings:** Capital Investment: zero dollars. Operating Costs: minimal. Savings: $600. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 7 - Employ drag out recovery tanks to reduce generations of drag-out. **Costs and Savings:** Capital Investment: $500 per tank. Savings: $4,700. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 8 - Install counter-current rinsing operation to reduce water consumption. **Costs and Savings:** Capital Investment: $1,800-2,300. Savings: $1,350 per year. Waste Savings/Reductions: reduce water use by 90-99 percent. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 9 - Redesign rinse tank to reduce water conservation. **Costs and Savings:** Capital Investment: $100. Savings: $750 per year. **Contact:** NC Department of Natural Resources & Community Development, Gary Hunt (919) 733-7015.

Option 10 - Increase parts drainage time to reduce drag-out. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 11 - Regenerate plating bath by activated carbon filtration to remove built up organic contaminants. **Costs and Savings:** Capital Investment: $9,192. Costs: $7,973. Savings: $122,420. Waste Savings/Reduction: 10,800 gallons. Reduce volume of plating baths disposed and requirements for virgin chemicals. **Contact:** EPA Hazardous Waste Engineering Research Laboratory, Cincinnati, OH, Harry Freeman.

Option 12 - Install pH controller to reduce the alkaline and acid concentrations in tanks. **Contact:** Securus, Inc., and DBA Hubbard Enterprises.

Option 13 - Install atmospheric evaporator to reduce metal concentrations. **Contact:** Securus, Inc., and DBA Hubbard Enterprises.

Option 14 - Install process (e.g., CALFRAN) to reduce pressure to vaporize water at cooler temperatures and recycle water by condensing the vapors in another container, thus concentrating and precipitating solutes out. **Costs and Savings:** Waste Savings/Reduction: reduce volume and quantity of aqueous waste solutions by recovering pure water. **Contact:** CALFRAN International, Inc., (413) 525-4957.

Option 15 - Use reactive rinsing and multiple drag-out baths. **Costs and Savings:** Savings: Reduce cost of treating spent process baths and rinse waters. Waste Savings/Reduction: increase lifetime of process baths and reduce the quantity or rinse water requiring treatment. **Contact:** SAIC, Edward R. Saltzberg.

Option 16 - Improve control of water level in rinse tanks, improve sludge separation, and enhance recycling of supernatant to the process by aerating the sludge. **Costs and Savings:** Savings: $2,000. Waste Savings/Reduction: reduce sludge generation by 32 percent. **Contact:** NJ Hazardous Waste Facilities Siting Commission, Hazardous Waste Source Reduction and Recycling Task Force.

Option 17 - Install system (e.g., Low Solids Fluxer) that applies flux to printed wiring boards, leaving little residue and eliminates the need for cleaning CFCs. **Costs and Savings:** Waste Savings/Reduction: reduce CFC emissions over 50 percent. **Contact:** AT&T Bell Laboratories, Princeton, NJ.

Technique - Raw Material Substitution

Option 1 - Substitute cyanide plating solutions with alkaline zinc, acid zinc, acid sulfate copper, pyrophosphate copper, alkaline copper, copper fluoborate, electroless nickel, ammonium silver, halide silver, methanesulfonate-potassium iodide silver, amino or thio complex silver, no free cyanide silver, cadmium chloride, cadmium sulfate, cadmium fluoborate, cadmium perchlorate, gold sulfite, and cobalt harden gold. **Contact:** Braun Intertec Environmental Inc., and MN Office of Waste Management (612) 649-5750.

Option 2 - Substitute sodium bisulfite and sulfuric acid for ferrous sulfate in order to oxidize chromic acid wastes, and substitute gaseous chlorine for liquid chlorine in order to reduce cyanide reduction. **Costs and Savings:** Savings: $300,000 per year. Waste Savings/Reduction: reduces feedstock by 50 percent. **Contact:** Eastside Plating and OR Department of Environmental Quality (800) 452-4011.

Option 3 - Replace hexavalent chromium with trivalent chromium plating systems. **Contact:** City of Los Angeles Hazardous and Toxic Material Project. Board of Public Works (213) 237-1209.

Option 4 - Replace cyanide with non-cyanide baths. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 5 - Replace conventional chelating agents such as tartarates, phosphates, EDTA, and ammonia with sodium sulfides and iron sulfates in removing metal from rinse water which reduces the amount of waste generated from precipitation of metals from aqueous wastestreams. **Costs and Savings:** Costs: $178,830 per year. Savings: $382,995 per year. Waste Savings/Reduction: 496 tons of sludge per year. **Contact:** Tyndall Air Force Base, FL, (904) 283-2942, Charles Carpenter, Dan Sucia, Penny Wilcoff; and John Beller at EG&G (108) 526-1149.

Option 6 - Replace methylene chloride, 1,1,1-trichloroethane, and perchloroethylene (solvent-based photochemical coatings) with aqueous base coating of 1 percent sodium carbonate. **Costs and Savings:** Waste Savings/Reduction: reduce solvent use by 60 tons per year. **Contact:** American Etching and Manufacturing, Pacoima, CA.

Option 7 - Replace methanol with nonflammable alkaline cleaners. **Costs and Savings:** Waste Savings/Reduction: eliminate 32 tons per year of flammable methyl alcohol. **Contact:** American Etching and Manufacturing, Pacoima, CA.

Option 8 - Substitute a non-cyanide for a sodium cyanide solution used in copper plating baths. **Costs and Savings:** Waste Savings/Reduction: reduce 7,630 pounds per year. Contact: Highland Plating Company, Los Angeles, CA.

Technique - Waste Segregation and Separation

Option 1 - Wastewaters containing recoverable metals should be segregated from other wastewater streams.

Technique - Recycling

Option 1 - Install ion exchange system to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $78,000. Operating Costs: $3,200 per year. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 2 - Employ reverse osmosis system to reduce generation of drag-out. **Costs and Savings:** Savings: $40,000 per year. Capital Investment: $62,000. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 3 - Use electrolytic metal recovery to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $1,000. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 4 - Utilize electrodialysis to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $50,000. **Contact:** NC Department of Natural Resources & Community Development; Pollution Prevention Pays Program Gary Hunt (919) 733-7015.

Option 5 - Implement evaporative recovery to reduce generation of drag-out. **Costs and Savings:** Capital Investment: $2,500. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 6- Reuse rinse water. **Costs and Savings:** Savings: $1,500 per year. Capital Investment: $340 per tank. No direct costs. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 7- Reuse drag-out waste back into process tank. **Contact:** NC Department of Natural Resources & Community Development; Gary Hunt (919) 733-7015.

Option 8- Recover process chemicals with fog rinsing parts over plating bath. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 9- Evaporate and concentrate rinse baths for recycling. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 10 - Use ion exchange and electrowinning, reverse osmosis, and thermal bonding when possible. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 11 - Use sludge slagging techniques to extract and recycle metals. **Costs and Savings:** Capital Investment: $80,000 for 80 tons/year and $400,000 for 1,000 tons/year. Operating Costs: $18,000 per year for an 80 ton facility. Waste Savings/Reduction: reduces volume of waste by 94 percent. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 12 - Use hydrometallurgical processes to extract metals from sludge. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 13- Convert sludge to smelter feed. **Contact:** City of Los Angeles Hazardous and Toxic Material Project, Board of Public Works (213) 237-1209.

Option 14- Remove and recover lead and tin from boards by electrolysis or chemical precipitation. **Contact:** Control Data Corporation and MN Office of Waste Management (612) 649-5750.

Option 15 - Install a closed loop batch treatment system for rinse water to reduce water use and waste volume. **Costs and Savings:** Savings: $58,460 per year. Capital Investment: $210,000. Waste Savings/Reduction: 40,000 gallons per year (40 percent). **Contact:** Pioneer Metal Finishing, Inc., Harry Desoi (609) 694-0400.

Option 16 - Install an electrolytic cell which recovers 92 percent of dissolved copper in drag-out rinses and atmospheric evaporator to recover 95 percent of chromatic acid drag-out, and recycle it into chromic acid etch line. **Contact:** Digital Equipment Corporation and Lancy International Consulting Firm, William McLay (412) 452-9360.

Option 17 - Implement the electrodialysis reversal process for metal salts in wastewater. **Costs and Savings**: Savings: $40,100 per year in operating costs. **Contact:** Ionics, Inc., Separations Technology Division.

Option 18 - Oxidize cyanide and remove metallic copper to reduce metal concentrations. **Contact:** Securus, Inc. and DBA Hubbard Enterprises.

V.D.4. Other Finishing Operations

FINISHING OPERATIONS

Technique - Training and Supervision

Option 1 - Always use proper spraying techniques.

Option 2 - Improved paint quality, work efficiency, and lower vapor emissions can be attained by formal training of operators.

Option 3 - Avoid buying excess finishing material at one time due to its short shelf-life.

Technique - Production Planing and Sequencing

Option 1 - Use the correct spray gun for particular applications:
- conventional air spray gun for thin-film-build requirements
- airless gun for heavy film application
- air assisted airless spray gun for a wide range of fluid output.

Option 2 - Preinspect parts to prevent painting of obvious rejects.

Technique - Process or Equipment Modification

Option 1 - Ensure the spray gun air supply is free of water, oil, and dirt.

Option 2 - Replace galvanizing processes requiring high temperature and flux with one that is low temperature and does not require flux. **Costs and Savings:** Capital Investment: $900,000. Annual Savings: 50 percent (as compared to conventional galvanizing). Product Throughput Information: 1,000 kg/h.

Option 3 - Investigate use of transfer methods that reduce material loss such as:
- dip and flow coating
- electrostatic spraying
- electrodeposition.

Option 4 - Change from conventional air spray to an electrostatic finishing system. **Costs and Savings:** $15,000 per year. Payback Period: less than 2 years.

Option 5 - Use solvent recovery or incineration to reduce the emissions of volatile organics from curing ovens. **Costs and Savings:** Annual Savings: $400,000.

Option 6 - Regenerate anodizing and alkaline silking baths with contemporary recuperation of aluminum salts. **Costs and Savings:** $0.20 per meter of aluminum treated per year. Waste Throughput Information: based on an example plant that previously disposed 180,000 liters of acid solution per year at $0.07 per litre.

Technique - Raw Material Substitution

Option 1 - Use alternative coatings for solvent based paints to reduce volatile organic materials use and emissions, such as:

- high solids coatings (this may require modifying the painting process; including high speed/high pressure equipment, a paint distributing system, and paint heaters); **Costs and Savings:** Waste Savings/Reduction: 30 percent net savings in applied costs per square foot.

- water based coatings - **Costs and Savings:** Waste Savings/Reduction: 87 percent drop in solvent emissions and decreased hazardous waste production;

- powder coatings - **Costs and Savings:** Capital Investment: $1.5 million. Payback Period: 2 years. Example is for a large, wrought iron patio furniture company.

Technique - Waste Segregation and Separation

Option 1 - Segregate non-hazardous paint solids from hazardous paint solvents and thinners.

Technique - Recycling

Option 1 - Do not dispose of extended shelf life items that do not meet your facility's specifications. They may be returned to the manufacturer, or sold or donated as a raw material.

Option 2 - Recycle metal sludges through metal recovery vendors.

Option 3 - Use activated carbon to recover solvent vapors, then recover the solvent from the carbon by steam stripping, and distill the resulting water/solvent mixture. **Costs and Savings:** Capital Investment: $817,000 (1978). Waste Savings/Reduction: releases of solvent to the atmosphere were reduced from 700 kg/ton of solvent used to 20 kg/ton.

Option 4 - Regenerate caustic soda etch solution for aluminum by using hydrolysis of sodium aluminate to liberate free sodium hydroxide and produce a dry, crystalline hydrate alumina byproduct. **Costs and Savings:** Capital Investment: $260,000. Savings: $169,282 per year; from reduced caustic soda use, income from the sale of the byproduct, and a reduction in the cost of solid waste disposal. Payback Period: 1.54 years. Product/Waste Throughput Information: anodizing operation for which the surface area is processed at a rate of 200 M^2/hour.

PAINT CLEANUP

Technique - Production Planning and Sequencing

Option 1 - Reduce equipment cleaning by painting with lighter colors before darker ones.

Option 2 - Reuse cleaning solvents for the same resin system by first allowing solids to settle out of solution.

Option 3 - Flush equipment first with dirty solvent before final cleaning with virgin solvent. **Costs and Savings:** Waste Savings/Reduction: 98 percent; from 25,000 gallons of paint cleanup solvents to 400 gallons. Company uses cleanup solvents in formulation of subsequent batches.

Option 4 - Use virgin solvents for final equipment cleaning, then as paint thinner.

Option 5 - Use pressurized air mixed with a mist of solvent to clean equipment.

Technique - Raw Material Substitution

Option 1 - Replace water-based paint booth filters with dry filters. Dry filters will double paint booth life and allow more efficient treatment of wastewater. **Costs and Savings:** Savings per year: $1,500. Waste Savings/Reduction: 3,000 gallons/year.

Technique - Loss Prevention and Housekeeping

Option 1 - To prevent spray gun leakage, submerge only the front end (or fluid control) of the gun into the cleaning solvent.

Technique - Waste Segregation and Separation

Option 1 - Solvent waste streams should be kept segregated and free from water contamination.

Technique - Recycling

Option 1 - Solvent recovery units can be used to recycle spent solvents generated in flushing operations.

- Install a recovery system for solvents contained in air emissions. **Costs and Savings:** Savings: $1,000 per year.
- Use batch distillation to recover isopropyl acetate generated during equipment cleanup. **Costs and Savings:** Payback Period: 2 years.
- Use batch distillation to recover xylene from paint equipment cleanup. **Costs and Savings:** Payback Period: 13 months. Savings: $5,000 per year.
- Use a small solvent recovery still to recover spent paint thinner from spray gun cleanups and excess paint batches. **Costs and Savings:** Capital Investment: $6,000 for a 15 gallons capacity still. Savings: $3,600 per year in new thinner savings; $5,400 in disposal savings. Payback Period: less than 1 year. Waste Savings/Reduction: 75 percent (745 gallons of thinner recovered from 1,003 gallons). Product/Waste Throughput Information: 1,500 gallons of spent thinner processed per year.
- Install a methyl ethyl ketone solvent recovery system to recover and reuse waste solvents. **Costs and Savings:** Savings: $43,000 per year; MEK recovery rate: 20 gallons per day, reflecting a 90 percent reduction in waste.

Option 2 - Arrange an agreement with other small companies to jointly recycle cleaning wastes.

VI. Summary of Applicable Federal Statutes and Regulations

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements so that the reader is aware of these requirements. The section provides a summary of each major environmental statute, and a description of regulations that may specifically apply to the profiled industry. Some profiles also provide information regarding current rulemaking activity that might specifically impact this sector. The descriptions within Section VI are intended solely for guidance. No statutory or regulatory requirements are in any way altered by any statement(s) contained herein. For more in-depth information, readers should consult the United States Code and the Code of Federal Regulations as well as State or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.B. Industry Specific Regulations

A number of statutes and regulations affect the metal fabrication and finishing industry. The electroplating and metal finishing pretreatment standards promulgated under the Clean Water Act regulate the chemicals in wastewater, the Clean Air Act regulates air emissions, and the Resource Conservation and Recovery Act regulates hazardous waste generation, transportation, treatment, storage, and disposal. Each is discussed briefly below.

Clean Water Act (CWA)

Two Clean Water Act regulations affect the fabricated metal products industry (SIC 34): the Effluent Guidelines and Standards for Metal Finishing (40 CFR Part 433) and the Effluent Guidelines and Standards for Electroplating (40 CFR Part 413). The regulations targeting the electroplating industry were issued before those targeting the metal finishing industry as a whole. Companies regulated by the electroplating standards (40 CFR Part 413) before the metal finishing standards (40 CFR Part 433) were promulgated, become subject to the requirements of the metal finishing standards when (or if) they make modifications to their facility's operating functions (e.g., facility, equipment, process modifications). If companies made no such modifications, they remain regulated by the electroplating standards. All new facilities are subject to the standards set forth in 40 CFR Part 433.

The Effluent Guidelines and Standards for Metal Finishing (40 CFR Part 433) are applicable to wastewater generated by any of these operations:

- Electroplating
- Electroless Plating
- Anodizing
- Coating
- Chemical Etching and Milling
- Printed Circuit Board Manufacturing.

If any of the above processes are performed, the metal finishing standards will also apply to discharges from 40 additional processes, including: cleaning, polishing, shearing, hot dip coating, solvent degreasing, painting, etc.

The standards include daily maximums and maximum monthly average concentration limitations. The standards are based on milligrams per square meter of operation and determine the amount of wastewater pollutants from various operations that may be discharged. The uniformity in standards meets industry requests for equivalent limits for process lines often found together. The metal finishing standards also reduce the need to use the Combined Wastestream Formula.

Specific pretreatment standards may also apply to wastewater discharges from other metal finishing operations. The more specific standards will apply to those metal finishing wastestreams which appear to be covered by both standards. The requirements in the following regulations take precedence over those contained in the general metal finishing regulation:

- Iron and Steel Manufacturing (40 CFR Part 420)
- Battery Manufacturing (40 CFR Part 461)
- Plastic Molding and Forming (40 CFR Part 463)
- Coil Coating (40 CFR Part 465)
- Porcelain Enameling (40 CFR Part 466)

- Aluminum Forming (40 CFR Part 467)
- Copper Forming (40 CFR Part 468)
- Electrical and Electronic Components (40 CFR Part 469)
- Nonferrous Forming (40 CFR Part 471)
- Lead-Tin-Bismuth Forming Category (40 CFR Part 471, Subpart A)
- Zinc Forming Subcategory (40 CFR Part 471, Subpart H).

The Effluent Guidelines and Standards for Electroplating (40 CFR Part 413) cover wastewater dischargers from electroplating operations, in which metal is electroplated on any basis material, and to related metal finishing operations. As stated previously, facilities regulated by the electroplating standards may become subject to the metal finishing standards if they make modifications to their facility's operating functions (e.g., facility, equipment, process modifications). Independent printed circuit board manufacturers are defined as facilities which manufacture printed circuit boards principally for sale to other companies. These facilities remain subject only to the electroplating standards (40 CFR Part 413), primarily to minimize the economic impact to these relatively small facilities. Also excluded from the metal finishing regulations are facilities which perform metallic platemaking and gravure cylinder preparation conducted within printing and publishing facilities.

Operations similar to electroplating which are specifically exempt from coverage under the electroplating standards include:

- Continuous strip electroplating conducted within iron and steel manufacturing facilities (40 CFR Part 420)
- Electrowinning and electrorefining conducted as part of nonferrous metal smelting and refining (40 CFR Part 421)
- Electrodeposition of active electrode materials, electroimpregnation, and electroforming conducted as part of battery manufacturing (40 CFR Part 461)
- Metal surface preparation and conversion coating conducted as part of coil coating (40 CFR Part 465)
- Metal surface preparation and immersion plating or electroless plating conducted as a part of porcelain enameling (40 CFR Part 466)

- Metallic platemaking and gravure cylinder preparation conducted within printing and publishing facilities
- Surface treatment including anodizing and conversion coating conducted as part of aluminum forming (40 CFR Part 467).

Clean Air Act (CAA)

The following standards and requirements promulgated under the CAA apply to metal finishing processes:

- National Emission Standards for Chromium Emissions From Hard and Decorative Chromium Electroplating and Chromium Anodizing Tanks (40 CFR Parts 9 and 63, Subpart N, 60 FR 498, January 1995)
- Standards of Performance for Surface Coating of Metal Furniture (40 CFR Part 60, Subpart EE)
- Standards of Performance for Automobile and Light-Duty Truck Surface Coating Operations (40 CFR Part 60, Subpart MM)
- Standards of Performance for Industrial Surface Coatings: Large Appliances (40 CFR Part 60, Subpart SS)
- Standards of Performance for Metal Coil Surface Coating (40 CFR Part 60, Subpart TT)
- Standards of Performance for the Beverage Can Surface Coating Industry (40 CFR Part 60, Subpart WW)
- Standards of Performance for Industrial Surface Coating: Surface Coating of Plastic Parts for Business Machines (40 CFR Part 60, Subpart TTT).

These standards and requirements, although to varying degrees, regulate the discharge of volatile organic chemicals (VOCs).

Resource Conservation and Recovery Act (RCRA)

The greatest quantities of RCRA listed waste and characteristic hazardous waste present in the fabricated metal products industry are identified in Exhibit 33. For more information on RCRA hazardous waste, refer to 40 CFR Part 261.

Exhibit 33
Hazardous Wastes Relevant to the Metal Finishing Industry

EPA Hazardous Waste No.	Hazardous Waste
D006 (cadmium) D007 (chromium) D008 (lead) D009 (mercury) D010 (selenium) D011 (silver)	Wastes which are hazardous due to the characteristic of toxicity for each of the constituents.
F001	Halogenated solvents used in degreasing: tetrachloroethylene, methylene chloride, 1,1,1-trichloroethane, carbon tetrachloride, and chlorinated fluorocarbons; all spent solvent mixtures/blends used in degreasing containing, before use, a total of 10 percent or more (by volume) of one or more of the above halogenated solvents or those solvents listed in F002, F004, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F002	Spent halogenated solvents; tetrachloroethylene, methylene chloride, trichlorethylene, 1,1,1-trichloroethane chlorobenzene, 1,1,2-trichloro-1,2,2-trifluoroethane, ortho-dichlorobenzene, trichlorofluoromethane, and 1,1,2-trichloroethane; all spent solvent mixtures/blends containing, before use, one or more of the above halogenated solvents or those listed in F001, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F003	Spent non-halogenated solvents: xylene, acetone, ethyl acetate, ethyl benzene, ethyl ether, methyl isobutyl ketone, n-butyl alcohol, cyclohexanone, and methanol; all spent solvent mixtures/blends containing, before use, only the above spent non-halogenated solvents; and all spent solvent mixtures/blends containing, before use, one or more of the above non-halogenated solvents, and, a total of 10 percent or more (by volume) of one of those solvents listed in F001, F002, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F004	Spent non-halogenated solvents: cresols and cresylic acid, and nitrobenzene; all spent solvent mixtures/blends containing, before use, a total of 10 percent or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F005	Spent non-halogenated solvents: toluene, methy ethyl ketone, carbon disulfide, isobutanol, pyridine, benzene, 2-ethoxyethanol, and 2-nitropropane; all spent solvent mixtures/blends containing, before use, a total of 10 percent or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, or F004; and still bottoms from the recovery of these spent solvents and spent solvents mixtures.
F006	Wastewater treatment sludges from electroplating operations except from the following processes: (1) sulfuric acid anodizing of aluminum; (2) tin plating on carbon steel; (3) zinc plating (segregated basis) on carbon steel; (4) aluminum or zinc-aluminum plating on carbon steel; (5) cleaning/stripping associated with tin, zinc, and aluminum plating on carbon steel; and (6) chemical etching and milling of aluminum.
F007	Spent cyanide plating bath solutions from electroplating operations.
F008	Plating bath residues from the bottom of plating baths from electroplating operations where cyanides are used in the process.

R0076037

Exhibit 33
Hazardous Wastes Relevant to the Metal Finishing Industry

EPA Hazardous Waste No.	Hazardous Waste
F009	Spent stripping and cleaning bath solutions from electroplating operations where cyanides are used in the process.
F010	Quenching bath residues from oil baths from metal heat treating operations where cyanides are used in the process.
F011	Spent cyanide solutions from salt bath pot cleaning from metal heat treating operations.
F012	Quenching wastewater treatment sludges from metal heat treating operations where cyanides are used in the process.
F019	Wastewater treatment sludges from the chemical conversion coating of aluminum from zirconium phosphating is an exclusive conversion coating process.
K090	Emission control dust or sludge from ferrochromiumsilicon production (ferroalloy industry).
K091	Emission control dust or sludge from ferrochromium production (ferroalloy industry).

Source: Sustainable Industry: Promoting Strategic Environmental Protection in the Industrial Sector, Phase 1 Report, U.S. EPA, OERR, June 1994.

VI.C. Pending and Proposed Regulatory Requirements

Clean Water Act (CWA)

The effluent guidelines and standards for Electroplaters (40 CFR Part 413) and Metal Finishers (40 CFR Part 433) are currently under review. EPA is also currently developing effluent guidelines and standards for the metal products and machinery industry (40 CFR Part 438), which are due by May 1996. It appears that EPA will integrate new regulatory options for the metal finishing industry into this new guideline. Under the anticipated scenario, effluent guidelines for electroplaters and metal finishers would most likely reference appropriate sections of the guideline for the metal products and machinery industry. In is unclear, however, how "job shop" operations, which are not part of the metal products and machinery industry, would be covered under this scenario.

For Phase I of the regulation, EPA will propose effluent limitation guidelines for facilities that generate wastewater while processing metal parts, metal products, and machinery, including: manufacture, assembly, rebuilding, repair, and maintenance. The Phase I regulation will cover seven major industrial groups, including: aircraft, aerospace, hardware (including machine tools, screw machines, metal forgings and stampings, metal springs, heating equipment, and fabricated structural metal, ordinance, stationary industrial equipment (including electrical equipment), mobile industrial equipment, and electronic equipment (including communication equipment). The legal deadline is May 1996.

Phase II, EPA will propose effluent limitation guidelines for facilities that generate wastewater while processing metal parts, metal products and machinery, including: manufacture, assembly, rebuilding, repair, and maintenance. The Phase II regulation will cover eight major industrial groups, including: motor vehicles, buses and trucks, household equipment, business equipment, instruments, precious and nonprecious metals, shipbuilding, and railroads. The legal deadline is December 31, 1997.

Clean Air Act (CAA)

In addition to the CAA requirements discussed above, EPA is currently working on several regulations that will directly affect the metal finishing industry. Many proposed standards will limit the air emissions from various industries by proposing Maximum Achievable Control Technology (MACT) based performance standards that will set limits on emissions based upon concentrations in the waste stream. Various potential standards are described below.

Organic Solvent Degreasing/Cleaning

EPA proposed a NESHAP (58 FR 62566, November 19, 1993) for the source category of halogenated solvent degreasing/cleaning that will directly affect the metal finishing industry. This will apply to new and existing organic halogenated solvent emissions to a MACT-equivalent level, and will apply to new and existing organic halogenated solvent cleaners (degreasers) using any of the HAPs listed in the CAA Amendments. EPA is specifically targeting vapor degreasers that use the following HAPs: methylene chloride, perchloroethylene, trichloroethylene, 1,1,1-trichloroethane, carbon tetrachloride, and chloroform.

This NESHAP proposes to implement a MACT-based equipment and work practice compliance standard. This would require that a facility use a designated type of pollution prevention technology along with proper operating procedures. However, EPA has also provided an alternative compliance standard. Existing operations, which utilize performance-based standards, can continue to do so if such standards can be shown to achieve the same emission limit as the equipment and work practice compliance standard.

Steel Pickling, HCl

Hydrochloric acid (HCl) and chlorine are among the pollutants listed as hazardous air pollutants in Section 112 of the Clean Air Act Amendments of 1990. Steel pickling processes that use HCl solution and HCl regeneration processes have been identified by the EPA as potentially significant sources of HCl and chlorine air emissions and, as such, a source category for which national emission standards may be warranted. EPA is required to promulgate national emission standards for 50 percent of the source categories listed in Section 112(e) by November 15, 1997.

Other Future Regulatory Actions

EPA is developing MACT standards for several industries, including: miscellaneous metal parts and products (surface coating), asphalt/coal tar application-metal pipes, metal can (surface coating), metal coil (surface coating), and metal furniture (surface coating). The legal deadline for these rulemakings is November 15, 2000.

VII. COMPLIANCE AND ENFORCEMENT PROFILE

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[2] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

---

[2] EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

R0076042

Compliance and Enforcement Data Definitions

General Definitions

Facilities Indexing System (FINDS) --- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Fabricated Metal Products Industry Compliance History

Exhibit 34 presents enforcement and compliance information specific to the fabricated metal products industry. As indicated in this exhibit, Regions IV, V, and IX conduct the largest number of inspections in this industry. This is consistent with the fact that the fabricated metal products industry is geographically concentrated near industrial areas. The data also indicates that nearly all of Region IV's enforcement actions are State-lead.

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 35 - 38 provide enforcement and compliance information for selected industries. The fabricated metal products industry comprises the largest number of facilities tracked by EPA across the selected industries. Likewise, it has the largest number of inspections and enforcement actions. For this industry, RCRA inspections comprise over half of all inspections conducted, while CWA inspections account for 15 percent of these inspections. The low CWA inspection rate is in conflict with the large number of water discharges that are generated by this industry.

VII.C. Review of Major Legal Actions

VII.C.1 Review of Major Cases

This section provides summary information about major cases that have affected this sector. As indicated in EPA's *Enforcement Accomplishments Report, FY 1991, FY 1992, FY 1993* publications, 15 significant enforcement actions were resolved between 1991 and 1993 for the metal finishing industry. CWA violations comprised eight of these actions, the most of any statute. Following CWA violations were five actions involving RCRA violations, three involving CERCLA violations, one with a CAA violation, and one with a SDWA violation. The companies against which the cases were brought are primarily metal finishers, including those that provide electroplating, coating, and plating services. Two of the companies perform metal forming and fabrication functions.

Twelve of the fifteen cases resulted in the assessment of a penalty. Penalties ranged from $15,000 to $500,000, and in four cases, additional money was spent by the defendant to improve the processes or technologies and to increase future compliance. For example, in U.S. v. North American Philips Corp. (1992), the company paid a $500,000 penalty and spent approximately $583,000 to eliminate wastewater discharges from some of its non-federally regulated processes. The average penalty per case was approximately $322,000. Supplemental Environmental Projects (SEPs) were required in two of the cases. Texas Instruments, Inc. (1993), for example, was required to pay a penalty and replace a vapor degreaser unit with a more environmentally-protective unit.

Although many cases involved civil penalties, four of the cases involved criminal convictions, resulting in penalties and/or jail sentences for the owners and/or operators of the facilities. For example, the case of U.S. v. John Borowski and Borjohn Optical Technology, Inc., resulted in the first criminal endangerment conviction under CWA; the company president was sentenced to 26 months in prison, folloshwed by two years of supervised release.

VII.C.2 Supplemental Environmental Projects

Supplementary Environmental Projects (SEPs) are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement and Compliance Assurance to provide information on the number and type of SEPs entered into by the Regions. The following exhibit contains a representative sample of the Regional responses addressing the fabricated metal products industry. The information contained in the exhibit is not comprehensive and provides only a sample of the types of SEPs developed for the fabricated metal products industry. Please note that the projects describes in this section do not necessarily apply to all facilities in this sector. Facility-specific conditions must be considered carefully when evaluating potential supplemental environmental projects.

Exhibit 39
Supplemental Environmental Projects
Fabrication of Metal Products (SIC 34)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Truex, Inc. Pawtucket, RI (metal parts manufacturing)	1	EPCRA	Pollution Reduction	$ 70,000	Install and operate a cooling water and process rinse recycling system and a metal recovery system to reduce the water used and to recover copper and zinc process waste for recycling.	$ 54,000	$ 29,000
Walton & Lonsbury Attleboro, MA (electroplating facility)	1	RCRA	Pollution Prevention and Pollution Reduction	$ 18,270	Implement a system to reclaim and reuse chromic acid rinse waters. Eliminate the use of trichloroethane in the degreasing operation. Install a filtration system which will extend the life of the hydrochloric acid strip solution.	$ 15,100	$ 15,100
Verilyte Gold, Inc. Chelsea, MA (electroplatting facility)	1	RCRA	Pollution Prevention	$ 21,450	Install a hot-air metal parts drying unit which eliminates 100 percent of the use of freon.	$ 26,400	$ 15,675
The Torrington Company (precision bearings, assemblies, gears, and couplings manufacture)	1	EPCRA	Equipment Donation	$ 16,792	Donate emergency and/or computer equipment to the Local Emergency Planning Committee (LEPC) to respond to and/or plan for chemical emergencies. Participate in LEPC activities.	$ 35,364	$ 18,572
Texas Instruments, Inc. Attleboro, MA (metallurgic materials manufacture)	1	EPCRA	Equipment Donation	$ 8,063	Purchase computer hardware and software for the LEPC and Attleboro Fire Department (AFD) to assist the LEPC in tracking and storing information about identity and location of hazardous chemicals and to assist the AFD in responding to accidental releases.	$ 14,025	$ 5,962

Exhibit 39
Supplemental Environmental Projects
Fabrication of Metal Products (SIC 34)

Texas Instruments, Inc. Attleboro, MA (metal finishing)	1	CAA	Pollution Prevention	$ 170,000	Replace the current vapor degreasor unit with a closed-loop degreaser unit to prevent the use of Freon 113.	$ 90,000	$ 49,900
L.S. Starrlett Company, Inc. Athol, MA (tool manufacture)	1	EPCRA	Pollution Prevention	$ 290,000	Install three alkaline-based aqueous agitation wash systems, replace Freon cleaning units in two departments, and a methylene chloride cleaning unit in a third department to reduce Freon and methylene chloride by 100 percent.	$ 176,800	$ 83,200
Teradyne, Inc Nashua, NH (soldering products manufacture)	1	RCRA	Pollution Prevention	$ 800,000	Purchase and install solvent replacement units for two facilities. Stop using Freon 113 in manufacturing operations at one facility and stop using 1,1,1-trichloroethane (except in water sensitive assemblies) at another facility.	$ 120,000	$ 50,000
M.W. Dunton Company West Warwick, RI (soldering products manufacture)	1	EPCRA	SERC/LERC	$ 4,754	Donate emergency response equipment to the volunteer fire department to assist the LEPC in tracking and storing information about identity and location of hazardous chemicals and to assist the fire department in responding to accidental releases.	$ 9,500	$ 4,745

Exhibit 39
Supplemental Environmental Projects
Fabrication of Metal Products (SIC 34)

The Drawn Metal Tube Company Thomaston, CT	1	CWA	Pollution Prevention	$ 145,000	Install a closed loop evaporator system to eliminate the discharge of copper forming wastewater to the river.	$ 77,624	$ 45,000
Pioneer Metal Finishing	2	EPCRA	Pollution Prevention	$ 13,128	Pretreat used nickel bags and used filter bags from nickel filters to recover waste nickel, thus minimizing the disposal of hazardous nickel waste.		$ 5,000
Elken Metals Company Alloy, WV	3	xxxx	Pollution Reduction	$ 449,000	Remove PCB transforers, PCB capapcitors, and retrofilling PCB-contaminated transformers to reduce the amount of PCBs which may be released.	$ 280,000	$ 17,250
Southern Foundry Supply	4	EPCRA	Pollution Reduction	$ 34,000	Assess the feasibility of a process to recover pure nickel from plant wastestreams and construct a pilot plant to perform the recovery to reduce the quantity of heavy metals entering the environment.	$ 15,840	$ 2,376
Cerro Metal Products, Inc. Bellefonte, PA	3	TSCA	Accelerated Compliance	$ 40,000	Replace PCB transformers fluid with non-PCB fluid to eliminate the potential for uncontrolled releases of PCBs.	$ 31,700	$ 18,450

VIII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Activities

Numerous compliance activities and initiatives are occurring throughout the fabricated metal products industry. Many companies are conducting private research on developing new alloys and experimenting with the use of citric acid oils or terpenes instead of the more toxic degreasers (e.g., 1,1,1-trichloroethane).

Several projects currently underway are sponsored by Federal, State, and county governments; universities; and trade associations. Several of these initiatives are described below.

Common Sense Initiative

The Common Sense Initiative (CSI), a partnership between EPA and private industry, aims to create environmental protection strategies that are cleaner for the environment and cheaper for industry and taxpayers. As part of CSI, representatives from Federal, State, and local governments; industry; community-based and national environmental organizations; environmental justice groups; and labor organizations, come together to examine the full range of environmental requirements affecting the following six selected industries: automobile manufacturing; computers and electronics, iron and steel, metal finishing, petroleum refining; and printing.

CSI participants are looking for solutions that:

- Focus on the industry as a whole rather than one pollutant
- Seek consensus-based solutions
- Focus on pollution prevention rather than end-of-pipe controls
- Are industry-specific.

R0076057

The Common Sense Initiative Council (CSIC), chaired by EPA Administrator Browner, consists of a parent council and six subcommittees (one per industry sector). Each of the subcommittees have met and identified issues and project areas for emphasis, and workgroups have been established to analyze and make recommendation on these issues. (Contact: Greg Waldrip at (202) 564-7024)

Design for the Environment (DfE)

DfE is an EPA program operated by the Office of Pollution Prevention and Toxics. DfE is a voluntary program which promotes the use of safer chemicals, processes, and technologies in the earliest product design stages. The DfE program assists industry in making informed, environmentally responsible design choices by providing standardized analytical tools for industry application and providing information on the comparative environmental and human health risk, cost, and performance of chemicals, processes, and technologies. DfE also helps small businesses by analyzing pollution prevention alternatives and disseminating the information to industry and the public. By helping to translate pollution prevention into meaningful terms, DfE contributes to building the institutional structure in corporations to support pollution prevention. DfE activities fall into two broad categories: (1) the industry-specific projects which encourage businesses to incorporate pollution prevention into their designs; and (2) long-term projects that translate pollution prevention into terms that make sense to professions such as chemistry, chemical engineering, marketing, accounting, and insurance.

One DfE effort (in partnership with the Manufacturing Extension Partnership) is the development of a benchmarking database and accompanying questionnaire to serve as an incentive mechanism for companies. Metal fabricators are encouraged to complete a company-specific questionnaire and return it to the Manufacturing Extension Partnership for analysis. The company will then receive a report comparing its data to that of other companies. Based on the results, companies are encouraged to voluntarily implement mechanisms that will minimize environmental damage resulting from the manufacturing processes. Subjects included in the questionnaire, database, and report range from the use of automation and monitoring technologies to the volumes of wastes generated, treated, and recycled.

Minnesota Technical Assistance Program (MnTAP)

In the State of Minnesota, waste reduction is receiving increased attention as an alternative to waste disposal. To help companies reduce waste, Minnesota developed MnTAP, a program that helps facilities identify waste reduction opportunities. MnTAP recognizes that each company's operations are unique and has, therefore, developed a series of checklists to help identify waste reduction possibilities. The checklists are designed to assist each facility evaluate wastestreams and identify waste reduction opportunities. The checklists cover several areas relevant to this profile, including operating procedures, cleaning, machining, plating/metal finishing, coating/painting, and formulating.

To ensure effective use of MnTAP's checklists, staff is available to answer questions over the phone or on-site once checklists have been completed. MnTAP has also gathered vendor and technical information for many of the options listed which may be useful in assessing a facility's waste reduction opportunities. In addition, MnTAP has developed lists of vendors who provide recycling services on a contract basis if it is not feasible to implement the options listed on the checklists. MnTAP staff can be reached at (612) 625-4949.

Pollution Prevention and Waste Minimization in the Metal Finishing Industry Workshop

The University of Nebraska-Lincoln sponsored a Pollution Prevention and Waste Minimization in the Metal Finishing Industry workshop in 1993. The workshop was designed for managers and operators of electroplating and galvanizing operations; engineers; environmental consultants; waste management consultants; Federal, State, and local government officials; and individuals responsible for training in the area of metal finishing waste management. Topics covered included:

- Saving money and reducing risk through pollution prevention and waste minimization
- Incorporating pollution prevention into planning electroplating and galvanizing operations
- Conducting waste minimization audits
- Developing and analyzing options for pollution prevention/waste minimization

- Innovative techniques for implementing a pollution prevention/waste minimization program.

For more information concerning this workshop, contact David Montage of the University of Nebraska at W348 Nebraska Hall, Lincoln, NE 68588-0531.

Pollution Prevention Opportunities Checklists

The County Sanitation Districts of Los Angeles County developed a detailed pollution prevention opportunities checklist to help companies identify and implement pollution prevention methods where possible. The County Sanitation Districts has identified specific opportunities for the metal fabricators and metal finishing industries.

Southeast Michigan Initiative (SEMI)

EPA and the Michigan Department of Natural Resources (MDNR) have launched a geographic initiative in the Southeast Michigan area because of the magnitude of contaminant releases and human population in the area. Eight counties within the Initiative have been identified as having major environmental problems. Several rivers in the area suffer from impaired uses, polluted airsheds, combined sewer overflows, contaminated sediments, and major toxic pollutant releases.

A Steering Committee, composed of senior managers of MDNR and EPA, meet quarterly and are responsible for making decisions concerning the overall direction of the Initiative. There are also four working committees, including: public participation; remedial action plans/sediments; pollution prevention; and compliance and enforcement.

For more information regarding SEMI contact Rufus Anderson, Assistant Deputy Director, MDNR Region 5 at (313) 953-1444 or Mardi Klevs, EPA SEMI Coordinator at (312) 353-5490.

The Blackstone Project

The Blackstone Project, a joint initiative by the Massachusetts Department of Environmental Protection (DEP) and the Department of Environmental Management (DEM), is intended to make environmental protection more efficient and less costly to companies. As Doug Fine, the Compliance and Enforcement Coordinator, explains, the Blackstone Project's two goals are to encourage industry to use less toxic material in manufacturing, and to increase the efficiency of DEP's industrial inspections by conducting one-stop, facility-wide inspections. The project focused first on fabricated metal products facilities near the Blackstone River Valley and later expanded to all types of manufacturers in that region. The State of Massachusetts now conducts facility-wide inspections in a continuous effort to reduce pollution.

The NCMS/NAMF Pollution Control Assessment Project

The National Center for Manufacturing Sciences (NCMS) and the National Association of Metal Finishers (NAMF) worked jointly to develop the *Pollution Prevention and Control Technology for Plating Operations* publication which documents pollution prevention techniques and pollution control equipment used in plating operations. To develop this document and the associated database, NCMS and NAMF collected pollution prevention information through surveys, literature searches, and interviews with industry experts. The resulting publication illustrates pollution prevention techniques and equipment used, assesses the effectiveness of these techniques as illustrated by historical data, and indicates the types of facilities in which these techniques were employed.

The Sustainable Industry Project

The EPA Office of Policy, Planning, and Evaluation's Sustainable Industry Project represents a new approach to the development of environmental policy for industry. The primary goal of the Sustainable Industry Project is to develop, test, and implement industry-specific policy recommendations that will remove barriers to innovation and promote strategic environmental protection in the selected industries (i.e., photoimaging, metal finishing, and thermoset plastics). To do this, EPA gained a thorough understanding of the relevant characteristics of the industries—the industry-specific economic, institutional, cultural, technical, life-cycle, and regulatory factors that may promote or hinder environmental improvements. Further, EPA identified driving factors and barriers that influence corporate decision-making and environmental performance. Understanding the factors that influence environmental performance in a given industry provides the basis for designing policies that will encourage improved performance. Working with industries, States, non-government organizations (NGOs), and other interested parties, EPA intends to design policies that will protect the environment and human health while fostering competitive and sustainable industries.

U.S. Bureau of Mines (USBM)

The U.S. Bureau of Mines has developed a technique to regenerate chromium bearing solutions such as those used in chromate conversion aluminum electroplating. The process is in commercial use and a company is preparing to license the technology to manufacture and market solution treatment equipment. In related work, the Bureau worked with the specialty steel industry to reduce waste generated by pickling operations. Other USBM research includes the dewatering of sludges, extraction of metals from a variety of liquid and solid wastes, recycling of metals, and development of lead-free free-machining copper alloys.

Wastewater Technology Center

The Wastewater Technology Center (WTC) is an organization of scientists, chemists, technologists, and support staff dedicated to the research and development of technologies to control industrial and municipal discharges. Conducting bench-scale, pilot plant, and full-scale studies for 25 years, over 100 WTC staff have assisted industry in solving a wide variety of environmental concerns. Recently, WTC has worked closely with the Metal Finishing Task Force, a committee of Federal government, provincial government, and metal finishing industry representatives to develop a pollution prevention guide. The document is designed to assist metal finishers in establishing a pollution prevention planning process. WTC also provides assistance in interpreting and using this guide and facilitates other pollution prevention planning programs that metal finishers have or are anticipating establishing. In addition, to help metal finishers better understand and use the pollution prevention planning, WTC, in conjunction with Sheridan College, has prepared an extensive training course in pollution prevention planning in metal finishing.

Other Initiatives

The metal finishers and platers industry is being considered by EPA for several upcoming initiatives. Work has already begun by the NPDES and the RCRA programs. The NPDES Branch began an Industrial User initiative in May 1993 that targeted metal finishers who failed to report their compliance status with categorical pretreatment effluent standards (40 CFR 433). In addition, the RCRA program has an initiative that applies to iron and steel and metal plating/finishing industries. The State of Utah plans to inspect each of the iron and steel and metal plating/finishing industries in the State.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of 17 chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given to participants who meet their 1992 goals. The list of chemicals includes 17 high-use chemicals reported in the Toxics Release Inventory.

The number of companies that use 33/50 chemicals per industry sector ranged from a low of six in the tobacco industry to a high of 1,803 in the fabricated metal products industry. Of these companies, 187 participate in the 33/50 program. Some 33/50 chemicals that are particularly relevant to this industry include: lead and lead compounds, methyl ethyl ketone, nickel and nickel compounds, tetrachloroethylene, toluene, trichloroethane, trichlorethylene, and xylenes.

Exhibit 40 lists those companies participating in the 33/50 program that reported under SIC code 34 to TRI. Many of the participating companies listed multiple SIC codes (in no particular order), and are therefore likely to conduct operations in addition to Fabricated Metal Products industry. The table shows the number of facilities within each company that are participating in the 33/50 program; each company's total 1993 releases and transfers of 33/50 chemicals; and the percent reduction in these chemicals since 1988.

Exhibit 40

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. At present, no metal finishing or fabricating facilities are carrying out ELP pilot projects. (Contact: Tai-ming

Chang, ELP Director, (202) 564-5081 or Robert Fentress, (202) 564-7023)

Gillette ELP Project

The objective of the Gillette Environmental Leadership Program is the development and implementation of a third party compliance and management systems audit and verification process. The project will involve the development of environmental compliance and environmental management systems audit protocol criteria that can be adopted and easily implemented by other facilities to assess compliance with relevant regulations. The three Gillette facilities that are participating are: South Boston Manufacturing Center, blade and razor manufacturing; North Chicago Manufacturing Center, batch chemical manufacturing; and Santa Monica, CA, stationary products manufacturing. (Contact: Scott Throwe, (202) 564-7013).

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. Contact Jon Kessler, Office of Policy Analysis, (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard, (202) 233-9065 or the Green Light/Energy Star Hotline at (202) 775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn, (202) 260-0700 or the WasteWi$e Hotline at (800) 372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, (202) 260-4407)

NICE3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, (303) 275-4729)

VIII.C. Trade Association/Industry Sponsored Activity

Associations, universities, and the industry are currently working with EPA to make the Agency aware of issues that relate to metal fabricating and finishing industries. As a result of these relationships and overall interest in achieving compliance and reducing pollution, additional research relating to process techniques and pollution prevention alternatives is being conducted. Various workshops and training opportunities have resulted from these efforts. A summary of some trade association and industry activities is presented below, along with some associations related to this industry.

VIII.C.1. Environmental Programs

Several trade and professional associations are working with EPA to make the Agency aware of issues that relate to metal fabricating industries. For example, the Copper and Brass Fabricators Council (CBFC) has been assisting EPA's Office of Solid Waste regarding recycling issues as it develops or redrafts RCRA regulations. CBFC is communicating its experiences with metal fabricating to EPA, in terms of materials used and possible recycling options, in hopes that future regulations might complement the industry's processes.

Additionally, several organizations have sponsored workshops focusing on waste minimization and pollution prevention in several fabricated metal related industries. Three workshops, the

Hazardous Waste Management for Small Business Workshop, the Environmentally Conscious Painting Workshop, and the Pollution Prevention Workshop for the Electroplating Industry, are discussed below.

Hazardous Waste Management for Small Business Workshop

The University of Northern Iowa, with support from EPA, Des Moines Area Community College, Northeast Iowa Community College, Scott Community College, and Indiana Hills Community College, sponsored a *Hazardous Waste Management for Small Business* workshop. This workshop was geared towards small businesses and was intended to provide practical answers to environmental regulatory questions. Small businesses covered by the workshop include: manufacturers, vehicle maintenance and repair shops, printers, machine shops, and other businesses that generate potentially hazardous waste. Topics covered include: hazardous waste determination, waste generator categories, management of specific common waste streams, including used oil and solvents, and pollution prevention. (Contact: Duane McDonald, (319) 273-6899)

Environmentally Conscious Painting Workshop

Kansas State University, NIST/Mid-America Manufacturing Technology Center, Kansas Department of Health & Environment, EPA Region 7, Allied Signal, Inc., Kansas City Plant, and the U.S. Department of Energy sponsored the *Environmentally Conscious Painting* workshop. This workshop covered topics such as upcoming regulations and the current regulatory climate, methods to cost-effectively reduce painting wastes and emissions, and alternative painting processes. (Contact: the Kansas State University Division of Continuing Education, (913) 532-5566)

Pollution Prevention Workshop for the Electroplating Industry

Kansas State University Engineering Extension, EPA Region 7, Kansas Department of Health and Environment, and the University of Kansas sponsored the *Pollution Prevention Workshop for the Electroplating Industry.* The workshop described simple techniques for waste reduction in the electroplating industry, including: plating, rinsing processes and wastewater, wastewater management options, metals recovery options, waste treatment and management, and product substitutions and plating alternatives. (Contact: the Kansas State University Division of Continuing Education, (800) 432-8222)

VIII.C.2. Summary of Trade Associations

Various trade associations represent the interests of metal fabricator workers and the industry itself. Some of these organizations are discussed in greater detail below.

American Electroplaters and Surface Finishers Society (AESF) 12644 Research Parkway Orlando, FL 32826 Phone: (407) 281-6441 Fax: (407) 281-6446	Members: 10,000 Staff: 21 Budget: 2,000,000 Contact: Ted Witt, Executive Director

Founded in 1909, AESF is an international professional society of scientists, technicians, job shop operators, and others interested in research in electroplating, surface finishing, and allied arts. AESF offers classroom training courses, home study courses, cooperative programs, and a voluntary certification program. In addition, it bestows awards, conducts research programs, and provides an insurance program for job shop owners. AESF also publishes *Plating and Surface Finishing* (monthly), *AESF Shop Guide*, books, symposia proceedings, research reports, and training booklets with slide presentations; and makes available films and videotapes.

ASM International (ASM) 9639 Kinsman Materials Park, OH 44073 Phone: (216) 338-5151	Members: 54,000 Staff: 145 Budget: $19,500,000 Contact: Edward L. Langer

Founded in 1920, ASM represents metallurgists; materials engineers; executives in materials producing and consuming industries; and teachers and students. This association disseminates technical information about the manufacture, use, and treatment of engineered materials. It offers in-plant, home study, and intensive courses through the Materials Engineering Institute; conducts conferences, seminars, and lectures; presents awards to teachers of materials science and for achievements in the field; and grants scholarships and fellowships. Additionally, it maintains a library of 10,000 volumes on metals and other materials.

Copper and Brass Fabricators Council (CBFC) 1050 17th Street, NW, Suite 440 Washington, DC 20036 Phone: (202) 833-8575	Contact: Joseph L. Mayer

Founded in 1966, CBFC represents copper and brass fabricators. Its activities involve foreign trade in copper and brass fabricated products, and Federal regulatory matters including legislation, regulations, rules, controls, stockpiling, and other similar measures affecting domestic fabricators of copper and brass products. CBFC holds an annual convention.

Metal Construction Association (MCA) 1101 14th Street, NW, Suite 1100 Washington, DC 20005 Phone: (202) 371-1243 Fax: (202) 371-1090	Members: 100 Staff: 5 Contact: David W. Barrack

Founded in 1983, MCA represents individuals engaged in the manufacture, design, engineering, sale, or installation of metal used in construction, and others interested in the metal construction industry. It promotes the use of metal in all construction applications. Additionally, MCA represents all sectors of the metal construction industry; fosters better trade practices and improved communication within the industry; serves as liaison between members and other industry organizations. The association collects and disseminates information; maintains the Merit Award Program to acknowledge outstanding buildings, products, and systems in the industry; plans programs in institutional advertising, voluntary standards, and statistics; proposed educational programs including structure erection, estimating, and bookkeeping; compiles statistics; and bestows scholarships. MCA also prepares and distributes two publications: the *Metal Construction Association-Membership Directory* (annually) and the *Metal Construction Association-Newsletter* (quarterly). Its newsletter includes technical articles, meeting reviews, committee reports, minutes, and a calendar of events. MCA holds a semiannual meeting and Metalcon International Trade Show and an annual meeting.

Metal Fabricating Institute (FMI) PO Box 1178 Rockford, IL 61105 Phone: (815) 965-4031	Staff: 4 Contact: Ronald L. Fowler

Founded in 1968, MFI conducts technical seminars for structural and sheet metal fabricators to update management on the latest manufacturing techniques. MFI also presents a Fabricating Engineer of the Year Award. In addition, it publishes *Metal Fabricating News* (bimonthly), which contains a calendar of events, new products and literature, book reviews, and a buyers guide. The association also holds a semiannual conference in West Lafayette, Indiana.

Metal Finishers Suppliers Association (MFSA) 801 North Cass, Ste. 300 Westmont, IL 60559 Phone: (708) 887-0797	Members: 180 Companies Staff: 2-4 Budget: $400,000 Contact: Richard Crain

Incorporated in 1951, MFSA is the only trade association representing companies that supply chemicals and equipment to the metal finishing industry. MFSA works closely with organizations that represent the metal finishing industry, such as AESF (see above) and the National Association of Metal Finishers (see below), and is involved in several joint programs, including an annual conference. In addition, MFSA publishes a monthly newsletter and has published a dozen technical papers to inform and assist its members.

National Association of Metal Finishers (NAMF) 401 N. Michigan Avenue Chicago, IL 60611-4267 Phone: (312) 644-6610	Members: 940 Staff: 6 Budget: $750,000 Contact: Brad Parcells

Founded in 1955, NAMF represents management executives of firms engaged in plating, hard chroming, galvanizing, electroforming, metalizing, organic coating, phosphating, rust proofing, polishing, buffing, anodizing, and other forms of metal finishing. NAMF is concerned primarily with management education, development of finishing standards, and legislative issues. In addition, it publishes *Finishers' Management*, a trade magazine of the plating and finishing industry. NAMF also produces *Finishing Line* (monthly), *Legislative Line* (bi-monthly), and *NAMF Regulatory Compliance Manual.* NAMF holds an annual trade show.

Precision Metalforming Association (PMA) 27027 Chardon Road Richmond Heights, OH 44143 Phone: (216) 585-8800 Fax: (216) 585-3126	Members: 1,000 Staff: 20 Budget: $3,000,000 Contact: Jon E. Jenson

Founded in 1942, PMA represents manufacturers of metal stampings, precision metal fabrications, and metal spinnings, and their suppliers. PMA provides information and technical services to members. It also presents numerous awards and publishes *Metalforming*, a monthly magazine that addresses: materials and equipment, electronics in metal forming and assembly, taxes, legal issues, and management.

Society for Mining, Metallurgy, and Exploration, Inc. (SME) PO Box 625005 Littleton, CO 80162 Phone: (303) 973-9550	Members: 20,000 Staff: 31 Budget: $3,700,000 Contact: Gary D. Howell

Founded in 1871, SME represents individuals engaged in the finding, exploitation, treatment, and marketing of all classes of minerals (metal ores, industrial minerals, and solid fuel) except petroleum. Additionally, it offers specialized education programs; and compiles enrollment and graduation statistics from schools offering engineering degrees in mining, mineral, mineral processing/metallurgical, geological, geophysical technology.

United Steelworkers of America (USWA) 5 Gateway Center Pittsburgh, PA 15222 Phone: (412) 562-2400 Fax: (412) 562-2445	Members: 675,000 Staff: 475 Contact: George Becker

Founded in 1936, this association has absorbed numerous associations for steel workers. Currently, this agency publishes *Steelabor* ten times a year. This news magazine reports on legislation and regulation affecting the union, union activities at the national and chapter levels, economic developments, pension news, and information on safety and health. USWA also publishes the *Steelworker Old Time*, quarterly; and holds a biennial convention.

INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators. the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

ISBN 0-16-048275-5

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

UIC - Underground Injection Control (SDWA)
UST - Underground Storage Tanks (RCRA)
VOCs - Volatile Organic Compounds

METAL MINING
(SIC 10)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

Because this profile was not intended to be a stand-alone document concerning the metal mining industry, appended is a full reference of additional EPA documents and reports on this subject, as listed in the March edition of the Federal Register.

II. INTRODUCTION TO THE METAL MINING INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the metal mining industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

The metal mining industry includes facilities engaged primarily in exploring for metallic minerals, developing mines, and ore mining. These ores are valued chiefly for the metals they contain, which are recovered for use as constituents of alloys, chemicals, pigments, or other products. The industry sector also includes ore dressing and beneficiating operations. The categorization corresponds to the Standard Industrial Classification (SIC) code 10, published by the Department of Commerce to track the flow of goods and services within the economy.

The SIC 10 group consists of the following three-digit breakout of industries:

SIC 101 - Iron Ores
SIC 102 - Copper Ores
SIC 103 - Lead and Zinc Ores
SIC 104 - Gold and Silver Ores
SIC 106 - Ferroalloy Ores, Except Vanadium
SIC 108 - Metal Mining Services
SIC 109 - Miscellaneous Metal Ores.

Although the group includes all metal ore mining, the scope of mining industries with a significant domestic presence is concentrated in iron, copper, lead, zinc, gold, and silver. These represent the most common hardrock minerals mined domestically, and comprise an essential sector of the nation's economy by providing basic raw materials for major sectors of the U.S. economy. In addition, the extraction and beneficiation of these minerals generate large amounts of wastes. For these reasons, this profile's focus is limited to the above-stated sectors of the SIC 10 metal mining industry.

While such metals as molybdenum, platinum, and uranium are also included in SIC code 10, mining for these metals does not constitute a significant portion of the overall metal mining industry, nor of the

R0076099

waste generation in mining processes; these metals are therefore excluded from this profile.

In the global market, the U.S. is a major producer of iron, copper, lead, zinc, gold, and silver. In 1993, domestic mines were responsible for six percent of iron ore production, 13 percent of copper ore production, 13 percent of lead production, eight percent of zinc production, 14 percent of gold production, and 11 percent of silver production. Despite an extraordinary wealth of domestic metal sources, with the exception of gold, the U.S. is a net importer of all the above-mentioned metals.

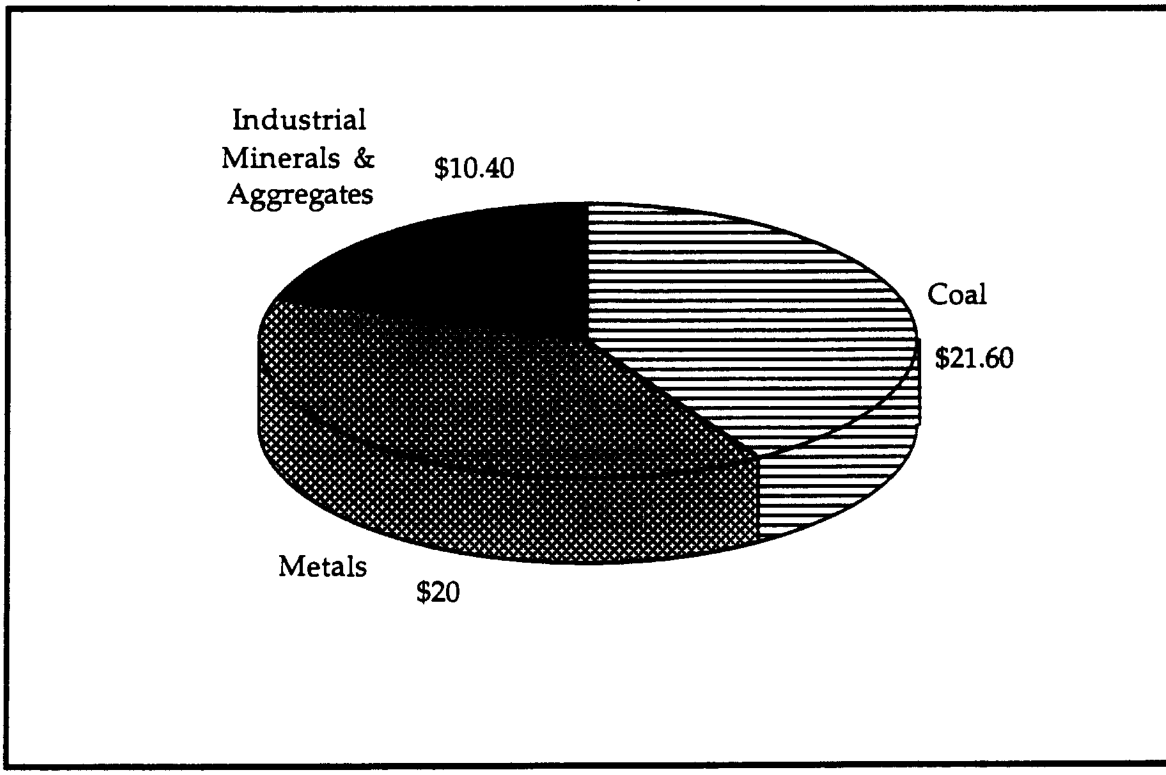
Regulations pertaining to the industry are numerous, but an emphasis is placed on point source discharges to waters, regulated by the Clean Water Act. These industries also face existing and future regulation under the Clean Water Act, Comprehensive Environmental Response, Compensation and Liability Act, and the Clean Air Act. Unlike manufacturing facilities, facilities involved in mining metals are not currently required to report chemical releases and transfers to the Toxic Release Inventory (TRI) Public Release Database under the Emergency Planning and Community Right-To-Know Act of 1986. As a result, TRI data is not available as a source of information on chemical releases in the metal mining industry; alternative sources of data have been identified for purposes of this profile.

II.B. Characterization of the Metal Mining Industry

The metal mining industry is predominantly located in the Western States, where most copper, silver, and gold mining occurs. Iron ore production is centered in the Great Lakes region, while zinc mining occurs in Tennessee and lead mining in Missouri. Large companies tend to dominate mining of such metals as copper, silver, and gold, while more diverse mine operators may be involved in mining lead, zinc, and iron metals. Metals generated from U.S. mining operations are used domestically in a wide range of products, including automobiles, electrical and industrial equipment, jewelry, and photographic materials. Metal mine production has remained somewhat stagnant over recent years, and metals exploration has declined, although future production is expected to climb as a result of continued industrial manufacturing and a growing economy.

The following exhibit depicts the proportion of metal mining production within the entire mining industry.

Exhibit 1
Total Mine Production - USA, in Billions of Dollars



Source: Randol Mining Directory 1994/95.

II.B.1. Industry Size and Distribution

Variation in facility counts occur across data sources due to many factors, including reporting and definition differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

Geographic Distribution

Though mining operations are performed throughout the U.S., the concentration of metal mining is located in the Western region of the country. Copper, gold, and silver deposits are primarily found in Utah, Montana, Nevada, California, and Arizona. Zinc is mined primarily in Alaska, Missouri, New York, and Tennessee. Lead deposits are mined primarily in Missouri, Alaska, Colorado, Idaho, and Montana, while Minnesota and Michigan are the primary sources of domestic iron ore production. The U.S. Bureau of Mines lists 482 active mines in its 1994 Mineral Commodity Summaries. (See Exhibits 2, 3, and 4). Exhibit 5 illustrates the number of facilities performing metal-specific operations by State.

Metals mined under SIC 10 are used for a wide variety of products, and are the primary raw materials used in many industrial applications. As noted in a series of Technical Resource Documents prepared by EPA's Office of Solid Waste, copper is essential to the electronics and construction industry; iron ore provides the base material for the steel, automotive, and transportation industries; gold is used primarily in jewelry and the decorative arts, but is also used in the electronics industry and in dentistry. Gold also serves as an important investment vehicle and reserve asset. All of these metals are essential to the operation of a modern economy. Exhibit 6 provides a more detailed list of the uses for these metals.

Exhibit 6
Major Uses for Selected Metal Minerals

Commodity	Number of Mines	Major Uses	Total U.S. Production (metric tons)
Copper	50	Building construction, electrical and electronic products, industrial machinery and equipment, transportation equipment, and consumer and general products	1,765,000
Gold	212+	Jewelry and arts, industrial (mainly electronic), dental	329
Iron Ore	22	Steel	55,593,000
Lead	23	Transportation (batteries, fuel tanks, solder, seals, and bearings); electrical, electronic, and communications uses	398,000
Silver	150	Photographic products, electrical and electronic, electroplated ware, sterling ware, and jewelry	1,800
Zinc	25	Galvanizing, diecast alloys, brass, and bronze	524,000

R0076104

II.B.2. Economic Trends

The estimated U.S. metal mine production value for 1993 was $12.15 billion, accounting for less than one percent of gross national product. In 1993, the total employment in the metal mining industry stood at nearly 50,000 according to the National Mining Association (See Exhibit 7 for the distribution of employment by facility size). Motor vehicle manufacturing helped support demand for materials such as steel (an iron alloy), copper, lead, and zinc. However, mining production volumes remained relatively stagnant. In some cases, ore production was down (lead - four percent; iron ore - one percent; zinc - four percent; silver - six percent). The other principal metal ore industries, copper and gold, remained even with 1992 production levels. Metals production in general is expected to increase, due to anticipated continued growth in the motor vehicle industry.

Exhibit 7

SIC 1031 - Lead and Zinc	40	8	16	64
SIC 1041 - Gold	586	122	53	761
SIC 1011 - Iron	81	14	11	106
SIC 1044 - Silver	73	9	2	84

Source: Dun and Bradstreet, 1993.

**Note: Sources define the term "facility" differently, which causes the apparent disparity between those totals cited above and those accounted for by the U.S. Bureau of Mines. Represented in these facility numbers are recreational mine operators predominantly located in Alaska, California, and Montana.*

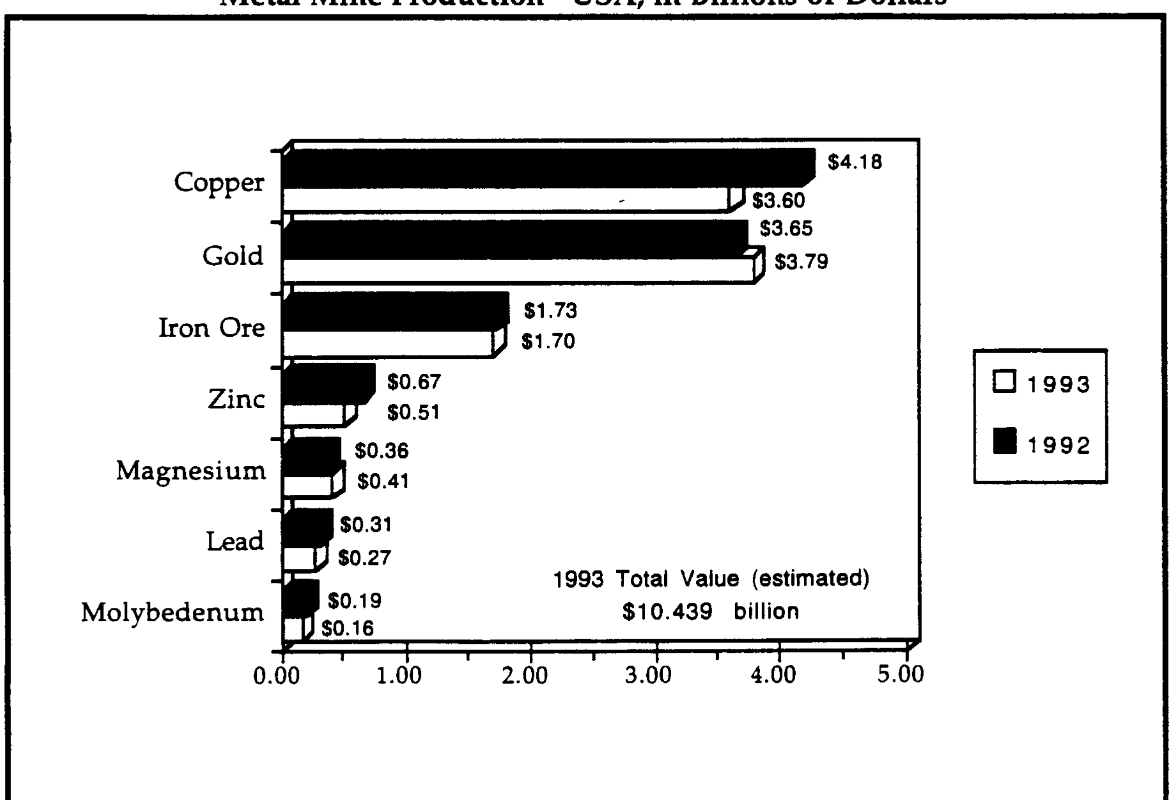
A preliminary evaluation of 1992 survey responses from 36 Canadian and 25 U.S. mineral companies operating in the U.S. suggests that the average corporate exploration budget was reduced by more than one-half from 1991 levels. Metal exploration in the U.S. during 1992 appears to have declined on an average company basis by more than 60 percent. Although specific gold and copper deposits continue to command attention, most U.S. programs have been curtailed. The BLM estimated that 75 percent of company claims were dropped during 1993 (Federal mining law grants sole mineral rights to a prospector if there is a discovery of economic value; prior to such a discovery, a "claim" is honored if the prospector maintains an actual presence on site and completes a progressive amount of developmental work per year).

The number of companies that have shifted portions of their exploration budgets to Latin America is growing. More than 250 companies, about 10 percent of the North American mining exploration industry, are now active in Latin America, especially Mexico and Chile. Among the forces driving U.S. companies abroad is the recent privatization of world-class mineral deposits, the presence of rich overseas ore deposits, depletion of prime domestic ore sources, labor costs, and the lack of significant regulatory pressure in the developing world.

The U.S. economy's slow but steady growth rate of the last several years is expected to spur demand in major domestic materials-consuming industries, such as the auto industry. In addition, developing economies in South America and Asia have had higher consumption of mineral materials as political regimes have liberalized their economies to meet demands for higher standards of living.

The following exhibit illustrates production values in 1993 for various metal mining industry sectors.

Exhibit 8
Metal Mine Production - USA, in Billions of Dollars



Source: Randol Mining Directory 1994/95.

R0076106

Following is a brief summary of current trends in domestic mining industries. Much of the information presented is based on a report prepared by EPA's Office of Research and Development.

Iron

In 1993, domestic production of iron ore remained at approximately the same level as that of 1992. The value of usable ore shipped from mines in Minnesota, Michigan, and six other States in 1993 was estimated at $1.7 billion. Iron ore was produced domestically by 16 companies operating 22 mines, 16 concentration plants, and 10 pelletizing plants. The mines included 19 open pits and one underground operation. Nine of these mines, operated by six companies, accounted for the vast majority of the output.

The U.S. steel industry was the primary consumer of iron ore, accounting for 98 percent of domestic iron ore consumption in 1992. Domestic demand for iron ore has fallen behind that for iron and steel due to changes in industrial processes, including the increased use of scrap (especially by mini-mills) and the use of imported semi-finished steel. Twelve percent of domestic iron consumption in 1993 was imported. While world consumption of iron ore increased slightly, prices declined for the third consecutive year.

Copper

World copper production remained at approximately the same level in 1993 as in 1992, while world consumption of refined copper declined. However, refined copper demand in the U.S. and Canada ran counter to the world trend. Domestic demand for copper rose by approximately eight percent in 1993; the U.S. imported six percent of its copper needs in 1993. Consumption was expected to increase in 1994 to more than 2.4 million tons, up from the previous year's 2.3 million tons. Domestic brass mills (a mixture of copper and zinc) ran at capacity.

Copper was recovered at 50 mines in 1993, and the top 15 mines accounted for more than 95 percent of production. The primary end uses for copper are building construction (42 percent), electrical and electronic products (24 percent), industrial machinery and equipment (13 percent), transportation equipment (11 percent), and consumer and general products (10 percent).

According to Standard & Poor's, the copper mining industry is dominated by three producers (ASARCO Incorporated, Cyprus Amax Mining Company, and Phelps Dodge), which are financially viable operations. However, not all copper mining firms are as healthy financially. From 1989 to 1992, the industry was characterized by decreasing operating revenues and net income, while short and long-term liabilities increased for some companies. With the recent economic recovery, however, the overall outlook for the copper industry is financially secure.

Lead

The U.S. imported 15 percent of its lead needs in 1993. Transportation is the major end use for lead, with approximately 83 percent being used to produce batteries, fuel tanks, solder, seals, and bearings. Electrical, electronic, and communications uses, ammunition, TV glass, construction, and protective coatings accounted for more than nine percent of lead consumption.

According to the U.S. Bureau of Mines, U.S. lead production has remained relatively constant through 1994, while prices for lead continued an upward trend that began in 1993. Consumption of lead in the U.S. increased in 1994, due to greater demand for original equipment batteries in the automotive industry. This trend is expected to continue.

Zinc

In 1993, the U.S. imported 26 percent of its zinc needs. Domestically, 25 zinc mines produced 99 percent of the output; Alaska's Red Dog Mine accounted for nearly one-half of the total. Zinc's main use has traditionally been to provide corrosion protection through galvanization for iron and steel. In 1991, the largest consumers of zinc were the construction (43 percent), transportation (20 percent), machinery (12 percent), and electrical (12 percent) sectors.

Domestic mine production increased substantially in 1994 in response to domestic demand, according to the U.S. Bureau of Mines. The largest growth occurred in the galvanizing and brass and bronze industries, due to increased automobile production. Exports of zinc concentrates were up slightly in 1994.

Gold

Domestic gold mines continue to produce at record levels, maintaining the U.S. position as the world's second largest gold-producing nation (12 percent of world resources), after the Republic of South Africa. The U.S was a net exporter of gold in 1993. Gold was produced at 200 lode mines and numerous placer mines (see discussion below for definition of lode and placer mines). Twenty-five mines yielded 75 percent of the gold produced. Estimated end-uses for 1993 were as follows: jewelry and arts (70 percent); industrial (mainly electronic; 23 percent); and dental (seven percent).

The gold mining industry is dominated by a few firms that are gaining an increasing portion of the market share and that remain financially strong. Smaller firms have seen decreasing operating revenues and net incomes, and may have greater difficulty in the future meeting short-term debt. The trend in gold exploration activities continues to be toward Latin American nations, where favorable geology and liberalized mining regulations hold the promise for greater long-term success and reduced risk to investment capital.

Silver

Continuing the trend begun in 1991, several large domestic silver producers halted mining operations in 1993 due to the continuing low price of silver. As a result, U.S. mine production of silver declined for the fourth consecutive year, and three major silver producers had negative net income. Silver prices have recently begun to rise, however; with the prospect of continued higher prices, some companies are considering resuming operations at currently inactive mines.

The U.S. is a net importer of silver. One hundred and fifty mines in 14 States mined silver in 1993. However, Nevada, Idaho, Arizona, and Montana accounted for 74 percent of all domestic production. Estimated end-uses for 1993 were as follows: photographic products (50 percent); and electrical and electronic products (20 percent).

III. Industrial Process Description

This section describes the major industrial processes within the metal mining industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of available reference documents.

This section describes commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Metal Mining Industry

Much of the following information has been presented previously in reports and issue papers drafted in support of various EPA offices, including the Office of Solid Waste, the Office of Pollution Prevention and Toxics, and the Office of Enforcement and Compliance Assurance. For a complete listing of reference documents, please see Section IX.

Metals are mined from two types of deposits. The first, lode deposits, are concentrated deposits that are fairly well-defined from surrounding rock. Iron, copper, lead, gold, silver, and zinc are mined mainly from lode deposits. The second type of deposits, placer deposits, occur with sand, gravel, and rock; they are usually deposited by flowing water or ice, and contain metals that were once part of a lode deposit. Only a small percentage of domestic gold and silver is derived from placer deposits.

There are three general approaches to mining metals:

Surface or **open-pit mining** requires extensive blasting, as well as rock, soil, and vegetation removal, to reach lode deposits. Benches are cut into the walls of the mine to provide access to progressively deeper ore, as upper-level ore is depleted. Ore is removed from the mine and transported to milling and beneficiating plants for concentrating the ore, and smelting, and/or refining. Open pit mining is the primary domestic source of iron, copper, gold, and silver.

Underground mining entails sinking a shaft to reach the main body of ore. "Drifts," or passages, are then cut from the shaft at various depths to access the ore, which is removed to the surface, crushed, concentrated, and refined. While underground mines do not create the volume of overburden waste associated with surface mining, some waste rock must still be brought to the surface for disposal. Waste rock may either be returned to the mine as fill or put in a disposal area. In the U.S., only lead, antimony, and zinc are solely underground operations.

Solution or fluid mining entails drilling into intact rock and using chemical solutions to dissolve lode deposits. During solution mining, the leaching solution (usually a dilute acid) penetrates the ore, dissolving soluble metals. This pregnant leach solution is then retrieved for recovery at a solvent extraction and electrowinning (SX/EW) plant. This method of mining is used in some parts of Arizona, Nevada, and New Mexico to recover copper.

Historically, the primary mining method has been underground mining. However, with the advent in recent decades of large earth moving equipment, less expensive energy sources, and improved extraction and beneficiation technologies, surface mining now prevails in most industry sectors. Open-pit mining is generally more economical and safer than underground mining, especially when the ore body is large and the overburden (surface vegetation, soil, and rock) relatively shallow. In fact, the lower cost of surface mining has allowed much lower-grade ores to be exploited economically in some industry sectors.

Metal mining processes include extraction and beneficiation steps during production. Extraction removes the ore from the ground, while beneficiation concentrates the valuable metal in the ore by removing unwanted constituents. Often, more than one metal is targeted in beneficiation processes. For example, silver is often beneficiated and recovered with copper. The beneficiation method selected varies with mining operations and depends on ore characteristics and economic considerations.

The following sections provide more detail on extraction methods and beneficiation processes, as they relate to the mining of each metal.

R0076111

Extraction Processes

As described in a report drafted for EPA's Office of Pollution Prevention and Toxics, extraction involves removing any overburden, then drilling, blasting, and mucking the broken ore and waste rock.

Mobile rigs drill holes in rock, which can then be filled with explosives for blasting waste rock and ore. Potential pollutants involved in this step in the mining process include the fuel, lubricants, and hydraulic oils consumed by the rigs; fuels and oils typically contain such constituents as benzene, ethylbenzene, and toluene.

Explosives (usually a mixture of ammonium nitrate and fuel oil) are used to break up the rock. Other explosives, including trinitrotoluene (TNT) and nitroglycerine, may also be used.

Mucking is the process of removing broken ore from the mine, using a variety of loading and hauling equipment to transport ore to a mill for beneficiation. Depending on ore volume, trucks, rail cars, conveyers, and elevators may all be required to haul ore. Equipment involved in this step of the mining process uses hydraulic fluid (containing glycol ethers); batteries (containing sulfuric acid, lead, antimony, and arsenic); and lubricants and fuel (containing petroleum hydrocarbons).

Beneficiation Methods

Ore beneficiation is the processing of ores to regulate the size of the product, to remove unwanted constituents, or to improve the quality, purity, or grade of a desired product. Under regulations drafted pursuant to the Resource Conservation and Recovery Act (40 CFR §261.4), beneficiation is restricted to the following activities: crushing; grinding; washing; dissolution; crystallization; filtration; sorting; sizing; drying; sintering; pelletizing, briquetting; calcining to remove water and/or carbon dioxide; roasting, autoclaving, and/or chlorination in preparation for leaching; gravity concentration; magnetic separation; electrostatic separation; flotation; ion exchange; solvent extraction; electrowinning; precipitation; amalgamation; and heap, dump, vat, tank, and *in situ* leaching.

The most common beneficiation processes include gravity concentration (used only with placer gold deposits); milling and floating (used for base metal ores); leaching (used for tank and heap leaching); dump leaching (used for low-grade copper); and magnetic separation. Typical beneficiation steps include one or more of the following: milling; washing; filtration; sorting; sizing; magnetic separation; pressure oxidation; flotation; leaching; gravity concentration; and agglomeration (pelletizing, sintering, briquetting, or nodulizing).

Milling extracted ore produces uniform-sized particles, using crushing and grinding processes. As many as three crushing steps may be required to reduce the ore to the desired particle size. Milled ore in the form of a slurry is then pumped to the next beneficiation stage.

Magnetic separation is used to separate iron ores from less magnetic material, and can be classified as either high- or low-intensity (requiring as little as 1,000 gauss or as much as 20,000). Particle size and the solids content of the ore slurry determine which type of magnetic separator system is used.

Flotation uses a chemical reagent to make one or a group of minerals adhere to air bubbles for collection. Chemical reagents include collectors, frothers, antifoams, activators, and depressants; the type of reagent used depends on the characteristics of a given ore. These flotation agents may contain sulfur dioxide, sulfuric acid, cyanide compounds, cresols, petroleum hydrocarbons, hydrochloric acids, copper compounds, and zinc fume or dust.

Gravity concentration separates minerals based on differences in their gravity. The size of the particles being separated is important, thus sizes are kept uniform with classifiers (such as screens and hydrocyclones).

Thickening/filtering removes most of the liquid from both slurried concentrates and mill tailings. Thickened tailings are discharged to a tailings impoundment; the liquid is usually recycled to a holding pond for reuse at the mill. Chemical flocculants, such as aluminum sulfate, lime, iron, calcium salts, and starches, may be added to increase the efficiency of the thickening process.

Leaching is the process of extracting a soluble metallic compound from an ore by selectively dissolving it in a solvent such as water, sulfuric or hydrochloric acid, or cyanide solution. The desired metal is then removed from the "pregnant" leach solution by chemical precipitation or another chemical or electrochemical process. Leaching methods include "dump," heap," and "tank" operations. Heap leaching is widely used in the gold industry, and dump leaching in the copper industry.

The following exhibit summarizes the various processes used within each mining sector, and the primary wastes associated with those processes.

Exhibit 9
Sector-Specific Processes and Wastes/Materials

Sector	Mining Type	Beneficiation/Processing	Primary Wastes/Materials
Gold-Silver	• Surface • Underground • *In Situ* (experimental)	• Cyanidation • Elution • Electrowinning/zinc precipitation • Milling • Base metal flotation • Smelting • Amalgamation (historic)	• Mine water * • Overburden/waste rock • Spent process solutions • Tailings • Spent Ore
Gold Placer	• Surface	• Gravity separation •Roughing, cleaning, fine separation • Some magnetic separation	• Mine water* • Overburden/waste rock • Tailings
Lead-Zinc	• Underground (exclusively)	• Milling • Flotation • Sintering • Smelting	• Mine water* • Overburden/waste rock • Tailings • Slag
Copper	• Surface • Underground • *In Situ*	• Milling • Flotation • Smelting • Acid leaching • SX/EW recovery • Iron precipitation/smelting	• Mine water* • Overburden/waste rock • Tailings • Slag • Spent ore • Spent leach solutions
Iron	• Surface (almost exclusively) • Underground	• Milling • Magnetic separation • Gravity separation • Flotation • Agglomeration • Blast furnace	• Mine water* • Overburden/waste rock • Tailings • Slag

* *Note: Mine water is a waste if it is discharged to the environment via a point source*

Below is a more detailed discussion of the various beneficiation methods and processes used for each of the sectors presented in the table above.

Iron Ore

Typical beneficiation steps applied to iron ore include: milling, washing, sorting, sizing, magnetic separation, flotation, and agglomeration. Milling followed by magnetic separation is the most common beneficiation sequence used, according to the American Iron Ore Association. Flotation is primarily used to upgrade the concentrates generated from magnetic separation, using frothers, collectors, and antifoams.

Steel mills generally agglomerate or pelletize the iron ore concentrates to improve blast furnace operations that utilize iron ore. Pelletizing operations produce a moist pellet (often using clay as a binder), which is then hardened through heat treatment. Agglomeration generates by-products in the form of particulates and gases, including compounds such as carbon dioxide, sulfur compounds, chlorides, and fluorides. These emissions are usually treated using cyclones, electrostatic precipitators, and scrubbing equipment. These treatment technologies generate iron-containing effluent, which is recycled into the operation. Agglomeration produces large volumes of sulfur dioxide and nitrogen dioxide.

Copper

Copper is commonly extracted from surface, underground, and, increasingly, from *in situ* operations. According to the U.S. Bureau of Mines, surface mining accounted for 83 percent of copper production in 1992, with underground mining accounting for the remainder. *In situ* mining is the practice of percolating dilute sulfuric acid through ore to extract copper, by pumping copper-laden acid solutions to the surface for solvent extraction/electrowinning (SX/EW). This leaching operation uses both ammonium nitrate and sulfuric acid.

Beneficiation of copper consists of crushing and grinding; washing; filtration; sorting and sizing; gravity concentration; flotation; roasting; autoclaving; chlorination; dump and *in situ* leaching; ion exchange; solvent extraction; electrowinning; and precipitation. The methods selected vary according to ore characteristics and economic factors; approximately half of copper beneficiation occurs through dump leaching, while a combination of solvent extraction/froth flotation/electrowinning is generally used for the other half. Often, more than one metal is the target of beneficiation activities (silver, for example, is often recovered with copper).

According to EPA's Office of Solid Waste *Technical Resource Document*, copper is increasingly recovered by solution methods, including dump and *in situ* leaching. Because most copper ores are insoluble in water, chemical reactions are required to convert copper into a water-soluble form; copper is recovered from a leaching solution through precipitation or by SX/EW. Solution beneficiation methods account for approximately 30 percent of domestic copper production; two-thirds of all domestic copper mines use some form of solution operations. Typical leaching agents used in solution beneficiation are hydrochloric and sulfuric acids. Microbial (or bacterial) leaching is used for low-grade sulfide ores, however this type of leaching is much slower than standard acid leaching and its use is still being piloted.

Dump leaching is a method of treating copper ore that has been extracted from a deposit, and refers to the leaching of oxide and low-grade sulfide ore on (typically) unlined surfaces. These operations involve the application of leaching solution, collection of pregnant leach solution (PLS), and the extraction of copper by SX/EW or cementation. Natural precipitation or mine water is generally used to leach low grade sulfide ore, while dilute sulfuric acid is commonly used to leach oxide ores. Copper dump leaches are massive, ranging in height from 20 to hundreds of feet, covering hundreds of acres, and containing millions of tons of ore. Dump leaching operations may take place over several years.

The solvent extraction process is a two-stage method; in the first stage, low-grade, impure leach solutions containing copper, iron, and other base-metal ions are fed to the extraction stage mixer-settler. In the mixer, the aqueous solution contacts an active organic extractant in an organic diluent (usually kerosene), forming a copper-organic complex; impurities are left behind in the aqueous phase. The barren aqueous solution, called raffinate, is typically recirculated back to the leaching units while the loaded organic solution is transferred from the extraction section to the stripping section. In the second stage, the loaded organic solution is stripped with concentrated sulfuric acid solution to produce a clean, high-grade solution of copper for electrowinning. Electrowinning is the method used to recover copper from the electrolyte solution produced by solvent extraction.

Exhibits 10 and 11 illustrate a typical dump leach operation and a representative solution-based process for recovering copper from ore. Variations exist in exact methods and processes used at each operation.

Lead and Zinc

Beneficiation of lead and zinc ores includes crushing and grinding; filtration; sizing; flotation; and sintering of concentrates. Flotation is the most common method for concentrating lead-zinc minerals. Ore may be treated with conditioners during or after milling to prepare the ore pulp for flotation. Common conditioners may include lime, soda ash, caustic soda, or sulfuric acid. The conditioned ore is then slurried in fresh or salt water with chemical reagents to beneficiate the ore. Several separate flotation steps may be needed to concentrate individual metal values from the ore. Reagents used in the flotation processes typically include such chemicals as sulfur dioxide, zinc sulfate, coal tar, copper sulfate, and sodium or calcium cyanide.

Lead and zinc mineral concentrates that will be smelted and refined may require sintering, typically performed at the smelter site. Sintering partially fuses the ore concentrates into an agglomerated material for processing, and involves several steps. First, ore concentrates are blended with moisture and then fired (sintered) and cooled. During cooling, the sinter is crushed, graded, and further crushed to produce a smaller sinter product. By-products of the roasting and sintering processes include sulfur dioxide, nitrogen dioxide, and carbon monoxide. Residues generated also include dust and primary lead process water.

Gold and Silver

Three principal techniques are used to process gold and silver ore: cyanide leaching, flotation of base metal ores followed by smelting, and gravity concentration. According to the U.S. Bureau of Mines, cyanide leaching generated 88 percent of all domestic lode gold in 1991, and 38 percent of silver. Processing of base metal ores produced 11 percent of the gold; over half of the silver produced in 1991 was from smelting concentrates produced by flotation of silver and base metal ores. Gravity concentration is used primarily by gold and silver placer operations.

Cyanide leaching is a relatively inexpensive method of treating gold ores and is the chief method in use. In this technique, sodium or potassium cyanide solution is either applied directly to ore on open heaps or is mixed with a fine ore slurry in tanks; heap leaching is generally used to recover gold from low-grade ore, while tank leaching is used for higher grade ore.

Compared to tank leaching, **heap leaching** has several advantages, including simplicity of design, lower capital and operating costs, and shorter start-up times. Depending on the local topography, a heap or a valley fill method is typically employed. The size of heaps and valley fills can range from a few acres to several hundred. Heap leaching may involve any or all of the following steps:

- Preparation of a pad with an impervious liner. Some liners may simply be compacted soils and clays, while others may be of more sophisticated design, incorporating clay liners, french drains, and multiple synthetic liners.
- Placement of historic tailings, crushed ore, or other relatively uniform and pervious material on the uppermost liner to

protect it from damage by heavy equipment or other circumstances.

- Crushing and/or agglomerating the ore.
- Placing the ore on the pad(s).
- Applying cyanide solution using drip, spray, or pond irrigation systems, with application rates generally between 0.5 and 1.0 pounds of sodium cyanide per ton of solution. This is known as the barren solution because it contains little or no gold.
- Collecting the solution via piping laid on the liner, ditches on the perimeter of the heap, or pipes/wells laid through the heap into sumps at the liner surface. The recovered pregnant solution, now laden with gold (and silver), may be stored in ponds or routed directly to tanks for gold recovery, or it may be reapplied to the heap for additional leaching.
- Recovering the gold from the pregnant solution (typically containing between 1 and 3 ppm of gold).

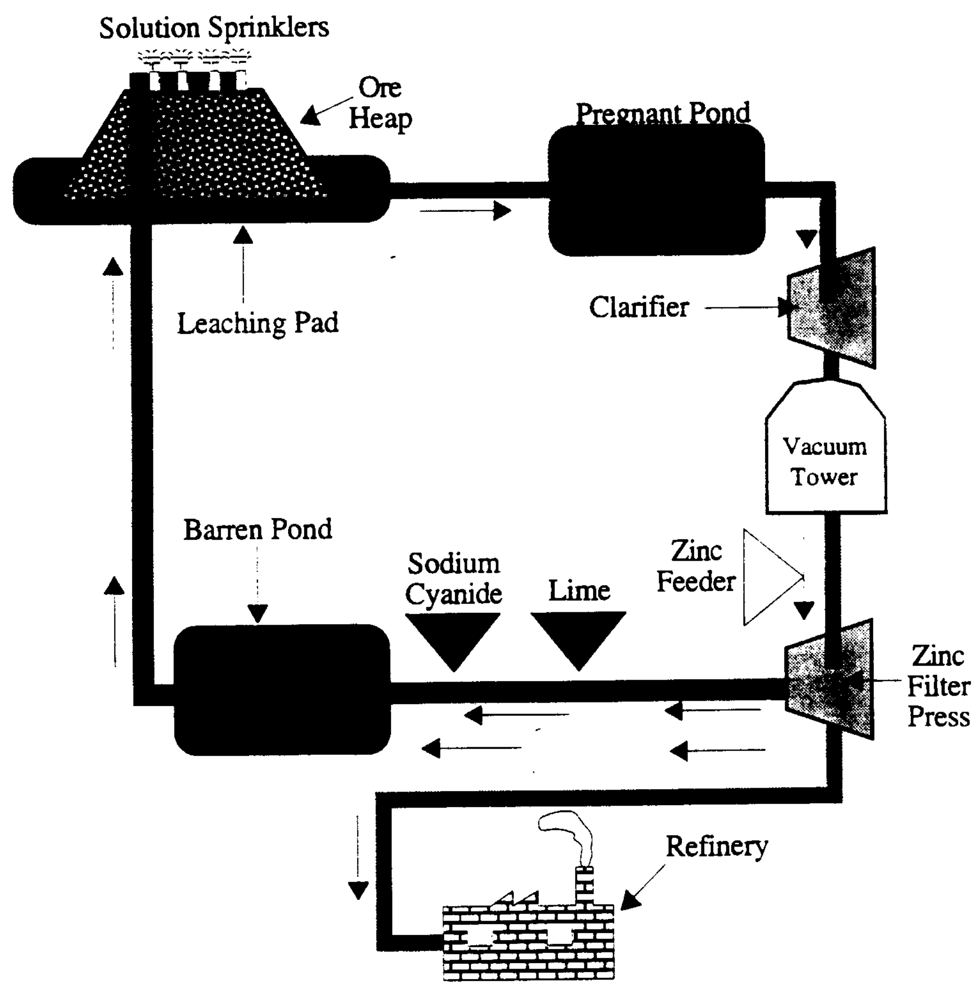
The leaching cycle can range from weeks to several months, depending on permeability, size of the pile, and ore characteristics. The average leach cycle is approximately three months.

Recovery of gold from the pregnant solution is accomplished using carbon adsorption or, less commonly, by direct precipitation with zinc dust. These techniques may be used separately or in a series with carbon adsorption followed by zinc precipitation. Both methods separate the gold-cyanide complex from other remaining wastes. Carbon adsorption involves pumping the pregnant solution into a series of activated carbon columns, which collect gold from the cyanide leachate. The precious metals are then stripped from the carbon by elution with the use of a boiling caustic cyanide stripping solution, or similar solution. Gold in the pregnant eluate solution may be electrowon or zinc precipitated.

Although carbon adsorption/electrowinning is the most common method of gold recovery domestically, zinc precipitation is the most widely used method for gold ore containing large amounts of silver. In zinc precipitation, pregnant solution (or the pregnant eluate stripped from carbon) is filtered and combined with metallic zinc dust resulting in a chemical reaction which generates a gold precipitate. The solution is then forced through a filter that removes the gold.

The following exhibit illustrates a typical gold heap leach operation using zinc precipitation; variations exist in exact processes and methods used at each operation.

Exhibit 12
Gold Heap Leaching Operation



Source: U.S. EPA, Office of Enforcement and Compliance Assurance.

To prepare for **tank leaching**, ore is ground to expose the metal values to the cyanide. Finely ground ore is slurried with the leaching solution in tanks. The resulting gold-cyanide complex is then adsorbed on activated carbon. The pregnant carbon then undergoes elution, followed either by electrowinning or zinc precipitation, as described previously. The recovery efficiencies attained by tank leaching are significantly higher than for heap leaching. The tank leaching process may occur over a series of days, rather than the weeks or months required in heap leaching.

After heap leaching and rinsing, the spent ore becomes waste and is left as is or is deposited in disposal areas similar to those used for waste rock. Spent ore may contain wastewater from rinsing the ore, residual cyanide, metal-cyanide complexes, and small quantities of heavy metals. Tailings produced from tank leaching may contain arsenic, barium, chloride, nitrate, sodium, and sulfate. Cyanide residues may require destruction using alkaline chlorination, ozone, or hydrogen peroxide addition.

Gravity concentration, a beneficiation method used mostly in placer mines, involves passing a slurry of ore and water over a series of riffles to catch heavier gold particles. Amalgamation, or wetting metallic gold with mercury to form an amalgam, is another recovery technique used in placer operations. Its high cost, inefficiency for large-scale mining operations, and environmental and safety considerations have greatly restricted amalgamation's previous widespread use.

Chemical Usage

The following exhibit lists the chemicals used in greatest volume in the metal mining processes for several of the main commodities. While volume does not necessarily correlate with potency, this data indicates which chemicals are present in greatest quantity, and to which chemicals mine workers may be most frequently exposed. Although it does not appear in the chart below, cyanide is also consumed in massive quantities by the gold industry. In 1990 alone, Dow Chemical supplied over 160 million pounds of reagent-grade cyanide for use in gold mining, according to the *Chicago Tribune* (February 2, 1992, p.27).

Exhibit 13
Chemicals Used in High Volume

Type of Mine	Chemical Name	Volume/Mass at Mine Site
Iron Ore	Acetylene	5,577,726 gallons
	Argon	15,892,577 gallons
	Diesel Fuel	3,417,487 gallons
	Nitrogen	9,398,026 gallons
Lead/Zinc	Acetylene	1,021,795 gallons
	Calcium Oxide	932,129 lbs.
	Diesel Fuel No. 2	1,640,271 gallons
	Propane	171,733 lbs.; 1,015,962 gallons
	Sulfur Dioxide*	1,843,080 lbs.

Exhibit 13 (cont'd)
Chemicals Used in High Volume

Type of Mine	Chemical Name	Volume/Mass at Mine Site
Copper	Acetylene	10,909,868 gallons
	Calcium Oxide	512,620,243 lbs.

III.B. Mining Process Pollution Outputs

The extraction and beneficiation of metals produce significant amounts of waste and byproducts. Total waste produced can range from 10 percent of the total material mined to well over 99.99 percent. The volume of total waste can be enormous: in 1992, gold mining alone produced over 540 million metric tons of waste. The following exhibit provides further detail on the volume of product and waste material generated from metal mineral mining.

Exhibit 14
Volume of Waste Generated for Selected Metals

Commodity	Number of Mines	Total Commodity Produced (1,000 mt)	Tailings Generated (1,000 mt)	Other Waste Handled (1,000 mt)
Copper	50	1,765	337,733	393,332
Gold	+212	0.329	247,533	293,128
Iron Ore	22	55,593	80,204	106,233
Lead	23	398	6,361	--
Silver	150	1.8	2,822	--
Zinc	25	524	4,227	--

Source: U.S. Bureau of Mines, Mineral Commodity Summaries 1994 and Minerals Yearbook, Volume I: Metals and Minerals, 1992.

The industry (including non-metallic minerals) is estimated to have generated 50 billion metric tons of waste through 1985, and currently generates approximately one billion metric tons annually. It is important to note, however, that virtually none of this annual production related to extraction and beneficiation is classified as RCRA hazardous waste. Exhibit 15 summarizes some of the potential effects of industrial mining on the environment.

Exhibit 15
Steps in the Mining Process and Their Potential Environmental Impacts

Mining Process	Process Wastes	Air Emissions	Other Waste	Land, Habitat, Wildlife
Site Preparation	Erosion due to removal of vegetation	Exhaust from construction vehicles; fugitive dust	Run-off sediment	Deforestation and habitat loss from road and site construction
Blasting/ Excavation	Acid Rock Drainage (ARD); erosion of sediments; petroleum wastes from trucks	Dust blown to surrounding area; exhaust from heavy machinery	Non-reused overburden; waste rock	Loss of habitat; increase in erosion; loss of plant population from dust and water pollution; reduction in localized groundwater recharge resulting from increased runoff; loss of fish population from water pollution; nearby structural damages from vibration and settling; competition for land use
Crushing/ Concentration	Acid Rock Drainage (ARD) from tailings	Dust created during transportation	Additional waste rock; tailings

Wastes

Several wastes are created when metal ores are extracted from the earth. The first is overburden and waste rock, which is soil and rock removed in order to access an ore or mineral body. Overburden typically includes surface soils and vegetation, while waste rock also includes rock removed while sinking shafts, accessing or exploiting the ore body, and rock embedded within the ore or mineral body.

Most overburden and waste rock are disposed of in piles near the mine site, although approximately nine percent is backfilled in previously excavated areas, and nearly four percent is used off-site for construction. Waste rock dumps are generally constructed on unlined terrain, with underlying soils stripped, graded, or compacted depending on engineering considerations. Drainage systems may be incorporated into dump foundations to prevent instability due to foundation failures from groundwater saturation, and may be constructed of gravel-filled trenches or gravel blankets.

Tailings are a second type of common mining waste. Most beneficiation processes generate tailings, which contain a mixture of impurities, trace metals, and residue of chemicals used in the beneficiation process. Tailings usually leave the mill as a slurry consisting of 40 to 70 percent liquid mill effluent and 30 to 60 percent solids; liquids are commonly re-used in milling processes. Most mine tailings are disposed in on-site impoundments. Design of the impoundment depends on natural topography, site conditions, and economic factors; generally it is economically advantageous to use natural depressions to contain tailings. Impoundments are designed to control the movement of fluids both vertically and horizontally.

In some cases, tailings are dewatered or dried and disposed in piles; this minimizes seepage volumes and the amount of land required for an impoundment. However, dry disposal methods can be prohibitively expensive due to additional equipment and energy costs.

Slurried tailings are sometimes disposed of in underground mines as backfill to provide ground or wall support. This decreases the above-ground surface disturbance and can stabilize mined-out areas. Subaqueous tailings disposal, practiced primarily in Canada, is the placement of tailings below a permanent water surface such as a lake or ocean; it is used primarily to minimize the acid-generating potential of tailings by preventing sulfide ore from oxidizing. This disposal method is not currently practiced commercially in the United Stated.

Water

Water removed from a mine to gain or facilitate access to an ore body is known as mine water. Mine water can originate from precipitation, from flows into pits or underground workings, and/or from groundwater aquifers that are intercepted by the mine. Mine water is only a waste if it is discharged to the environment via a point source. Mine water can be a significant problem at many mines, and enormous quantities may have to be pumped continuously during operations. When a mine closes, removal of mine water generally ends. However, underground mines can then fill and mine water may be released through adits or fractures that reach the surface. Surface mines that extend below the water table fill to that level when pumping ceases, either forming a lake in the pit or inundating and saturating fill material. Pumped mine water is typically managed in on-site impoundments. Collected water may be allowed to infiltrate/evaporate, used as process water or for other on-site applications such as dust control, and/or discharged to surface water, subject to permit requirements.

Acid drainage is a potentially severe pollution hazard associated with mining, and can be difficult to predict. It occurs when pyrite and other sulfide minerals, upon exposure to oxygen and water, oxidize to create ferrous ions and sulfuric acid. Catalyzed by bacteria, the ferrous ions react further with oxygen, producing hydrated iron oxide, known as "yellowboy." This combination of yellowboy and sulfuric acid may contaminate surrounding soil, groundwater, and surface water, producing water with a low pH. When this reaction occurs within a mine it is called Acid Mine Drainage (AMD). When it occurs in waste rock and tailings piles it is often known as Acid Rock Drainage (ARD), although AMD is the most widely used term for both.

AMD is a significant problem at many abandoned mine sites: a 1993 survey by the U.S. Forest Service (*Acid Mine Drainage from Mines on National Forests, A Management Challenge*) estimates that 5,000 to 10,000 miles of domestic streams and rivers are impacted by acid drainage. Acid drainage can lower the pH of surrounding water, making it corrosive and unable to support many forms of aquatic life; vegetation growing along streams can also be affected. Mine water can also carry toxic, metal-bearing sediment into streams, which can kill waterborne plant and animal species. In extreme cases, acid drainage can kill all living organisms in nearby streams. Humans may also increase disease risks by consuming drinking water and fish tissue with a heavy metal content.

According to the 1994 *Technical Document/ Background for NEPA Reviewers: Non-Coal Mining Operations*, prepared by EPA's Office of Solid Waste (OSW), acid drainage can pose significant threats to surface and groundwater quality and resources during active mining and for decades after operations cease. Although mines that began operating after 1978 are required to treat their effluent water, the need for water treatment may persist for decades after mining operations have ceased. Abandoned mines and refuse piles can produce acid damage for over 50 years. According to EPA's hardrock mining strategy framework, for example, "negative changes in geochemistry over time can occur when the materials' environment changes (e.g., going from a reducing environment to an oxidizing one) or buffering capacity is exceeded (such as when the total neutralizing capacity of a rock mass is exceeded by acid generation). When these conditions are present, a facility can close in full environmental compliance, only to have a severe problem show up decades later." Because remediating acid drainage is so damaging and costly, predictive tools, design performance, financial assurance, and monitoring have become increasingly important.

Acid leaching operations are an additional source of water pollution. The leaching process itself resembles acid drainage, but it is conducted using high concentrations of acids to extract metals from ore. Since acid leaching produces large volumes of metal-bearing acid solutions, it is vital that leach dumps and associated extraction areas be designed to prevent releases. Most environmental damage associated with acid leaching is caused by leakage, spillage, or seepage of the leaching solution at various stages of the process. Potential problems include: seepage of acid solutions through soils and liners beneath leach piles; leakage from solution-holding ponds and transfer channels; spills from ruptured pipes and recovery equipment; pond overflow caused by excessive runoff; and ruptures of dams or liners in solution-holding ponds. Cyanide leaching solution processes carry a similar potential for damage as a result of leakages, spills, overflows, and ruptures.

Solution ponds associated with leaching operations are potential sources of acid and metal releases to ground and surface water. Ponds associated with precious metal leaching operations and newer copper facilities are generally lined with synthetic materials (although liners are often susceptible to failure). At older copper sites, solution ponds may be unlined or lined only with natural materials. Leakage, run-off from precipitation, and the like, may cause contamination of ground and surface waters.

Air

Substantial air pollution can occur at mining sites during excavation and transportation. Fugitive dust may be a significant problem at some sites, depending on site conditions and management practices, and is created at many stages of the mining process. The inherent toxicity of the dust depends on the proximity of environmental receptors and type of ore being mined; high levels of arsenic, lead, and radionuclides in windblown dust tend to pose the greatest risk, according to EPA's 1995 hardrock mining framework strategy. Sources of dust may be from road traffic in the mine pit and surrounding areas, rock crushers located in pits and in mills, and tailings ponds.

Dust control methods aim to reduce amounts and concentrations of dust produced and to minimize human exposure to remaining dust. The most important element of dust control at underground mines is a properly designed ventilation system. Water sprays are also used during ore transportation and crushing, and can greatly reduce dust levels at the site. Dust suppressants, such as lignin sulfonates and magnesium chloride, can stabilize solid piles or tailing areas that might otherwise become airborne in windy conditions. After mine closure, revegetation or other stabilizing methods may be used for dust control.

Exhaust fumes from diesel engines and blasting agents may also be serious hazards at underground mines. These exhausts produce carbon monoxide and nitrogen oxide gas, which collect in underground areas. Ventilation and monitoring are important steps taken to reduce the potential harm these fumes may cause workers.

The following exhibit, derived from EPA's OSW 1994 *Technical Document/Background for NEPA Reviewers: Non-Coal Mining Operations*, describes the various measures mining operators may take to mitigate potential environmental impacts of waste products generated through different phases of the extraction and beneficiation processes.

Exhibit 16
Potential Mine Waste Mitigation Measures

Mining Waste Product	Mitigation Measures
Extraction - Mine Workings	• Evaporation and re-use of mine water in processing operations • Run-on and runoff control measures, such as berms and ditches • Neutralization/precipitation or other treatment practices prior to discharges • Clean-up of blasting residuals • Provide for post-closure mine water management • Monitor discharges and surface water quality • Site mine water containment units to minimize potential for surface water recharge
Extraction - Waste Rock/ Overburden	• Backfill into dry mine workings with waste rock • Maximize use of overburden in reclamation • Collect and monitor seepage, drainage, and runoff • Segregate and cover reactive waste rock with non-reactive materials where ARD is observed • Use non-reactive waste rock for on-site construction • Provide for adequate dump drainage to minimize potential for slope failure • Conduct baseline surface water monitoring; continue monitoring throughout operation and post-closure • Use run-on controls to minimize potential for infiltration
Beneficiation - Tailings Impoundments	• Design unit to contain maximum reasonable storm event • Consider natural and/or synthetic liners for units located in drainages; consider liners for any seepage/runoff collection sumps/ditches • Maximize the reclaim/reuse of tailings water • Limit mill reagents to least extent necessary • Provide adequate drainage of berms • Include secondary containment of tailings pipelines • Continue ARD testing throughout operations and closure • Collect and treat runoff/seepage from outer slopes of impoundment

R0076129

Exhibit 16 (cont'd)
Potential Mine Waste Mitigation Measures

Mining Waste Product	Mitigation Measures
Beneficiation - Copper Dump Leach Operations and SX/EW Plants, Gold Heap Leaching	• Design dump leach units to fully drain to collection areas • Ensure that collection, pregnant solution, and raffinate ponds are designed to contain up to the maximum reasonable storm event; line process ponds, heap leach pads, and conveyances • Install leachate detection and collection systems under ponds and heaps; construct seepage ponds downgradient of ponds, heaps, and dumps • Recycle process water • Lime neutralization or wetlands treatment of acid drainage • Provide secondary containment for solution pipes to minimize impacts from pipe failures/spills • Collect and treat drainage that occurs after closure, as necessary • Perform baseline groundwater monitoring and conduct groundwater quality monitoring during operations and post-closure; monitor post-closure discharges and downstream surface water quality • Detoxification of heaps, dumps, and any spent solutions to reduce cyanide, acidity, and metal loadings • Biological treatment for cyanides, nitrates, and heavy metals
Beneficiation - Cyanide Leaching Operations	• Where possible, do not locate leaching operations in or near drainages • Ensure that pregnant and barren ponds and ditches are designed to contain all solution flows and any runoff up to the maximum reasonable storm event • Use double liners and leak detection systems for all heaps, ponds, and drainage ditches • Test detoxified materials prior to disposal or closure to ensure cyanide levels are reduced • Collect and test seepage and runoff from spent ore piles; treat runoff/seepage as necessary; perform downstream water quality monitoring
Beneficiation - *In Situ* Mining	• Ensure proper production well installation/completion to avoid uncontrolled solution releases; provide for adequate well abandonment • Perform a detailed characterization of the site hydrogeology to guide design of recovery systems and determine potential for releases • Carefully monitor pumping pressures of solutions entering and leaving deposits to assure that solutions are not migrating into groundwater • Line surface collection systems and provide for leak detection; design collection systems to contain maximum volumes of leaching solutions and runoff/precipitation/snow melt

R0076130

Because proposed mining activities may also impact aquatic resources, vegetation, and wildlife, EPA suggests the following potential mitigation measures for use at mine sites:

Exhibit 17
Ecosystem Mitigation Measures

- Employ sediment retention structures to minimize amount of sediment migrating off-site
- Employ spill prevention and control plans to minimize discharge of toxic/hazardous materials into water bodies
- Site roads, facilities, and structures to minimize extent of physical disturbance
- Avoid construction or new disturbance during critical life stages
- Reduce the chance of cyanide poisoning of waterfowl and other wildlife by neutralizing cyanide in tailings ponds or by installing fences and netting to keep wildlife out of ponds
- Minimize use of fences or other such obstacles in big game migration corridors; if fences are necessary, use tunnels, gates, or ramps to allow passage of these animals
- Use "raptor proof" designs on power poles to prevent electrocution of raptors
- Use buses to transport employees to and from mine from outer parking areas to minimize animals killed on mine-related roadways
- Limit impacts from habitat fragmentation, minimize number of access roads, and close and restore roads no longer in use
- Prohibit use of firearms on site to minimize poaching

IV. WASTE RELEASE PROFILE

This section provides a general overview of the waste release activities and issues common to the metal mining industry. Unlike facilities covered by SIC codes 20 through 39 (manufacturing facilities), metal mining (extraction and beneficiation) facilities are not required by the Emergency Planning and Community Right-to-Know Act to report to the Toxic Release Inventory (TRI). EPA is considering expanding TRI reporting requirements in the future, including participation of previously exempt industries such as metal mining. Because TRI reporting is not required in the metal mining industry, other sources of waste release data have been identified for this profile.

IV.A. Waste Release Data for the Metal Mining Industry

In 1994 EPA's OSW studied the unpermitted mining waste releases and environmental effects for nine States: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, South Carolina, and South Dakota. Researchers examined State records to document waste release events for various types of mines throughout each State. These releases generally were not authorized under existing permits or regulations, and therefore should not be considered "accepted," "standard," or "typical" waste outputs of metal mining facilities. Rather, the data presented below offer a picture of representative unpermitted mining release events, and of the magnitude of these events in many Western States, where most metal mining facilities are located. It should be noted that most of these releases were properly mitigated by the associated mining companies.

The release information presented below is categorized by mineral type, and is derived from the *Mining Waste Releases and Environmental Effects Summaries* reports prepared for OSW (see "References" for further information). Release data are presented in the units of measurement reported by each State and are therefore not standardized. Iron ore is not represented in the data because all U.S. iron ore mining occurs outside of the States selected for the survey. Note that the common types of waste released pose the greatest potential for polluting water sources, as stated elsewhere in this profile. Breaches of tailings impoundments, and subsequent spills of tailings, are not included in the data.

Copper

As evidenced in the following exhibit, the most prevalent waste release events related to copper mining involve leachate or process wastewater, reflecting the predominant extraction method for this ore.

Acid Mine Drainage is a significant release associated with abandoned copper mines.

Exhibit 18
Copper-Related Waste Releases

Site	Waste Released	Release Event Year
Cyprus Miami Mine, Claypool, AZ	Copper leachate (amount unknown) Waste water (amount unknown) Non-potable water (37,000 gallons) (min 185, 000 gallons)	1990 1980, 85, 86 1990 1989
Magma Copper, Miami Tailings Reprocessing Pit and Copper Cities Pit, Miami, AZ	Pregnant leach (5000-10000 gallons) Slurry (15,600 gallons, 35,000 gallons, 1000-2000 gallons, 216,600 gallons) Recycle (1,320 gallons) Effluent (amount unknown)	1984 1989 1991 1991 1989 1991
Oracle Ridge Mine, Pima County, AZ	Copper concentrate (100 pounds) Process water (5000 gallons)	1991 1991
ASARCO, Ray Mines, Gila County, AZ	Diesel fuel (amount unknown) PCB, dielectric fluid (10 gallons) Sulfuric acid (20 tons) Gasoline (amount unknown) Acidic water (amount unknown) Cooling tower blowdown (4340m^3/day) Sulfur dioxide (amount unknown)	1989 1989 1989 1989 1985 1985 1988
Sierrita Mine and Mill, Cyprus Minerals Corp., Pima County, AZ	Process water (1 gallon/min) Pregnant leachate (amount unknown)	1987 extended
Chino Mines, NM	Heavy metals and sulfuric acid Acidic water (16,200 gallons) (2 million gallons)	extended 1986 1988
Tyearone Mine, NM	TDS and sulfuric acid from tailings (4,270 acre feet per year)	1978-89
Montana Resources, Inc. Butte, MT	Leach (amount unknown)	1986
Bully Hill Mine, Redding, CA	Acid mine drainage (30 gallons/min)	since 1927
Penn Mine, New Penne Mines, Inc., Campo Seco, CA	Acid mine drainage Leaching of heavy metals (no known flow rate)	since 1955
Walker Mine, Calicopia Corp., Plumas County, CA	Acid mine drainage Heavy metals (no known flow rate)	since 1941
Mammoth, Keystone & Stowell Mines, Shasta County, CA	Acid mine drainage (100-275 gallons/min)	extended time period
Red Ledge Mine, NV	See Gold and Silver	
Arimetco Facility, ArimetcoInc./Copper Tek Corp., Lyon County, NV	Acid leach (amount unknown) Pregnant solution (2000 gallons)	1989-91 1990
Nevada Moly Project, Cyprus Tononpah Mining, Tononpah, NV	Process solution (amount unknown) Mercury (5.783 kg)	1989 1990
Rio Tinto Mine, US Forest Service, Elko County, NV	Acid (amount unknown)	extended

R0076133

Lead and Zinc

Because lead and zinc are often mined as a byproduct of other primary ores (copper or silver, for example), less data is available concerning releases specific to lead and zinc mining processes. Unless a mine operates exclusively as a lead/zinc operation, waste releases associated with these minerals are generally subsumed in the primary ore category and is included in the "Gold and Silver" data.

Exhibit 19
Lead and Zinc - Related Waste Releases

Site	Waste Released	Release Event Year
Black Cloud Mine, Res-ASARCO Joint Venture, Lake County, CO	Copper sulfate (2 gallons, 10 gallons, 50 gallons, amount unknown) Water and sediments (amount unknown) Acid leak (amount unknown)	1987 1987 1983 extended
Taylor/Ward Project ,White Pine County, NV	Lead only, see gold and silver	
Central Valley of CA	Zinc only, see gold and silver	
Red Ledge Mine, ID	Zinc only, see gold and silver	
Montana Tunnels Mine, MT	See gold and silver	
Lucky Friday Mine, Mullan, ID	See gold and silver	
Taylor/Ward Project, Alta Gold Co., White Pine County, NV	Lead only, see gold and silver	

Gold and Silver

As might be expected from the predominant beneficiation methods associated with gold and silver mining, release of leachate solutions (pregnant, process, barren, etc.) is by far the most common type of release for these ores, followed by release of cyanide, a common treatment solution. Release of cyanide is reported as presented in State files and is presumed to be released in solution form. Acid Mine Drainage is also problematic for gold and silver ore mining.

IV.B Other Data Sources

AIRS Data

The Aerometric Information Retrieval System (AIRS) is an air pollution data delivery system managed by the Technical Support Division in EPA's Office of Air Quality Planning and Standards, located in Research Triangle Park, North Carolina. AIRS is a national repository of data related to air pollution monitoring and control. It contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. States are the primary suppliers of data to AIRS. Data are used to support monitoring, planning, tracking, and enforcement related to implementation of the Clean Air Act. AIRS users include State environmental agency staff, EPA staff, the scientific community, other countries, and the general public.

Exhibit 21 summarizes AIRS annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs). This information is compared across industry sectors.

Exhibit 22 lists the air emissions of particular chemicals reported for the metal mining industry in the Air Facility Subsystem (AFS) of AIRS, presented in a "SIC Code Profile, Metal Mining," prepared by EPA's Office of Pollution Prevention and Toxics in April, 1992. The release data are expressed in pounds released per year, per facility. Most of the chemicals released in the highest quantities and those released by the largest number of facilities are metals. In total, 17,654,112 pounds of the chemicals listed in Exhibit 22 were released by the mines covered.

National Priorities List

Presented in Exhibit 23 is a table of mining sites listed on the National Priorities List (NPL) for environmental remediation. These sites have been involved primarily in the extraction and beneficiation of those metal ores covered in this profile and represent only a small fraction of the total number of sites on the NPL, currently numbering over 1,200. The total number of mining-related sites on the NPL is far greater, and includes smelting and other metal processing facilities, and a wider range of metal and non-metal mining facilities.

Exhibit 23
Selected NPL Mining Sites

Site Name/Location	Type of Mine	Contaminant of Concern	Environmental Damage
Silver Bow Creek, Butte, MT	Copper	Arsenic, heavy metals	Contaminated surface soils and sediments; contamination of primary drinking water sources
Clear Creek/Central City Site, Clear Creek, CO	Gold, silver, copper, lead, zinc, molybdenum	AMD, aluminum, arsenic, cadmium, chromium, lead, manganese, nickel, silver, copper, fluoride, zinc	Surface water contamination from AMD; contaminated sediments and groundwater; potential air-borne contamination from tailings
Silver Mountain Mine, Loomis, WA	Silver, gold, copper	Arsenic, antimony, cyanide	Soil, groundwater, and surface water contamination
Summitville Mine, South Fork, CO	Gold, copper, silver	AMD, heavy metals, cyanide	Surface water contamination; fishkills
Whitewood Creek, Lawrence/Meade/Butte Co's., SD	Gold	Arsenic, cadmium, copper, manganese, other metals	Contaminated alluvial groundwater, surface water, surface soils, and vegetation
Cherokee County-Galena Subsite, Cherokee Co., KS	Lead and Zinc	Cadmium, lead, zinc, AMD	Ground and surface water contamination; contaminated soils
Oronogo-Duenweg Mining Belt, Jasper Co., MO	Lead and Zinc	Cadmium, lead, zinc	Contaminated ground and surface water, and sediments; contamination of primary drinking water supplies
Tar Creek, Ottawa Co., OK/Cherokee Co., KS	Lead and Zinc	AMD, heavy metals	Contaminated aquifer serving approx. 21,000 residents; acute surface water contamination; high mortality rate of most surface water biota
California Gulch, Leadville, CO	Gold, silver, lead, zinc, copper	AMD, cadmium, copper, lead, zinc	Contaminated surface water, groundwater, and sediments
Eagle Mine, Gilman, CO	Zinc, copper, silver	AMD, antimony, arsenic, cadmium, chromium, copper, lead, manganese, nickel, silver, thallium, uranium, zinc	Contaminated surface water and groundwater; contaminated soils and sediments
Iron Mountain Mine, Redding, CA	Gold, silver, copper, zinc, pyrite	AMD, cadmium, copper, zinc	Contamination of surface water; elimination of aquatic life; fishkills
Richardson Flat Tailings	Multiple	Arsenic, cadmium, copper, lead, selenium, zinc	Surface water contamination; possible contamination of wetlands
Smuggler Mountain, Pitkin County, CO	Silver, lead, zinc	Lead, cadmium, zinc, arsenic, barium, copper, manganese, silver, mercury	Soil contamination; potential air, ground and surface water contamination

V. POLLUTION PREVENTION OPPORTUNITIES

As a national policy, the Pollution Prevention Act of 1990 (PPA) and the Resource Conservation and Recovery Act (RCRA) encourage the reduction in volume, quantity, and toxicity of waste. While RCRA focuses primarily on the reduction in volume and/or toxicity of hazardous waste, the PPA encourages maximum possible elimination of all waste through source reduction.

In the PPA, Congress defined source reduction as any practice that reduces the amount of any hazardous substance, pollutant, or contaminant entering any waste stream or otherwise releases into the environment (including fugitive emissions) prior to recycling, treatment, or disposal; and reduces the hazards to public health and the environment associated with the release of such substances, pollutants, or contaminants. Source reduction includes equipment or technology modifications, process or procedure modifications, reformulation or redesign of products, substitution of raw materials, and improvements in housekeeping, maintenance, training, or inventory control.

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways, such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, employee awareness and education, and employing substitutions for toxic chemicals.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the metal mining industry. While the list is not exhaustive, it does provide core information that can be used as a starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can or are being implemented by this sector. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

Much of the information presented is drawn from EPA's OSW report on *Innovative Methods of Managing Environmental Releases at Mine sites, April 1994.*

V.A. Controlling and Mitigating Mining Wastes

Mining Water Control

As discussed previously, acid drainage is an environmental concern at many mining sites. There are no widely-applicable technologies to stop a fully-developed acid drainage situation. This makes it particularly important to prevent acid drainage before it starts. Prevention of acid drainage requires control of oxygen, water, bacteria, and sulfide minerals. Within a mine, oxygen levels cannot be controlled, so AMD prevention measures focus on control of the other three parameters, particularly on water flows.

The primary strategy for minimizing acid drainage focuses on water control. A comprehensive water control strategy works both to limit contact between water and exposed mine rock and to control the flow of water that has been contaminated by mineral-bearing rock. Development of systems for water control at mine sites requires consideration of rainfall runoff as well as process water used or produced when mine dewatering is required in excavation, concentration, and leaching. Although the type of water controls used varies widely according to topography, rock type, and climactic conditions, efforts are typically aimed at directing water flows to containment ponds for treatment or evaporation. The five principal technologies used to control water flow at mine sites are: diversion systems, containment ponds, groundwater pumping systems, subsurface drainage systems, and subsurface barriers.

Surface water is controlled by diversion systems, made up primarily of drainage ditches. Some drainage ditches channel water away from mining sites before runoff reaches exposed minerals, while others direct contaminated water into holding ponds for evaporation or treatment. The ponds used to hold leaching solutions are more sophisticated than holding ponds for mine runoff because of environmental concerns and the valuable nature of the metal-rich solutions in leaching holding ponds.

Groundwater sources can also be protected with water control systems. Groundwater pumping systems are used to control or reduce underground seepage of contaminated water from collection ponds and waste piles. Wells are drilled where underground water movement is detected, and pumps are then used to move the water out of the ground to holding ponds and/or to a treatment plant. Subsurface drainage systems are also used to control seepage in mining areas. These systems use a drain channel and wells to collect contaminated water that has seeped underground and move it to a

R0076149

treatment plant. Subsurface barriers are used to divert groundwater away from mining operations. The most common forms are slurry walls and grouting. Slurry walls are made of low-permeability materials that are sunk into the ground around mining operations.

Grouting involves the injection of a liquid solution, which then solidifies, into rock crevices and joints to reduce water flow. The EPA and DOE-sponsored Mining Waste Technology Program (MWTP) in Butte, Montana is conducting a clay-based grouting demonstration project at the Mike Horse Mine in Lincoln. Researchers have found that clay-based grouts retain their plasticity throughout stabilization, unlike cement-based grouts; clay grouts are not easily eroded; and clay grouts generally penetrate mine fractures better than cement-based grouts. Through this project, researchers hope to use a clay grout, developed specifically for the site's geological characteristics, to isolate specific mineralized structures within the mine. This grouting barrier will lower the groundwater flow entering the mine, reducing contact with the mine's sulfide minerals. Consequently, acid generation will decrease and lower quantities of acid and dissolved metals will be delivered to area surface water sources.

MWTP is also demonstrating a sulfate-reducing bacteria project at the nearby abandoned Lilly/Orphan Boy mine, where acid production is a continuing problem. This technology uses bacteria to reduce contamination in mine wastewater by reducing sulfates to hydrogen sulfide. This hydrogen sulfide reacts with dissolved metals, resulting in the formation of insoluble metal sulfides. Finally, the sulfate reduction produces bicarbonate, which increases the pH of the water. This biotechnology also acts as a source control by slowing or reversing the process of acid generation. Because biological sulfate reduction is an anaerobic process, it reduces the quantity of dissolved oxygen in the mine water and increases the pH, thereby slowing or stopping the production of acid. Final reporting on this demonstration project is expected after the three-year trial ends in late 1997.

Waste Rock Disposal Area and Tailing Impoundment Design

In addition to controlling water flow, acid drainage minimization also requires that waste rock disposal areas and tailings impoundments be properly designed and sited. When selecting a site for waste disposal areas, mine operators should consider the topography of the site and the proximity to groundwater, streams, and rivers. Waste rock can be sloped to minimize uncontrolled runoff and to control the velocity of water that flows into containment ponds.

Wetlands

One promising technique for treating AMD is the use of constructed wetlands. There are currently approximately 400 such systems in operation, mostly as a result of U.S. Bureau of Mines research programs. Constructed wetlands systems have been particularly effective at removing iron from acid mine water. These wetlands rely on bacterial sulfate reduction (the opposite of bacterial oxidation, the formation of acid) to remove iron and other minerals and to reduce the acidity of contaminated water. The iron is precipitated out, deposited in the substrate, and eventually accumulated by plants. Although a few wetland systems have been built to treat large flows of acid mine drainage, the technique seems best suited to handling seeps and small flows. Their effectiveness is also limited when there are large seasonal changes in flow rates, or high concentrations of nonferrous metals, as occurs in some metal mining areas.

The Dunka mine site, an iron ore mine operated by LTV Steel Mining Company (LTV SMCo) is currently using wetlands treatment methods to mitigate an existing seepage problem. The facility has experienced seepage from a specific type of acid generating waste rock found at the site. Seepage from the waste rock piles has flowed to a creek, which enters Birch Lake; a previous study estimated 50 million gallons a year of discharge. Studies conducted at the mine's active wetlands site indicate 30 percent removal of nickel and 100 percent removal of copper by peat sequestration. Overall mass analyses indicate more than 80 percent of copper entering the wetlands were retained. Other technologies currently being used at the site include pile capping to reduce infiltration; diverting the creek away from the waste rock stockpiles; and a lime neutralization treatment system for removing metals from collected waste rock seepage.

Pump and Treat

The conventional approach to treating contaminated ground or surface water produced through acid drainage involves an expensive, multi-step process that pumps polluted water to a treatment facility, neutralizes the contaminants in the water, and turns these neutralized wastes into sludge for disposal. The first step in the process, equalization, involves pumping polluted water into a holding basin. The holding basin may be the containment pond at the base of the waste rock disposal area or tailings impoundment, or may be an additional basin constructed for this purpose. A steady "equalized" flow of water is then pumped out of the holding basin to a treatment plant for neutralization. Lime is commonly added to the water in the treatment plant to neutralize the acid. The next step, aeration, involves moving the treated water to another basin where it is exposed to air. The metals precipitate typically as hydroxides, forming a gelatinous sludge. The floc then settles to the bottom of the pond as sediment. This sediment contains most of the contaminants that had previously been mixed with the water, as well as unreacted neutralizing reagents. The accumulated sludge at the bottom of the basin can then be removed for disposal.

MWTP is exploring a variety of options for improving mine wastewater treatment technologies. Among its projects is an effort to use photoassisted electron transfer to remove toxic substances, specifically nitrate and cyanide, from wastewater. Researchers are also developing new treatment technologies involving chemical precipitation, with or without aeration, to neutralize acid waters and precipitate contaminants from a nearby abandoned open-pit mine that contains over 20 billion gallons of wastewater. Final study results for this project will be published in early 1996.

Sludge Disposal

Sludge disposal is the most expensive and difficult part of acid drainage treatment. The easiest method for final disposal is to pump the sludge into abandoned mines. The long-term environmental impact of this method is undetermined. While the mine is still active, the sludge may be placed in a basin next to the sediment pond. The sludge is left in this second pond until evaporation takes place and the sludge dries. The sludge can then be transferred to an appropriate location for long-term storage or disposal.

MWTP is currently completing a research project on sludge stabilization. The research team, led by faculty at University of Montana's Montana Tech, is studying the properties and stability of sludges generated through water treatment techniques for acid-polluted water from sulfide mines. Researchers are analyzing the chemical properties of sludges, and will propose various storage environments to optimize long-term sludge stability.

Mine Planning

One way to mitigate the problems caused by acid water draining from underground and surface mines is to carefully consider a site's topography, geology, hydrogeology, geochemistry, and the like in determining approaches to ore production and the siting of such process wastes as waste rock piles, tailings impoundments, and solution ponds. Proper planning of operations can greatly reduce such environmental hazards as potential releases to ground and surface waters and AMD production.

Acid Zone Isolation

An alternative to removing acid producing zones, which may be neither feasible nor economical, is to isolate them by using a mining sequence that avoids extracting material that will create AMD-producing wastes and exposing "hot" zones. This is accomplished by leaving rock barriers between mining operations and the potential acid-producing zone, and, if necessary, grouting or otherwise sealing off the flow of water into the "hot" zone.

V.B. Innovative Waste Management Practices

New techniques for recovering metal resources that may have less of an environmental impact include *in-situ* leaching, use of robotic systems, and underground leaching. These techniques could reduce surface disturbances and eliminate waste piles and impoundments, but may have serious impacts on groundwater. Alternatively, existing waste piles may be remined to meet environmental standards, if economically feasible. Another possibility is the development of techniques to extract metals more economically from common rocks. Waste from these common rocks may not contain the hazardous components common in the sulfide ore that are the source of many metals. Industry groups suggest, however, that metals in common rock may not be present in recoverable form and amounts.

The Bureau of Mines has developed a froth flotation process to remove heavy-metal-bearing minerals from tailings. This process recovers not only the desired mineral components of the tailings, but also the acid-forming minerals, and renders the wastes less susceptible to AMD. A combination of conventional and non-conventional flotation reagents lowers the metal content of tailings by as much as 95 percent. Two other possibilities for dealing with wastes created during processing is to concentrate potential contaminants, which would then require a smaller disposal area, or to treat contaminants with a chemical or physical coating, which reduces the rate of release.

Following is an exhibit that describes some of the waste minimization/prevention opportunities for different steps of the mining process.

Exhibit 24
Waste Minimization and Prevention Opportunities

Activity	Waste	Waste Minimization Options
Flotation	Sodium cyanide	• Non-toxic reagents may be substituted for cyanide compounds in copper beneficiation; sodium sulfide/ bisulfide may be used as alternatives to sodium cyanide
	Zinc sulfate, sodium cyanide	• Flotation process control equipment w/sensors, computing elements, and control units may be installed to reduce amount of flotation reagents necessary and to improve separation of waste from product
	Ammonia	• Alkalinity in the beneficiation circuits may be maintained by reagents less toxic than ammonia, such as lime
Tailings Management	Sulfuric acid	• Pyrites could be segregated from other gangue material before discharge to tailings impoundments to reduce the potential for sulfuric acid formation after closure • Thin Layer (TL) process for copper reduces water use by as much as 75 percent as the amount needed for agitation leaching; also reduces fugitive dust generation • Up to 90 percent of metals and cyanide can be removed through use of ion exchange, heavy metal removal systems and cyanide destruction systems, precipitation of heavy metals using lime, oxidization of cyanide using sodium hypochlorite, then electrolysis, and filtration through a high flow rate sand filter
	Water (and associated pollutants)	• Water may be removed from the tailings slurry for reuse in the milling circuit
Leaching	Trace metals	• A Pachuca reactor reduces the elution time for recovering cobalt from spent copper leach solutions • Substitute thiourea, thiosulfate, malononitriles, bromine, and chlorine compounds for cyanide under certain conditions
Metal Parts Cleaning	Miscellaneous chlorinated solvents	• Switching to semi-aqueous cleaners such as terpene and hydrocarbon cleaners or aqueous cleaners which are water-based cleaning solutions would reduce or eliminate solvent emission and liquid waste generation
Blasting	Ammonium nitrate	• Maintain storage containers properly • Use used oil instead of new oil in the preparation of ANFO (if allowed by MSHA)
Crushing	Zinc liners	• Zinc mantle liner pieces in the secondary crushers may be recycled

Metals Recovery

In cooperation with domestic steel makers, the Bureau of Mines has developed an innovative, efficient, and cost-effective recycling process to treat the estimated 1.8 million annual tons of iron-rich dusts and sludges that are contaminated with heavy metals, by mixing various dusts and wastes to produce recyclable metal pellets. The process has been proven on a 1,000 lb/hour pilot scale, and full scale industrial tests are being scheduled. In addition, the Bureau of Mines has worked with DOE and industry representatives to develop a 1,000 lb/hour electric arc furnace suitable for demonstrating the vitrification of mineral wastes and/or the recovery of heavy-metal-rich fume products for recycling. If the contaminated mineral wastes cannot be easily treated, furnace treatment is possible. This treatment has been shown to be effective in rendering unleachable and safe for discarding any unrecoverable trace metals left in the resulting slag.

Cyanide Removal

Bureau of Mines scientists are also investigating new methods of rinsing heaps to remove cyanide. Researchers have determined that interrupted or pulsed water rinsing, as opposed to continuous washing, more efficiently rinses cyanide from heaps and produces less liquid waste to be chemically neutralized or destroyed. Chemical neutralization methods are also being studied for a suite of cyanide complexes typically found in mining waste. In addition, an alternative to destroying cyanide or preventing its escape is the development of leaching agents other than cyanide. Several reagents such as thiourea are effective for recovering gold under certain circumstances. Thiosulfate, malononitriles, bromine, and chlorine compounds also have been shown to leach gold under specific conditions.

Reclamation

Bureau of Mines researchers are currently developing methods for reclamation and closure of mining operations. The focus of this work is on controlling hydrology at sites, decontaminating wastes when necessary, and stabilizing wastes for closure. For example, the current practice for sealing mine shafts is to install a concrete plug. This practice is difficult and expensive because it requires drilling into rock walls to provide support for the plug; access to remote shafts and portals is also a problem. One possible solution being investigated is the use of low-density foaming plastics and/or cements. The cost of the foaming plastic closure is about one-half that of concrete plugs, and the expansion characteristic of the foaming materials may eliminate the need for drilling into intact rock. Another important advantage of using foamed plastic or cement plugs is that these materials may provide a resistant seal to acidic mine waters.

Flotation Technology

Flotation mills separate metalliferrous minerals from waste rock, using surfactants to cause air bubbles to attach themselves to mineral particles and to float to the top of a frothing bath of ore slurry. The goal of flotation mill operators is to maximize the amount of valuable material floated, while minimizing the ore concentrate's gangue content. In order to also improve environmental quality, operators must minimize the amount of surfactants and heavy metals in the waste stream fed to the tailings pond. Reliable on-line measurements of metals content at various points throughout the mill is thus necessary to effect control of the operation.

X-Ray Fluorescence (XRF) is an analytical technique designed to rapidly measure the metals content of a flotation slurry sample. In mills with on-line X-ray analyzers, operators can base their responses to process changes on absolute determinations of the metals content of each stream sampled. In its simplest form the operator uses output information from the analyzer to adjust surfactant addition rates to meet quality goals. Some mills are moving toward a more advanced system of incorporating XRF technology, using central computers to store historical data and/or a detailed model of the total process to establish automatic control setpoints.

This technology is now in use at the Doe Run Fletcher mill, which beneficiates a mixed sulfide ore. During the flotation process, assay data from the XRF unit is sent to a process control computer. Flowmeter readings from all of the reagent addition lines are also sent to the computer, as are the outputs from a variety of process monitors. The computer displays most of this data on an operator console in the mill control room. Based on the data presented, the operator can vary the reagent addition rates to obtain better mineral separation. The computer maintains an archive of the historical behavior of the mill, enabling mill managers to specify empirical formulae relating reagent needs to assay results.

Use of an on-line X-ray analyzer, coupled with a process control computer, greatly simplifies the operation of a mill. One mill required 24 operators, three engineers, and three supervisors before this technology was introduced; it now requires about eight staff to operate. Benefits associated with this process control technology may include a decrease in reagent consumption, a significant environmental benefit; a stabilized process, increasing metal recovery rates; and more effective grinding control, allowing an increase in mill tonnage throughput. Doe Run estimates its cost savings to approach $785,000 per year, including a 14 percent reduction in reagent costs per year and improved metallurgy resulting from higher purity concentrates. In addition, the technology has resulted in a reduction of 4,500 to 5,000 pounds of metal entering the tailings pond per day.

Pyrite Flotation

At the Superior Mine in Arizona, Magma Copper Company is currently producing a high grade pyrite product by subjecting copper tailings to an additional flotation circuit. Instead of generating a tailings high in sulfide, the facility produces less reactive tailings and two marketable pyrite products.

Pyrite easily oxidizes to form sulfuric acid and, at many mine sites, is associated with acid generation from tailings piles and other mining activities. Removing pyrite prior to discharging the tailings will decrease the potential for acid generation from tailings, which may in turn minimize possible waste treatment and remediation costs.

Magma's pyrite flotation circuit is similar to its copper flotation circuit and uses existing flotation equipment. Operators use reagents to float pyrite from copper tailings, producing a 99 percent pure pyrite concentrate. This concentrate is pumped to a settling pond for dewatering after exiting the flotation circuit. As the pyrite dries, it is excavated from the pond and sent to the plant to package for sale.

Currently, the operation of pyrite flotation circuit is demand-driven, with the circuit used only as needed to meet the demand for the pyrite product. At other times, the pyrite is discharged with the tailings to the tailings impoundment. According to Magma's facility personnel, "breaking even" financially with the pyrite flotation project is a satisfactory result because of the resultant savings or avoidance of waste treatment costs associated with acid generation caused by pyrite in the tailings.

Possible limitations to widespread application of this technology are related to the Superior Mine's unique ore, in which pyrite concentration reaches 25 percent (concentration at most copper mines is closer to five percent). Lower pyrite concentrations in other ore may make pyrite flotation more difficult and/or expensive. In addition, because the operation is demand-driven and operates only when needed, pyrite is removed from only a portion of the copper tailings.

Tailings Reprocessing

Magma Copper is also recovering additional copper from a tailings pile at its Pinto Valley operation. The tailings pile covers 210 acres and contains 38 million tons of tailings; it was deposited between 1911 and 1932. Pinto Valley hydraulically mines the tailings pile, leaches the tailings, and produces copper by using a SX/EW facility. After leaching and washing of the slurried tailings, the remaining slurry is piped overland approximately five miles to an abandoned open copper pit mine for final disposal.

The pile's oldest tailings contain .72 percent copper, while those deposited most recently contain .11 percent copper; Magma thus pre-strips the top layer in order to get to an economically recoverable zone. Magma still reprocesses this pre-stripped layer, although the copper recovered is extremely low.

The hydraulic mining system's water jets and vacuum pumps break down clay aggregates, allowing more efficient tailings separation, and renders the tailings into a slurry for beneficiation processes. The slurry first enters a leach tank, then goes to the first of two thickeners. Overflow from this thickener becomes the pregnant leach solution (PLS), which is sent to the solvent extraction circuit. The underflow from the first thickener is pumped to a second thickener. Overflow from this thickener is returned to the mining circuit as feed for the hydraulic operations; the underflow is pumped into a tailings disposal area. Magma uses the same SX/EW operation for reprocessed tailings and its in situ leach operation; there is no difference between the SX/EW operation for the reprocessed tailings and other SX/EW plants in use at other copper sites.

According to facility personnel, the operation has recently been financially profitable due to the increase of copper prices and is expected to continue to be profitable in the future. Environmentally, the benefit derived from the operation results from the removal of the tailings pile located in a drainage adjacent to a town and redepositing the tailings in an abandoned open pit in a relatively remote location. Magma credits the success of this operation to the high concentration of copper present in the tailings; other sites may have a lower percentage of copper in the tailings, which may make reprocessing less economical.

Pipe Recycling/Reuse

IMC operates phosphate rock mines in West Central Florida, and has implemented a waste minimization program involving the reuse and recycling of steel pipe used to transport slurry, water, tailings, and other materials. IMC obtains maximum use from its pipe in several ways:

- Pipe used for matrix and clay transport is periodically rotated to ensure that wear is evenly spaced over the full diameter of the pipe
- To the extent possible, pipe no longer suitable for the most demanding use is used in other, less demanding pipelines
- Pipe no longer suitable for use in pipelines is either used for other purposes (such as culverts) or is sold for off-site reuse or scrap.

IMC has developed a computerized model to predict how long a section of pipe can remain in each position and when it needs to be turned. When pipe can no longer be used for materials transport, any undamaged portions of pipe are removed for onsite reuse as culvert or sold to a local scrap dealer as usable pipe. Damaged pipe is sold to a scrap dealer. By reusing pipe onsite, IMC estimates that it saves approximately $1.5 million each year. In 1991, $316,000 was received for pipe that could be reused offsite, and 4,200 tons of scrap piping was sold for an estimated total of $42,000 - $84,000. IMC's program reduces capital expenditures by reducing the amount of new pipe that must be purchased, as well as saving operating costs by avoiding costly shutdowns when pipes fail.

Mine Tire Recycling

Mine representatives have estimated the price of one large tire to range from $10,000 to $16,000, or over $100,000 to fit one large piece of equipment. Several options exist for recycling or reusing whole large tires. One alternative is retreading the tires for reuse; retreading reduces the demand for new tires and conserves resources (retreading a used tire requires less than 40 percent of the fossil fuel to make a new tire). The purchase price for retreaded tires is less than for new tires, providing an additional savings incentive. In addition to retreading, whole scrap tires are used in civil engineering applications, including construction, erosion control, and agriculture (feeding troughs, for example).

Processing scrap tires involves shearing, cutting and/or shredding tires into smaller pieces. The major markets for processed tires are as tire derived fuel and in civil engineering applications. Scrap tires are an excellent fuel source, generating about 80 percent as much energy as crude oil per pound. In recent years, there have been major increases in the use of scrap tires as fuel by a number of industries, including power plants, cement kilns, pulp and paper mills, and tire manufacturing facilities.

Mining companies may be able to access the tire retreading market through their current tire vendors. Depending on their condition and suitability, some vendors may offer reimbursement for used tires. Cobre, a tire vendor for the Dee Gold Mine, performs on-site evaluations of used tires to determine each tire's potential for retreading. If a tire is retreadable, Dee Gold Mine is reimbursed $500 per tire; if it isn't, Cobre will remove the tire free of charge.

Two major impediments to recycling mine vehicle tires are the distance to existing resource recovery markets and the size of these large scrap tires. Large mining operations are not usually located near their potential markets in larger cities. For remote mine locations, some added effort may be necessary to find or develop markets. In order to reduce size and handling difficulties associated with used mine tires, shredders or shears may be used to cut large tires into pieces more suited to handling.

Mine Water Management

One of the major concerns regarding runoff from mining activities is the potential for acid generation and metal mobilization in waste associated with mining. Sources of potentially contaminated non-process waters at a mine site include: seepage from underground mine workings; runoff from abandoned/inactive mines; runoff from waste rock, overburden, and tailings piles; overflow from ponds or pits, especially during high precipitation or snow melt events; runoff from chemical storage areas; former mining and processing areas with contaminated residue; leaks from liquid/slurry transport lines; and runoff from other areas disturbed by mining operations.

Effective practices for managing and controlling runon/runoff are also known as best management practices, or BMPs. BMPs can be measures or practices used to reduce the amount of pollution entering surface or groundwater, air, or land, and may take the form of a process, activity, or physical structure. BMPs include treatment requirements, operating procedures, and practices to control plant site runoff, spillage or leaks, waste disposal, drainage from raw material storage or other disturbed areas. BMPs applicable to mine site discharges can be divided into three general areas: 1) construction/reclamation; 2) management and housekeeping; and 3) treatment. The following table provides examples of specific techniques used within each of these areas.

Exhibit 25
Mine Water Management Techniques

Construction/Reclamation Techniques	Management & Housekeeping Techniques	Treatment Techniques
Diversion ditches and drainage systems	Comprehensive pollution prevention plan	Sedimentation basins Oil/water separators
Rip-rap	Immediate spill clean-up	Neutralization
Dikes and berms	Inspection	Artificial wetlands
Grading or terracing	Training and education	
Collection basins	Routine maintenance	
Capping or sealing	Proper handling procedures	
Vegetation and mulching	Periodic systems reviews	
Silt fences		

The following cases illustrate how some facilities are approaching water management at their operations. First, the Hayden Hill Project is operated in Lassen County, California by Lassen Gold Mining, Inc., a subsidiary of Amax Gold Inc.. Amax Gold won a California Mining Association award for its facility reclamation plan, and the 1992 DuPont/Conoco Environmental Leadership Award for environmental excellence in the precious metals industry. Mining operations include an open pit mine, waste rock disposal area, a heap leach pad, and mill processing facilities.

Storm water control measures undertaken at Hayden Hill include:

- Baseline and continual monitoring of ground and surface water
- Double liner and leak detection for heap leach pad and processing ponds
- Lined tailings impoundment, with a surrounding freeboard berm to protect against runon and overflow
- Erosion control measures, such as retention ponds to intercept runoff and stream crossing constructed during low flow periods
- Protection of stream bank to prevent grazing impacts
- Groundwater springs near the open pit will be rerouted

- Diversion of natural drainage around the heap leach pad
- Solution pipes located in lined ditches.

In addition, all runoff from the shops and warehouse areas is collected in a storm water collection ditch; above the mill area are storm water diversion ditches to route storm water around the mill to avoid potential contact with material at the mill. The waste rock dump basin is designed with interior benches that slope towards the inside of the basin to allow storm water to be captured as it flows across the bench. These "V" ditches will drain the runoff to a heap toe drain.

Revegetation will be an important step in the mine's reclamation. To aid this effort, various erosion controls will be used, including rip-rap in shallow interception ditches, sediment collection basins, rock dikes, and straw bales as check dams around culverts. Expectations are to return the site to livestock grazing, watershed protection, wildlife habitat, and recreational use after mining is complete.

The Cyprus Bagdad Mine, operated by the Cyprus Bagdad Copper Corporation in Baghdad, Arizona, is another facility using an integrated approach to water management as part of its pollution prevention plan. Cyprus' pollution prevention plan was prepared in response to Arizona Department of Environmental Quality requirements, and addresses many areas of the facility, including non-mining activities such as vehicle fueling.

Examples of Cyprus' pollution prevention controls include:

- Diversion ditches to carry runoff away from the solvent exchange leach and tailings disposal areas; regular ditch inspections and repairs
- Runoff and spills channeled to collection basins and surge ponds; planned upgrades for many existing ponds with double liners and leak detection systems
- Earthen berms around petroleum tanks to prevent runon from contacting the tank and surrounding areas
- Visual leak/spill inspections of tailing disposal, reclaim water, seepage return, and leaching systems
- Redirection and control of water from mine shop parking lot
- Collection and recycling of spilled fuel and oil; monitor equipment areas for spilled fuel and oil

R0076162

- Cover copper-concentrate trucks with heavy tarps to prevent in transit losses; store concentrate on concrete and asphalt pads
- Construction of a lined impoundment and oil/water separator at truck wash area; chlorinated solvents no longer used at the truck wash, eliminating a contaminant source.

A notable feature of Cyprus' pollution prevention and control plan is its comprehensiveness. All facets of facility operation are addressed, including frequency of routine maintenance and inspections; employee training; supervisor maintenance of monitoring logs; emergency backup systems testing, inspection of piping, sumps, and liners; and monitoring pump rates and pond and dam elevations.

Lastly, the Valdez Creek Mine in Cantwell, Alaska is using stream diversion to both improve access to ore and prevent stream discharges. In order to access ore sources beneath an active stream channel, the Valdez Creek was diverted by constructing a diversion dam upstream of the active pit; the dam impounds water, which then flows through the diversion channel approximately one mile before rejoining the stream. The diversion channel is lined with a synthetic liner and riprap to prevent erosion and incision of the channel. To aid water management in the active pit, the facility uses two diversion ditches on either side of the valley above the mined area to intercept runoff before it reaches the pit.

The lined diversion channel for Valdez Creek and the diversion ditches minimize impact to the downstream environment by reducing turbidity and sedimentation caused by mining operations. Stream diversion not only prevents stream discharges, but also improves access to the ore and has lowered operating costs by reducing pit dewatering requirements.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities

R0076164

that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties

that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the

Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The

Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

R0076174

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry-Specific Requirements

Three types of laws govern and/or regulate the mining of metal resources. The first type, (i.e., the Mining in National Parks Act and the Wild and Scenic Rivers Act), define areas that are off-limits to metal mining. The second type of law, (i.e., the General Mining Law of 1872), defines methods for allocating metal deposits for extraction. The third type of law, those governing the extraction process and establishing restrictions on the types and amounts of wastes that may be generated, comprises most of the following discussion.

General Mining Law of 1872

The General Mining Law of 1872 is one of the major statutes that direct the Federal government's land management policy. The Mining Law grants free access to individuals and corporations to prospect for minerals in public domain lands, and allows them, on discovery, to stake a claim on that deposit. According to staff in EPA's Office of Solid Waste, roughly 40 percent of U.S. mines operate under this provision.

The Bureau of Land Management (BLM), under the Department of the Interior, has authority to regulate these mining claim operations under the Federal Land Policy and Management Act (FLPMA) of 1976. FLPMA established BLM's general land management and planning authority (43 CFR Part 3809), and requires that mining operations on Federal lands are regulated to prevent "unnecessary and undue degradation."

While mining operations are subject to varying levels of scrutiny, all operations must be reclaimed and must comply with all applicable State and Federal laws, including air and water quality standards such as those established under the CAA and CWA, and standards for the disposal of solid waste under RCRA.

In addition to requiring reclamation bond posting, BLM requires mining operations that involve cyanide leaching to meet the following standards:

- Fencing must be used to ensure protection of the public, livestock, and wildlife
- Facilities must be designed to contain the maximum operating water balance in addition to the water from a 100-year, 24-hour storm event; containment ponds must be included in all containment systems
- Leakage detection and recovery systems must be designed for heap and solution containment structures; monitoring of ground and surface water through closure and final reclamation is required
- Cyanide solution and heaps must be neutralized or detoxified.

Although BLM has general management authority for the mineral resources on Federal lands, the Forest Service (FS) also regulates mining activities on Forest Service land, with a similar mandate to minimize adverse environmental impacts. The National Forest Management Act of 1976 provides the Forest Service with authorities and responsibilities similar to those provided to BLM by FLPMA. Like BLM's regulations, they require compliance with the Clean Water Act and other environmental statutes and regulations. FS generally consults with appropriate agencies of the Department of the Interior, including BLM, in reviewing technical aspects of proposed mining operations. FS also conducts environmental assessments of proposed plans and, if necessary, prepares EISs pursuant to the National

Environmental Policy Act. FS also specifies standards for reclamation and may require bond posting.

EPA is currently pursuing a Memorandum of Understanding (MOU) with the Department of the Interior to formally coordinate regulatory and enforcement efforts concerning mining operations on Federal lands. Ongoing enforcement efforts are commonly coordinated with BLM State offices, as part of a broader strategy to simplify and coordinate oversight of mining operations at the State and Federal level.

Clean Water Act (CWA)

Under the Clean Water Act, National Pollution Discharge Elimination System (NPDES) permits must be acquired before any pollutant can be discharged from a point source into U.S. waters. EPA has established national technology-based effluent limitation guidelines for ore mining and dressing operations (40 CFR Part 440). These include new source performance standards based on Best Available Demonstrated Technology (BADT). For mine and mill point source discharges, 40 CFR Part 440 establishes the maximum levels of pollutants that can be released daily and monthly. The discharger must not exceed the daily allowance nor the average allowed over an entire month in order to comply with regulations. For most metals, the monthly averages are one-half the daily maximums for metal pollutants.

Contaminated storm water runoff from some mining operations has been documented as causing water quality degradation, according to a Technical Resource Document on extraction and beneficiation of copper by EPA's OSW. In the past, point source storm water discharges have received limited emphasis under the NDPES program. However, EPA has promulgated regulations that specifically address point source discharges of storm water from industrial facilities, including active and inactive/abandoned mine sites (55 FR 47990; November 16, 1990). These regulations require NPDES permits for all discharges of contaminated storm water. The Water Quality Act of 1987 added §402(p)(2)(B), requiring that point source discharges of storm water associated with industrial activity (including active and inactive mining operations) be permitted by October, 1992. This provision includes discharges from "areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water." The storm water permitting regulations address discharges from mine sites that occur as a result of precipitation events where the runoff from those sites is contaminated by exposed overburden, raw material, intermediate products, finished products, byproducts, or waste materials resulting from present or past mining activities.

In the case of active mine sites, the storm water regulations apply to both storm water discharges from mining operations as well as to areas used for the storage and maintenance of material handling equipment, shipping and receiving areas, and haul roads. For inactive or abandoned mines, all point source discharges of contaminated storm water (i.e., storm water that has come into contact with mine facilities, materials or wastes) must be covered under an NPDES storm water permit. Some storm water discharges from mine sites are not subject to NPDES permitting, including storm water that is not contaminated by contact with overburden, raw material, or waste materials located on the site of the operation.

The following exhibit highlights examples of discharges from ore mining and dressing facilities that are subject to 40 CFR Part 440 or to storm water permitting.

Exhibit 26
Mine Discharges Subject to Permitting

Runoff/drainage discharges subject to 40 CFR Part 440 effluent limitation guidelines	Subject to storm water permitting (not subject to 40 CFR Part 440)
Land application area Crusher area Spent ore piles, surge piles, ore stockpiles, waste rock/overburden piles Pumped and unpumped drainage and mine water from pits/underground mines Seeps/French drains On-site haul roads, if constructed of waste rock or spent ore or if wastewater subject to mine drainage limits is used for dust control Tailings dams/dikes when constructed of waste rock/tailings Unreclaimed disturbed areas	Topsoil piles Haul roads not on active mining area On-site haul roads not constructed of waste rock or spent ore (unless wastewater subject to mine drainage limits is used for dust control) Tailings dams, dikes when not constructed of waste rock/tailings Concentration/mill building/site (if discharge is storm water only, with no contact with piles) Reclaimed areas released from reclamation bonds prior to 12/17/90 Partially, inadequately reclaimed areas or areas not released from reclamation bond Most ancillary areas (e.g., chemical and explosives storage, power plant, equipment/truck maintenance and wash areas, etc.)

The concentration of pollutants discharged in mine drainage from mines operated to obtain copper bearing ores, lead bearing ores, zinc bearing ores, gold bearing ores, silver bearing ores, or any combination of these ores in open-pit or underground operations other than placer deposits shall not exceed:

Exhibit 27
Mine Discharge Limitations

Effluent Characteristic	Maximum of any 1 day (mg/l)	Average of daily values for 30 days (mg/l)
TSS	30	20
Cu	30	15
Zn	15	7.5
Pb	6	3
Hg	2	1
pH	*	*
*Within the range 6.0 to 9.0		

Source: 40 CFR 440.102(a).

Beneficiation is regulated by the same effluent limitation guidelines as extraction processes.

The concentration of pollutants discharged from mills that employ the froth flotation process alone or in conjunction with other processes, for the beneficiation of copper ores, lead ores, zinc ores, gold ores, or silver ores, or any combination of these ores shall not exceed:

Exhibit 28
Mill Discharge Limitations

Effluent Characteristic	Maximum for any 1 day	Average of daily values for 30 consecutive days
TSS	30	20
Cu	30	15
Zn	10	5
Pb	6	3
Hg	0.002	0.001
Cd	10	0.05
pH	*	*
*Within the range 6.0 to 9.0		

Source: 40 CFR 440.102(b).

Safe Drinking Water Act (SDWA)

The Safe Drinking Water Act may also apply to mine operations if primary drinking water sources and Class 3 wells are affected by mine wastewater releases. EPA regulates cadmium, lead, and arsenic under its primary drinking water standards (40 CFR 141.11(b)), and regulates copper, iron, manganese, and zinc under its secondary drinking water standards (40 CFR 143.3).

Resource Conservation and Recovery Act (RCRA)

The Bevill Amendment

In 1980, Congress amended RCRA in the Solid Waste Disposal Act Amendments, adopting what has been dubbed the Bevill Amendment, after Representative Tom Bevill of Alabama. The amendment temporarily exempted from Subtitle C regulation solid waste from ore and mineral extraction, beneficiation, and processing. The Amendment directed EPA either to develop Subtitle C regulations for the waste or determine that the exemption should continue, and to present its findings in a report to Congress.

EPA modified its hazardous waste regulations to reflect the Bevill exclusion and issued a preliminary, and quite broad, interpretation of the exclusion's scope. In particular, it interpreted the exclusion as covering "solid waste from the exploration, mining, milling, smelting and refining of ores and minerals." Based on this broad interpretation of the Bevill Amendment, EPA suspended its Subtitle C listing of six hazardous smelter wastes.

In 1985 the U.S. District Court for the District of Columbia awarded judgment to the Environmental Defense Fund and two public interest groups that had sued EPA for failing to submit the required report to Congress and make the regulatory determination by the statutory deadline. The court imposed two schedules, one for completing studies of extraction and beneficiation wastes and submitting them in a report to Congress, and the second for proposing reinterpretation of mineral-processing wastes. In so doing, the court effectively split the wastes that might be eligible for exclusion from regulation into two groups: mineral extraction and beneficiation wastes; and mineral processing wastes.

In December 1985 EPA submitted a report to Congress on mining wastes (*1985 Report to Congress: Wastes from the Extraction and Beneficiation of Metallic Ores, Phosphate Rock, Asbestos, Overburden from Uranium Mining, and Oil Shale*) in which EPA found that some mining wastes exhibit hazardous characteristics, that waste management practices have caused environmental damage, and that the range of risk from mining waste is broad. In July 1986 EPA published a regulatory determination, upheld in subsequent court challenges, that RCRA Subtitle C regulation of extraction and beneficiation wastes was unwarranted because mining wastes tend to be disposed of in arid climates, facilities and wastes are located in sparsely populated areas where human contact is minimal, and waste volumes are high. It also determined that it should develop a risk-based, State-run mining waste program under RCRA Subtitle D.

In keeping with its court-ordered directive to reinterpret the Mining Waste exclusion for mineral processing wastes, EPA proposed to narrow the scope of the exclusion for mineral-processing wastes to include only a few specific waste streams. Unable to articulate criteria for selecting these wastes, EPA later withdrew this proposal and was subsequently sued by the Environmental Defense Fund. The courts ruled against EPA, holding that the Agency's interpretation of Bevill exclusions was overbroad. The court ordered EPA to restrict the scope of the exclusion as it applied to mineral-processing wastes to include only "large volume, low hazard" wastes.

In a series of rulemaking notices, EPA reinterpreted the exclusion for mineral-processing wastes and defined which mineral-processing wastes met the high-volume, low-hazard criteria. The vast majority of mineral-processing wastes did not meet both criteria. EPA published its final regulatory determination in 1991, in compliance with a court-ordered deadline. The final rule permanently retains the Bevill exemption for 20 mineral-processing wastes. EPA determined that regulation under RCRA Subtitle C was inappropriate for these wastes because of the extremely high cost to industry and the technical infeasibility of managing them under Subtitle C requirements; 18 of the wastes are subject to applicable State requirements, while the remaining two (phosphogypsum and phosphoric acid process waste water) are currently being evaluated by EPA.

Wastes from the extraction and beneficiation of ores and minerals remain exempt from Subtitle C requirements, irrespective of their chemical characteristics; EPA may, in the future, evaluate the appropriateness of regulating these wastes under RCRA Subtitle D as an industrial waste. Wastes from mineral processing, however, are not exempt from Subtitle C unless they are one of the 20 specific wastes identified in EPA's final ruling.

In addition, only wastes that are uniquely associated with the extraction and beneficiation of ores and minerals (or one of the 20 listed mineral processing wastes) are excluded from hazardous waste regulation. Non-uniquely associated wastes are typically generated as a result of maintaining mining machinery or as a result of other facility activities, and continue to be subject to Subtitle C regulation. These non-uniquely associated wastes may include used oil, polychlorinated biphenyls, discarded commercial chemicals, cleaning solvents, filters, empty drums, laboratory wastes, and general refuse.

Determining how and under what circumstances the Bevill Amendment exclusions should be interpreted in regulating mining wastes continues to be a subject of discussion and study, at least in part because many beneficiation terms are used to describe activities common to a wide range of nonexempt industries and to describe mineral-processing operations that occur at the same location as the beneficiation operations. Beneficiation and mineral-processing operations are often closely linked; in order to apply Subtitle C regulations at a mine site, a regulator often must prove that the waste is not a beneficiation waste. Because a variety of regulators, at both Federal and State levels, are independently interpreting the Bevill rules, the potential for inconsistent interpretations is significant. Staff in EPA's OSW have suggested the following guidelines for regulators and the regulated community in distinguishing between exempt and nonexempt wastes at mines and mineral-processing sites:

- Determine whether the material is considered a solid waste under RCRA.
- Determine whether the facility is using a primary ore or mineral to produce a final or intermediate product and also whether 50 percent of the feedstocks are from secondary sources.
- Establish whether the material and the operation that generates it are uniquely associated with mineral production.
- Determine where in the sequence of operations beneficiation ends and mineral processing begins.
- If the material is a mineral-processing waste, determine whether it is one of the 20 special wastes from mineral processing.

This sequence will result in one of three determinations: 1) the material is not a solid waste and therefore not subject to RCRA; 2) the material is a solid waste but is exempt from RCRA Subtitle C because of the Mining Waste Exclusion; or 3) the material is a solid waste that is not exempt from RCRA Subtitle C and is subject to regulation.

R0076182

Comprehensive Response Compensation and Liability Act (CERCLA)

Although Bevill wastes are excluded from regulation under RCRA Subtitle C, they can be addressed under CERCLA. Mining companies may be liable under CERCLA for the release or threat of release of hazardous substances, covering releases to air, surface water, groundwater and soils. Many mines, where practices did not incorporate the safeguards now required under the CWA, allowed runoff from mine and tailings sites to flow into nearby streams and lakes. Even newer mines, which have been subject to CWA regulations, have been targeted for CERCLA enforcement. Some of these mines, such as Colorado's Summitville Mine, have been listed on the National Priorities List (NPL). Mine owners may also be liable for damages to natural resources as a result of mining activity.

Clean Air Act (CAA)

Under §111 of CAA, New Source Performance Standards (NSPS) applicable to metallic mineral-processing plants have been established (40 CFR 60 Subpart LL). These standards regulate emissions of particulate matter in metal mining operations in crushers, conveyor belt transfer points, thermal dryers, product packaging stations, storage bins, truck loading and unloading stations, and rail car loading and unloading. Although all underground mining facilities are exempt from these provisions, fugitive dust emissions from mining activities may be regulated (usually by requiring dust suppression management activities) through State permit programs established to meet Federal NAAQSs.

National Environmental Policy Act (NEPA)

NEPA requires that all Federal agencies prepare detailed statements assessing the environmental impact of, and alternatives to, major Federal actions that may "significantly affect" the environment. An environmental impact statement (EIS) must provide a fair and full discussion of significant environmental impacts and inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts on the environment; EISs must explore and evaluate all reasonable alternatives, even if they are not within the authority of the lead agency. NEPA authorities are solely procedural; NEPA cannot compel selection of the environmentally preferred alternative.

Federal actions specifically related to mining that may require EISs include Federal land management agency (e.g. BLM and Forest Service) approval of plans of operations for hardrock mining on

Federally-managed lands. All effected media (e.g., air, water, soil, geologic, cultural, economic resources, etc.) must be addressed. The EIS provides the basis for the permit decision; for example, an NPDES permit may be issued or denied based on EPA's review of the overall impacts, not just discharge-related impacts, of the proposed project and alternatives. Issues may include the potential for acid rock drainage, aquatic and terrestrial habitat value and losses, sediment production, mitigation, and reclamation.

Endangered Species Act (ESA)

The ESA provides a means to protect threatened or endangered species and the ecosystems that support them. It requires Federal agencies to ensure that activities undertaken on either Federal or non-Federal property do not have adverse impacts on threatened or endangered species or their habitat. In a June 1995 ruling, the U.S. Supreme Court upheld interpretations of the Act that allow agencies to consider impact on habitat as a potential form of prohibited "harm" to endangered species. Agencies undertaking a Federal action (such as a BLM review of proposed mining operations) must consult with the U.S. Fish and Wildlife Service (USFWS); an EIS must be prepared if "any major part of a new source will have significant adverse effect on the habitat" of a Federally or State-listed threatened or endangered species.

State Statutes

In addition to Federal laws, State and common laws also affect waste generation from mining activities. State law generally requires that permits be obtained prior to commencement of mining activities; permits may require design, performance, closure, and reclamation standards, and may impose monitoring requirements. Under common law, a mine owner may be liable for trespassing if wastes migrate into and damage another's property, or if the waste impacts the community as a whole, a miner may be liable for creating a public nuisance. Over the last five years several States have substantially altered their mining regulations to prevent the damage caused by past mining operations. Considerable disagreement remains, however, between mining industry groups and the environmental community regarding the effectiveness of these State regulations in preventing damage to the environment.

Many Western States require mining operations to obtain reclamation bonds and mining permits that are designed to regulate and monitor mining activity. States that require bonding and/or permitting include Alaska, Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, South Dakota, Utah, Washington, and Wyoming. To regulate mining activity in the State of Colorado, for example, the State requires mining operations to obtain: 1) a performance bond, 2) a reclamation bond, and 3) a permit. The performance bond outlines what the mining operation intends to do on the land, and is simply a promise from the mining operation that it will reclaim the land. This bond gives Colorado the authority to pursue reclamation costs from mining operations that fail to properly reclaim the land. The reclamation bond, also known as a financial warranty, equals the cost the State would incur if it were to hire someone to reclaim the site should the mining operation fail to do so. Although performance bonds are updated periodically, the bonds have not always been adequate to cover closure costs.

VI.C. Pending and Proposed Regulatory Requirements

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

The Emergency Planning and Community Right-To-Know Act of 1986 (EPCRA) Section 313 mandates that owners and operators of facilities that manufacture, process, or otherwise use a listed chemical report to EPA their annual releases of these chemicals to any environmental medium. EPA makes this information available to the public in the form of the Toxics Release Inventory (TRI). TRI currently requires reporting from facilities in SIC codes 20-39 that meet various threshold requirements.

EPCRA Section 313 gives EPA discretionary authority to modify the coverage of facilities required to report to EPA for inclusion in the TRI. EPA is considering expanding the TRI through the development of reporting requirements for additional facilities. These additional facilities include a list of 25 SIC codes that contribute 99 percent of the non-manufacturing TRI chemical loadings to the environment. SIC code 10 is among these 25 SIC codes. EPA anticipates publication of a proposed rule in late 1995 or early 1996 requiring additional facilities to report the use, release, and transfer of TRI chemicals.

Clean Water Act (CWA)

A comprehensive bill was introduced in Congress in 1995 to reauthorize the Clean Water Act. The bill may affect EPA's authority to require changes in production processes, products, or raw materials to control emissions of toxins; may require risk assessments for water quality standards, effluent limitations or other regulatory requirements; and may require social, economic, and environmental benefits to be weighed in establishing regulations. Potentially large sectors of the mining industry could be affected by this legislation.

Clean Air Act (CAA)

EPA continues to prepare rules for industry sources subject to hazardous air pollutant standards under the CAA, as amended. The sources are those that emit one or more of the 189 substances defined as hazardous air pollutants (HAPs) under the CAA. The EPA published a list of these sources in 1992 and has begun to define Maximum Achievable Control Standards that will apply to them. Although the timetable for issuing regulatory controls varies, proposed standards for most mineral industries are due by November 15, 1997.

EPA is also reviewing and updating national ambient air quality standards (NAAQS) for particulate matter, ozone, and sulfur dioxide to incorporate new scientific and technical information that has become available since the last reviews. Based on these revised data, EPA will determine whether revisions to the standards are appropriate. The metal mining sector will be affected by any revisions to these standards.

Resource Conservation and Recovery Act (RCRA)

The Hazardous and Solid Waste Amendments of 1984 require EPA to promulgate regulations establishing treatment standards that must be met before hazardous waste may be disposed on land. An announcement of new proposed rulemaking was made on October 24, 1991 in 56 CFR 55160. The proposed rulemaking established treatment standards for certain mineral processing waste and toxicity characteristic metals. Proposed rulemaking is expected mid-1995 and final action is expected mid-1996.

In a July 1986 Regulatory Determination, EPA stated that it was not appropriate to regulate the extraction and beneficiation wastes covered in the 1985 *Report to Congress: Wastes from the Extraction and Beneficiation of Metallic Ores, Phosphate Rock, Asbestos, Overburden from Uranium Mining, and Oil Shale*. Among the reasons cited by EPA for the special treatment of mining wastes were: 1) mining waste is generated in much larger volumes than industrial wastes (the average mining waste facility produces 3,000,000 metric tons of waste annually, while the average RCRA Subtitle C regulated waste producer produces 50,000 metric tons annually); 2) mining waste sites are usually much larger than traditional waste producers. The average tailings pile covers 494 acres and the average mining waste piles cover 126 acres, while the average Subtitle C hazardous waste impoundment of landfill is six to ten acres; 3) mining waste streams are believed to have lower human exposure and risk potential.

As a result, EPA determined that RCRA Subtitle C controls may be neither technically nor economically feasible, nor at times necessary to protect human health and the environment. EPA recommended development of a primarily State-implemented, site-specific, and risk-based regulatory approach under Subtitle D of RCRA. The result was the preparation of *Strawman I* and *II* proposals, which would regulate material uniquely associated with mining that the regulatory authority determines could pose a threat to human health and the environment, including mill tailings, stockpiled ores, leaching solutions, and water that may accumulate hazardous constituents.

While the Strawman proposals no longer represent a viable and current Agency approach to the mining industry, EPA may in the future evaluate the appropriateness of regulating mining waste under RCRA Subtitle D as an industrial waste.

VII. COMPLIANCE AND ENFORCEMENT PROFILE

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multi-media indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consist only of records from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS), which tracks facilities in all media databases. Please note that in this section EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well-defined within EPA databases.

R0076188

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within EPA databases may be small compared to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single-media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[1] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS

[1] EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources, such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Section VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action

R0076190

within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or

Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Metal Mining Compliance History

The following exhibit provides a summary of five-year enforcement and compliance data for the metal mining industry. Consistent with information presented in previous sections, the greatest concentration of metal mining activity occurs in the Western States, where the greatest number of inspections and enforcement actions also occur.

Exhibit 29
Five Year Enforcement and Compliance Summary for the Metal Mining Industry

A	B	C	D	E	F	G	H	I	J
Metal Mining SIC 10	Facilities in Search	Facilities Inspected	Number of Inspections	Average Number of Months Between Inspections	Facilities w/One or More Enforcement Actions	Total Enforcement Actions	State Lead Actions	Federal Lead Actions	Enforcement to Inspection Rate
Region I	2	1	1	120	1	1	0%	100%	1.00
Region II	15	11	74	12	2	14	100%	0%	0.19
Region III	9	8	47	11	1	1	100%	0%	0.02
Region IV	28	20	209	8	5	7	86%	14%	0.03
Region V	27	17	129	13	5	15	67%	33%	0.12

Region X	549	154	282	117	19	43	2%	98%	0.15
Total/Average	873	339	1,519	34	67	155	47%	53%	0.10

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibit 30 highlights enforcement and compliance information across selected industries. The metal mining industry had one of the lowest numbers of inspections among those industries represented, as well as the highest average number of months between inspections.

Exhibit 31 provides enforcement and compliance summary data for one year for selected industries. Over half of the facilities inspected were cited for a violation. The metal mining industry also represented the greatest percentage of facilities with enforcement actions taken, at 19 percent.

Exhibit 32 presents inspection and enforcement data by statute for selected industries. As discussed previously, water pollution represents the most common problem associated with the metal mining industry, followed by air. Thirty-four percent of total enforcement actions taken were under the Clean Water Act, while 11 percent were under the Clean Air Act.

Exhibit 33 provides a one-year summary of inspection and enforcement data by statute for selected industries. Again emphasizing the weight given to water pollution in the metal mining industry, inspections under the Clean Water Act represented over 50 percent of total metal mining inspections.

Exhibit 30
Five Year Enforcement and Compliance Summary for Selected Industries

A	B	C	D	E	F	G	H	I	J

VII.C. Review of Major Legal Actions

This section provides a listing of major legal cases and supplemental enforcement projects that pertain to the Metal Mining Industry. Information in this section is provided by EPA's *Enforcement Accomplishments Reports FY 1991, FY 1992, FY 1993* and the Office of Enforcement and Compliance Assurance. As indicated in the EPA's *Enforcement Accomplishments Report,* publications, nine significant enforcement actions were resolved between 1991 and 1993 for the metal mining industry. CERCLA violations comprised three of these actions, the most of any statute. The remaining cases were distributed fairly evenly with CWA and RCRA cited twice, and CAA, EPCRA, and TSCA each cited once.

Two of the cases involved cyanide contamination from heap leaching of gold ores. Each of the settlements, one under CERCLA and one under the CAA, resulted in monetary penalties. The CERCLA settlement provided for company reimbursement of the Superfund for $250,000 in past response costs. Two other CERCLA settlements resulted in penalties: a penalty for failure to notify authorities of a release resulted in a $75,000 fine; a judgment in U.S. vs. Smuggler-Durant Mining Corporation resulted in a $3.4 million award in favor of the EPA.

Both of the CWA actions cited Section 404 for destruction of wetlands. Both instances involved placer mining and resulted in monetary penalties; one of the actions involved a Supplemental Environmental Project (SEP) requiring stream/wetland restoration. Another SEP involved a TSCA violation by Kennecott Utah Copper. In addition to a monetary penalty, Kennecott agreed to upgrade an emergency computer system at an estimated cost of $70,000.

VII.C.1. Supplemental Environmental Projects

This section provides a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement and Compliance Assurance to provide information on the number and type of SEPs entered into by the Regions. The following chart contains a representative sample of the Regional responses addressing the metal mining industry. The information contained in the chart is not comprehensive and provides only a sample of the types of SEPs developed for the metal mining industry. (See Exhibit 34)

Exhibit 34
Supplemental Environmental Projects

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Sunshine Precious Metals, Inc. Kellogg, ID	X	TSCA	Pollution Reduction	$6,588	Early disposal of PCB equipment	$6,588	$3,294

VII.D. EPA Hardrock Mining Framework

EPA is currently developing a multi-media, multi-statute hardrock mining strategy for existing EPA authorities, resources, and expertise in order to address the environmental problems posed by mining activities in the U.S., in concert with other Federal, State, tribal and local agencies. Some of the driving issues behind the strategy's development are concerns about overlapping and poorly coordinated regulatory authorities and actions; liability under CERCLA and other statutes, which may create a recurring barrier to voluntary remediation of mine sites; and rapid changes in mining practices that are leading to new environmental challenges.

The strategy establishes **environmental goals**, to protect human health and ecological resources through pollution prevention, control, and remediation at active, inactive, and/or abandoned mine sites on both Federal and non-Federal lands; **administrative goals**, to use available resources and authorities most efficiently and to focus on the highest priority concerns; and **fiscal responsibility goals**, to promote inter- and intra-governmental efficiency and fiscal responsibility in control of mining sites, as well as to prevent future unfunded public burdens.

Several objectives have been defined in support of these goals, including the following:

- Facilitate coordination with co-regulators: employ a range of approaches to ensure coordination and communication
- Use innovative approaches to foster efficiency: wherever possible, innovative tools (particularly non-regulatory) will be employed to help achieve efficient and timely action

- Consolidate priority-setting: establish multi-agency priorities to maximize scarce resources, help ensure benefits for costs incurred, and address the most problematic sites first
- Promote fiscal/personal responsibility: promote responsibility to help owners reflect true costs of activities and to avoid incurring unnecessary and unfunded environmental and financial burdens for the public
- Enhance capabilities of existing tools: use current administrative authorities to improve environmental problem-solving capabilities
- Be proactive and preventative: ensure that environmental performance standards are quantified to the maximum extent, and that assumptions, risks, and uncertainties are identified
- Promote protective closure standards and adequate financial assurances: establish closure performance standards and bonding requirements that will ensure mines are properly closed and that adequate post-closure care is performed
- Perform timely and environmentally sound clean-up of abandoned mines: ensure that priority inactive and abandoned mines are cleaned up in a timely manner, addressing worst sites first, while avoiding costly efforts addressing mines with little or no environmental effects.

In compliance and enforcement issues, the strategy promotes multi-agency compliance approaches, developing a ranking system for determining inspection priorities, and developing a multi-media inspection protocol for mine sites. Other compliance and enforcement measures include:

- Promoting use of environmental audits within the regulated community
- Conducting an enforcement initiative to target mine owners and operators who violate requirements to obtain and comply with storm water permits
- Compiling and circulating within EPA brief descriptions of successful mining-related enforcement actions brought by the Agency
- Prioritizing action based on the extent of actual human health and environmental impacts; the potential for additional

impacts; the likely success, technical feasibility, and cost effectiveness of response actions; and the availability of staff, equipment, and funding

- Developing enforcement MOAs with other Federal agencies to facilitate consultations and joint actions
- Improving consultation between EPA and the States to determine whether violations of Federal and State law warrant joint enforcement action.

As noted above, however, EPA seeks to strengthen its use of non-regulatory tools to encourage environmental compliance and clean-up at mining sites. These tools are intended to complement existing regulatory programs in addressing mining impacts. Common themes of most non-regulatory approaches include: active participation by principal stakeholders, creative use of funding resources, site-specific flexibility, prioritization of clean-up projects, and regulatory discretion to promote creative problem-solving and early implementation of clean-up projects.

Most non-regulatory approaches have one or more of the following characteristics:

- **Financial** - Financial support often comes from a variety of sources when non-regulatory approaches are used; funds are often leveraged and budgets are typically tight. Other Federal agency funds are often used to supplement EPA funds; State/local partnerships can fill financial holes; and voluntary efforts by private parties can contribute significantly to clean-up of inactive or abandoned mine sites.
- **Institutional** - Interagency Agreements (MOUs, MOAs, and IAGs) are tools that can be used to streamline the mining permitting and regulatory processes; more informally, interagency groups are often used to focus attention on certain projects or issues. Agreements to encourage consistent Federal positions are particularly important for siting criteria, operating criteria, and reclamation and bonding standards.
- **Technical Assistance and Outreach** - Forms of technical assistance vary and may include dedicating either EPA staff or contractor hours to directly help a stakeholder; developing analytic methodologies, such as monitoring and testing standards; providing education and training; and providing materials to small business assistance centers.

EPA has identified several examples of existing approaches to using non-regulatory tools. Site-specific examples include the Coeur D'Alene Basin Restoration Project, the Clear Creek Watershed Project, and the Arizona Copper Mine Initiative. Non-site specific examples include the CWA non-point source funding approaches; RCRA Subtitle D Strawman guidelines; Mining Headwaters Initiative; technology demonstration programs; and the Western Governors' Association Mine Waste Task Force.

As part of its hardrock mining strategy, EPA is developing detailed guidance for regulatory personnel who must apply various regulatory tools to specific mine sites. This matrix will highlight areas of overlap, gaps, unused but available authorities, and synergy among the various regulatory authorities. Envisioned is a document that will present various sources of pollution, a range of possible associated problems/concerns/threats, and a short description of the tools applicable to each situation.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

Compliance Projects

Region VIII has introduced "The Mining Initiative," whose goal is to obtain compliance with the Clean Water Act at active metal mines and metal mining exploration sites. The Regional NPDES program is in the process of determining the compliance status of the active metal mines located in the Region. Most of the mines (98 percent) are located in Colorado, Montana, and Utah. The States are trying to achieve deterrence through high profile enforcement actions which remove the economic advantage of noncompliance by assessing financial penalties.

The Region VIII Water Division is taking an active role in monitoring State enforcement actions against mining facilities and State-issued NPDES permits for mines, encouraging States to apply consistent requirements to all metal mining facilities. EPA has requested that each State appoint a contact to work with EPA on this initiative.

The Bureau of Mines Waste Research Program

In 1988 the debate over the Bevill exclusion wastes and other environmental issues led the Bureau of Mines to initiate a new, comprehensive research program to investigate the environmental problems posed by the mining and minerals processing industry in managing waste. The new research program was named the "Environmental Technology Program" and was established to develop mining technologies that would ameliorate environmental damage caused by mining activities.

The program's main elements are "Control of Mine Drainage and Liquid Wastes" and "Solid Waste Management and Subsidence." Control of Mine Drainage and Liquid Wastes examines acid mine drainage and migration of toxic waters from mines and waste disposal piles that threaten the quality of surface and groundwater. The Solid Waste Management and Subsidence program has two objectives: to investigate management and disposal methods for the solid waste produced by mining and minerals processing; and to develop new technology to mitigate the effects of subsidence and other environmental hazards caused by underground mining. Under ETP, National Mine Land Reclamation Centers have also been established in several regions to investigate the surface effects of mining and the problems associated with reclaiming abandoned, as well as active, mine lands. An important element of the program is cooperation with universities, industry, labor, State and Federal government agencies, and international institutions.

The Bureau of Mines has also established an Environmental Health Research Program to focus on monitoring and controlling airborne dusts and emissions from diesel engines that are inhaled deep into the lungs, and which can cause respiratory diseases. Under this program, a dust monitor is being developed that will continuously evaluate dust conditions during the mineral ore extraction process and will alert workers to hazardous dust concentrations. Dust control techniques are primarily directed at reducing concentrations through use of water sprays, more effective use of ventilation, and modification of mining machine operations. Current Federal regulatory efforts for mining operations seek to limit the amount of diesel soot in the mine environment, while researchers are developing instruments that will allow diesel soot particulate to be sampled and measured in the underground atmosphere. The Bureau of Mines is also conducting research to reduce diesel soot emissions by filtration, ventilation, fuel modifications, and catalytic conversion techniques. Because of the confined, dusty, humid, and often hot conditions in the mine environment, this research will be widely applicable to the most difficult industrial and environmental dust problems.

Mine Safety and Health Administration (MSHA) Mines Initiative

Electrical transformers or capacitors containing polychlorinated biphenyls (PCBs) are often used as power sources in underground mines. This equipment is regulated by EPA to prevent environmental release of PCBs, chemicals classified as probable human carcinogens. Abandoned mines often fill with groundwater, which can cause PCB-containing equipment, if left in place, to corrode and leak chemicals into the water; EPA regulations currently require removal of this equipment prior to mine closure.

EPA and MSHA launched a joint effort in early 1993 to identify all underground mines using electrical transformers or capacitors that contain PCBs. During 1993, MSHA inspectors conducted PCB surveys to identify mines using PCB- or other liquid-filled equipment underground. Inspectors also identified any violations of EPA regulations governing PCB use, marking, storage, or disposal. A total of 85 underground mines that may use PCB-containing equipment were identified. EPA has since used the PCB surveys in its enforcement efforts, resulting in four mining companies being cited for PCB mismanagement and facing Federal penalties of up to $317,575. EPA has settled one of these cases, while filing three additional complaints.

Mine Waste Technology Program (MWTP)

In 1991 Congress allocated $3.5 million to establish a pilot program for treating mine wastes in Butte, Montana. Both bench-scale research and field demonstrations are conducted through the MWTP. Sponsored by EPA's Risk Reduction Engineering Laboratory and the Department of Energy (DOE), the program is implemented by DOE's Western Environmental Technology Office (WETO) contractor, MSE, and the University of Montana's Montana Tech. MWTP program goals include the following:

- Identify mine waste problems that are most severely affecting human health and the environment
- Evaluate engineering and economic factors for selected technologies
- Prioritize the most promising mine waste treatment technologies based on their engineering and economic value
- Demonstrate, test, and evaluate the most promising mine waste treatment technologies
- Accelerate the commercialization of selected mine waste treatment technologies
- Transfer knowledge gained from the above through systematic training of user communities, and the use of workshops, short courses, video outreach, and graduate study support.

The program focuses on developing and proving technologies that offer solutions to the remedial problems facing abandoned mines and the ongoing compliance problems associated with active mines. Other Federal agencies, such as USBM, BLM, and the Forest Service, are also participating in various phases of the research. Within EPA, the Butte program is coordinated and teamed with the Superfund Innovative Technology Evaluation (SITE) program, and is coordinated with the DOIT (Demonstration of Innovative Technologies) Committee of the

Western Governor's Association to assist in technology outreach and coordination among the States most affected by mining activities.

The priority areas for research are:

1) *Source controls, including in situ treatments and predictive techniques.* Such at-source control technologies as sulfate-reducing bacteria, biocyanide oxidation, transport control/pathway interruption techniques, and AMD production prediction techniques will help generate permanent solutions to mining waste problems.

2) *Treatment technologies.* Technologies such as unique reagent utilization and use of natural and enhanced wetlands are high priorities for research to protect the environment from immediate damage until long-range solutions can be developed.

3) *Resource recovery.* Much of the mining wastes represent a potential resource, since they contain significant quantities of heavy metals. Membrane technologies, ion exchange systems, electrochemical separation processes, selective precipitation, enhanced magnetic separation, biological treatment/recovery schemes, and advanced metallurgical processes are techniques that might provide effective and efficient separation and recovery of the metal values in both liquid and solid waste streams.

In addition to those cited previously in the profile, specific MWTP projects include the following:

- *Nitrate Removal Demonstration Project* focuses on developing innovative technologies to remove nitrates from effluent and drinking water through ion exchange, biological denitrification, and electrochemical ion exchange.
- *Neutral Chelating Polymers Research Project* focuses on treating acid mine wastewater by using chelates (chemical substances with more than one binding site on the molecule) to remove metal ions from wastewater.
- *Photoassisted Electron Transfer Reactions Research Project* focuses on treating mine wastewaters by using dissolved and solid photocatalysts to remove toxic cyanide and nitrate anions.
- *Science and Technology Information Retrieval System (STIRS)* facilitates centralized access to various databases developed by EPA, DOE, Bureau of Mines, and others, including CD ROM databases.

- *Remote Mine Site Demonstration Project* seeks to operate a water-powered remote treatment facility for acidic metal-laden mine wastewater, using the Crystal Mine near Basin, Montana. The facility treats 10-25 gallons of wastewater per minute, using a series of rip-rap channels, water wheel-powered feeders, and settling ponds to conduct oxidation, adjust pH levels, and separate solids and liquids for ultimate disposal.
- *Biocyanide Demonstration Project* focuses on using bacteria to degrade cyanide and cyanide complexes in mining wastewater.

Western Governors' Association

Over the past few years, EPA has enlisted the assistance of the States in developing an approach to regulating mining activities under RCRA. In order to facilitate the States' involvement in this effort, EPA has provided funding to the Western Governors' Association (WGA), an independent non-partisan organization of 21 member governors. In 1988, WGA formed a Mine Waste Task Force to coordinate the views of member States and to work with the EPA, the mining industry, the environmental community, and the public to develop workable mine waste management programs.

Kansas State University

Kansas State University's Hazardous Substance Research Center (HSRC) is an EPA-funded center that provides research and technology transfer services for pollution prevention and other waste management techniques, including mining waste. HSRC programs include outreach for industry, assistance to government, education materials, and workshops on pollution prevention and hazardous waste remediation.

VIII.B. EPA Voluntary Programs

EPA sponsors a variety of programs aimed at waste reduction and pollution prevention. Some research-oriented programs, such as the Mining Waste Technology Program, are funded through other Federal and State agencies and are described in previous sections of this profile. Other programs that may serve the metal mining industry are highlighted below.

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations to demonstrate the ELP program principles. These principles include: environmental management systems, multi-media compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In exchange for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek change in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

NICE^3

DOE and EPA's Office of Pollution Prevention are jointly administering a grant program called the "National Industrial Competitiveness through Energy, Environment, and Economics" (NICE^3). By providing grants of up to 50 percent of total project cost, the program encourages industry to reduce industrial waste at its source and to become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries, however priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, 303-275-4729)

VIII.C. Trade Association Activity

The metal mining industry's many associations have been active participants in exploring new avenues of pollution prevention. As noted above, some are participating in Bureau of Mines or MSHA research. A description of various industry associations is provided in the following section.

The trade and professional organizations serving the metal mining industries are primarily organized according to commodity. In light of the controversy over mining law and the possible legislative reform of current mining practices, there are also several associations whose sole intent is to influence the reform process.

National Mining Association 1130 17th St. Washington, D.C. 20036 Phone: (202) 861-2800 Fax: (202) 861-7535	Members: 400 Contact: Richard Lawson

Founded in 1995 with the merger between the American Mining Congress and the National Coal Association, the National Mining Association represents producers of domestic coal, metals, and industrial and agricultural minerals; manufacturers of mining and mineral processing machinery, equipment, and supplies; engineering/consulting firms; and financial institutions that serve the mining industry. The Association also offers tax, communications, and technical workshops.

Coalition for Responsible Mining Law c/o Coeur D'Alene Mines Corp. PO Box 1 Coeur D'Alene, ID 83816-0316 Phone: (208) 667-3511 Fax: (208) 667-2213	Members: 300 Staff: Budget: Contact: Justin Rice

The Coalition for Responsible Mining Law (CRML) comprises mining company executives, exploration geologists, small miners, and others interested in mining laws, organized as a means of coalescing Western mining interests behind a proposal to preserve the basic provisions of the National Mining Law (Mining Law of 1872). The coalition seeks to raise awareness about the law within the mineral industry, Congress, and the general public through specialized education. Publications include a periodic newsletter.

Interstate Mining Compact Commission 459B Carlisle Dr. Herndon, VA 22070 Phone: (703) 709-8654 Fax: (703) 709-8655	Members: 17 Staff: 2 Budget: $150,000 Contact: Gregory E. Conrad

The Interstate Mining Compact Commission (IMCC) is comprised of States engaged in surface mining operations. The commission's purpose is to bring together State officials to discuss mining problems of national scope and significance. An effort is made to promote cooperation between States, private mining groups, and the Federal government, and to discuss, encourage, endorse, or sponsor activities, programs, and legislation to advance mined land reclamation. The IMCC publishes the *NASL Newsletter* quarterly.

Gold

Gold Institute 1112 16th St. NW, Ste. 240 Washington, DC 20036 Phone: (202) 835-0185 Fax: (202) 835-0155	Members: 66 Staff: 10 Budget: Contact: John Lutley

The institute represents gold mining and refining companies, manufacturers of products containing gold, and others who hold and supply gold. The institute advances the gold industry's interests by "developing information from worldwide sources on gold uses, research, technology, markets, and reference data," and encourages the development and use of gold and gold products. Publications include the bi-monthly *Gold News*.

R0076211

Lead

Lead Industries Association 295 Madison Ave. New York, NY 10017 Phone: (212) 578-4750 Fax: (212) 684-7714	Members: 70 Staff: 4 Budget: Contact: Jerome Smith

The Lead Industries Association consists of mining companies, smelters, refiners, and manufacturers of lead products. The association provides technical information to consumers, maintains a library, and gathers statistics. Its primary semi-annual publication is LEAD.

Iron and Steel

American Iron and Steel Institute 1101 17th St. NW, Suite 1300 Washington, DC 20036-4700 Phone: (202) 452-7100 Fax: (202) 463-6573	Members: 1200 Staff: 44 Budget: Contact: Andrew G. Sharkey III

Members of the American Iron and Steel Institute operate steel mills, blast furnaces, finishing mills, and iron ore mines. The Institute conducts extensive research programs on manufacturing technology, basic materials, environmental quality control, energy, and fuels consumption. In addition to technical manuals and pamphlets, the Institute also publishes the *American Iron and Steel Institute-Annual Statistical Report.*

American Iron Ore Association 614 Superior Ave, W Cleveland, OH 44113-1383 Phone: (216) 241-8261 Fax: (216) 241-8262	Members: 12 Staff: Budget: $260,000 Contact: George Ryan

The American Iron Ore Association represents iron ore producing companies in the U.S. and Canada. The organization's goals are to compile and disseminate statistics concerning the iron ore industry, and to provide a forum for discussing industry problems. The Association publishes a variety of documents, among them annual and monthly reports that detail significant occurrences in the industry.

Aluminum

Aluminum Association 900 19th St. NW, Ste. 300 Washington, DC 20006 Phone: (202) 862-5100 Fax: (202) 862-5164	Members: 86 Staff: 27 Budget: $4,300,000 Contact: David Parker

The Aluminum Association consists of producers of aluminum and manufactures of semi-fabricated aluminum products. The association represents members' interests in legislative activity and conducts seminars and workshops. In addition, the Association maintains a library and publishes various documents, including a monthly *Aluminum Situation*.

Copper

American Copper Council 2 South End Ave., No. 4C New York, NY 10280 Phone: (212) 945-4990	Members: 175 Staff: 2 Budget: $300,000 Contact: Mary Boland

The American Copper Council consists of producers, fabricators, merchants, consumers, and traders of copper. The council provides a forum for exchanging news and opinions between copper industry executives and government officials. In addition, the council maintains a relationship with the metal trade press and contributes data and background information related to copper industry events. A newsletter is published quarterly.

Zinc

American Zinc Association 1112 16th St., NW, Suite 240 Washington, DC 20036 Phone: (202) 835-0164 Fax: (202) 835-0155	Contact: George Vary

The AZA is an international association that represents primary and secondary producers of zinc metal, oxide, and dust from the U.S., Canada, Mexico, Australia, Finland, Norway, and Spain, who sell in the U.S. market -- the largest single-country zinc market in the world. The association's primary goal is to promote awareness of and to educate the public about zinc and its many uses; *Zinc Essentials* is the association's newsletter.

EPA Document Availability

Per the March 1, 1995 Federal Register, the following technical documents concerning wastes from non-coal extraction and beneficiation, were issued by the U.S. EPA, and are available at the RCRA docket, EPA Headquarters, Washington, D.C., and all EPA Regional Libraries. Copies of most documents may be purchased from the National Technical Information Service at (800) 553-NTIS. Most documents are also available electronically on the Internet System, through the EPA Public Access Gopher Server.

The following technical resource documents (TRDs) have been peer reviewed by State representatives, Federal land management agencies, mining companies, and public interest groups:

TRD Vol.1: Lead-Zinc (NTIS PB94-170248)
TRD Vol.2: Gold (NTIS PB94-170305)
TRD Vol.3: Iron (NTIS PB94-195203)
TRD Vol.4: Copper (NTIS PB94-200979)
TRD Vol.5: Uranium (NTIS PB94-200987)
TRD Vol.6: Gold Placer (NTIS PB94-201811)
TRD Vol.7: Phosphate & Molybdenum (NTIS PB94-201001)

The documents listed below discuss current mining waste management and engineering practices, and have been peer reviewed by State representatives, Federal land management agencies, mining companies, and public interest groups:

Innovative Methods of Managing Environmental Releases at Mine Sites (NTIS PB94-170255)
Design and Evaluation of Tailings Dams (NTIS PB94-201845)
Treatment of Cyanide Heap Leaches & Tailings (NTIS PB94-201837)
Acid Mine Drainage Prediction (NTIS PB94-201829)

WASTE: An Information Retrieval System for Mill Tailings References (not at NTIS; available electronically or at RCRA docket)

The following documents provide historical context for EPA's mine waste activities:

- Report to Congress on Wastes from the Extraction and Beneficiation of Metallic Ores, Phosphate Rock, Asbestos, Overburden from Uranium Mining, and Oil Shale (NTIS PB88-162631)
- Strawman II (NTIS PB91-178418)
- U.S. EPA Mine Waste Policy Dialogue Committee Meeting Summaries and Supporting Material (NTIS PB95-122529).

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies: environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

MOTOR VEHICLE ASSEMBLY INDUSTRY (SIC 37)

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Motor Vehicle Equipment industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

This industry notebook is designed to provide an overview of the motor vehicles and motor vehicle equipment industry as listed under the Standard Industrial Classification (SIC) code 37. Establishments listed under this code are engaged primarily in the manufacture and assembly of equipment for the transportation of passengers and cargo by land, air, and water.

Due to the broad scope of the industries listed under SIC 37, this notebook will focus on the three-digit SIC 371 which is limited to motor vehicles and motor vehicle equipment (also known as the automotive industry). The primary focus within SIC 371 are numbers 3711 - motor vehicles and passenger car bodies, 3713 - truck and bus bodies, and 3714 - motor vehicle parts and accessories.

Industry groups not covered by this profile include: SIC 372 - Aircraft and Parts; 373 - Ship and Boat Building and Repairing; 374 - Railroad Equipment; 375 - Motorcycles, Bicycles, and Parts; 376 - Guided Missiles and Space Vehicles and Parts; and 379 - Miscellaneous Transportation Equipment. The following automotive products are also not covered in this profile: diesel engines, tires, automobile stampings, vehicular lighting equipment, carburetors, pistons, ignition systems, and cabs for off-highway construction trucks.

II.B. Characterization of Motor Vehicle and Motor Vehicle Equipment Industry

The U.S. motor vehicle and motor vehicle equipment industry is a diverse and technically dynamic industry which plays a vital role in the U.S. economy. The massive size of the automotive industry and the diverse nature of parts required to produce a car requires the support of many other major U.S. industries such as the plastics and rubber industry and the electronic components industry.

R0076238

Facilities involved with the manufacturing of automobiles are located across the U.S. and are organized based on the types of products produced. Businesses involved in the manufacturing of these products range from the large "Big Three" automakers, General Motors Corporation (GM), Ford Motor Company., and Chrysler Corporation, to smaller, independent automotive parts suppliers such as Dana Corporation, Allied Signal, and Borg Warner. Other facilities involved in the manufacture of automobiles include Toyota, Honda, Nissan, Subaru, Isuzu, Auto Alliance, BMW, and Mitsubishi.

II.B.1. Industry Size and Geographic Distribution

The motor vehicle and motor vehicle equipment industry is a key component in the U.S. economy, accounting for a substantial percentage of direct and indirect employment as well as overall industrial output. The vast size and scope of the industry is best understood by examining the quantity and distribution of automotive facilities located around the U.S and the number of individuals employed by these facilities.

The U.S. Industrial Outlook 1994 states that an estimated 6.7 million persons were employed directly and in allied automotive industries in 1991. According to the Department of Commerce's *U.S. Global Trade Outlook, 1995-2000,* in 1992 the total direct employment for SIC 3711, industries manufacturing just motor vehicles and passenger car bodies alone, was 314,000. This figure is down from a peak high in 1985 of 408,000. The U.S. Bureau of Labor Statistics estimates that an additional six percent employment loss will occur by 2005 in the motor vehicles manufacturing industry. This loss in jobs will most likely result from a decrease in the number of individuals needed to manufacture a car.

Most individuals employed by the motor vehicle and motor vehicle equipment industry work at facilities employing between 20 and 49 individuals (See Exhibit 1). These facilities, as well as the larger and smaller operations, are located throughout the United States. The vast majority of production is concentrated in the Great Lakes Region. According to 1991 data in the *AAMA Motor Vehicle Facts and Figures '94,* the Great Lakes Region contains over 1,700 motor vehicle and equipment manufacturers. This figure represents 39 percent of the 4,467 facilities in the United States. California, Missouri, and Texas also post a large number of automotive industries. The number of establishments manufacturing motor vehicles and motor vehicle equipment increased for all size facilities from 1982 to 1987. The value of shipments also increased during the same five year period.

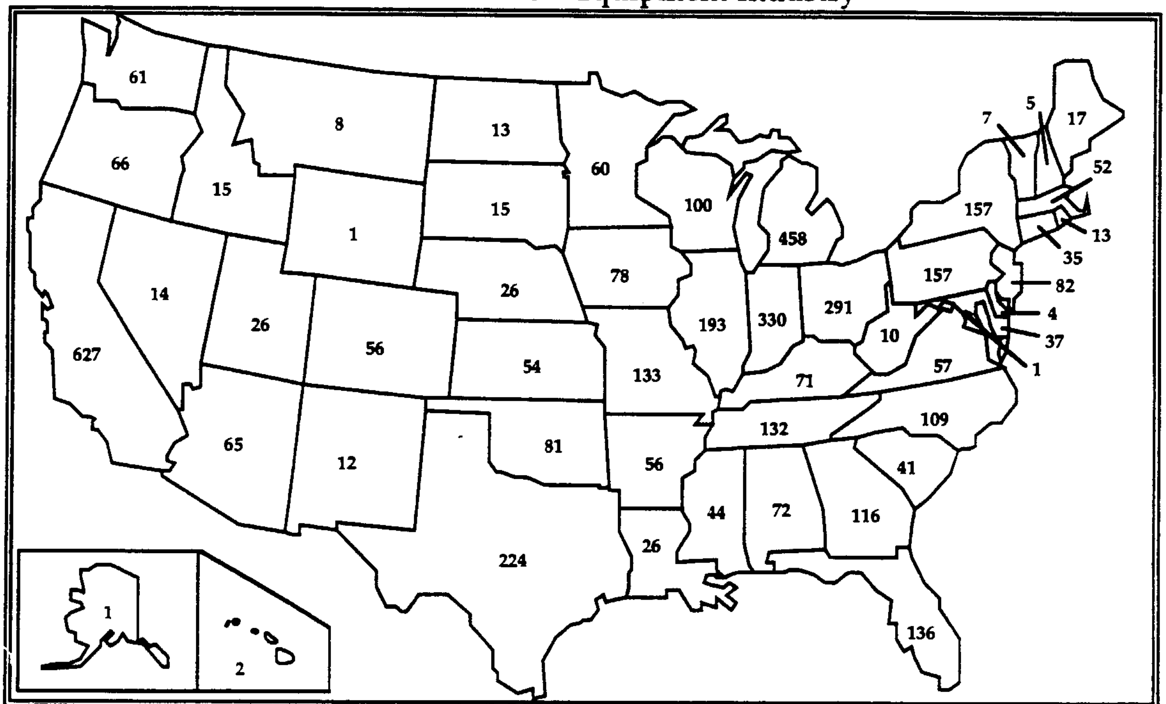
Exhibit 1
Size Distribution of Motor Vehicle and Motor Vehicle Equipment Manufacturing Establishments

	1982		1987	
Number of Employees	**Number of Establishments**	**Value of Shipments (millions of dollars)**	**Number of Establishments**	**Value of Shipments (millions of dollars)**
1-4	851	127.5	918	197.7
5-9	502	246.5	549	407.3
10-19	562	567.5	647	895.9
20-49	579	1,306.9	650	2,132.4
50-99	320	1,897.5	382	2,919.8
100-249	295	4,062.0	362	6,761.1
250-499	148	4,739.9	202	9,475.3
≥500	218	96,580.0	226	177,151.5
Totals	**3,475**	**128,057.4**	**3,936**	**199,941.0**

Source: Census of Manufacturers: 1982, 1987, Bureau of the Census, U.S. Department of Commerce.

States in the Great Lakes Region are home to the majority of automotive assembly plants. As International companies have moved facilities to the U.S., additional States, including Tennessee, California, and Kentucky have become the site of automotive plants. The geographic distribution of manufacturing plants will further increase with the completion of a BMW plant in Spartansburg, SC in 1995 and start of production at the Mercedes Benz plant in January 1997 in Tuscaloosa, AL. Exhibit 2 shows the geographic distribution of industries listed under SIC 37 producing motor vehicles and motor vehicle equipment.

Exhibit 2
Geographic Distribution of the Motor Vehicles and Motor Vehicle Equipment Industry



Source: AAMA Motor Vehicle Facts & Figures '94, compiled from 1991 U.S. Department of Commerce, Bureau of the Census data.

Motor Vehicle Equipment

In 1992, the largest number of automotive parts producers, including approximately 450 relatively small aftermarket part manufacturers, were located in California, while approximately 315 original equipment parts manufacturers were located in Michigan. Indiana and Ohio were the sites of 228 and 205 equipment parts manufacturers respectively. In order to minimize transportation costs and maximize responsiveness to automakers, producers of original equipment parts are located in close proximity to auto assembly facilities; most are located in Michigan, Indiana, Illinois, and Ohio. Conversely, aftermarket suppliers have little incentive to locate near automotive plants and are thus located across the country. A concentration of aftermarket suppliers are located in California, Texas, and Florida.

The U.S. automotive industry is the largest manufacturing industry in North America, accounting for approximately four percent of the gross national product (GNP). The U.S. automotive industry contains the number one and two manufacturers of automobiles in the world, GM and Ford (see Exhibit 3). According to 1993 data from the American Automobile Manufacturers Association (AAMA), the U.S. was the third largest producer of cars in the world, behind Europe and Asia respectively, dominating 30.3 percent of the market.

Exhibit 3
Top 10 Motor Vehicle Manufacturers Ranked by World Production-1994

Manufacturer	Country	Passenger Cars	Commercial Vehicles	Total
General Motors	United States	4,989,938	875,890	6,865,828
Ford	United States	3,685,415	2,058,877	5,744,294
Toyota	Japan	3,649,640	838,251	4,487,891
Volkswagen	Germany	3,119,997	165,699	3,285,696
Nissan	Japan	2,222,985	675,200	2,898,185
PSA	France	2,252,121	185,605	2,437,726
Renault	France	1,929,858	334,473	2,264,331
Chrysler	United States	727,928	1,254,748	1,982,676
Fiat	Italy	1,557,556	242,844	1,800,400
Honda	Japan	1,629,666	132.531	1,762,19

II.B.2. Product Characterization

The motor vehicles and motor vehicle equipment industry produces a wide range of diverse products from ambulances and automobiles to the cylinder heads, ball joints, and horns that go in these vehicles. The Bureau of the Census' SIC code categorizes the automotive industry based on the type of products manufactured. The following is a list of the four-digit SIC codes found under Industry Group Number 371:

SIC 3711 - Motor Vehicle and Passenger Car Bodies
SIC 3713 - Truck and Bus Bodies
SIC 3714 - Motor Vehicle Parts and Accessories
SIC 3715 - Truck Trailers - (not covered in this profile)
SIC 3716 - Motor Homes - (not covered in this profile)

The motor vehicle and motor vehicle equipment industry is organized into four primary areas based on the types of product produced. These areas are: (1) passenger cars and light trucks; (2) medium and heavy duty trucks; (3) truck trailers; (4) and automotive parts and accessories. The automotive parts industry is further broken down into two sectors, original equipment suppliers and aftermarket suppliers. Original equipment suppliers provide parts directly to automakers while aftermarket suppliers provide parts exclusively to the replacement parts market. The original equipment market accounts for approximately 80 percent of all motor vehicle parts and accessories consumed in the U.S., with the remaining 20 percent accounted for by the aftermarket.

II.B.3. Economic Trends

Economic Health

Motor Vehicles

According to the Department of Commerce's *U.S. Global Trade Outlook, 1995-2000,* worldwide sales volume of cars, trucks, and buses have grown 1.2 percent annually during the past ten years. Slow growth in the industry can be attributed to the saturation of the market in developed nations. In order to adjust to the long-term changes in demand, the motor vehicle industry is currently undergoing a global reorganization. Within the next ten years, as companies consolidate and restructure, perhaps as few as ten mega-manufacturing alliances will dominate developed markets.

The Big Three suffered global net losses in 1992 of $30 billion, due in large part to competition from foreign manufacturers. These competitive pressures have stimulated the development of a number of cooperative manufacturing and marketing ventures. Examples of such ventures include GM's "Geo," a compact sedan manufactured in a 50-50 joint venture between GM and Toyota, and a sport-utility vehicle produced in a 50-50 joint venture between GM and Suzuki. Another example is the Ford and Auto Alliance Michigan plant, which manufactures the Ford Probe and the Mazda MX-6 in a 50-50 venture between Ford and Mazda.

Production of passenger cars and light trucks increased 13 percent in 1993. Total sales also increased nine percent from 1992. These increases are likely the result of improvements in vehicle design and added features, product quality, and manufacturing technology. One factor dampening sales in the U.S. market is the fact that the general population is keeping their cars longer. Data collected by the AAMA shows that the mean average age of the passenger cars in the U.S. automobile fleet in 1993 was 8.3 years - the highest since 1948. Another factor expected to effect sales is that fewer individuals will be reaching driving age in the next several years. This negative impact could potentially be offset by the baby boom's entry into their peak earning years, a time when they can afford more expensive cars.

Future growth in the passenger car and light truck sector of the automotive industry is expected to be no more than one to two percent in the coming years. In response to an essentially saturated U.S.

market for new passenger cars and light trucks, competition among foreign and U.S. manufacturers is growing. As a result of this competition, many companies have gone out of business, while others have become more competitive and increased their market share, often by investing in new or renovated facilities. In 1993, motor vehicle and equipment manufacturers spent approximately $12 billion on new plant facilities and equipment (AAMA, 1995), and AAMA estimates that motor vehicle and equipment manufactures spent an additional estimated $15.7 billion in 1994. Another benefit of the increased competition has been a reduction of operating expenses as manufacturers have made strides in improving technology and increasing productivity while reducing overhead.

In 1992, 28 percent of all vehicle miles traveled in the U.S. can be attributed to commercial truck use (AAMA Facts and Figures, 1994). In fact, the U.S. truck market tends to be a magnification of the U.S. economy's business cycle (outside of normal replacement cycles). U.S. sales of medium-and heavy-duty trucks (14,050 gross vehicle weight rating (GVWR) and greater), grew 16 percent between 1993 and 1994, an increase of approximately 50,000 units. Sales for the industry through the first five months of 1995 were 167,000 units, a 22 percent increase over the same period in 1994. New safety regulations outlined by the National Highway Traffic Safety Administration (NHTSA) will impact the truck and trailer industry. Safety performance standards for new anti-lock brake systems are expected to be complete by October 1995. Regulations for automatically adjustable brakes went into effect in October 1993 for hydraulic brakes and for air brakes in October 1994. Regulations proposed by NHTSA for under-ride guards are in the early stages of the regulatory development process. Once in place, these new regulations should reduce the number of fatalities that are attributed to rear-end collisions involving straight body trucks and truck trailers.

Motor Vehicle Equipment

According to the Department of Commerce's *U.S. Global Trade Outlook, 1995-2000,* the U.S. automotive parts industry is emerging from a massive restructuring that has enabled it to greatly strengthen its competitive position in relation to Japan, its major rival. Since 1987, productivity has increased about three percent annually and quality has improved greatly. The global automotive parts market will total about $460 billion in 1995 and an estimated $519 billion in 2000.

In 1992, the U.S. International Trade Commission estimated that there were approximately 5,000 U.S. parts and accessories manufacturers. These manufacturers are estimated to produce 22 percent, or $65 billion, of world production of certain motor vehicle parts. The U.S. is the third largest producer of automotive parts, behind Japan at 35 percent and the European Union at 23 percent of worldwide production. A reduction in passenger car production and an increase in the use of foreign-produced parts has resulted in a decline in shipments of U.S. parts, from $68 billion in 1988 to $65 billion in 1992. The drop in production has resulted in a decline of sales and employment. In 1988, 453,000 were employed in the motor vehicle equipment industry. Employment dropped to a low of 407,000 in 1991 before increasing to 437,000 in 1992.

The industry is currently undergoing a significant restructuring. Factors influencing this restructuring include: increased competition from Japan, new and innovative organizational systems, and the passage of the North American Free Trade Agreement (NAFTA). U.S. automakers and parts producers are trying to produce higher-quality motor vehicles and parts in a more cost effective manner. To accomplish this goal, lean and/or agile production techniques are being implemented. These techniques, which ultimately use less of everything in the production process, also limit the number of direct suppliers of components.

Original equipment suppliers have been subject to changes in supplier relations with the Big Three automakers over the past few years. Between 1988 and 1991, taking advantage of new manufacturing technologies, the Big Three gradually reduced the number of suppliers needed. Chrysler, for example, ordered parts from more than 3,000 suppliers in the 1970s, but by 1993 reduced the number of suppliers to between 600 and 800 per model line. As a result of this change in supplier relationships, original equipment manufacturers have altered their role in the industry by providing automakers with services such as financing for research and development, inventory, logistics, and tooling.

Economic uncertainties caused consumers to defer scheduled maintenance and servicing of their cars between 1988 and 1992. This resulted in a leveling off of aftermarket parts sales during the same years. Industry sources claim that better designed and engineered original equipment parts, such as longer lasting shock absorbers, also contributed to the flat market. New diagnostic technologies which identify possible faulty parts and reduce the need for preventative maintenance also played a role. The market is predicted to see a turn-around based on the Clean Air Act Amendments of 1990 and stricter emissions standards, which is anticipated to result in more used car repairs and an increase in replacement parts.

Future Economic Outlook

Estimates of third-quarter earnings for 1994 show that earnings of U.S. automakers will likely triple from the previous year. This boom in business comes despite plant closures that are traditional during the third quarter due to employee vacations and production changeovers for new fall models. AAMA estimates that the Big Three earned $2.3 billion during the period, compared to $773 million during third-quarter 1993. AAMA indicates that sales and earnings may be dropping in 1995.

According to AAMA, growth has continued through the first quarter of 1995, compared to the same period in 1994, with a combined earnings for the Big Three of about $4.3 billion. Financial strength over the last few quarters has been due, in part, to plants operating at high capacity, and to new models being sold without discounts. The weak dollar and strong Japanese yen also have played a role. Predictions for continued growth of that magnitude through the remainder of 1995, however, are less certain.

In the past 25 years, a growing number of foreign automobile manufacturers have started doing business in the U.S., and they now play an important role in the U.S. economy. Since the mid-1980s, seven large foreign automobile manufacturing plants have been constructed, representing an investment of over $11 billion (See Exhibit 4). According to AIAM, factories which produce automobile brands such as Honda, Isuzu, Mazda, Mitsubishi, Nissan, Subaru, and Toyota, provide approximately 36,000 manufacturing jobs in the U.S.; with over 216,000 jobs in the automotive supply industries. These plants have proven to be extremely efficient, with output increasing 90 percent since 1988. In 1992 alone, 1,787,500 passenger cars were produced in new U.S. factories by international companies, a figure second only to GM's output. One out of every four passenger cars produced in the U.S. today is the product of a foreign manufacturer.

Exhibit 4
Distribution of Automotive Assembly Plants - 1992

State	Number of Big Three Plants	Number of Foreign-Owned Plants
Michigan	16	1
Ohio	2	2
Kentucky	2	1
Illinois	2	1
Tennessee	1	1
Indiana	1	1
California	U.S. Foreign Joint Ventures 1	

Source: Ward's Automotive Reports, Automotive News Market Data Book.

The recent passage of the NAFTA should prove beneficial to the auto industry as goods and services will be able to flow more freely between the U.S. and Mexico and Canada. Although Mexico has been a strong market for U.S. automotive and heavy-duty aftermarket components in the past, exports to Mexico have been limited by quotas and other trade restrictions. The passage of NAFTA and the elimination of past barriers to truck imports should also prove beneficial to medium- and heavy-duty trucks manufacturers, and Mexico could prove to be one of the fastest growing truck markets of this decade.

Another recent development that should facilitate further trade between the U.S. and Mexico was the creation of the Pan American Automotive Components Exposition (PAACE). PAACE, which had its first meeting in July 1994, is sponsored by 12 North American associations. The purpose of the exposition is to bring an international show to the Mexican marketplace as well as establish PAACE as the dominant show for automotive and heavy duty equipment in the future. Plans are currently underway for PAACE 1995.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the Motor Vehicles and Motor Vehicle Equipment industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.
