This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Motor Vehicle and Motor Vehicle Equipment Industry

There is no single production process for Industry Group Number 371. Instead, numerous processes are employed to manufacture motor vehicles and motor vehicle equipment. This section will focus on the significant production processes including those used in the foundry, metal shop, assembly line, and paint shop.

III.A.1. Motor Vehicle Equipment Manufacturing

Motor vehicle parts and accessories include both finished and semi-finished components. Approximately 8,000 to 10,000 different parts are ultimately assembled into approximately 100 major motor vehicle components, including suspension systems, transmissions, and radiators. These parts are eventually transported to an automotive manufacturing plant for assembly.

According to a 1993 publication by the University of Michigan Transportation Research Institute entitled "Material Selection Process in the Automotive Industry," material selection plays a vital role in the production process. Materials are ultimately selected based on factors such as performance (strength vs. durability, surface finish, corrosion resistance), cost, component manufacturing, consumer preference, and competitive responses.

In the past, automobiles have been composed primarily of iron and steel. Steel has remained a major automotive component because of its structural integrity and ability to maintain dimensional geometry throughout the manufacturing process (See Exhibit 5).

In response to increasing demands for more fuel efficient cars, the past ten years have seen changes in the composition of materials used in automobiles (See Exhibit 6). Iron and steel use has steadily decreased, while plastics and aluminum has steadily increased. Aluminum and plastics are valuable car components not only for their lighter weight, but also because of their inherent corrosion resistance. Although the use of plastics in the automotive industry is increasing, expansion in this area is finite because of limitations in current plastics materials.

* Represents consumption per passenger car unit built in the U.S., rounded to the nearest tenth of a pound.

The manufacturing processes used to produce the thousands of discrete parts and accessories vary depending on the end product and materials used. Different process are employed for the production of metal components versus the production of plastic components. Most processes, however, typically include casting, forging, molding, extrusion, stamping, and welding. Exhibit 7 lists major automotive parts and the primary materials and production processes used to manufacture them.

III.A.1.a. *Foundry Operations*

Foundries, whether they are integrated with automotive assembly facilities or independent shops, cast metal products which play a key role in the production of motor vehicles and motor vehicle equipment. As discussed previously, even though aluminum and other metals are used increasingly in the production of automobiles and their parts, iron and steel are still the major metal components of an automobile. Because of this, the following discussion will focus on iron foundries and the typical production processes.

The main steps in producing cast iron motor vehicle products are as follows (see Exhibit 8):

- Pattern design and production
- Sand formulation
- Mold and core production
- Metal heating and alloying
- Metal molding
- Mold shakeout
- Product finishing and heat treating
- Inspection.

The process begins with the mixing of moist silica sand with clay (3 to 20 percent) and water (two to five percent) to produce the "green sand," which forms the basis of the mold. Other additives, including organics such as seacoal or oat hulls, may be added to the green sand to help prevent casting defects. The core is then created using molded sand and often includes binders, such as resins, phenol, and/or formaldehyde. The core is the internal section of a casting used to produce the open areas needed inside such items as an engine or a drive train. After the core has been molded, it is baked to ensure its shape, and then combined with the rest of the casting mold in preparation for casting. At the same time the core is being created, iron is being melted. The iron charge, whether it be scrap or new iron, is combined with coal (as a fuel) and other additives such a calcium carbide and magnesium, and fed into a furnace, which removes sulfur, (usually an electric arc, an electric induction, or a cupola furnace).

Calcium carbide may be added for certain kinds of iron casting, and magnesium is added to produce a more ductile iron. Once the iron reaches the appropriate temperature, it is poured into the prepared mold. The mold then proceeds through the cooling tunnel and is placed on a grid to undergo a process called "shakeout. " During shakeout the grid vibrates, shaking loose the mold and core sand from the casting. The mold and core are then separated from the product which is ready for finishing.

The finishing process is made up of many different steps depending upon the final product. The surface may be smoothed using an oxygen torch to remove any metal snags or chips, it may be blast-cleaned to remove any remaining sand, or it may be pickled using acids to achieve the correct surface. If necessary, the item may be welded to ensure the tightness of any seams or seals. After finishing, the item undergoes a final heat treatment to ensure it has the proper metallurgical properties. The item is then ready for inspection. Inspection may take place in any number of ways be it visually, by x- or gamma ray, ultrasonic, or magnetic particle. Once an item passes inspection, it is ready to be shipped to the assembly area.

III.A.1.b. *Metal Fabricating*

Another major process in the manufacturing of automotive parts is metal fabrication. Metal fabrication involves the shaping of metal components. Many automotive parts, including fenders, hubcaps, and body parts are manufactured in metal fabricating shops. A typical large-scale production of these items starts with molten metal (ferrous or nonferrous) containing the correct metallurgical properties. Once the metal has been produced, it is cast into a shape that can enter the rolling process. Shearing and forming operations are then performed to cut materials into a desired shape and size and bend or form materials into specified shapes.

Shearing (or cutting) operations include punching, piercing, blanking, cutoff, parting, shearing, and trimming. Basically, these are operations that produce holes or openings, or that produce blanks or parts. The most common hole-making operation is punching. Piercing is similar to punching, but produces a raised-edge hole rather than a cut hole. Cutoff, parting, and shearing are similar operations with different applications: parting produces both a part and scrap pieces; cutoff and shearing produce parts with no scrap; shearing is used where the cut edge is straight; and cutoff produces an edge shape other than straight. Trimming is performed to shape or remove excess material from the edges of parts.
Forming operations shape parts by forcing them into a specified configuration, and include bending, forming, extruding, drawing, rolling, spinning, coining, and forging. Bending is the simplest forming operation; the part is simply bent to a specific angle or shape. Bending operations normally produce flat-shapes, while forming produces both two- and three-dimensional shapes.

Extruding is the process of forming a specific shape from a solid blank by forcing the blank through a die of the desired shape. Complicated and intricate cross-sectional shapes can be produced by extruding. Rolling is a process that passes the material through a set or series of rollers that bend and form the part into the desired shape. Coining is a process that alters the form of the part by changing its thickness; it produces a three-dimensional relief on one or both sides of the part, as found on coins.

Drawing and spinning form sheet stock into three-dimensional shapes. Drawing uses a punch to force the sheet stock into a die, where the desired part shape is formed in the space between the punch and die. In spinning, pressure is applied to the sheet while it spins on a rotating form so that the sheet acquires the shape of the form.

Forging operations produce a specific part shape, much like casting. The forging process is used in the automotive industry when manufacturing parts such as pistons, connecting rods, and the aluminum and steel portion of the wheels. However, rather than using molten materials, forging uses externally applied pressure that either strikes or squeezes a heated blank into a die of the required shape. Forging operations use machines that apply repeated hammer blows to a red-hot blank to force the material to conform to the shape of the die opening. Squeezing acts in much the same way, except it uses pressure to squeeze rather than strike the blank. Forging uses a series of die cavities to change the shape of the blank in increments. The blank is moved from station to station in the die to form the part. Depending on the shape, a forging die can have from one to over a dozen individual cavities.

Once shearing and forming activities are complete, the material is machined. This entails shaping or forming a workpiece by removing material from pieces of raw stock with machine tools. The principal processes involved in machining are hole-making, milling, turning, shaping/planing, broaching, sawing, and grinding.

III.A.1.c. *Metal Finishing/Electroplating*

Numerous methods are used to finish metal products. However, prior to applying the finishing application, the surface must be prepared. One of the most important aspects of a finished product is the surface cleanliness and quality. Without a properly cleaned surface, even the most expensive coatings will fail to adhere or prevent corrosion.

Pickling and salt bath processes are used to finish steel products by chemically removing oxides and scale from the surface of the steel. Most carbon steel is pickled with sulfuric or hydrochloric acid, while stainless steel is pickled with hydrochloric, nitric, and hydrofluoric acids. Steel generally passes from the pickling bath through a series of rinses. Alkaline cleansers are used to remove mineral oils and animal fats and oils from the steel surface. Common alkaline cleaning agents include: caustic soda, soda ash, alkaline silicates, and phosphates. Electrolytic cleaning as well as various abrasive methods, such as sand blasting, are also commonly used to remove surface oxides.

Steel products are often coated to inhibit oxidation and extend the life of the product. Coated products can also be painted to further inhibit corrosion. Common coating processes include galvanizing, tin coating, chromium coating, and terne coating (lead and tin). An example of a coated automotive part is the radiator, which is usually spray painted with a chromium coat to prevent corrosion; some water based coats are now being utilized. Rinse water from the coating process may contain zinc, lead, cadmium, or chromium.

Metal finishing and electroplating activities are performed on a number of metals and serve a variety of purposes; the primary purpose being protection against corrosion. This is particularly important to the automotive industry because of the harsh weather and road conditions to which automobiles may be subject. Metal finishing and electroplating can also be performed for decorative purposes. These plating processes involve immersing the article to be coated/plated into a bath consisting of acids, bases, salts, etc.

The metals used in electroplating operations (both common and precious metal plating) include cadmium, lead, chromium, copper, nickel, zinc, gold, and silver. Cyanides are also used extensively in electroplating solutions and in some stripping and cleaning solutions.

Electroless plating is the chemical deposition of a metal coating onto a metal object, by immersion of the object in an appropriate plating solution. In electroless nickel plating, the source of nickel is a salt, and a reducer is used to reduce the nickel to its base state. A complexing agent is used to hold the metal ion in the solution. Immersion plating produces a metal deposit by chemical displacement. Immersion plating baths are usually formulations of metal salts, alkalies, and complexing agents (typically cyanide or ammonia).

Etching is the process used to produce specific design configurations or surface appearances on parts by controlled dissolution with chemical reagents or etchants. Etching solutions are commonly made up of strong acids or bases with spent etchants containing high concentrations of spent metal. The solutions include ferric chloride, nitric acid, ammonium persulfate, chromic acid, cupric chloride, and hydrochloric acid.

Anodizing uses the piece to be coated, generally with an aluminum surface, as an anode in an electrolytic cell. Anodizing provides aluminum parts with a hard abrasion- and corrosion-resistant film. This coating is porous, allowing it to be dyed or to absorb lubricants. This method is used both in decorative applications, including automotive trim and bumper systems, and in engineering applications such as aircraft landing gear struts. Anodizing is usually performed using either sulfuric or chromic acid often followed by a hot water bath, though nickel acetate or sodium potassium dichromate seal may also be used.

III.A.2. Motor Vehicle Assembly

Once the various automotive parts are produced, they are ready to be brought together for assembly. Automotive assembly is a complex process that involves many different steps. Assembly begins with parts which arrive in the assembly plant "just-in-time." "Just-in-time" is a concept that means parts arrive only when they are needed for assembly; only enough product is sent for a given day's work. This concept, which revolutionized the automotive industry, has improved productivity, lowered costs, and provided for better quality management.

Although techniques used to assemble an automobile vary from manufacturer to manufacturer, the first major step in assembly is the body shop. At this stage the car begins to take shape as sides are welded together and then attached to the underbody of the car. The underbody is composed of three primary pieces of galvanized steel which include the floor pan and components for the engine and trunk. After the underbody has been welded together by robotics, it is tested for dimensional and structural accuracy. It is then joined together in a tab-slot fashion with the side frame and various other side-assemblies. A worker then taps tabs into slots, and a robot clamps the tabs. Roof supports and the roof are now ready for installation. The car is now ready for final welding. Approximately 3,500-4,000 spots require welding. Most welding is done by robots, with workers doing only spot jobs. Trunk lids and hoods will then be installed.

III.A.3. Motor Vehicle Painting/Finishing

Automotive finishing is a multi-step process subdivided into four categories: 1) anti-corrosion operations, consisting of cleaning applications, a phosphate bath, and a chromic acid bath; 2) priming operations, consisting of a electrodeposition primer bath, an anti-chip application, and a primer-surfacer application; 3) joint sealant application; and 4) finishing operations, consisting of a color coat application, a clear coat application, and any painting necessary for two-tone color or touch-up applications. The stages of the automotive finishing process are illustrated in Exhibit 9.

After the automobile body has been assembled, anti-corrosion operations prepare the body for the painting/finishing process. Initially, the body is sprayed with and immersed in a cleaning agent, typically consisting of detergents, to remove residual oils and dirt. The body is then dipped into a phosphate bath, typically zinc phosphate, to prevent corrosion. The phosphate process also improves the adhesion of the primer to the metal. The body is then rinsed with chromic acid, further enhancing the anti-corrosion properties of the zinc phosphate coating. The anti-corrosion operations conclude with another series of rinsing steps.

Priming operations further prepare the body for finishing by applying various layers of coatings designed to protect the metal surface from corrosion and assure good adhesion of subsequent coatings. Prior to the application of these primer coats, however, plastic parts to be painted and finished with the body are installed.

As illustrated in Exhibit 10, a primer coating is applied to the body using an electrodeposition method, creating a strong bond between the coating and the body to provide a more durable coating. In electrodeposition, a negatively-charged auto body is immersed in a positively-charged 60,000 to 80,000 gallon bath of primer for approximately three minutes. The coating particles, insoluble in the liquid and positively-charged, migrate toward the body and are, in effect, "plated" onto the body surface.

Exhibit 9
Car Painting Process

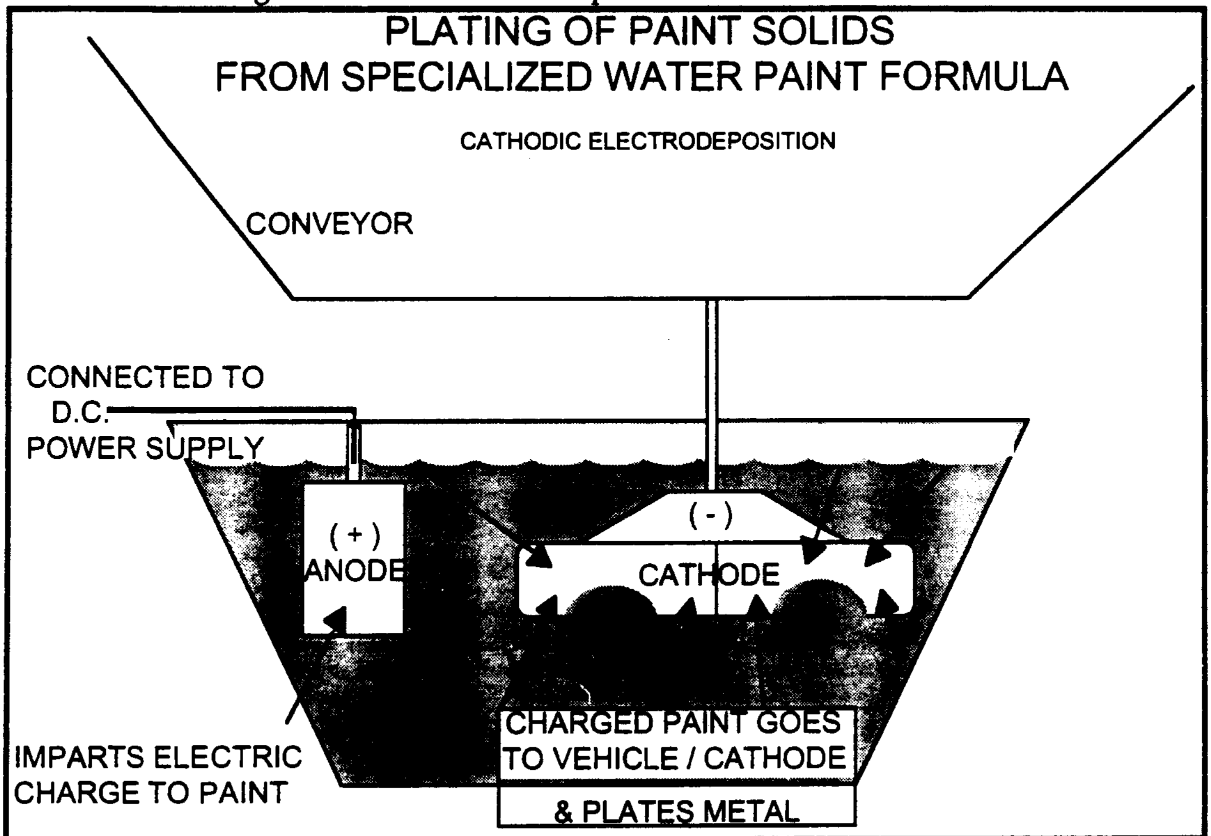
R0076260

Exhibit 10
Plating of Paint Solids from Specialized Water Paint Formula



Source: American Automobile Manufacturers Association.

Although the primer bath is mostly water-based with only small amounts of organic solvent (less than five to ten percent), fugitive emissions consisting of volatile organic compounds (VOCs) can occur. However, the amount of these emissions is quite small. In addition to solvents and pigments, the electrodeposition bath contains lead, although the amount of lead used has been decreasing over the years.

Prior to baking, excess primer is removed through several rinsing stages. The rinsing operations use various systems to recover excess electrodeposited primer. Once the body is thoroughly rinsed, it is baked for approximately 20 minutes at 350 to 380 degrees Fahrenheit. VOC emissions resulting from the baking stage are incinerated at approximately 90 percent of automotive and automotive parts facilities.

Next, the body is further water-proofed by sealing spot-welded joints of the body. Water-proofing is accomplished through the application of a paste or putty-like substance. This sealant usually consists of polyvinyl chloride and small amounts of solvents. The body is again baked to ensure that the sealant adheres thoroughly to the spot-welded areas.

After water-proofing, the automobile body proceeds to the anti-chip booth. Here, a substance usually consisting of a urethane or an epoxy ester resin, in conjunction with solvents, is applied locally to certain areas along the base of the body, such as the rocker panel or the front of the car. This anti-chip substance protects the lower portions of the automobile body from small objects, such as rocks, which can fly up and damage automotive finishes.

The primer-surfacer coating, unlike the initial electrodeposition primer coating, is applied by spray application in a water-wash spray booth. The primer-surfacer consists primarily of pigments, polyester or epoxy ester resins, and solvents. Due to the composition of this coating, the primer-surfacer creates a durable finish which can be sanded. The pigments used in this finish provide additional color layers in case the primary color coating is damaged. The water-wash spray booth is generally 100 to 150 feet long and applies the primer-surfacer in a constant air stream through which the automobile body moves. A continuous stream of air, usually from ceiling to floor, is used to transport airborne particulates and solvents from primer-surfacer overspray. The air passes through a water curtain which captures a portion of the airborne solvents for reuse or treatment at a waste water facility. Efforts have been made at certain facilities to recycle this air to reduce VOC emissions.

After the primer-surfacer coating is baked, the body is then sanded, if necessary, to remove any dirt or coating flaws. This is accomplished using a dry sanding technique. The primary environmental concern at this stage of the finishing process is the generation of particulate matter.

The next step of the finishing process is the application of the primary color coating. This is accomplished in a manner similar to the application of primer-surfacer. One difference between these two steps is the amount of pigments and solvents used in the application process. VOC emissions from primary color coating operations can be double that released from primer-surfacer operations. In addition to the pigments and solvents, aluminum or mica flakes can be added to the primary color coating to create a finish with unique reflective qualities. Instead of baking, the primary color coat is allowed to "flash off," in other words, the solvent evaporates without the application of heat.

Pigments, used to formulate both primers and paints, are an integral part of the paint formulation, which also contains other substances. The pigmented resin forms a coating on the body surface as the solvent dries. The chemical composition of a pigment varies according to its color, as illustrated in Exhibit 11.

Exhibit 11
Chemical Components of Pigments Found in Paint

Pigment Color	Chemical Components
White	Titanium dioxide, white lead, zinc oxide
Red	Iron oxides, calcium sulfate, cadmium selenide
Orange	Lead chromate-molybdate
Brown	Iron oxides
Yellow	Iron oxides, lead chromate, calcium sulfide
Green	Chromium oxide, copper, phosphotungstic acid, phosphomolybdic acid
Blue	Ferric ferrocyanide, copper
Purple	Manganese phosphate
Black	Black iron oxide
Metallic	Aluminum, bronze, copper, lead, nickel, stainless steel, silver, powdered zinc

Source: McGraw Hill Encyclopedia of Science and Technology, 1987.

After the primary color coating is allowed to air-dry briefly, the final coating, a clear coat, is applied. The clear coat adds luster and durability to the automotive finish. This coating generally consists of a modified acrylic or a urethane and is baked for approximately 30 minutes.

Following the baking of the clear coat, the body is inspected for imperfections in the finish. Operators finesse minor flaws through light sanding and polishing and without any repainting.

Once the clear coat is baked, a coating known as deadener is applied to certain areas of the automobile underbody. Deadener, generally a solvent-based resin of tar-like consistency, is applied to areas such as the inside of wheel wells to reduce noise. In addition, anti-corrosion wax is applied to other areas, such as the inside of doors, to further seal the automobile body and prevent moisture damage. This wax contains aluminum flake pigment and is applied using a spray wand.

After painting and finishing, two types of trim are installed - hard and soft. Hard trim, such as instrument panels, steering columns, weather stripping, and body glass, is installed first. The car body is then passed through a water test where, by using phosphorous and a black light, leaks are identified. Soft trim, including seats, door pads, roof panel insulation, carpeting, and upholstery, is then installed. The only VOC emissions resulting from this stage of the process originate from the use of adhesives to attach items, such as seat covers and carpeting.

Next, the automobile body is fitted with the following: gas tank, catalytic converter, muffler, tail pipe, and bumpers. Concurrently, the engine goes through a process known as "dressing," which consists of installing the transmission, coolant hoses, the alternator, and other components. The engine and tires are then attached to the body, completing the assembly process.

The finished vehicle is then rigorously inspected to ensure that no damage has occurred as a result of the final assembly stages. If there is major damage, the entire body part is replaced. However, if the damage is minor, such as a scratch, paint is taken to the end of the line and applied using a hand-operated spray gun. Because the automobile cannot be baked at temperatures as high as in earlier stages of the finishing process, the paint is catalyzed prior to application to allow for faster drying at lower temperatures. Approximately two percent of all automobiles manufactured require this touch-up work. Because the paint used in this step is applied using a hand-operated spray gun, fugitive air emissions are likely to be generated (depending on system design).

R0076264

Generally, spray and immersion finishing methods are to a certain extent interchangeable, and the application method for various coatings varies from facility to facility. The same variance applies to the number and order of rinsing steps for cleaning, phosphating, and electrodeposition primer operations. Spray rinsing the body prior to immersion rinsing decreases the amount of residues deposited in the bath and allows for greater solvent recovery.

In addition to the above-mentioned uses of solvents as ingredients of coatings, solvents are often used in facility and equipment cleanup operations. Efforts have been made at several facilities to reduce the amount of solvent used for this purpose, thereby reducing fugitive VOC emissions, and to reuse these solvents when preparing batches of coatings used in certain stages of the finishing process.

The expanded use of alternative coating methods, such as electrostatic powder spray, is being researched. Powder coatings are being used instead of solvent-based coatings for some initial coating steps, such as the anti-chip and the primer-surfacer process.

III.A.4. Emerging Industry Trends

Motor vehicles manufactured today are produced more efficiently, brought to market more quickly, and designed to be more environmentally sensitive than the models of the 1980s. As a result, these vehicles are proving to have less of a negative impact on the environment. Automobile manufacturers are striving to meet new air emission standards, and are developing motor vehicles and motor vehicle equipment that meet the demands of the growing market niche for "green" automobiles. Much of the information for this section was adapted from the 1994 publication entitled "Automotive Demand, Markets, and Material Selection Processes" by David J. Andrea and Brett C. Smith of the University of Michigan.

In order for motor vehicle and motor vehicle equipment manufacturers to remain competitive, it is becoming more important to strike a balance between environmental issues and industrial demands. Approaches such as life cycle assessment (LCA), design for recycling (DFR™), and design for disassembly (DFD) encourage the development of products that are more environmentally acceptable. These approaches are in various stages of implementation in the automotive industry. Evidence of their influence can be seen in some of the initiatives currently underway in the automotive industry, some of which are addressed later in this profile.

III.A.4.a. *Life Cycle Assessment*

LCA is an environmental approach that focuses on the environmental costs associated with each stage of the product life cycle (See Exhibit 12). LCA requires the evaluation of environmental effect at every stage of the cycle. The evaluation focuses on such factors the waste streams generated during material acquisition and manufacturing, as well as energy consumption during processing and distribution. Attempts to implement this structured approach have begun, although full LCAs for automobiles have not yet been achieved due to product complexity.

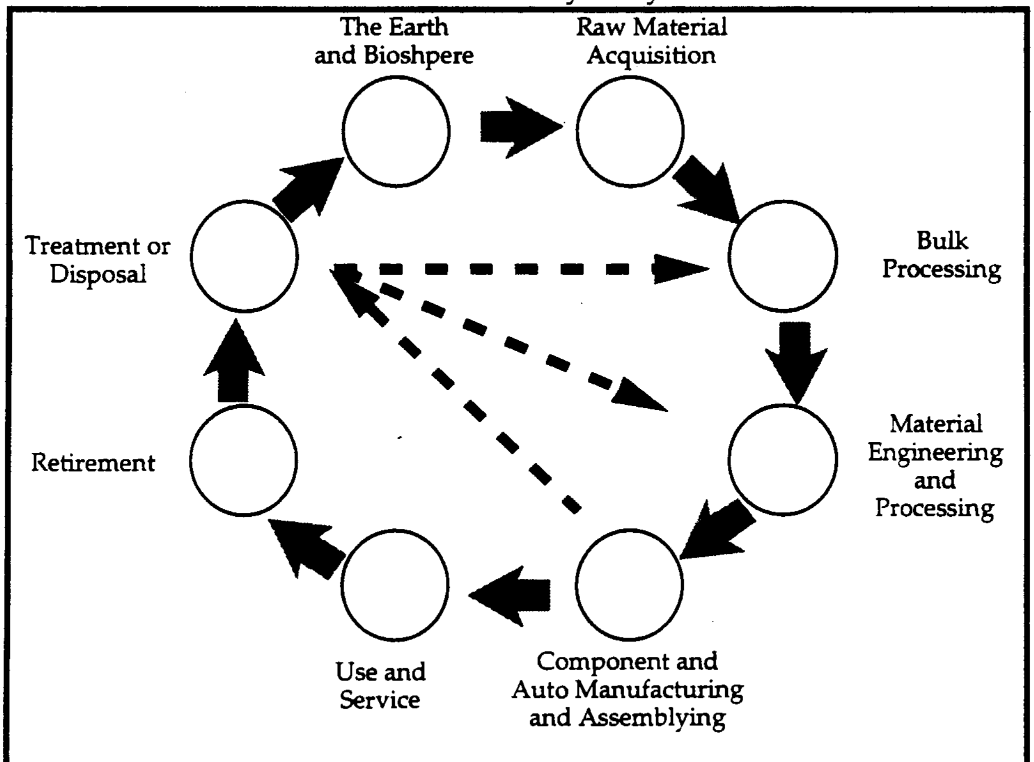
According to General Motors' 1994 Environmental Report, LCA is an important part of the company's commitment to product stewardship. To implement this commitment, GM environmental personnel work closely with vehicle design teams to integrate environmental principles into the earliest possible stages of the product program management process. As part of this process, various statements of work, which specify the health, safety, and facility environmental criteria that must be met before a product can be released to the next development phase, are used to provide a framework for an environmental and health evaluation of GM products. Ford and other automakers are also working to develop LCA technology. LCA promises to be a useful tool and its future applications in the automotive industry should improve overall industry environmental performance.

III.A.4.b. *Recycling*

An important part of LCA is the "retirement" of a given product. Once a product reaches the retirement stage, it becomes eligible for recycling, another environmental trend.

Autos have been recycled for many years in the U.S., and today approximately 94 percent (or approximately 9 million) of all automobiles scrapped in the U.S. are collected and recycled. This effort results in approximately 11 million tons of recycled steel and 800,000 tons of recycled nonferrous metals, and saves an estimated 85 million barrels of oil that would be used to manufacture new parts. The U.S. boasts one of the most effective and prosperous vehicle recycling industries in the world. At least 75 percent of the material collected from scrap vehicles (steel, aluminum, copper) is recycled for raw material use. According to the Automotive Recyclers Association (ARA), the automotive remanufacturing and recycling industry is responsible for approximately five billion dollars in annual sales.

Exhibit 12
The Product Life Cycle System



Source: Automotive Demand, Markets, and Material Selection Process, Society of Automotive Engineers - Technical Paper Series, International Congress & Exposition, Detroit, Michigan, 1994.

Three operations are primarily responsible for vehicle recycling - automobile scrappage/disassembly, automobile shredders, and materials recycling. There are an estimated 12,000 automobile scrappage/disassembly operations in the United States. Vehicles taken to these businesses are subject to two major dismantling steps: (1) drainage and removal of hazardous and recyclable fluids (oil, auto coolants, CFCs), and (2) removal of parts from the vehicle, which, if undamaged, are then cleaned, tested, inventoried, and sold, and if damaged, are recycled with similar materials. The remaining hulk is then flattened and taken to a shredder.

There are an estimated 200 shredding operations in North America. These operations use large machines to shred the hulk into fist-sized pieces which are then separated by material types: ferrous, nonferrous, and automotive shredder residue (ASR) or "shredder fluff."

Shredder output is first sorted by magnetic separation to "capture" the ferrous materials, which are then transported to a mill. Nonferrous metals are then hand-sorted from a conveyor belt and sold for use in new products. The remaining material (approximately 25 percent) is sent to landfills. This material is composed primarily of plastics, rubber, glass, dirt, fibers from carpet, seat foam, and undrained fluids. This waste currently constitutes about 1.5 percent of total municipal landfill waste. The amount of waste generated by shredding will be greatly reduced when vehicles are designed using concepts such as DFR and DFD.

III.A.4.c. *Other Initiatives*

Three important trends impacting vehicle development are: the increased use of lighter weight materials such as aluminum, plastic, and the various composites; the use of alternative fuels; and increased use of electric components.

The Federal Corporate Average Fuel Economy (CAFE) Requirements, which mandate average motor-vehicle fuel economy standards for passenger automobiles and light trucks, will push the increased usage of lighter-weight materials by encouraging lower vehicle weight and increased fuel efficiency. Industry experts predict that the use of lighter weight materials will increase 38 percent between 1992 and 2000. A study conducted by the University of Michigan Transportation Research Institute, Office for the Study of Automotive Transportation (OSAT), entitled Delphi VII, states that industry experts expect to see a three percent drop in average weight of a North American produced automobile by 1998 and an eight percent drop by 2003. Light-truck weight is expected to see similar reductions with a five percent decrease by 1998 and a seven percent decrease by 2003.

In order to produce lighter-weight vehicles, new lightweight materials are needed. The use of materials such as aluminum, magnesium, and plastic could potentially increase 15 to 20 percent by 2003. The use of heavier material such as steel and cast iron, which account for the majority of car weight, is expected to fall 9 to 15 percent within the same time frame (See Exhibit 13). Currently, Ford is the largest user of aluminum per vehicle in North America. In 1991, the use of aluminum in Ford vehicles was 15 percent above the industry average. Likewise, Ford researchers and engineers embarked on the "Synthesis 1020" program, which is part of a $25 million effort to determine the feasibility of a high-volume aluminum intensive vehicle (AIV). Under that initiative, Ford built 40 AIV's which now are being fleet-tested. Chrysler is also exploring the use of aluminum in cars and may begin building an aluminum intensive car in 1996, employing 600 to 700 pounds of aluminum per car. The reduction in weight for a midsize vehicle would cut gasoline consumption by one gallon for each 100 miles driven.

** Percent change in material content

In order to satisfy the requirements of the CAA by lowering the emission of hydrocarbons, carbon monoxide, and oxides of nitrogen, the use of alternative fuel sources is being explored. Various alternatives are being explored with different levels of success (See Exhibit 14). Oxygenated fuels, fuels that are blended with either alcohol or ethers, are slowly becoming more common in the United States. Oxygenated fuels are beneficial because they reduce emissions of carbon monoxide without requiring vehicle adjustments. This is particularly true in older cars (pre-1981) which do not have systems which maintain a constant air-fuel mixture. At least two States with severe carbon monoxide problems, Colorado and Arizona, have implemented mandatory oxygenated fuel programs in order to meet ambient air quality standards. Currently, the State of California plans to mandate the sale of electric cars beginning in 1998. Research and development on electric car technology by the U.S. car companies predates the California mandate by several years. The main problem with manufacturing as well as driving electric cars is the battery; a long-lasting battery has not yet been developed.

Exhibit 14
Use of Alternative Fuels Forecast

Alternative Fuels	Estimate 1992	Passenger Cars Median Response	
		1998	2003
Alcohol or Alcohol/gasoline (>10% alcohol; includes flex fuel or variable fuel)	0.5%	1.0%	5.0%
Diesel	1.2%	1.0%	2.0%
Electric	0.0%	0.2%	2.0%

Natural gas	0.0%	0.5%	2.0%
Propane	0.0%	0.1%	0.5%

Source: UMTRI Research Review, *Delphi VII - Forecast and Analysis of the North American Automotive Industry, Information taken from various OSAT estimates.*

Electronic components such as anti-lock brakes, electric windows, sun- and moon-roofs have become more prominent in vehicles. This being so, producers of specific motor-vehicle parts and accessories will be replaced or transformed from manufacturers of mechanically engineered products to producers of electronic goods. By the year 2000, the proportionate value of electronic components used in the automotive industry is expected to increase by more than 200 percent from 1987 levels. A study by Volkswagen estimates that by the year 2000, approximately 25 percent of a vehicle's manufacturing cost will be attributed to electronics.

III.A.4.d. *Manufacturer Initiatives*

In response to new standards and other environmental concerns, the Big Three have committed substantial resources to researching and developing new technology. One Big Three joint research initiative, under the umbrella of the U.S. Council for Automotive Research (USCAR), is Low Emission Paint Consortium (LEPC), which aims to develop new technologies for low emitting paint processes. In July 1995, the LEPC dedicated a new facility at Wixom, Michigan, to test powder paint and other technologies. In addition to other research initiatives relating to production, USCAR sponsors several that relate to releases from the car. One example is the Low Emissions Technologies Research and Development Partnership. This partnership was formed to explore ways to reduce automotive emissions by improving the performance of catalytic converters and other exhaust related components, and by refining the internal combustion process. The partnership is also researching the feasibility of alternative fuel sources such as ethanol/methanol gasoline mixtures, liquid natural gas (LNG), and liquid petroleum gas.

To respond to perceived future demands for electric cars, The Big Three, together with the U.S. Department of Energy (DOE), formed the U.S. Advanced Battery Consortium. The goal of this consortium is to develop new battery storage technology.

Another Big Three initiative is aimed at developing new materials for vehicles. The U.S. Automotive Materials Partnership will explore the use of materials such as polymer composites, aluminum, plastics, iron, steel, ceramics, and advanced metals. The use of these products in automotive manufacturing is expected to lead to lighter, cleaner, and safer vehicles. Automakers are also exploring the feasibility of developing aluminum vehicles. The Aluminum Association reports that a mid-size sedan using 1,000 pounds of aluminum would be 25 percent lighter and 20 percent more fuel efficient than a car composed entirely of steel. The aluminum content of cars has increased over the years from an average of 78 pounds in 1970 to 191 pounds today.

An additional Big Three initiative - the Vehicle Recycling Partnership (VRP) - is exploring techniques to increase automotive recycling. Although 94 percent of all vehicles are taken to recycling facilities, only 75 percent of a vehicle's actual weight is claimed for recycling purposes. One area of particular interest in automotive recycling is plastics. A recent industry study claims that as much as one billion pounds of automotive plastics end up in landfills. New technologies such as "polymer renewal" recycling are being developed to recycle thermoplastic polyester, nylon, and acetal into first-quality polymers. Ford was the first North American automaker to recycle plastic parts from previously built vehicles. Ford and GM also are making new parts from recycled plastic bumpers. According to AAMA, the automakers are helping to stimulate the market for used materials by incorporating recycled materials into the car. For example, Ford is making: protective seat covers from recycled plastic; splash shields from battery casings; grille opening reinforcements and luggage racks from recycled soda pop bottles; grilles from computer housings and telephones, head lamp housings from plastic water cooler bottles, and on a test basis, brake pedal pads from tires.

Heightened competition has led the Big Three to initiate several jointly funded research products, including the Partnership for a New Generation of Vehicles (PNGV). PNGV is designed to generate technologies that will lead to more environmentally friendly cars. PNGV is joining Federal agencies, under the leadership of the Commerce Department's Technology Administration, to initiate the New Technology Initiative. The goal of this initiative, introduced by

President Clinton in 1993, is to develop a new generation of vehicles with three times greater fuel efficiency.

III.B. Raw Material Inputs and Pollution Outputs

The many different production processes employed to manufacture a motor vehicle require a vast amount of material input and generate large amounts of waste. The outputs resulting from the various stages of production range from air emissions from foundry operations to spent solvents from surface painting and finishing.

Exhibit 15 highlights the production processes, the material inputs, and the various wastes resulting from these operations. Process waste pollutants are treated or neutralized before discharge.

Exhibit 15
Material Inputs/Pollution Outputs

Process	Material Input	Air Emissions	Process Wastes (Waste Water & Liquids	Other Wastes
Metal Shaping				
Metal Cutting and/or Forming	Cutting oils, degreasing and cleaning solvents, acids, and metals	Solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)	Acid/alkaline wastes (e.g., hydrochloric, sulfuric and nitric acids) and waste oils	Metal wastes (e.g., copper, chromium and nickel) and solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)
Heat Treating	Acid/alkaline solutions (e.g., hydrochloric and sulfuric acid), cyanide salts, and oils		Acid/alkaline wastes, cyanide wastes, and waste oils	Metal wastes (e.g., copper, chromium, and nickel)
Surface Preparation				
Solvent Cleaning	Acid/alkaline cleaners and solvents	Solvent wastes (e.g., acetone, xylene, toluene, etc.)	Acid/alkaline wastes	Ignitable wastes, solvent wastes, (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.) and still bottoms
Pickling	Acid/alkaline solutions		Acid/alkaline wastes	Metal wastes
Surface Finishing				
Electroplating	Acid/alkaline solutions, metal bearing and cyanide bearing solutions		Acid/alkaline wastes, cyanide wastes, plating wastes, and wastewaters	Metal wastes, reactive wastes, and solvent wastes

R0076273

Exhibit 15
Material Inputs/Pollution Outputs (cont'd)

Process	Material Input	Air Emissions	Process Wastes (Waste Water & Liquids	Other Wastes
Surface Finishing (contd)				
Surface Finishing	Solvents	Solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)		Metal paint wastes, solvent wastes, ignitable paint wastes, and still bottoms
Facility Cleanup	Solvents	Solvent wastes (e.g., 1,1,1-trichloroethane, acetone, xylene, toluene, etc.)		Solvent wastes and still bottoms

The discussion of pollution outputs from automotive manufacturing follows the same format as the discussion of the manufacturing process: foundry operations; metal fabricating; metal finishing; assembly; painting/coating; and dismantling/shredding.

III.B.1. Foundry Operations

Iron foundries create a number of wastes which may pose environmental concerns. Gas and particulate emissions are a concern throughout the casting process. Dust created during sand preparation, molding, and shakeout is of concern due to the carcinogenic potential of the crystalline silica in the sand. Gases containing lead and cadmium and other particulate matter and sulfur dioxide are also created during foundry operation, especially during the melting of the iron.

The wastewaters generated during foundry operations may also be of an environmental concern. Wastewaters are generated primarily during slag quenching operations (water is sprayed on the slag to both cool it as well as pelletize it) and by the wet scrubbers employed as air pollution control devices connected to furnaces and sand and shakeout operations. Due to the presence of cadmium and lead in iron, these metals may both be present in wastewaters.

Foundry operations also create many waste materials that meet the definition of a RCRA hazardous waste. Of primary concern is the calcium carbide desulfurization slag created during the melting of the iron. This slag readily reacts with water to create acetylene gas, a trait which causes it to be classified as a D003 reactive hazardous waste. Other materials such as wastewater sludges and baghouse dust may also fail the toxicity characteristic for lead and cadmium and would then be classified as D008 and D006 respectively. Foundries may also use solvents for cleaning, which when spent, may be characterized as characteristic (ignitable or toxic) or listed hazardous waste depending upon the formulations used.

III.B.2. Metal Fabricating

Each of the metal shaping processes can result in wastes containing constituents of concern (depending on the metal being used). In general, there are two categories of waste generated in metal shaping operations: scrap metal and metalworking fluids/oils.

Scrap metal may consist of metal removed from the original piece (e.g., steel or aluminum). Quite often, scrap is reintroduced into the process as a feedstock.

In general, metalworking fluids can be petroleum-based, oil-water emulsions, or synthetic emulsions that are applied to either the tool or the metal being tooled to facilitate the shaping operation. Metalworking fluid is used to:

- Keep tool and workpiece temperature down and aid lubrication,
- Provide a good finish
- Wash away chips and metal debris
- Inhibit corrosion or surface oxidation.

Metalworking fluids typically become contaminated and spent with extended use and reuse. When disposed, these oils may contain constituents of concern, including metals (cadmium, chromium, and lead), and therefore must be tested to see if they are considered a RCRA hazardous waste. Many fluids may contain chemical additives such as chlorine, sulfur and phosphorus compounds, phenols, cresols, and alkalines. In the past, such oils have commonly been mixed with used cleaning fluids and solvents (including chlorinated solvents). Air emissions may result through volatilization during storage, fugitive losses during use, and direct ventilation of fumes.

Surface preparation operations generate wastes contaminated with solvents and/or metals depending on the type of cleaning operation. Concentrated solvent-bearing wastes and releases may arise from degreasing operations. Degreasing operations may result in solvent-bearing wastewaters, air emissions, and materials in solid form.

R0076275

Solvents may be rinsed into wash waters and/or spilled into floor drains. Although contamination of the wastewater is possible, procedures are in place to prevent such pollution in the first place. Air emissions may result through volatilization during storage, fugitive losses during use, and direct ventilation of fumes. Any solid wastes (e.g., wastewater treatment sludges, still bottoms, cleaning tank residues, machining fluid residues, etc.) generated by the operation may be contaminated with solvents, some of which may meet RCRA hazardous waste listings F001 and F005.

Chemical treatment operations can result in wastes that contain metals of concern. Alkaline, acid, mechanical, and abrasive cleaning methods can generate waste streams such as spent cleaning media, wastewaters, and rinse waters. Such wastes consist primarily of the metal complexes or particles, the cleaning compound, contaminants from the metal surface, and water. In many cases, chemical treatment operations are used in conjunction with organic solvent cleaning systems. As such, many of these wastes may be cross-contaminated with solvents.

The nature of the waste will depend upon the specific cleaning application and manufacturing operation. Wastes from surface preparation operations may contribute to commingled waste streams such as wastewaters discharged to centralized treatment. Further, such operations can result in direct releases such as fugitive emissions and easily segregated wastes such as cleaning tank residues.

III.B.3. Metal Finishing

Surface finishing and related washing operations account for a large volume of wastes associated with automotive metal finishing. Metal plating and related waste account for the largest volumes of metal (e.g., cadmium, chromium, copper, lead, mercury, and nickel) and cyanide-bearing wastes.

Electroplating operations can result in solid and liquid wastestreams that contain constituents of concern. Liquid wastes result from workpiece rinses and process cleanup waters. Most surface finishing (and many surface preparation) operations result in liquid wastestreams. Centralized wastewater treatment systems are common, and can result in solid-phase wastewater treatment sludges. In addition to these wastes, spent process solutions and quench bathes are discarded periodically when the concentrations of contaminants inhibit proper function of the solution or bath. When discarded, process bathes usually consist of solid- and liquid-phase wastes that may contain high concentrations of the constituents of concern, especially cyanide (both free and complex).

Related operations, including all non-painting processes, can contribute wastes including scrap metals, cleaning wastewaters, and other solid materials. The nature of these wastes will depend on the specific process, the nature of the workpiece, and the composition of materials used in the process.

III.B.4. Motor Vehicle Assembly

Due to advances in technology, well designed operating procedures, and the implementation of strategies to limit waste from assembly, little hazardous waste is generated during the actual assembly of an automobile (with the exception of painting/finishing which is discussed in the following section).

The majority of wastes generated during assembly are solid wastes resulting from parts packaging. Parts packaging can be grouped into two categories - returnable and expendable. Returnable packaging (containers) is shipped back to the original suppliers once empty. It includes such items as: metal racks, metal skids, returnable bins, totes, and rigid plastic racks and dunnage. Expendable packaging is used once and recycled, for the most part. Examples include styrofoam peanuts, wood skids, plastic, corrugated boxes, metal barding, and shrink-wrap. Advances in packaging design, changes in purchasing, and the elimination of unneeded materials have greatly reduced the amount of expendable waste generated.

Additional wastes generated from assembly operations may be attributed to general plant operations, cleaning and maintenance, as well as the disposal of faulty equipment and parts.

III. B.5. Motor Vehicle Painting/Finishing

Many of the wastes generated during automotive production are the result of painting and finishing operations. These operations result in air emissions as well as the generation of solid and liquid wastes.

Air emissions, primarily VOCs, result from the painting and finishing application processes (paint storage, mixing, applications, and drying) as well as cleaning operations. These emissions are composed mainly of organic solvents which are used as carriers for the paint. Solvents are also used during cleanup processes to clean spray equipment between color changes, and to clean portions of the spray booth. The solvent utilized during cleaning is generally referred as "purge solvent" and is often composed of a mixture of dimethyl-benzene, 2-Pranone, 4-methyl-2-pentanone, butyl ester acetic acid, light aromatic solvent naphtha, ethyl benzene, hydrotreated heavy naphtha, 2-butanone, toluene, and 1-butanol.

Various solid and liquid wastes may be generated throughout painting operations and are usually the result of the following operations:

- Paint application - paint overspray caught by emissions control devices (e.g., paint booth collection systems, ventilation filters, etc.);
- Paint drying - ventilated emissions as paint carriers evaporate;
- Cleanup operations - cleaning of equipment and paint booth area; and
- Disposal - discarding of leftover and unused paint as well as containers used to hold paints, paint materials, and overspray.

Solid and liquid wastes may also contain metals from paint pigments and organic solvents.

III. C. Post Production Motor Vehicle Dismantling/Shredding

Dismantling operations involve both automotive fluids and solids. The fluids, such as engine oil, antifreeze, and air conditioning refrigerant, are recovered to the extent possible, reprocessed for reuse or sent to energy recovery facilities. Many solid parts, such as the radiator and catalytic converter, contain valuable metal materials which are removed for recycling or reuse. In addition, the dismantler will remove and recycle the battery, fuel tank, and tires to reduce shredder processing concerns. The shredder processes the remaining automotive hulk, along with other metallic goods (such as household appliances), into ferrous materials, non-ferrous materials, and shredder residue. The residue is a heterogeneous mix that may include plastics, glass, textiles, metal fines, and dirt. This material is predominantly landfilled.

III. D. Management of Chemicals in Wastestream

The Pollution Prevention Act of 1990 (EPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The EPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 16 shows that the motor vehicle, bodies, parts and accessories industry managed about 333 million pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, 66% was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 33% of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E and F, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production-related wastes (25.7%), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has decreased and the portions treated or managed through energy recovery on-site have increased between 1992 and 1995 (projected).

Exhibit 16
Source Reduction and Recycling Activity for SIC 37

A	B	C	D	E	F	G	H	I	J
	Production Related Waste Volume	% Reported As Released and	On-Site			Off-Site			Remaining Releases and
Year	(10^6lbs.)	Transferred	% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated	Disposal
1992	333	65%	19.99%	0.26%	12.38%	36.54%	3.99%	2.27%	25.84%
1993	333	66%	18.42%	0.23%	14.75%	34.11%	3.82%	2.97%	25.71%
1994	317	—	14.47%	0.35%	16.54%	34.96%	3.97%	3.36%	26.36%
1995	337	—	15.60%	0.28%	15.81%	36.89%	3.92%	3.21%	24.48%

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7% between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount, and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) - encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of waste to on-site landfills, waste that is land treated or incorporated into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Motor Vehicles and Motor Vehicle Equipment Industry

Exhibits 17-21 illustrate the TRI releases and transfers for the motor vehicles and motor vehicle equipment industry (SIC 37). Exhibit 18 shows the top TRI releasing transportation equipment facilities. As shown in Exhibit 19, the majority of TRI reporting facilities are located in Michigan, Ohio, Indiana, Illinois, and Tennessee. As mentioned earlier, these States, with the exception of Tennessee, have historically been the focal point of automobile manufacturing.

For the industry as a whole, solvents such as toluene, xylene, methyl ethyl ketone, and acetone, comprise the largest number of TRI releases. The large of quantity of solvent release, both fugitive and point source can be attributed to the solvent-intensive finishing processes employed by the industry. In addition to being used to clean equipment and metal parts, solvents are a component found in many of the coating and finishes applied to automobile during the assembly and painting/finishing operations.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear in Exhibit 17. Exhibit 18 contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, Exhibit 18 includes facilities that conduct multiple operations — some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

IV.B. Summary of Selected Chemicals Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the 1993 Toxics Release Inventory Public Data Release (EPA, 1994), and the Hazardous Substances Data Bank (HSDB), accessed via TOXNET. The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET[1]. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB.

The top TRI release for the motor vehicles and motor vehicle equipment industry (SIC 37) as a whole are as follows: toluene, xylene, methyl ethyl ketone, acetone, glycol ethers, 1,1,1,-trichloroethane, styrene, trichloroethylene, dichloromethane, and methanol. Summaries for several of these chemicals are provided below.

Acetone

Toxicity. Acetone is irritating to the eyes, nose, and throat. Symptoms of exposure to large quantities of acetone may include headache, unsteadiness, confusion, lassitude, drowsiness, vomiting, and respiratory depression.

Reactions of acetone (see environmental fate) in the lower atmosphere contribute to the formation of ground-level ozone. Ozone (a major component of urban smog) can affect the respiratory system, especially in sensitive individuals such as asthmatics or allergy sufferers.

---

1 TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released into water, acetone will be degraded by microorganisms or will evaporate into the atmosphere. Degradation by microorganisms will be the primary removal mechanism.

Acetone is highly volatile, and once it reaches the troposphere (lower atmosphere), it will react with other gases, contributing to the formation of ground-level ozone and other air pollutants. EPA is reevaluating acetone's reactivity in the lower atmosphere to determine whether this contribution is significant.

Physical Properties. Acetone is a volatile and flammable organic chemical.

Note: Acetone was removed from the list of TRI chemicals on June 16, 1995 (60 FR 31643) and will not be reported for 1994 or subsequent years.

Glycol Ethers

Due to data limitations, data on diethylene glycol (glycol ether) are used to represent all glycol ethers.

Toxicity. Diethylene glycol is only a hazard to human health if concentrated vapors are generated through heating or vigorous agitation or if appreciable skin contact or ingestion occurs over an extended period of time. Under normal occupational and ambient exposures, diethylene glycol is low in oral toxicity, is not irritating to the eyes or skin, is not readily absorbed through the skin, and has a low vapor pressure so that toxic concentrations of the vapor can not occur in the air at room temperatures.

At high levels of exposure, diethylene glycol causes central nervous depression and liver and kidney damage. Symptoms of moderate diethylene glycol poisoning include nausea, vomiting, headache, diarrhea, abdominal pain, and damage to the pulmonary and cardiovascular systems. Sulfanilamide in diethylene glycol was once used therapeutically against bacterial infection; it was withdrawn from the market after causing over 100 deaths from acute kidney failure.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Diethylene glycol is a water-soluble, volatile organic chemical. It may enter the environment in liquid form via petrochemical plant effluents or as an unburned gas from combustion sources. Diethylene glycol typically does not occur in sufficient concentrations to pose a hazard to human health.

Methanol

Toxicity. Methanol is readily absorbed from the gastrointestinal tract and the respiratory tract, and is toxic to humans in moderate to high doses. In the body, methanol is converted into formaldehyde and formic acid. Methanol is excreted as formic acid. Observed toxic effects at high dose levels generally include central nervous system damage and blindness. Long-term exposure to high levels of methanol via inhalation cause liver and blood damage in animals.

Ecologically, methanol is expected to have low toxicity to aquatic organisms. Concentrations lethal to half the organisms of a test population are expected to exceed 1 mg methanol per liter water. Methanol is not likely to persist in water or to bioaccumulate in aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Liquid methanol is likely to evaporate when left exposed. Methanol reacts in air to produce formaldehyde which contributes to the formation of air pollutants. In the atmosphere it can react with other atmospheric chemicals or be washed out by rain. Methanol is readily degraded by microorganisms in soils and surface waters.

Physical Properties. Methanol is highly flammable.

Methylene Chloride (Dichloromethane)

Toxicity. Short-term exposure to dichloromethane (DCM) is associated with central nervous system effects, including headache, giddiness, stupor, irritability, and numbness and tingling in the limbs. More severe neurological effects are reported from longer-term exposure, apparently due to increased carbon monoxide in the blood from the break down of DCM. Contact with DCM causes irritation of the eyes, skin, and respiratory tract.

Occupational exposure to DCM has also been linked to increased incidence of spontaneous abortions in women. Acute damage to the eyes and upper respiratory tract, unconsciousness, and death were reported in workers exposed to high concentrations of DCM. Phosgene (a degradation product of DCM) poisoning has been reported to occur in several cases where DCM was used in the presence of an open fire.

Populations at special risk from exposure to DCM include obese people (due to accumulation of DCM in fat), and people with impaired cardiovascular systems.

Carcinogenicity. DCM is a probable human carcinogen via both oral and inhalation exposure, based on inadequate human data and sufficient evidence in animals.

Environmental Fate. When spilled on land, DCM is rapidly lost from the soil surface through volatilization. The remainder leaches through the subsoil into the groundwater.

Biodegradation is possible in natural waters but will probably be very slow compared with evaporation. Little is known about bioconcentration in aquatic organisms or adsorption to sediments but these are not likely to be significant processes. Hydrolysis is not an important process under normal environmental conditions.

DCM released into the atmosphere degrades via contact with other gases with a half-life of several months. A small fraction of the chemical diffuses to the stratosphere where it rapidly degrades through exposure to ultraviolet radiation and contact with chlorine ions. Being a moderately soluble chemical, DCM is expected to partially return to earth in rain.

Methyl Ethyl Ketone

Toxicity. Breathing moderate amounts of methyl ethyl ketone (MEK) for short periods of time can cause adverse effects on the nervous system ranging from headaches, dizziness, nausea, and numbness in the fingers and toes to unconsciousness. Its vapors are irritating to the skin, eyes, nose, and throat and can damage the eyes. Repeated exposure to moderate to high amounts may cause liver and kidney effects.

Carcinogenicity. No agreement exists over the carcinogenicity of MEK. One source believes MEK is a possible carcinogen in humans based on limited animal evidence. Other sources believe that there is insufficient evidence to make any statements about possible carcinogenicity.

Environmental Fate. Most of the MEK released to the environment will end up in the atmosphere. MEK can contribute to the formation of air pollutants in the lower atmosphere. It can be degraded by microorganisms living in water and soil.

Physical Properties. Methyl ethyl ketone is a flammable liquid.

Toluene

Toxicity. Inhalation or ingestion of toluene can cause headaches, confusion, weakness, and memory loss. Toluene may also affect the way the kidneys and liver function.

Reactions of toluene (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Some studies have shown that unborn animals were harmed when high levels of toluene were inhaled by their mothers, although the same effects were not seen when the mothers were fed large quantities of toluene. Note that these results may reflect similar difficulties in humans.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases of toluene to land and water will evaporate. Toluene may also be degraded by microorganisms. Once volatized, toluene in the lower atmosphere will react with other atmospheric components contributing to the formation of ground-level ozone and other air pollutants.

Physical Properties. Toluene is a volatile organic chemical.

1,1,1-Trichloroethane

Toxicity. Repeated contact of 1,1,1-trichloroethane (TCE) with skin may cause serious skin cracking and infection. Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations.

Exposure to high concentrations of TCE causes reversible mild liver and kidney dysfunction, central nervous system depression, gait disturbances, stupor, coma, respiratory depression, and even death. Exposure to lower concentrations of TCE leads to light-headedness, throat irritation, headache, disequilibrium, impaired coordination, drowsiness, convulsions and mild changes in perception.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of TCE to surface water or land will almost entirely volatilize. Releases to air may be transported long distances and may partially return to earth in rain. In the lower atmosphere, TCE degrades very slowly by photooxidation and slowly diffuses to the upper atmosphere where photodegradation is rapid.

Any TCE that does not evaporate from soils leaches to groundwater. Degradation in soils and water is slow. TCE does not hydrolyze in water, nor does it significantly bioconcentrate in aquatic organisms.

Trichloroethylene

Toxicity. Trichloroethylene was once used as an anesthetic, though its use caused several fatalities due to liver failure. Short term inhalation exposure to high levels of trichloroethylene may cause rapid coma followed by eventual death from liver, kidney, or heart failure. Short-term exposure to lower concentrations of trichloroethylene causes eye, skin, and respiratory tract irritation. Ingestion causes a burning sensation in the mouth, nausea, vomiting and abdominal pain. Delayed effects from short-term trichloroethylene poisoning include liver and kidney lesions, reversible nerve degeneration, and psychic disturbances. Long-term exposure can produce headache, dizziness, weight loss, nerve damage, heart damage, nausea, fatigue, insomnia, visual impairment, mood perturbation, sexual problems, dermatitis, and rarely jaundice. Degradation products of trichloroethylene (particularly phosgene) may cause rapid death due to respiratory collapse.

Carcinogenicity. Trichloroethylene is a probable human carcinogen via both oral and inhalation exposure, based on limited human evidence and sufficient animal evidence.

Environmental Fate. Trichloroethylene breaks down slowly in water in the presence of sunlight and bioconcentrates moderately in aquatic organisms. The main removal of trichloroethylene from water is via rapid evaporation.

Trichloroethylene does not photodegrade in the atmosphere, though it breaks down quickly under smog conditions, forming other pollutants such as phosgene, dichloroacetyl chloride, and formyl chloride. In addition, trichloroethylene vapors may be decomposed to toxic levels

R0076296

of phosgene in the presence of an intense heat source such as an open arc welder.

When spilled on the land, trichloroethylene rapidly volatilizes from surface soils. The remaining chemical leaches through the soil to groundwater.

Xylene (Mixed Isomers)

Toxicity. Xylenes are rapidly absorbed into the body after inhalation, ingestion, or skin contact. Short-term exposure of humans to high levels of xylenes can cause irritation of the skin, eyes, nose, and throat, difficulty in breathing, impaired lung function, impaired memory, and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations can cause effects such as headaches, dizziness, confusion, and lack of muscle coordination. Reactions of xylenes (see environmental fate) in the atmosphere contribute to the formation of ozone in the lower atmosphere. Ozone can affect the respiratory system, especially in sensitive individuals such as asthma or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. The majority of releases to land and water will quickly evaporate, although some degradation by microorganisms will occur.

Xylenes are moderately mobile in soils and may leach into groundwater, where they may persist for several years.

Xylenes are volatile organic chemicals. As such, xylenes in the lower atmosphere will react with other atmospheric components, contributing to the formation of ground-level ozone and other air pollutants.

IV.C. Other Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 22 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 22

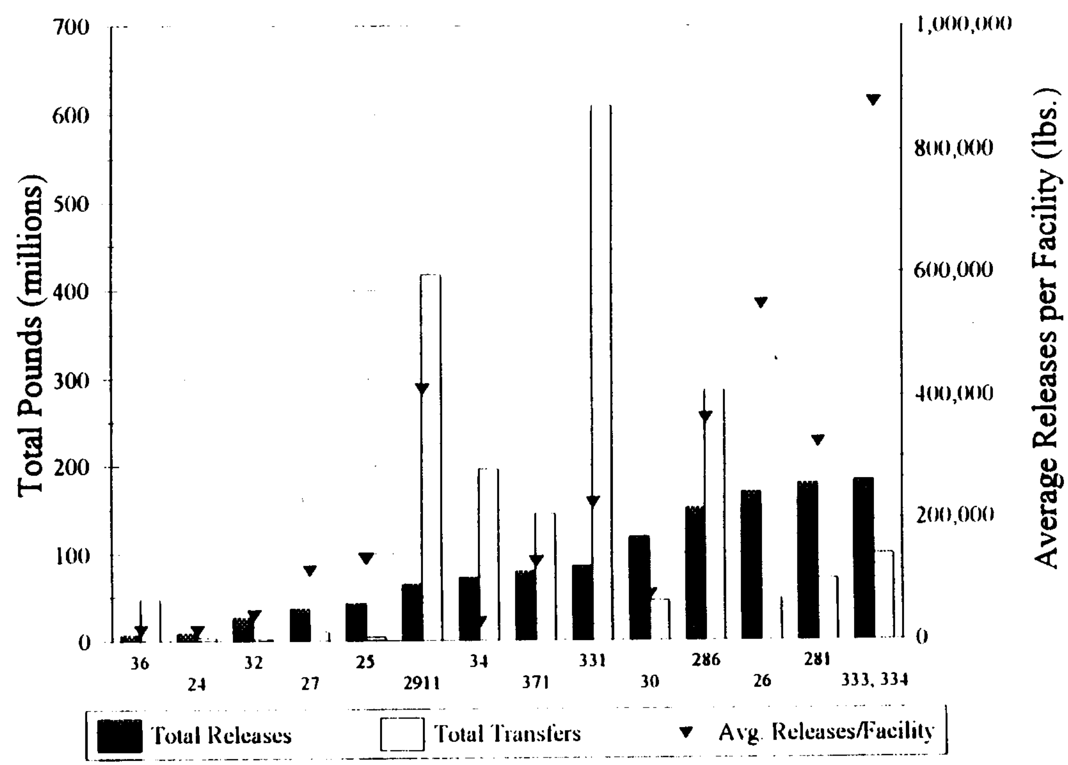
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following table does not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release book.

Exhibit 23 is a graphical representation of a summary of the 1993 TRI data for the motor vehicles assembly industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 24 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the motor vehicles assembly industry, the 1993 TRI data presented here covers 609 facilities. These facilities listed SIC 37 (Motor Vehicles Assembly Industry) as a primary SIC code.

Exhibit 23: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg.
24	Lumber and Wood Products	34	Fabricated Metals	26	Pulp and Paper
32	Stone, Clay, and Concrete	371	Motor Vehicles, Bodies, Parts, and Accecessories	281	Inorganic Chemical Mfg.
27	Printing	331	Iron and Steel	333, 334	Nonferrous Metals
25	Wood Furniture and Fixtures	30	Rubber and Misc. Plastics

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the Motor Vehicles and Motor Vehicle Equipment industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

Much of the automotive industry is involved in exploring pollution prevention opportunities. The discussion which follows highlights some of the current pollution prevention activities undertaken by manufacturers involved in all stages of the automotive manufacturing process. This is just a sampling of the numerous pollution prevention/waste minimization efforts currently underway.

V.A. Motor Vehicle Equipment Manufacturing

Non-Production Material Screening

As part of its Non-Production Material approval system, Chrysler Corporation implemented pollution prevention practices to eliminate, substitute, or reduce, to the extent possible, regulated substances from both products supplied to Chrysler as well as those resulting from their manufacturing process. First implemented in April 1993, the environmental strategy focuses on avoiding the use of regulated substances and materials of concern whenever possible as part of an effort to eliminate "end-of-pipe" controls. One example of how this screening approach has been utilized was the refusal to approve a transmission fluid for Chrysler's new TE Van which contained 10 to 30 percent butyl benzyl phthalate. This was accomplished by working with suppliers and design teams to identify a substitute material. As part of the initiative, suppliers are being requested to certify their parts regarding the presence of Chrysler's identified materials of concern.

Other similar Chrysler successes include:

- Elimination of hexavalent chromium from all materials and processes;
- Reformulating paints and solvents to exclude the majority of listed toxic solvents;
- Reformulating new coatings to reduce odor; and
- Elimination of lead from all paints except electrocoat primer.

Used Oil Recycling

In an effort to reduce the waste oil produced at Chrysler stamping, machining, and engine plants, the automobile manufacturer has developed comprehensive recycling programs with outside suppliers. More than 800 million gallons of used oil is recycled annually. Other company efforts designed to reduce waste oil include:

- Recovering and remanufacturing waste oil on-site for return to the process;
- Reducing the amount used by replacing petroleum-based metal working fluids with longer lasting semi-synthetic materials; and
- Developing purchasing programs to promote the use of recycled oils.

Trichloroethylene Reduction

Trichloroethylene (TCE) is traditionally employed by the automotive industry as a degreaser to clean oil from very thin aluminum parts. Although vapor collection systems are used during the degreasing process to collect and recycle TCE, some TCE inevitably remains on the high-surface-area parts. The remaining TCE then evaporates. In order to reduce emissions of TCE, Ford Motor Company developed a detergent and aqueous solution which was comparable to TCE. The new water wash did not etch or damage aluminum parts and met brazing process requirements. With assistance from a supplier, Ford also designed an enclosed water spray system for the new degreasing operations. According to AAMA, after a 1992 pilot evaluation proved successful, Ford began to convert production processes using heat exchangers (e.g., radiators) to one relying on aqueous cleaning instead of TCE degreasing. As a result, TCE releases at one plant dropped by 250,000 pounds annually. Ford expects comparable further reductions worldwide as the remaining plants implement this process change.

Elimination of Chromium From Radiator Paint

In past years, radiators were spray painted with a coating containing chromium for protection purposes. This process resulted in overspray paint waste (sludge) that contained hazardous constituents. Wastes were collected and shipped to an approved hazardous waste disposal facility. In order to minimize the risk associated with the material constituents and resultant waste associated with coating containing chromium, Chrysler's Dayton Thermal Products Plant explored the use of new products which would meet performance specifications for the required surface coating. The result is a water-based material which is chromium as well as lead-free. The use of this new water-based material will eliminate approximately 18,000 gallons of paint waste per year that was previously landfilled, as well as reduce substantially VOC emissions.

Lead-Free Black Ceramic Paint

Ceramic black glaze paint (ink), used for aesthetic purposes as well as an ultraviolet (UV) light shield for the adhesive (adhesive is sensitive to UV light), is applied to glass where the interior trim abuts the window. Application of the ink, which contains lead, to the glass involves a silk-screening process. In an attempt to minimize both solid and liquid waste, McGraw Glass (supplier for Chrysler assembly plants), launched a program to develop, test, and approve a lead-free black ceramic glass paint. A suitable substitute, which was approved

R0076304

and in use by 1994, would eliminate approximately 700 drums of hazardous waste per year.

Recovering Lead From Wastewater

One of the waste streams associated with battery-making operations is wastewater which contains lead. Although in the past it was possible to remove lead from the wastewater, it had not been possible to recycle the lead. In 1990, Delco Remy, a GM supplier, developed a method which allows the lead to be recycled. The process involves a series of steps and the use of a proprietary chemical (identified through a cooperative effort between the plant personnel and a chemical vendor) which allows lead to settle to the bottom when tank contents are neutralized. After the lead has settled, wastewater is decanted and filtered through a sand filter to remove remaining lead. The remaining water and lead are agitated with air to put lead back into suspension before the mixture is pumped into a filter press where water is removed leaving behind the lead. The dried, lead-containing mixture is then sent to a secondary smelter. As a result of this lead removing process, approximately 125,000 pounds of lead are reclaimed and recycled each year.

PCB Elimination Program

Polychlorinated biphenyls (PCBs), which are utilized as a coolant and flame retardant fluid in closed system high voltage electrical equipment, are one of the most persistent toxics used in the automotive industry. In order to eliminate the use of PCBs in its facilities, Chrysler initiated a program that would eliminate the use of PCB containing equipment at its facilities by 1998. The program also plans to minimize the risk of Superfund liability through alternate disposal practices. Similar programs are in place at GM and Ford.

Solvent-Free Spray Adhesive For Interior Trim

General Motors Inland Fisher Guide plant in Livonia, MI produces soft trim for the interior of automobiles. In order to produce car door panels that offer a variety of colors, textures, and materials, an assembly process which glues together small pieces is used. In the past, the adhesive used to bind these parts together contained four percent methylene chloride; 30 percent methyl ethyl ketone; 30 percent hexane, and 14 percent toluene. The combination of VOCs resulted in approximately 20 tons of emissions a year. In order to eliminate the emissions associated with this adhesive, a water-based adhesive was identified. The new adhesive, which was implemented in the beginning of 1993, converted the waste stream from hazardous to non-hazardous.

Reducing Chlorofluorocarbon Use

Chlorofluorocarbons (CFCs) and 1,1,1-trichlorethane are chemical substances that deplete the ozone layer. Depletion of the ozone layer causes skin cancer, cataracts and has other human and environmental effects. Under the Montreal Protocol on Substances that Deplete the Ozone Layer and the Clean Air Act, production of these chemicals will be halted by January 1996. The automobile industry used CFC-12 as a refrigerant in air conditioning systems, CFC-11 as foam blowing agent for flexible seating foams, and CFC-113 and 1,1,1-trichloroethane (methyl chloroform) as a solvent in electronics manufacturing and metal cleaning. The automobile industry undertook voluntary and cooperative projects with EPA's Stratopheric Protection Division to reduce and eliminate each of these uses. As a result of these efforts, recycling was implemented and most uses were halted well before regulations took effect (Stratopheric Protection Division 1995). For example, in order to reduce the use of CFCs, GM's Lansing Automotive Division (LAD) Facilities Division decided to remove CFCs wherever possible from its operating procedures. The first step was to identify CFC containing materials that were approved for purchase and which departments were authorized to use them. Departments were then sent a letter asking whether a non-CFC material could be substituted. Results from the inquiries led to identification of acceptable and cost-effective alternatives. Since mid-1992, no CFC-containing products have been purchased by LAD plants. In addition, LAD found a substitute for a degreaser it had been using that has only about 12 percent of ozone-depletion potential of the Freons it replaced. According to the Stratopheric Protection Division, another example of technology and engineering excellence is that Ford joined with other companies under the auspices of the International Cooperative for Ozone Layer Protection (ICOLP) to develop inert gas wave and "no clean" soldering which replaces CFC-cleaning of printed wiring boards, (PWBs). Electronics are the key to meeting vehicle emissions safety and security. The new process was designed for environmental reasons, but Ford found it also improved the quality of the PWBs.

V.B. Motor Vehicle Assembly

Plants Switch To Clean-Burning Gas

In an effort to reduce air emissions from manufacturing facilities, Ford has converted from coal-fired boilers to natural gas. An estimated

R0076306

$500,000 to $600,000 is saved each year in operating costs for each plant that converts from coal to natural gas. The environmental benefits of the conversion include: a reduction in carbon monoxide emissions by one half; a reduction in sulfur dioxide emissions by approximately 3,000 tons per year system wide; and a reduction in nitrogen oxide emissions of approximately 1,100 tons per year. The switch has also reduced particulate emissions by over 500 tons a year for Ford system-wide, and by as much as 95 percent at some facilities. In addition, 8,000 tons of ash a year, from coal burning, and 4,100 tons of ash collected by emission collectors will no longer have to be disposed of in a landfill.

Solid Waste Recycling

As part of an effort to reduce the amount of waste generated from assembly operations, Chrysler is using durable returnable containers. By using these containers, the company has successfully eliminated 55 percent of its expendable packaging wastes and diverted significant volumes of paper, cardboard, plastic and wood from landfills. Chrysler has designed new product programs which plan to eliminate 95 percent of packaging waste. In addition, each year the company salvages 700,000 tons of scrap metal and recycles thousands of tons of wooden pallets and cardboard from its plants. Chrysler has also instituted one of the largest paper recycling programs in the U.S., recycling more than 800 tons of paper per year.

Ford also has a program to reduce solid waste. At Ford Casting and Forging, steel drums are recycled in the foundry's melting process. Ford's North American assembly plants are recycling 380 million pounds of waste each year. European and North American suppliers have been asked to ship components in reusable and returnable containers. Ford's Romeo Engine Plant receives over 90 percent of its parts in returnable containers. Also, Ford uses recycled plastic shrink wrap from its own manufacturing operations to make plastic seat covers to protect seats during car shipment to dealers.

V.C. Motor Vehicle Painting/Finishing

Facility Emission Controls

During the past 10 years, automobile companies have reduced the amount of emissions resulting from vehicle painting operations through more efficient paint application techniques, use of lower solvent content paints, and incineration of process emissions. In an attempt to lower emissions without jeopardizing quality, a paint

R0076307

development pilot plant has been established at the Ford Wixom, Michigan Assembly Plant.

Rescheduling Paint Booth Cleaning Reduces Solvent Use And VOC Emissions

One of the major factors in customer satisfaction is the quality of a car's paint job. To insure that each vehicle of a given color has a uniform and consistent coating, paint spraying equipment must be cleaned properly each time a color is changed. It is also important that the paint booth be cleaned properly to prevent stray drops or flakes of old paint from dropping onto subsequent paint jobs. The solvent used in these cleaning operations is generally referred to as "purge solvent." One of the disadvantages of using purge solvent is that it readily evaporates causing VOC emissions. In March 1993 the GM Fairfax Assembly Plant initiated a new booth-cleaning schedule which reduced the number of required cleanings. In addition to changing cleaning frequency, the company also monitored the amount of purge solvent used in production and cleaning operations. Information from these monitoring activities helped to identify the most efficient cleaning techniques. Implementation of these practices is expected to greatly lower emissions from purge solvent.

Surface Coating Toxics Reduction Program

Painting operations account for the majority of total releases attributed to automobile assembly. This is because painting and finishing operations result in VOC emissions from solvents used as carriers to apply solids to the vehicle. In order to reduce the amount of toxics generated during the painting/finishing process as well as eliminate future regulatory burden, the following projects are either underway or being planned at Chrysler:

- Evaluation of the feasibility of using coatings which eliminate or reduce VOCs/toxics; the goal is a 75 percent reduction in toxics by 1996. Various process changes and material reformulation will be required.

- Elimination of lead from surface coatings - lead has already been eliminated from all Chrysler color coats (basecoats). Further reductions in lead are being pursued for the electrodeposition primer (E-coat), with a goal of total removal by 1995. A lead-free E-coat is currently being tested.

- Elimination of hexavalent chromium phosphate pre-treatment - hexavalent chromium has already been eliminated from phosphate pre-treatment. Trivalent chromium remains in the final rinse that seals the phosphate at all but one of Chrysler's assembly plants; elimination of trivalent chromium is slated for 1995.

V.D. Motor Vehicle Dismantling/Shredding

Management Standards For Used Antifreeze

An article in the September/October 1994 edition of *Automotive Recycling* stated that The Coalition on Antifreeze and the Environment, in conjunction with Automotive Recyclers Association (ARA), has developed voluntary management standards for antifreeze. Management standards were developed, in part, to encourage the Federal and State governments to consider less restrictive regulations on recycling and disposal of antifreeze. Recent data show that antifreeze can become hazardous when handled and stored improperly. The voluntary management standards address the following:

- **Handling** - procedures for good housekeeping and proper handling of antifreeze
- **Storage** - guidelines for proper storage, such as the use of dedicated and well-labeled collection equipment
- **Education** - methods for educating employees on the importance of keeping collected, used antifreeze free from exposure to chemicals such as petroleum products, cleaning solvents, and other solvent-containing materials. Employees should also be taught not to use chlorinated solvents to clean antifreeze collection equipment.

V.E. Pollution Prevention Case Studies

Pollution Prevention at General Motors Corporation

General Motor's internal pollution prevention initiative - Waste Elimination and Cost Awareness Reward Everyone (WE CARE) - was piloted in 1990 at selected GM facilities. The initiative was then expanded to GM's operations throughout the U.S. and Canada in 1991 and was introduced to Mexican facilities in 1992. The foundation for this program is provided in the mission statement:

> *To minimize the impact of our operations, we will reduce emissions to air, water, and land by putting priority on waste prevention at the source, elimination or reduction of wasteful practices, and the utilization of recycling opportunities whenever available. The responsibility for achievement of this goal is primarily dependent on both management's support and actions of every employee to modify existing methods, procedures, and processes and to incorporate waste prevention into all new endeavors.*

WE CARE provides guidance to individual facilities for setting up a multi-discipline committee to direct pollution prevention efforts. These committee include representatives from the following departments: maintenance, quality control, materials management, production, engineering, purchasing, environmental affairs, as well as from the local union. In bringing together representatives from all aspects of the company, GM is making pollution prevention part of everyone's job. In 1992, GM encouraged employees to suggest ways to reduce the use of raw materials (especially toxics), reduce waste generation, and simple ways to benefit the environment.

GM has undertaken two broad-based initiatives to implement this philosophy; chemicals management and packaging reduction and recycling. Each is discussed below.

Chemicals Management

The automotive industry is a large consumer of chemicals including cleaners, machining fluids, hydraulic fluids, quenching fluids, water treatment chemicals, and solvents. These chemicals are known as indirect chemicals because they are not directly incorporated into the final product. Direct chemicals, which are incorporated into the final product, include automotive paints, vehicle lubricants, and fluids. GM aims to reduce chemical waste and save money by: (1) leveraging resources and expertise from other sources; and (2) reshaping the relation between the supplier and the customer. By developing and implementing an effective chemical management system, GM has reduced the amount of chemicals used at the source and reduced waste treatment and disposal costs.

Under the new chemical management program, GM no longer simply purchases chemicals from suppliers. Instead, they purchase a chemical service. The goal was to have one supplier for all of the indirect chemicals used at a facility. Since no one supplier can supply every chemical, the primary supplier is responsible for getting chemicals from secondary suppliers. Under the program, the primary supplier ultimately becomes a part of the production team by providing GM with chemical management, analysis, inventory control, and information management services. The benefits of this initiative include:

- Cost savings through the reduced number of suppliers, types and volumes of chemicals, and chemical inventories
- Better environmental control (waste treatment and disposal)
- Improved information management
- Improved chemical technology application
- Reduced purchase order processing
- Reduced freight.

The first assembly plant to implement this program went from having 35 different suppliers providing 348 chemicals, to 12 suppliers supplying 200 chemicals. This equates to a 66 percent reduction in the number of suppliers and a 43 percent reduction in the number of chemicals. Total savings were well over $750,000 per year.

Packaging Reduction and Recycling

One of the major waste streams associated with automotive assembly is solid waste. Solid waste is primarily the result of parts packaging from suppliers. The goal of GM's packaging reduction and recycling initiative was to reduce the amount of packaging coming into the plant and to ensure that packaging was easily recycled or returned.

Because GM has many different divisions and business units, one packaging strategy was not feasible. Therefore, each division was responsible for setting its own goals and strategies. Packaging guidelines and requirements were developed and communicated to suppliers. The guidelines, which were used throughout GM include:

- Eliminate packaging altogether, where possible
- Minimize the amount of material used in packaging
- Use packages that are returnable or refillable/reusable, where practical
- Use packaging that is recyclable and uses recycled material.

Requirements pertaining to expendable packaging (packaging which is used once and not recycled) were established for suppliers. These requirements pertained to package construction (easy to disassemble), the use of recycled material (use recyclable packaging), the use of lead and cadmium (do not use), and other provisions which reduce the amount of waste generated and facilitate recycling.

The GM Midsize Car Division has been able to reduce the amount of packaging waste going to landfill per vehicle manufactured by 75 percent in just two years as part of its "zero packaging-to-landfill" goal. As of September 1993, one GM assembly plant has been able to reduce the amount of waste to less than one pound of packaging per vehicle.

Ford's Manufacturing Environmental Leadership Strategy includes the objective and practice of increasing the use of returnable containers and recycling expendable packaging. Ford's North American assembly plants now use returnable packaging for over 87 percent of all parts shipped to the plants. These plants alone recycle more than 380 million pounds of waste each year. Many parts are shipped in returnable containers and packaging plastic is made into protective seat covers for use during car shipment.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

R0076313

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the

Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)).

These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain operating permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created an operating permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Regulations

Though production processes associated with the industries listed under SIC 37 have few specific regulatory requirements, the diverse and complex nature of the industry makes it one of the most heavily regulated industries in the manufacturing sector.

The large number of facilities engaged in activities covered by SIC 37, as well as the diversity of processes and products involved, make it difficult to provide a precise regulatory framework; the statutes and regulations governing a producer of a specific part which uses a specific manufacturing process will differ significantly from those affecting an integrated manufacturing plant performing foundry, metal finishing, and painting operations. Thus, the discussion which follows identifies those regulations that are of concern to the industry at large.

VI.B.1. Clean Water Act (CWA)

The Clean Water Act regulates the amount of chemicals/toxics released by industries via direct and indirect wastewater/effluent discharges. Regulations developed to implement this Act establish effluent guidelines and standards for different industries. These standards usually set concentration-based limits on the discharge of a given chemical by any one facility. If a facility is discharging directly into a body of water, it must obtain a National Pollution Discharge Elimination System (NPDES) permit. However, if a facility is discharging to a publicly owned treatment works (POTW), it must adhere to the specified pretreatment standards. (Information provided by Chrysler indicates that all of the company's manufacturing facilities discharge process wastewater to POTWs. Much of their water is treated at an on-site industrial wastewater treatment plant prior to discharge to the POTW.)

The following regulations are potentially applicable to various stages in the auto and auto parts manufacturing and assembly processes. Because so many regulations are potentially applicable to segments of the industry, we have divided the regulations into the following categories: foundry/metal forming operations; metal finishing operations; and painting operations.

Foundry/Metal Forming Operations

The following effluent guidelines and standards are applicable to the activities performed during the foundry/metal forming operations.

- Iron and Steel Manufacturing (40 CFR Part 420)
- Metal Molding and Casting (40 CFR Part 464)
- Aluminum Forming (40 CFR Part 467)
- Copper Forming (40 CFR Part 468)
- Nonferrous Forming (40 CFR Part 471)
- Lead-Tin-Bismuth Forming Category (40 CFR Part 471 Subpart A)
- Zinc Forming Subcategory (40 CFR Part 471, Subpart H).

Metal Finishing Operations

The following effluent guidelines and standards are applicable to metal finishing activities:

- Electroplating (40 CFR Part 413)
- Metal Finishing (40 CFR Part 433)
- Coil Coating (40 CFR Part 465).

The standards applicable to metal finishing regulate discharges resulting from numerous activities performed by manufacturers of autos and auto parts. The metal finishing and electroplating guidelines address discharges from the following six activities: (1) electroplating; (2) electroless plating; (3) anodizing; (4) coating; (5) chemical etching and milling; and (6) printed circuit board manufacturing. If one of these operations is performed, the metal finishing guidelines provide effluent standards for 40 additional operations, including machining; grinding; polishing; welding; soldering; and solvent degreasing.

VI.B.2. Clean Air Act (CAA)

Several existing regulations promulgated under the CAA are applicable to various stages in the automobile production process. These are discussed below.

The Standards of Performance for Automobile and Light Duty Truck Surface Coating Operations (40 CFR Part 60, subpart MM) are applicable to assembly plant operations where prime coats, guide coats, and topcoats are applied. These standards prohibit assembly plants that begin construction, modification, or reconstruction after October 5, 1979 from discharging VOC emissions in excess of:

- 0.16 kg of VOC per liter of applied coating solids from each prime coat,
- 1.40 kg of VOC per liter of applied coating solids from each guide coat operation, and/or
- 1.47 kg of VOC per liter of applied coating solids from each top coat.

The Standards of Performance for Metal Coil Surface Coating (40 CFR Part 60, subpart TT) may be relevant to some facilities in the automotive industry. This standard regulates the discharge of VOCs.

The Standards of Performance for Fossil-Fired Steam Generators for Which Construction Commenced after August 17, 1971 (40 CFR Part 60, subpart D) are applicable to motor vehicle plants which have fossil-fuel-fired steam generating units of more that 73 megawatts (MW) heat input rate and fossil-fuel and wood-residue-fired steam generating units capable of firing fossil fuel at a rate of more that 73 MW (though these standards do not apply to electric utility steam generating units).

The regulations set emissions standards for sulfur dioxide, particulate matter, and nitrogen oxides, and contain compliance, performance, emissions testing, and recordkeeping requirements.

The Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units (40 CFR Part 60 subpart Dc) apply to motor vehicle and motor vehicle equipment plants which have steam generating units for which construction, modification, or reconstruction is commenced after June 9, 1989 and that have a maximum design capacity of 29 MW input capacity or less, but greater than or equal to 2.9 MW.

These regulations set emissions standards for sulfur dioxide and particulate matter and require certain compliance, performance, emissions testing, and recordkeeping requirements.

National Emission Standards for Hazardous Air Pollutants for Industrial Process Cooling Towers (40 CFR Part 63, subpart Q) apply to motor vehicle and motor vehicle equipment plants that have industrial process cooling towers (IPCTs) that are operated with chromium-based water treatment chemicals and are either major sources or are integral parts of facilities that are major sources. Major sources are those sources that emit or have the potential to emit 10 tons per year or more of any hazardous air pollutant or 25 tons per year or more of any combination of hazardous air pollutants.

The standards prohibit the use of chromium-based water treatment chemicals in:

- Existing IPCTs on or after March 8, 1996, and/or
- New IPCTs (IPCTs for which construction or reconstruction commenced after August 12, 1993) on or after September 8, 1994.

Chromium Electroplating

Human health studies suggest that various adverse effects result from acute, intermediate, and chronic exposure to chromium. As a result, in January 1995, EPA established National Emission Standards for Chromium Emissions From Hard and Decorative Chromium

Electroplating And Chromium Anodizing Tanks (40 CFR Part 9 and 63, Subpart N) The regulation is an MACT-based performance standard that sets limits on chromium and chromium compounds emissions based upon concentrations in the waste stream (e.g., mg of chromium/m^3 of air).

EPA holds that these performance standards allow a degree of flexibility since facilities may choose their own technology as long as the emissions limits (established by the MACT) are achieved. The standards differ according to the sources (e.g., old sources of chromium emissions will have different standards than new ones), further reducing the standards' rigidity.

VI.B.3. Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

CERCLA has had a much greater impact on the Big Three with facilities built before RCRA's enactment than it has had on the so-called transplant companies which have newer plants.

VI.B.4. Resource Conservation and Recovery Act (RCRA)

RCRA was passed in 1976, as an amendment to the Solid Waste Disposal Act, to ensure that solid wastes are managed in an environmentally sound manner. A material is classified under RCRA as a hazardous waste if the material meets the definition of solid waste (40 CFR 261.2), and that solid waste material exhibits one of the characteristics of a hazardous waste (40 CFR 261.20-24) or is specifically listed as a hazardous waste (40 CFR 261.31-33). A material defined as a hazardous waste is then subject to Subtitle C generator (40 CFR 262), transporter (40 CFR 263), treatment, storage, and disposal facility (40 CFR 254 and 265) and land disposal requirements (40 CFR 268). The motor vehicle and motor vehicle equipment manufacturing industry must be concerned with the regulations addressing all these. Most automobile and light truck assembly and component manufacturing facilities are not considered hazardous waste treatment, storage or disposal facilities requiring RCRA permits, although they may generate hazardous waste subject to RCRA management requirements.

The greatest quantities of RCRA listed waste and characteristically hazardous waste are identified in Exhibit 25. For more information on RCRA hazardous waste, refer to 40 CFR Part 261.

Exhibit 25
Hazardous Wastes Relevant to the Automotive Industry

EPA Hazardous Waste No.	Hazardous Waste
D001	Wastes which are hazardous due to the characterization of ignitibility
D002	Wastes which are hazardous due to the characteristic of corrosivity
D006 (cadmium) D007 (chromium) D008 (lead) D009 (mercury) D010 (selenium) D011 (silver) D035 (methyl ethyl ketone) D039 (tetrachloro-ethylene) D040 (trichloro-ethylene)	Wastes which are hazardous due to the characteristic of toxicity for each of the constituents.
F001	Halogenated solvents used in degreasing: tetrachloroethylene, methylene chloride, 1,1,1-trichloroethane, carbon tetrachloride, and chlorinated fluorocarbons; all spent solvent mixtures/blends used in degreasing containing, before use, a total of 10% or more (by volume) of one or more of the above halogenated solvents or those solvents listed in F002, F004, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F002	Spent halogenated solvents; tetrachloroethylene, methylene chloride, trichlorethylene, 1,1,1-trichloroethane chlorobenzene, 1,1,2-trichloro-1,2,2-trifluoroethane, ortho-dichlorobenzene, trichlorofluoromethane, and 1,1,2-trichloroethane; all spent solvent mixtures/blends containing, before use, one or more of the above halogenated solvents or those listed in F001, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F003	Spent non-halogenated solvents: xylene, acetone, ethyl acetate, ethyl benzene, ethyl ether, methyl isobutyl ketone, n-butyl alcohol, cyclohexanone, and methanol; all spent solvent mixtures/blends containing, before use, only the above spent non-halogenated solvents; and all spent solvent mixtures/blends containing, before use, one or more of the above non-halogenated solvents, and, a total of 10% or more (by volume) of one of those solvents listed in F001, F002, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F004	Spent non-halogenated solvents: cresols and cresylic acid, and nitrobenzene; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.

Exhibit 25 (cont'd)
Hazardous Wastes Relevant to the Automotive Industry

EPA Hazardous Waste No.	Hazardous Waste
F005	Spent non-halogenated solvents: toluene, methyl ethyl ketone, carbon disulfide, isobutanol, pyridine, benzene, 2-ethoxyethanol, and 2-nitropropane; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, or F004; and still bottoms from the recovery of these spent solvents and spent solvents mixtures.
F006	Wastewater treatment sludges from electroplating operations except from the following processes: (1) sulfuric acid anodizing of aluminum; (2) tin plating on carbon steel; (3) zinc plating (segregated basis) on carbon steel; (4) aluminum or zinc-aluminum plating on carbon steel; (5) cleaning/stripping associated with tin, zinc, and aluminum plating on carbon steel; and (6) chemical etching and milling of aluminum.
F007	Spent cyanide plating bath solutions from electroplating operations.
F008	Plating bath residues from the bottom of plating baths from electroplating operations where cyanides are used in the process.
F009	Spent stripping and cleaning bath solutions from electroplating operations where cyanides are used in the process.
F010	Quenching bath residues from oil baths from metal heat treating operations where cyanides are used in the process.
F011	Spent cyanide solutions from salt bath pot cleaning from metal heat treating operations.
F012	Quenching waste water treatment sludges from metal heat treating operations where cyanides are used in the process.
F019	Wastewater treatment sludges from the chemical conversion coating of aluminum except from zirconium phosphating in aluminum can washing when such phosphating is an exclusive conversion coating process.

VI.C. Pending and Proposed Regulatory Requirements

Numerous regulatory requirements which might affect the automotive industry are under consideration. Summaries of some of these potential future regulations are discussed below.

VI.C.1. Motor Vehicle Parts Manufacturing

Clean Water Act (CWA)

Although Congress did not reauthorize the Clean Water Act in 1994, future legislative requirements and/or reform may impact the motor vehicle manufacturer. Several of the regulations currently under

R0076330

consideration or development will have a significant impact on the automotive industry. The effluent guidelines and standards for Electroplaters (40 CFR Part 413) and Metal Finishers (40 CFR Part 433) are currently under review. EPA is also currently developing effluent guidelines and standards for the metal products and machinery industry (Phase II, 40 CFR Part 438), which are Scheduled to be finalized by December 1999. It is likely that EPA will integrate new regulatory options for metal finishing industry processes into this guideline.

The Effluent Guidelines and Standards for the Metal Products and Machinery Category, Phase II, will propose effluent limitation guidelines for facilities that generate wastewater while processing metal parts, metal products and machinery, including: manufacture, assembly, rebuilding, repair, and maintenance. The Phase II regulation will cover eight major industrial groups, including: motor vehicles, buses and trucks, household equipment, business equipment, instruments, precious and nonprecious metals, shipbuilding, and railroads. The court-ordered deadline is December 31, 1997.

Clean Air Act (CAA)

In addition to the CAA requirements discussed above, EPA is currently working on several regulations that will directly affect the metal finishing portion of the motor vehicle manufacturing industry. Many proposed standards will limit the air emissions from various industries by proposing Maximum Achievable Control Technology (MACT) based performance standards that will set limits on emissions based upon concentrations of pollutants in the waste stream. Various potential standards are described below.

Organic Solvent Degreasing/Cleaning

EPA has also proposed a NESHAP (58 FR 62566, November 19, 1993) for the source category of halogenated solvent degreasing/cleaning that will directly affect the metal finishing industry. This will apply to new and existing organic halogenated solvent emissions to a MACT-equivalent level, and will apply to new and existing organic halogenated solvent cleaners (degreasers) using any of the HAPs listed in the CAA Amendments. EPA is specifically targeting vapor degreasers that use the following HAPs: methylene chloride, perchloroethylene, trichloroethylene, 1,1,1-trichloroethane, carbon tetrachloride, and chloroform.

This NESHAP proposes to implement a MACT-based equipment and work practice compliance standard. This would require that a facility use a designated type of pollution prevention technology along with proper operating procedures. EPA has also provided an alternative compliance standard. Existing operations, which utilize performance-based standards, can continue if they reach the same limit as the equipment and work practice compliance standard.

Steel Pickling, HCl

Hydrochloric acid (HCl) and chlorine are among the pollutants listed as hazardous air pollutants in Section 112 of the Clean Air Act Amendments of 1990. Steel pickling processes that use HCl solution and HCl regeneration processes have been identified by the EPA as potentially significant sources of HCl and chlorine air emissions and, as such, a source category for which national emission standards may be warranted. EPA is required to promulgate national emission standards for 50 percent of the source categories listed in Section 112(e) by November 15, 1997. EPA plans to promulgate this standard by September 30, 1996.

VI.C.2. Motor Vehicle Painting/Finishing

Clean Air Act (CAA)

The 1990 CAAA identified a number of ozone non-attainment areas throughout the U.S. and gave those States most affected by high VOC emissions until November 1993 to develop implementation plans to combat the problem. The legislation further required that States reduce VOCs by 15 percent by 1996 and that States with extreme problems reduce emission an additional three percent each year following. Although State VOC limits have been established, national limits have not. A national rule on VOC limits is likely to come next year.

VOCs are one of the primary emissions from the automotive painting/finishing process and come from common paint solvents. Though no standards are currently proposed, industry officials are making their thoughts known. According to Ron Hilovsky, manager of regulatory affairs for PPG Fleet Finishes, as stated in an August 1994 article in Heavy Duty Trucking entitled "You Can Breath Easier, " national limits will effectively eliminate lacquer products and systems.

According to Heavy Duty Trucking, limits for paints and finishes are likely to be based on the pounds of VOCs released per gallon. Most topcoats have VOC levels of 5.5 lbs/gallon or more. New limits on VOCs are likely to be as follows:

- Pretreat/wash primer - 6.5 lbs./gallon

R0076332

- Primer/primer surfacer - 4.6 lbs./gallon
- Primer sealer - 4.6 lbs./gallon
- Topcoats (including single-stage solids and metallics and basecoat/clearcoat) - 5.0 lbs./gallon
- Tri and quad coat basecoat/clearcoat - 5.2 lbs./gallon
- Specialty coatings - 7.0 lbs./gallon.

VI.C.3. Motor Vehicle Dismantling/Shredding

According to AAMA, future U.S. regulatory activity affecting the vehicle recycling process, if it occurs at all, is likely to aim at improving the efficiency of the existing and already successful market infrastructure. For example, it may promote:

- Common definitions and terms
- Market incentives for the use of recycled materials, and
- Common standards for operating dismantling and shredding facilities

R0076333

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[2] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit,

---

2 EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

R0076335

compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100% because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Motor Vehicles and Motor Vehicle Equipment Compliance History

Exhibit 26 provides a Regional breakdown of the five year enforcement and compliance activities for the automobile industry. Of 2,734 total inspections performed during the five-year period, 1,255 (46 percent) were conducted in Region V. This large percentage is due to the concentration of automobile manufacturers in the Great Lakes Region.

Exhibit 26

R0076339

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 27-30 contain summaries of the one and five year enforcement and compliance activities for the motor vehicles and motor vehicle equipment industry, as well as for other industries. As shown in exhibits 27 and 28, the automotive industry has a moderately high enforcement to inspection rate when compared to other industries. Exhibits 29 and 30 provide a breakdown of inspection and enforcement activities by statute. Of all the automotive facilities inspected, approximately 54 percent were performed under RCRA and 33 percent under CAA. The large percentages of CAA and RCRA inspections for this industry are due to the high levels of VOC emissions released during solvent-intensive manufacturing processes. The low number of CWA inspections is fairly surprising due the large quantities of water used during metal finishing and painting/finishing processes.

R0076344

VII.C. Review of Major Legal Actions

As indicated in EPA's *Enforcement Accomplishments Report, FY 1991, FY 1992,* and *FY 1993* publications, eight significant enforcement cases were resolved between 1991 and 1993 for the motor vehicle industry. Two of these cases involved CAA violations, two were comprised of CERCLA violations, while the other four involved one RCRA, one TSCA, one CWA, and one action involving violations of multiple statutes. The companies against which the cases were brought are primarily motor vehicle and motor vehicle parts manufacturers.

VII.C.1. Review of Major Cases

This section provides summary information about major cases that have affected this sector. Four of the eight cases resulted in the assessment of a civil penalty. Penalties ranged from $50,000 to $1,539,326, and the average civil penalty paid was $691,965. In three cases, the defendant was required to spend additional money to improve production processes or technologies, and to increase further compliance. For example, in U.S. v. General Motors Corporation (1991), a consent decree was entered requiring GM to install a coating system that reduces VOCs from its paint shop operations from approximately 3,400 tons per year to 750-800 tons per year. GM also paid a civil penalty of $1,539, 326.

A Supplemental Environmental Project (SEP) was required in one of the cases. The settlement in In the Matter of the Knapheido Manufacturing Co., includes SEPs to partially offset the $428,533 penalty. The initial SEP requires performance of an environmental compliance audit, which will identify and propose additional SEPs as binding commitments.

In U.S. v. Raymark Industries, Inc. (1991), the Department of Justice filed a civil complaint requesting that the court order the company to study and perform corrective action at its facility in Stratford, CT. Raymark had manufactured automobile brakes and friction products at this 34-acre facility and had disposed of its hazardous wastes (principally lead-asbestos wastes and dust) onsite. In some areas, this lead-asbestos fill is 17 feet deep. The complaint requests that the court order Raymark to comply with an administrative order issued by EPA in 1987, pursuant to §3031 of RCRA, which instructs the company to study its site in order to ascertain the nature and extent of the hazard created by the presence and release of hazardous waste. Raymark has failed to comply with the terms of the order. Based on the results of this study, the complaint also requests that Raymark be ordered to carry out a corrective action plan as approved by EPA.

In U.S. v. Chrysler Corporation et. al. (1993), the court entered a CERCLA consent decree under which the settling defendants will clean up the PCB contamination at the Cater Industrials Superfund site in Detroit, Michigan and pay about $3 million in past costs. The total cost of the cleanup is estimated to be $24 million Settling defendants include Chrysler, Ford, GM, Michigan's two public utilities, and the City of Detroit. Unusual features of the decree include provisions for EPA to perform some of the work, and a special covenant not to sue in accordance with §122(f)(2) of CERCLA.

VII.C.2. Supplemental Environmental Projects

Below is list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement and Compliance Assurance to provide information on the number and type of SEPs entered into by the Regions. Exhibit 31 contains a sample of the Regional responses addressing the automotive industry. The information contained in the chart is not comprehensive and provides only a sample of the types of SEPs developed for the automotive industry.

Exhibit 31
Supplemental Environmental Projects
Motor Vehicle Assembly Industry (SIC 37)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Ford Motor Company St. Paul, MN	5	TSCA	Pollution Reduction	$ 35,000	Remove and destroy a PCB transformer and replace it with a non-PCB transformer to reduce the risk of discharge of PCBs into the environment.	$ 26,000	$ 10,100

R0076347

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Activities

The automotive industry is involved in numerous sector-related environmental activities. Some of these efforts are highlighted below.

Common Sense Initiative

The Common Sense Initiative (CSI), a partnership between EPA and private industry, aims to create environmental protection strategies that are cleaner for the environment and cheaper for industry and taxpayers. As part of CSI, representatives from Federal, State, and local governments; industry; community-based and national environmental organizations; environmental justice groups; and labor organizations, come together to examine the full range of environmental requirements affecting the following six selected industries: automobile manufacturing; computers and electronics, iron and steel, metal finishing, petroleum refining, and printing.

CSI participants are looking for solutions that:

- Focus on the industry as a whole rather than one pollutant
- Seek consensus-based solutions
- Focus on pollution prevention rather than end-of-pipe controls
- Are industry-specific.

The Common Sense Initiative Council (CSIC), chaired by EPA Administrator Browner, consists of a parent council and six subcommittees (one per industry sector). Each of the subcommittees have met and have identified issues and project areas for emphasis, and workgroups have been established to analyze and make recommendation on these issues.

EPA/Auto Protocol

Procedures for assessing compliance during automobile painting and finishing operations were first outlined in a December 1988 EPA publication entitled, Protocol for Determining the Daily Volatile Organic Compound Emission Rate of Automobile and Light-Duty Truck Topcoat Operations, (EPA-450/3-88-018). This document, which is referred to as the EPA/Auto Protocol, contains information on recordkeeping, testing, and compliance calculation procedures. The Protocol has been used to demonstrate compliance with emission limits for topcoat and spray primer/surface coating activities.

EPA and AAMA have discussed and hope to update the protocol. AAMA hopes to have an automotive spraybooth capture efficiency procedure as well as some acceptable spraybooth/oven split test modifications for in-plant simulation incorporated into the protocol as a technical update.

Research

The American Industry/Government Emissions Research Cooperative Research and Development Agreement (AIGER CRADA)

AIGER CRADA was officially launched in October 1992. The founding members - U.S. EPA, the California Air Resources Board, and USCAR's Environmental Research Consortium - came together to identify, encourage, evaluate, and develop the instrumentation and techniques needed to accurately and efficiently measure emissions from motor vehicles as required by the Clean Air Act and the California Health and Safety Code. This effort will help ensure that technologies are commercialized and available to emissions testing facilities.

Partnership For A New Generation Of Vehicles

Partnership For A New Generation Of Vehicles (PNGV), one of several research consortia under USCAR, is a partnership between domestic automotive manufacturers and the Federal government. The partnership is aimed at strengthening U.S. competitiveness by expanding the industry's technology base. Research will be performed in the following three areas:

- Advanced manufacturing techniques to make it easier to get new product ideas to the marketplace quickly;

R0076349

- Technologies leading to near-term improvements in automobile efficiency, safety, and emissions; and
- Research leading to production prototypes of a vehicle capable of up to three times current fuel efficiency.

President's Council on Sustainable Development - Eco-Efficiency Task Force

The purpose of the Eco-Efficiency Task Force is to develop and recommend to the President's Council on Sustainable Development a strategy for making eco-efficiency and sustainable development standard business practices in American industry. The Task Force will highlight how changes in economic, regulatory, statutory, and other policies will encourage industry to become more aware of the interdependence among environmental, economic, and social well-being, and recommend policies effective in promoting sustainable business practices. The Task Force is sub-divided into five Eco-Efficiency Task Force Teams: Autos Team; Chemicals Sector Team; Eco-Industrial Park Team; Policy Team; and Printers/Small Business Team. The three goals of the Auto Team are to recommend ways to:

- Improve the "eco-efficiency" of automobile manufacturing by making pollution prevention, waste reduction, and product stewardship standard business practices
- Improve the system of environmental policy and regulation affecting automobile manufacturing
- Improve the sustainability of road-based transportation.

As part of its efforts, the Auto Team is collecting information on the "life cycle" analysis of automobile painting operations at a GM assembly plant. The team is also collecting data from the paint and pigment industry, the steel, plastics, and aluminum manufacturing industries, as well as the auto repainting industry. The project will assess the environmental, energy, and economic implications of various auto body material/coating choices such as solvent, water, or powder. The Task Force is expected to deliver its findings in late 1995.

Outreach and Education Activity

Pollution Prevention and Waste Minimization in the Metal Finishing Industry Workshop

The University of Nebraska-Lincoln sponsored a *Pollution Prevention and Waste Minimization in the Metal Finishing Industry* workshop in 1993. The workshop was designed for managers and operators of electroplating and galvanizing operations; engineers; environmental consultants; waste management consultants; Federal, State, and local government officials; and individuals responsible for training in the area of metal finishing waste management. Topics covered:

- Saving money and reducing risk through pollution prevention and waste minimization;
- Incorporating pollution prevention into planning electroplating and galvanizing operations;
- Conducting waste minimization audits;
- Developing and analyzing options for pollution prevention/waste minimization; and
- Implementing a pollution prevention/waste minimization program.

For more information concerning this workshop, contact David Montage of the University of Nebraska at W348 Nebraska Hall, Lincoln, NE 68588-0531.

Hazardous Waste Management for Small Business Workshop

The University of Northern Iowa, with support from U.S. EPA, Des Moines Area Community College, Northeast Iowa Community College, Scott Community College, and Indiana Hills Community College, sponsored a *Hazardous Waste Management for Small Business* workshop. This workshop was geared for small businesses and was intended to provide practical answers to environmental regulatory questions. Small businesses covered by the workshop include: manufacturers, vehicle maintenance and repair shops, printers, machine shops, and other businesses that generate potentially hazardous waste. Topics covered included: hazardous waste determination, waste generator categories, management of specific common waste streams, including used oil and solvents, and pollution prevention. For more information regarding workshop, contact Duane McDonald (319) 273-6899.

Environmentally Conscious Painting Workshop

Kansas State University, NIST/Mid-America Manufacturing Technology Center, Kansas Department of Health & Environment, EPA Region VII, Allied Signal, Inc., Kansas City Plant, and the U.S. Department of Energy sponsored the *Environmentally Conscious Painting* workshop. This workshop covered topics such as upcoming regulations and the current regulatory climate, methods to cost-effectively reduce painting wastes and emissions, and alternative painting processes. For more information regarding this workshop, contact the Kansas State University Division of Continuing Education (913) 532-5566.

Pollution Prevention Workshop for the Electroplating Industry

Kansas State University Engineering Extension, EPA Region VII, Kansas Department of Health and Environment, and the University of Kansas sponsored the *Pollution Prevention Workshop for the Electroplating Industry*. The workshop described simple techniques for waste reduction in the electroplating industry, including: plating, rinsing processes and wastewater, wastewater management options, metals recovery options, waste treatment and management, and product substitutions and plating alternatives. For more information regarding this workshop, contact the Kansas State University Division of Continuing Education at (800) 432-8222.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of 17 chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given to participants who met their 1992 goals. The list of chemicals includes 17 high-use chemicals reported in the Toxics Release Inventory.

Sixty-six companies listed under SIC 37 (transportation) are currently participating in the 33/50 program. They account for approximately 20 percent of the 405 companies under SIC 37, which is slightly higher than the average for all industries of 14 percent participation. It should be noted, however, that the two digit SIC 37 covers a large number of small firms performing numerous manufacturing processes. (Contact: Mike Burns (202) 260-6394 or the 33/50 Program (202) 260-6907)

Exhibit 32 lists those companies participating in the 33/50 program that reported under SIC code 37 to TRI. Many of the participating companies listed multiple SIC codes (in no particular order), and are therefore likely to conduct operations in addition to the motor vehicle assembly industry. The table shows the number of facilities within each company that are participating in the 33/50 program; each company's total 1993 releases and transfers of 33/50 chemicals; and the percent reduction in these chemicals since 1988.

Exhibit 32
Motor Vehicle Assembly Facilities Participating in the 33/50 Program

Parent Facility name	Parent City	ST	SIC Codes	# of Participating Facilities	1993 Releases and Transfers (lbs.)	% Reduction 1988 to 1993
American Honda Motor Co., Inc.	Torrance	CA	3711	2	3,254,180	*
Chrysler Corporation	Highland Park	MI	3711	8	5,623,717	80
Ford Motor Company	Dearborn	MI	3465, 3711	19	15,368,032	15
General Motors Corporation	Detroit	MI	3711	23	16,751,198	*
Harsco Corporation	Camp Hill	PA	3711, 3713	1	415,574	**
Navistar International Corp.	Chicago	IL	3711	1	180,834	*
New United Motor Manufacturing	Fremont	CA	3711	1	420,125	**
Northrop Grumman Corp.	Los Angeles	CA	3711	1	2,357,844	35
Superior Coaches	Lima	OH	3711	1	87,900	44

*** = not quantifiable against 1988 data.**
**** = use reduction goal only.**
***** = no numerical goal.**

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director (202) 564-5081 or Robert Fentress (202) 564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at (202) 233-9065 or the Green Light/Energy Star Hotline at (202) 775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn (202) 260-0700 or the WasteWi$e Hotline at (800) 372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman (202) 260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and

R0076355

increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office (303) 275-4729)

VIII.C. Trade Associations/Industry Sponsored Activity

As one of the most highly regulated industries in the U.S., the automotive industry is constantly forced to identify and develop new ways to produce motor vehicles and motor vehicle parts more efficiently and with less waste. In an effort to pool resources, three manufacturers have formed a partnership to promote pollution prevention initiatives. Information is also provided on the various trade associations which support the industry.

VIII.C.1. Environmental Programs

Automobile Pollution Prevention Project (Auto Project)

Auto Project is a voluntary partnership between the Big Three automobile manufactures and the State of Michigan (on behalf of eight Great Lakes States and the U.S. EPA) to promote pollution prevention. Initiated on September 24, 1991, Auto Project is the first public/private initiative focused specifically on the environmental impacts resulting from automobile manufacturing. Auto Project is administered by the American Automobile Manufacturers Association (AAMA) and the Michigan Department of Natural Resources (MDNR). The purpose of the project is to:

- Identify Great Lakes Persistent Toxic (GLPT) substances and reduce their generation and release
- Advance pollution prevention within the auto industry and its supplier base
- Reduce releases of GLPT substances beyond regulatory requirements
- Address regulatory barriers that inhibit pollution prevention.

A progress report released in February 1994 states that significant accomplishments have been achieved in the last two years and that releases of the listed GLPT substances by auto companies have been cut by 20.2 percent in the first year of the Auto Project. Other accomplishments of Auto Project include:

- Developed criteria for identification of GLPT substances

- Identified 65 GLPT substances based on the criteria
- Provided highlights of historical pollution prevention efforts
- Established priorities and identified opportunities to reduce the generation and release of the listed substances
- Provided pollution prevention case study information for technology transfer to auto suppliers and other companies
- Established a pilot program to identify and reduce regulatory barriers to pollution prevention actions.

In October 1993 a comprehensive evaluation of the first two years of the Auto Project was conducted by members of the Great Lakes environmental community. Results of the evaluation were documented in a 1993 report entitled *So Much Promise, So Little Progress - An Evaluation of the State of Michigan/Auto Industry Great Lakes Pollution Prevention Initiative* written by the Ann Arbor, Michigan Ecology Center. The report concludes that although still promising, Auto Project has been mostly unsuccessful. The Great Lakes environmental groups claimed the following:

- Auto companies have not conducted the promised surveys of pollution generated by individual plants and manufacturing processes
- Auto companies have initiated few new pollution prevention projects
- Auto company suppliers, who account for more toxic releases than the auto companies themselves, have not been brought into the project
- Stakeholders (environmental groups and labor) have not had adequate opportunities to participate
- Auto companies have yet to establish clear goals or timetables for eliminating toxic substances from their processes.

VIII.C.2. Summary of Trade Associations

Trade Associations

Automotive Manufacturers

American Automobile Manufacturers Association (AAMA) 1401 H Street, NW, Suite 900 Washington, DC 20005 Phone: (202) 326-5500 Fax: (202) 326-5567	Members: 3 Staff: 100 Budget: $14,000,000 Contact: Andrew H. Card, Jr.

Founded in 1913, AAMA, formerly the Motor Vehicle Manufacturers Association, represents manufacturers of passenger and commercial cars, trucks, and buses to improve vehicle safety, reduce air pollution, and assist in long-term energy conservation objectives. This association compiles statistics, disseminates information, and conducts research programs and legislative monitoring on Federal and State levels. AAMA also maintains patents and communications libraries, and publishes the following annual documents: *Motor Vehicle Facts and Figures, Motor Vehicle Identification Manual,* and *World Motor Vehicle Data Book.*

Association of International Automobile Manufacturers (AIAM) 1001 19th Street, North, Suite 1200 Arlington, VA 22209 Phone: (703) 525-7788 Fax: (703) 525-3289	Members: 35 Budget: $4,200,000 Contact: Phillip Hutchinson

Founded in 1964, AIAM represents companies that manufacture automobiles or automotive equipment and that import into, or export from, the United States. This association acts as a clearinghouse for information, especially with regard to proposed State and Federal regulations in the automobile industry as they bear on imported automobiles, and reports proposed regulations by State or Federal governments pertaining to equipment standards, licensing, and other matters affecting members. AIAM publishes materials on State and Federal laws, regulations, and standards.

American Foundrymen's Society (AFS) 505 State Street Des Plaines, IL 60016 Phone: (708) 824-0181 Fax: (708) 824-7848	Members: 13,500 Staff: 52 Contact: Ezra L. Kotzin

Founded in 1896, AFS represents foundrymen, patternmakers, technologists, and educators and sponsors foundry training courses through the Cast Metals Institute on all subjects pertaining to the castings industry. The Society conducts educational and instructional activities on the foundry industry and sponsors ten regional foundry conferences and 400 local foundry technical meetings. AFS maintains the Technical Information Center, a literature search and document retrieval service, and the Metalcasting Abstract Service, which provides abstracts of the latest metal casting literature. In addition to providing environmental services and testing, AFS publishes *Modern Casting* (monthly), which covers current technology practices and other influences affecting the production and marketing of metal castings.

Automotive Presidents Council (APC) 1325 Pennsylvania Avenue, NW, 6th Floor Washington, D.C. 20004 Phone: (202) 393-6362 Fax: (202) 737-3742	Members: 50 Contact: Christopher Bates

Founded in 1966, APC represents presidents and chief executive officers of leading manufacturing companies producing automotive parts, equipment, accessories, tools, paint, and refinishing supplies. This council provides a forum in which chief executives can discuss areas of mutual interest or top management problems, share ideas, and exchange solutions.

Automotive Parts and Equipment

Automotive Parts and Accessories Association (APAA) 4600 East West Highway, Suite 300 Bethesda, MD 20814 Phone: (301) 654-6664 Fax: (301) 654-3299	Members: 2000 Staff: 26 Budget: $3,000,000 Contact: Lawrence Hecker

Founded in 1967, this association represents automotive parts and accessories retailers, distributors, manufacturers, and manufacturers' representatives. APAA conducts research, compiles statistics, conducts seminars, provides a specialized education program, and operates a speakers' bureau and placement service. This association publishes *APAA Frontlines* (bimonthly), *APAA Government Report* (periodic), *APAA Tech Service Report* (monthly), *APAA Who's Who* (annual), *APAA Membership Directory* (periodic), *Computer News for the Automotive Aftermarket* (monthly), and *Foreign Buyers Directory* (annual).

Motor and Equipment Manufacturers Association (MEMA) #10 Laboratory Drive P.O. Box 13966 Research Triangle Park, NC 27709-3966 Phone: (919) 549-4800 Fax: (919) 549-4824	Members: 750 Staff: 62 Budget: $3,500,000 Contact: Robert Miller

Founded in 1904, MEMA represents manufacturers of automotive and heavy-duty original equipment and replacement components, maintenance equipment, chemicals, accessories, refinishing supplies, tools, and service equipment. This organization provides the following manufacturer-oriented services: marketing consultation; Federal and State legal, safety, and legislative representation and consultation; personnel services; and manpower development workshops. In addition, MEMA conducts seminars on domestic and overseas marketing, Federal trade regulations, freight forwarding, and credit and collection. This association publishes the following documents: *Automotive Distributor Trends and Financial Analysis* (periodic), *Credit and Sales Reference Directory* (semiannual), *International Buyer's Guide of U.S. Automotive and Heavy Duty Products* (Biennial), *Marketing Insight* (quarterly), and *Autobody Supply and Equipment Market.*

Finishing and Dismantling

Paint, Body, and Equipment Association (PBEA) c/o Martin Fromm and Associates 9140 Ward Parkway, Suite 200 Kansas City, MO 64114 Phone: (816) 444-3500 Fax: (816) 444-0330	Members: 100 Staff: 6 Contact: Barbara Aubin

Founded in 1975, PBEA represents warehouse distributors and manufacturers specializing in the automotive paint, body, and equipment field. This organization conducts management seminars and publishes an annual *Membership Directory* and a bimonthly *Newsletter*.

R0076360

Automotive Recyclers Association (ARA) 3975 Fair Ridge Drive 320 Terrace Level North Fairfax, VA 22033 Phone: (703) 385-1001 Fax: (703) 385-1494	Members: 5,500 Staff: 12 Budget: $1,100,000 Contact: William Steinkuller

Founded in 1943, ADRA represents firms that sell used auto, truck, motorcycle, bus, farm, and construction equipment parts, as well as firms that supply equipment and services to the industry. This organization seeks to improve industry business practices and operating techniques through information exchange via meetings and publications, including *ADRA Newsletter* (monthly), *Automotive Recycling* (bimonthly), and *Industry Survey* (biennial).

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

ISBN 0-16-048277-1

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a

manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. Introduction to the Nonferrous Metals Industry

This section provides background information on the Nonferrous Metals Industry and the organization of this sector's notebook.

II.A. Introduction and Background of the Notebook

The Standard Industrial Classification (SIC) code 33 is composed of establishments that engage in: the primary and secondary smelting and refining of ferrous and nonferrous metal from ore or scrap; rolling, drawing, and alloying; and the manufacturing and casting of basic metal products such as nails, spikes, wire, and cable. Primary smelting and refining produces metals directly from ores, while secondary refining and smelting produces metals from scrap and process waste. Scrap is bits and pieces of metal parts, bars, turnings, sheets, and wire that are off-specification or worn-out but are capable of being recycled.

Two metal recovery technologies are generally used to produce refined metals. Pyrometallurgical technologies are processes that use heat to separate desired metals from other less or undesirable materials. These processes capitalize on the differences between constituent oxidation potential, melting point, vapor pressure, density, and/or miscibility when melted. Examples of pyrometallurgical processes include drying, calcining, roasting, sintering, retorting, and smelting. Hydrometallurgical technologies differ from pyrometallurgical processes in that the desired metals are separated from undesirables using techniques that capitalize on differences between constituent solubilities and/or electrochemical properties while in aqueous solutions. Examples of hydrometallurgical processes include leaching, chemical precipitation, electrolytic recovery, membrane separation, ion exchange, and solvent extraction.

During pyrometallic processing, an ore, after being concentrated by beneficiation (crushing, washing, and drying) is sintered, or combined by heat, with other materials such as baghouse dust and flux. The concentrate is then smelted, or melted, in a blast furnace in order to fuse the desired metals into an impure molten bullion. This bullion then undergoes a third pyrometallic process to refine the metal to the desired level of purity. Each time the ore or bullion is heated, waste materials are created. Air emissions such as dust may be captured in a baghouse and are either disposed of or returned to the process depending upon the residual metal content. Sulfur is also captured, and when concentrations are above four percent it can be turned into sulfuric acid, a component of fertilizers. Depending upon the origin of the ore and its residual metals content, various metals such as gold and silver may also be produced as by-products.

Production operations under this SIC code are subject to a number of regulations, including those imposed by the Resource Conservation and Recovery Act (RCRA), the Clean Water Act (CWA), and the Clean Air Act (CAA). A number of RCRA-listed hazardous wastes are produced during primary refining operations which require the heating of ores to remove impurities. Specific pretreatment standards under the CWA apply to the processes associated with copper and aluminum. Lastly, large amounts of sulfur are released during copper, lead, and zinc smelting operations which are regulated under the CAA.

The Department of Commerce classification codes divide this industry by production process. The two-digit SIC code is broken down as follows:

SIC 331	-	Steel Works, Blast Furnaces, and Rolling and Finishing Mills (covered in a separate profile)
SIC 332	-	Iron and Steel Foundries (covered in a separate profile)
SIC 333	-	Primary Smelting and Refining of Nonferrous Metals
SIC 334	-	Secondary Smelting and Refining of Nonferrous Metals
SIC 335	-	Rolling, Drawing, and Extruding of Nonferrous Metals (not covered in this profile)
SIC 336	-	Nonferrous Foundries (castings) (not covered in this profile)
SIC 339	-	Miscellaneous Primary Metal Products (not covered in this profile).

II.B. Organization of the Nonferrous Metals Notebook

SIC 33 is a diverse industrial area which is comprised of many different manufacturing processes. It is because of this diversity of processes and related pollutant issues that this notebook focuses only on SIC 333 and 334; Primary and Secondary Nonferrous Metals Processing. The metals aluminum, copper, lead, and zinc were chosen for inclusion in this profile because they are the four most widely used nonferrous metals in the United States. Where possible, information for the four metals is discussed separately. However, due to the SIC groupings, in many instances data for all four metals and other processes are intermingled. Every effort will be made to highlight where separate information is available and where information concerning more than one of the metals has been intermingled.

The notebook begins with a discussion of the primary and secondary aluminum industries. This discussion is comprised of economic and geographic characterizations of the industries and detailed discussions of the industrial processes involved, including production line raw material inputs and pollution outputs. The following three sections provide the same information for copper, lead, and zinc, respectively. The notebook continues with EPA Toxics Release Inventory data for the nonferrous metals industry. Much of this information is intermingled, but where possible has been separated. The notebook concludes with sections discussing pollution prevention opportunities, pending and proposed regulatory requirements, compliance and enforcement information, and compliance activities and initiatives.

III. PRIMARY AND SECONDARY ALUMINUM PROCESSING INDUSTRY

III.A. Characterization of Industry - Aluminum

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Primary and Secondary Aluminum Industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes.

III.A.1. Industry Size and Geographic Distribution - Aluminum

The following discussion is based upon the following materials: "Aluminum Know the Facts, July 1994," the Aluminum Association; "Industry & Trade Summary - Aluminum," the U.S. Trade Commission; and "U.S. Industrial Outlook 1994 - Metals," U.S. Department of Commerce.

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

In 1993, the majority of primary aluminum producers (SIC 3334) in the U.S. were located either in the Northwest (39.1 percent of U.S. capacity) or the Ohio River Valley (31.1 percent of U.S. capacity), while most secondary aluminum smelters were located in Southern California and the Great Lakes Region. The reason for the difference in plant locations is due to the energy intensive nature of the primary aluminum smelting process and the cost of fuels. Primary smelters are located in the Northwest and Ohio River Valley to take advantage of the abundant supplies of hydroelectric and coal-based energy, while secondary smelters locate themselves near major industrial and consumer centers to take advantage of the large amounts of scrap generated. Secondary smelting uses 95 percent less energy to produce the same product than primary reduction. On the average, a third of primary production costs are attributable to the cost of energy.

The domestic primary aluminum smelting industry consists of 23 smelting facilities operated by 13 firms which employ approximately 20,000. Of the thirteen firms, four integrated producers, Alcoa, Alumax, Reynolds, and Kaiser, accounted for 63 percent of 1993's capacity. The secondary smelting industry operates an estimated 68 plants employing 3,600. These figures have remained stable since 1988 and reflect an industry that emerged strong and competitive following the contractions and restructuring of the early 1980's that were caused by worldwide price swings and supply/demand disequilibrium.

About 40 percent of the domestic supply of aluminum is recovered by secondary refiners (SIC 334) from both purchased new and old aluminum scrap. New scrap is material generated during the fabrication of aluminum products. Old scrap includes products such as aluminum pistons and other aluminum engine or body parts from junked cars, used aluminum beverage cans, doors and siding, and used aluminum foil. In 1993, 2.3 million metric tons (Mmt) of metal, valued at an estimated $3.5 billion, were recovered from both new and old aluminum scrap. Of this total, approximaterly 55 percent was recovered from old scrap. Recycling rates for aluminum beverage containers reached 63 percent (60 billion cans) in 1993, keeping more than two billion pounds of material out of landfills.

III.A.2. Product Characterization - Aluminum

The primary and secondary aluminum industry produces ingots of pure (greater than 99 percent) aluminum that serve as feedstock for other materials and processes. Within the U.S., the leading end-users of aluminum come from three industries; containers and packaging, transportation, and building and construction. In 1993, demand from the three industries accounted for an estimated 60 percent of the eight Mmt of aluminum ingot and semifabricated products produced, with containers and packaging alone accounting for more than 25 percent of total shipments. Examples of materials produced with aluminum are: sheet metal; aluminum plate and foil; rod, bar, and wire; beverage cans, automobiles, aircraft components, and window/door frames.

III.A.3. Economic Trends - Aluminum

The amount of aluminum a plant could produce if working at engineered (full) capacity held steady in 1993. This was due to two factors: reduced hydroelectric supplies in the Northwest and falling aluminum prices. Hydroelectric supplies were reduced in the Northwest due to drought. Prices for primary aluminum fell to record-lows in 1993 despite a slight global increase in demand, due in large part to a flood of exports from the former Soviet republics.

U.S. aluminum shipments increased 12 percent in 1994, based on increased demands in the beverage can stock and transportation sectors. At present, the automotive sector is the largest end-user. The next largest end-user is the beverage can stock.

R0076388

Automotive use of aluminum is expected to sky-rocket as the sector increases its use of aluminum to increase fuel efficiency. Chrysler Corporation may begin building an aluminum-intensive car in 1996, employing 600-700 pounds of aluminum per car. The reduction in weight for a midsize vehicle would cut gasoline consumption by one gallon for each 100 miles driven.

III.B. Industrial Process Description - Aluminum

This section describes the major industrial processes within the Primary and Secondary Aluminum industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section XII for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provides a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

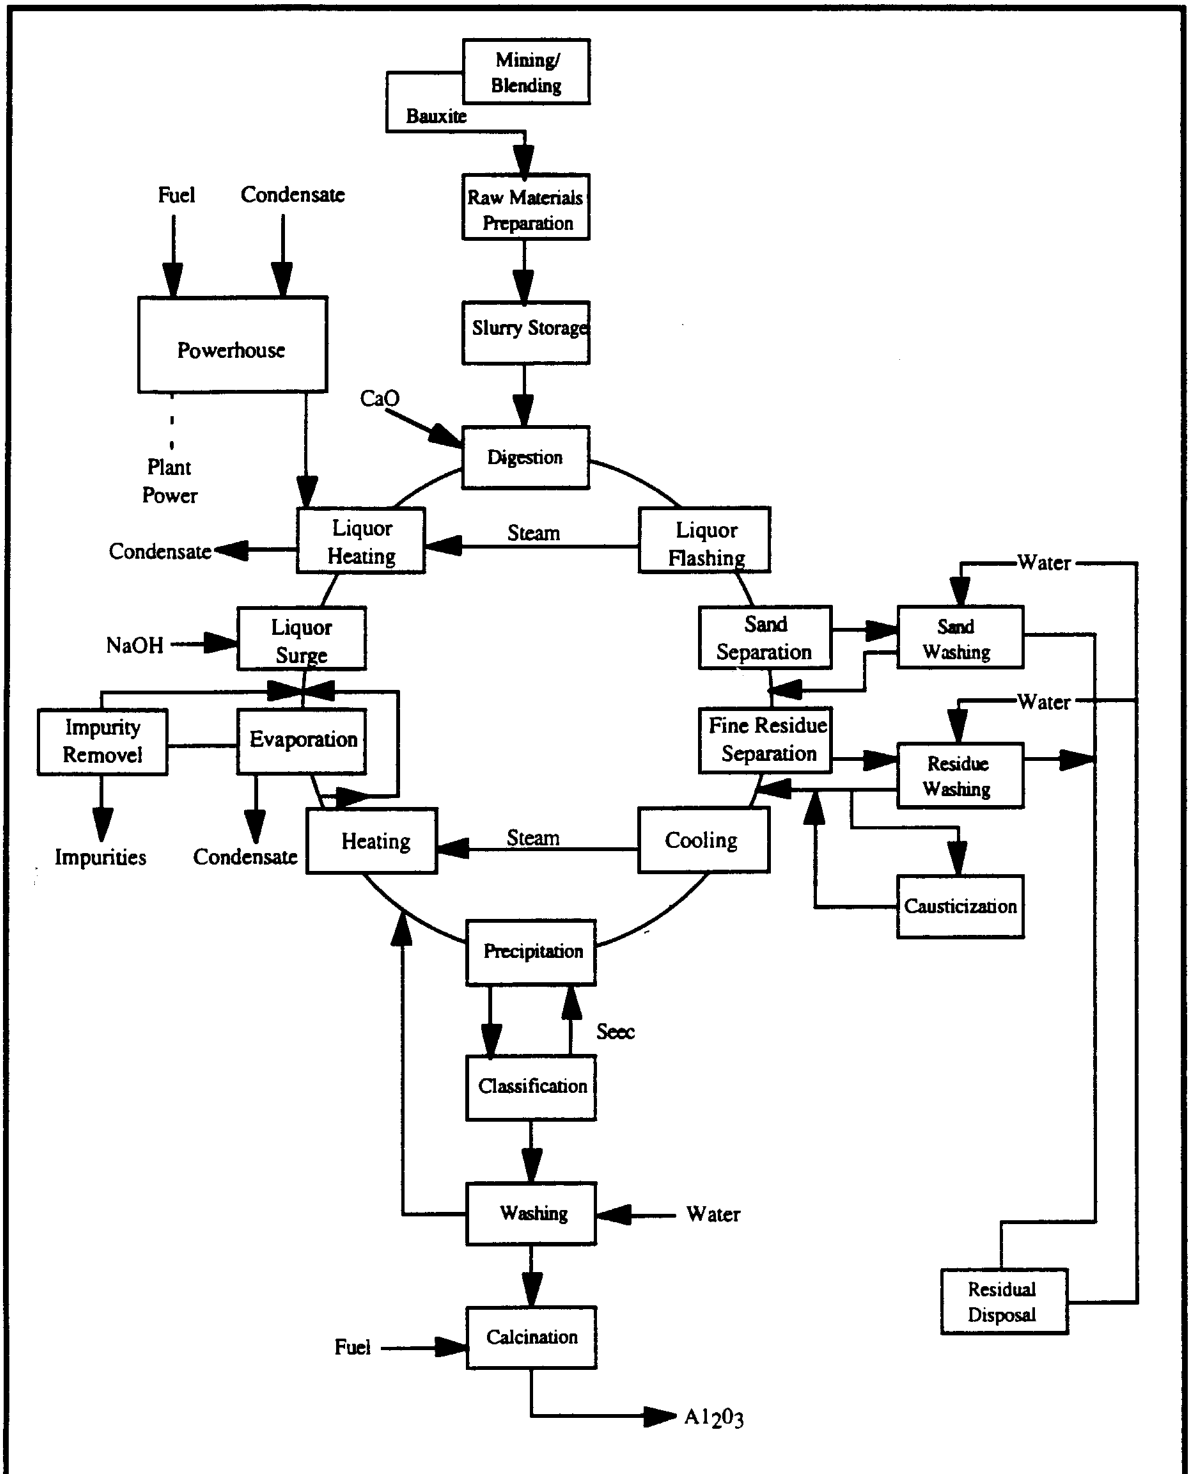
III.B.1. Industrial Processes in the Primary and Secondary Aluminum Industry

The following discussion is based in part upon the following documents: "Background Listing Document for K088," and AP42 from the U.S. Environmental Protection Agency, and materials provided by The Aluminum Association, Incorporated.

Primary Aluminum Processing

Primary aluminum producers generally employ a three step process to produce aluminum alloy ingots. First, alumina is extracted from bauxite ore using the Bayer process (See Exhibit 1). In the Bayer process, finely crushed bauxite is mixed with an aqueous sodium hydroxide (caustic soda) solution to form a slurry. The slurry is then reacted at a high temperature under steam pressure in a vessel known as a digester, and creates a mixture of dissolved aluminum oxides and bauxite residues. During the reaction a majority of the impurities such as silicon, iron, titanium, and calcium oxides drop to the bottom of the digester and form a sludge. The remaining sodium aluminate slurry is then flash cooled by evaporation and sent for clarification. During clarification, agents such as starch are added to help any fine impurities that remain in the slurry, such as sand, to drop out, further purifying the sodium aluminate solution. The solution is then fed into a precipitation tank to be crystallized. In the precipitator the solution is allowed to cool with the addition of a small amount of aluminum hydroxide "seed." The seed stimulates the precipitation of solid crystals of aluminum hydroxide and sodium hydroxide.

Exhibit 1 - Bayer Process (Alumina Refining)



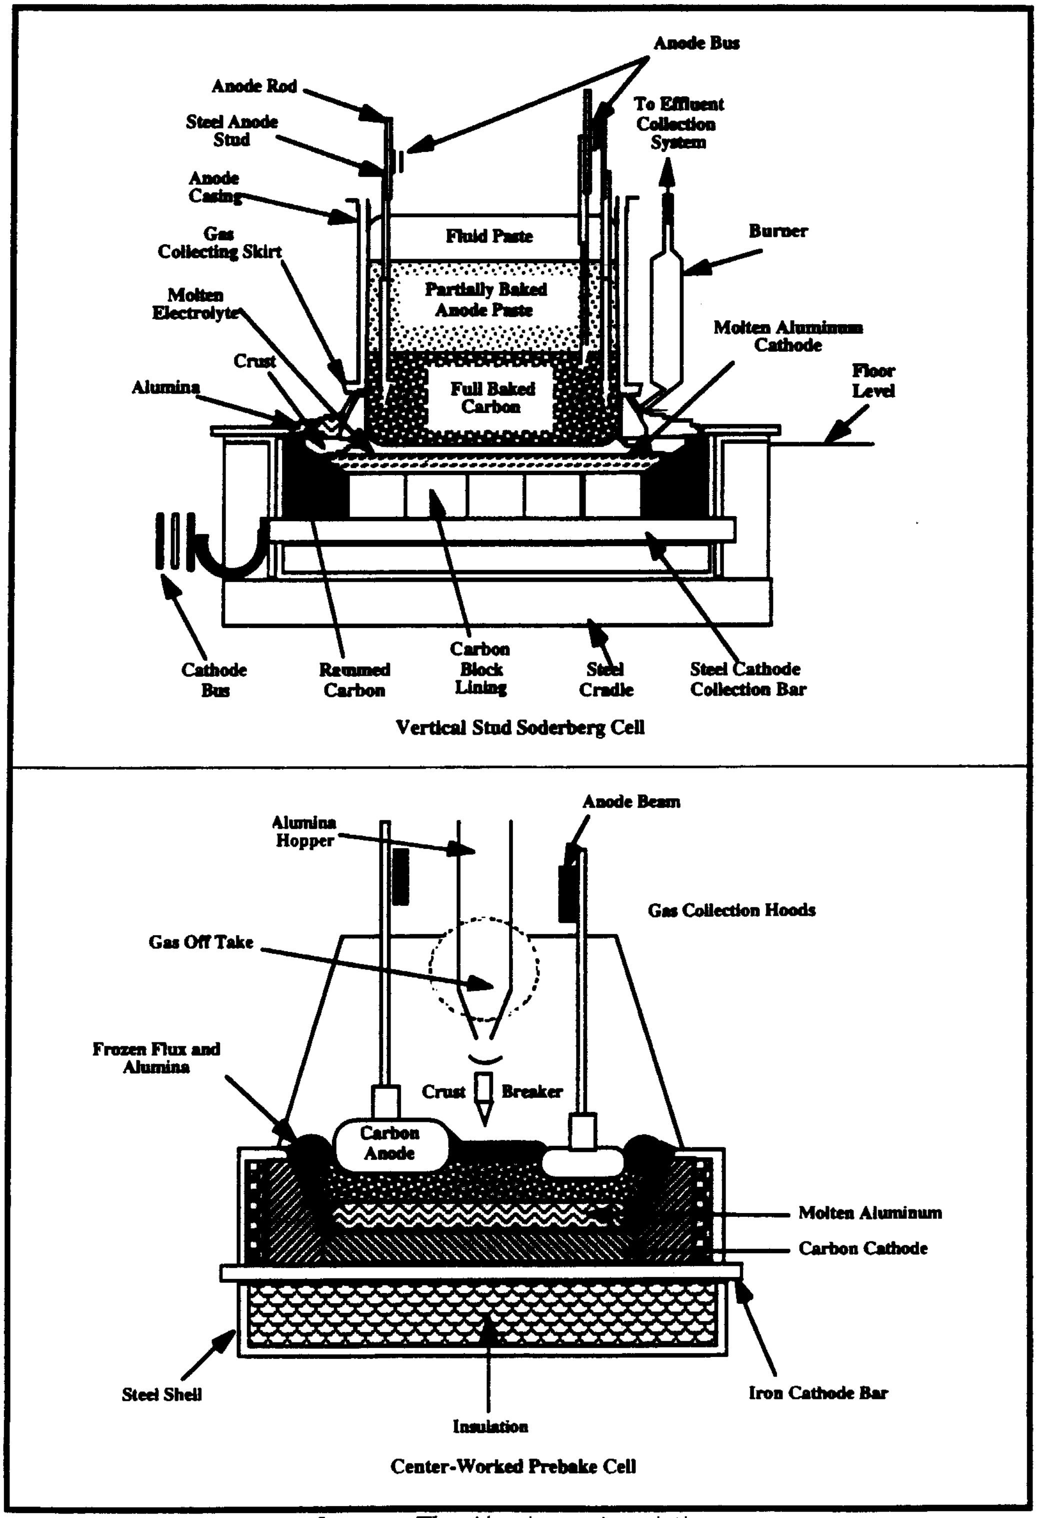
Source: *Air Pollution Engineering Manual*, *Anthony J. Buonicore and Wayne T. Davis, ed., Air & Waste Management Association, Van Norstrand Reinhold.*

R0076391

The aluminum hydroxide crystals settle to the tank bottom, and are removed. The crystals are then washed to remove any caustic soda residues, vacuum dewatered, and sent on for calcination. In the calciners (a type of rotating kiln) the aluminum hydroxide is roasted for further dewatering.

In the second step, the aluminum oxide (alumina) produced during the Bayer process is reduced to make pure molten aluminum. Alumina is a fine white powder, and consists of about equal weights of aluminum and oxygen. The strong chemical bond that exists between the aluminum and oxygen makes separating them difficult — pyrometallurgical separation requires a temperature of about 3600 degrees F. However, in 1866 it was discovered that alumina will dissolve when placed in the molten metal cryolite at around only 1742 degrees F. Once dissolved, the aluminum oxide is readily separated into aluminum and oxygen by electric current. The Hall-Heroult process, as this type of electrolytic reduction is known, begins with the placement of the alumina into electrolytic cells, or "pots," filled with molten cryolite (See Exhibit 2). Though the process requires large amounts of electricity (six or seven kilowatts of electricity per pound of aluminum produced), only a low voltage is needed. This allows the pots to be laid out in a series along one long electrical circuit to form what is known as a "potline." Within each pot a positive electric current is passed through the cryolite by means of a carbon anode submerged in the liquid cryolite. The oxygen atoms, separated from aluminum oxide, carry a negative electrical charge and are attracted to the carbon anodes. The carbon and the oxygen combine immediately to form carbon dioxide and carbon monoxide. These gases bubble free of the melt. The aluminum (which is more than 99 percent pure) collects at the bottom of the pot, is siphoned off, placed into crucibles, and then transferred to melting/holding furnaces.

Exhibit 2 - Aluminum Anodes



Source: The Aluminum Association.

R0076393

The third step consists of either mixing the molten aluminum with other metals to form alloys of specific characteristics, or casting the aluminum into ingots for transport to fabricating shops. Casting involves pouring molten aluminum into molds and cooling it with water. At some plants, the molten aluminum may be batch treated in furnaces to remove oxide, gaseous impurities and active metals such as sodium and magnesium before casting. Some plants add a flux of chloride and fluoride salts and then bubble chlorine gas, usually mixed with an inert gas, through the molten mixture. Chloride reacts with the impurities to form HCL, Al_2O_3, and metal chloride emissions. A dross forms to float on the molten aluminum and is removed before casting.

Two types of anodes may be used during the reduction process; either an anode paste or a pre-baked anode. Because the carbon is consumed during the refining process (about one-half pound of carbon is consumed for every pound of aluminum produced), if anode paste (Soderberg anode) is used, it needs to be continuously fed through an opening in the steel shell of the pot. The drawback to pre-baked anodes is that they require that a pre-baked anode fabricating plant be located nearby or on-site. Most aluminum reduction plants include their own facilities to manufacture anode paste and/or pre-baked anode blocks. These pre-baked blocks, each of which may weigh 600 or 700 pounds, must be replaced after 14 to 20 days of service.

One waste material produced during the primary production of aluminum are fluoride compounds. Fluoride compounds are principally produced during the reduction process. One reason that pre-baked anodes are favored is that the closure of the pots during smelting facilitates the capture of fluoride emissions, though many modern smelters employ other methods to capture and recycle fluorides and other emissions.

The pots used to hold the aluminum during smelting range in size from 30 to 50 feet long, 9 to 12 feet wide, and 3 to 4 feet high, and are lined with refractory brick and carbon. Eventually the carbon linings crack and must be removed and replaced. However, during the aluminum reduction process iron cyanide complexes form in the carbon portion of the liners. When the linings are removed they are "spent," and are considered to be RCRA listed hazardous waste K088.

Secondary Aluminum Processing

In the secondary production of aluminum, scrap is usually melted in gas- or oil-fired reverberatory furnaces of 30,000 to over 100,000 pounds capacity. The furnaces have one or two charging wells separated from the main bath by a refractory wall that permits only molten metal into the main bath. The principal processing of aluminum-base scrap involves the removal of magnesium by treating the molten bath with chlorine or with various fluxes such as aluminum chloride, aluminum fluoride, or mixtures of sodium and potassium chlorides and fluorides. To facilitate handling, a significant proportion of the old aluminum scrap, and in some cases new scrap, is simply melted to form sweated pig that must be processed further to make specification-grade ingot.

Another method of secondary aluminum recovery uses aluminum drosses as the charge instead of scrap. Traditionally, the term dross was defined as a thick liquid or solid phase that forms at the surface of molten aluminum, and is a by-product of melting operations. It is formed with or without fluxing and the free aluminum content of this by-product can vary considerably. Most people in the industry have generally referred to dross as being lower in aluminum content, while the material with a higher aluminum content is referred to as "skim," or "rich" or "white dross." If a salt flux is used in the melting process, the by-product is usually called a "black dross" or "salt cake." Drosses containing about 30 percent metallics are usually crushed and screened to bring the metallic content up to about 60 to 70 percent. They are then melted in a rotary furnace, where the molten aluminum metal collects on the bottom of the furnace and is tapped off. Salt slags containing less than 30 percent metallics may be leached with water to separate the metallics. In addition to this classic dross-recycling process, a new dross treatment process using a water-cooled plasma gas arc heater (plasma torch) installed in a specially-designed rotary furnace was patented recently. The new process eliminates the use of salt flux in the conventional dross treatment process, and reports recovery efficiencies of 85 to 95 percent.

III.B.2. Raw Material Inputs and Pollution Outputs

The material inputs and pollution outputs resulting from primary and secondary aluminum processing are presented by media in Exhibit 3.

Exhibit 3
Process Materials Inputs/Pollution Outputs - Aluminum

Process	Material Input	Air Emissions	Process Wastes	Other Wastes
Bauxite Refining	Bauxite, sodium hydroxide	Particulates		Residue containing silicon, iron, titanium, calcium oxides, and caustic
Alumina Clarification and Precipitation	Alumina slurry, starch, water		Wastewater containing starch, sand, and caustic	
Alumina Calcination	Aluminum hydrate	Particulates and water vapor		
Primary Electrolytic Aluminum Smelting	Alumina, carbon anodes, electrolytic cells, cryolite	Fluoride, both gaseous and particulates, carbon dioxide, sulfur dioxide, carbon monoxide, C_2F_6, CF_4, and perflourinated carbons (PFC)		Spent potliners, K088
Secondary Scrap Aluminum Smelting	Aluminum scrap, oil or gas, chlorine or other fluxes (aluminum chloride, aluminum fluoride, sodium and potassium chlorides, and fluorides)	Particulates and HCL/Cl_2		Slag containing magnesium and chlorides
Secondary Aluminum Dross Recycling	Aluminum dross, water	Particulates	Wastewater, salts	

Primary Aluminum Processing

Primary aluminum processing activities result in air emissions, proccess wastes, and other solid-phase wastes. Large amounts of particulates are generated during the calcining of hydrated aluminum oxide, but the economic value of this dust for reuse in the process is such that extensive controls are used to reduce emissions to relatively small quantities. Small amounts of particulates are emitted from the bauxite grinding and materials handling processes. Emissions from aluminum reduction processes are primarily gaseous hydrogen fluoride and particulate fluorides, alumina, carbon monoxide, volatile organics, and sulfur dioxide from the reduction cells; and fluorides, vaporized organics and sulfur dioxide from the anode baking furnaces. A variety of control devices such as wet scrubbers are used to abate emissions from reduction cells and anode baking furnaces.

Wastewaters generated from primary aluminum processing are produced during clarification and precipitation though much of this water is fed back into the process to be reused.

Solid-phase wastes are generated at two stages in the primary aluminum process; red mud produced during bauxite refining, and spent potliners from the reduction process. Red mud normally contains significant amounts of iron, aluminum, silicon, calcium, and sodium. The types and concentrations of minerals present in the mud depends on the composition of the ore and the operating conditions in the digesters. Red mud is managed on site in surface impoundments, and has not been found to exhibit any of the characteristics of hazardous waste (1990 Report to Congress on Special Wastes from Mineral Processing). The process does however, generate hazardous waste. The carbon potliners used to hold the alumina/cryolite solution during electrolytic aluminum reduction process eventually crack and need to be removed and replaced. When the liners are removed they are "spent," and are considered to be RCRA listed hazardous waste K088.

Secondary Aluminum Processing

Secondary aluminum processing also results in air emissions, wastewaters, and solid wastes. Atmospheric emissions from reverberatory (chlorine) smelting/refining represent a significant fraction of the total particulate and gaseous effluents generated in the secondary aluminum industry. Typical furnace effluent gases contain combustion products, chlorine, hydrogen chloride and metal chlorides of zinc, magnesium, and aluminum, aluminum oxide and various metals and metal compounds, depending on the quality of scrap charges. Emissions from reverberatory (fluorine) smelting/refining are similar to those from reverberatory (chlorine) smelting/refining. The use of AlF_3 rather than chlorine in the demagging step reduces demagging emissions. Fluorides are emitted as gaseous fluorides or as dusts. Baghouse scrubbers are usually used for fluoride emission control.

Solid-phase wastes are also generated during secondary scrap aluminum smelting. The slag generated during smelting contains chlorides resulting from the use of fluxes and magnesium. Waste waters are also generated during secondary aluminum processing when water is added to the smelting slags to aid in the separation of metallics. The waste waters are also likely to be contaminated with salt from the various fluxes used.

IV. PRIMARY AND SECONDARY COPPER PROCESSING INDUSTRY

IV.A. Characterization of the Industry - Copper

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Primary and Secondary Copper Industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes.

IV.A.1. Industry Size and Geographic Distribution - Copper

The following discussion is based in part upon the following documents: "U.S. Industrial Outlook 1994 - Metals," U.S. Department of Commerce, and information provided by the U.S. Department of the Interior, Bureau of Mines.

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

Copper ore is mined in both the Northern and Southern Hemispheres but is primarily processed and consumed by countries in the Northern Hemisphere. The U.S., is both a major producer (second only to Chile) and consumer of copper.

The domestic primary unwrought, or unworked, integrated copper industry consists of mines, concentrators, smelters, refineries, and electrowinning plants (SIC 3331 encompasses facilities engaging in primary smelting and refining, but not mining). The number of operating mines producing copper has decreased from 68 mines in 1989 to 65 mines in 1992. Of the 65 mines actively producing copper in the U.S., 33 list copper as the primary product. The remaining 32 mines produce copper either as a byproduct or co-product of gold, lead, zinc, or silver (U.S. DOI, Bureau of Mines). Nineteen of the 33 active mines that primarily produce copper are located in Arizona, which accounts for 65 percent of domestically mined copper ore. The remaining mines are located throughout New Mexico and Utah, which together account for 28 percent of domestic production, and Michigan, Montana, and Missouri account for the remainder (U.S. DOI, Bureau of Mines). Five integrated producers, Phelps Dodge Corp., Magma Copper Co., ASARCO Incorporated, Kennecott Corp., and Cyprus-AMAX Minerals Co., produce over 90 percent of domestic primary copper.

In 1988, there were 17 copper mines in the U.S. using leaching methods, with total production of approximately 227,000 metric tons of electrowon copper (U.S. EPA; U.S. DOI, Bureau of Mines). According to the U.S. Bureau of Mines, in 1991 441,000 metric tons of copper (an increase of 94 percent in three years) were recovered by leaching/electrowinning methods (U.S. DOI, Bureau of Mines). While solution operations are conducted throughout the Southwestern U.S., almost 75 percent of the facilities (14) are located in Arizona. There are two facilities in New Mexico, one in Utah, and one in Nevada.

In 1991, the consumption of refined copper in the U.S. decreased by four percent from 1990 levels. In 1992, refined copper was consumed at approximately 20 wire-rod mills, 41 brass mills, and 750 foundries, chemical plants, and other manufacturers. According to the Bureau of Mines, in 1992 U.S. consumption of copper was about 2.2 million tons. Consumption in 1993 and 1994 rose sharply to almost 2.7 million tons.

Fifty-six percent of recycled, or secondary copper, is derived from new scrap, while 44 percent comes from old scrap. Domestically, the secondary copper smelting industry is led by four producers: Franklin, Southwire Co., Chemetco., and Cerro Copper Co. Like the secondary aluminum industry, these producers buy the scrap they recycle on the open market, in addition to using scrap generated in their own downstream productions. The secondary copper industry is concentrated in Georgia, South Carolina, Illinois, and Missouri.

IV.A.2. Product Characterization - Copper

Because of its superior electrical conductivity, the leading domestic consumer of refined copper is wire mills, accounting for 75 percent of refined copper consumption. Brass mills producing copper and copper alloy semi-fabricated shapes are the other dominant domestic consumers at 23 percent. The dominant end-users of copper and copper alloy are the construction and electronic products industries, accounting for 65 percent of copper end-usage. Transportation equipment such as radiators also account for a fair amount of copper end-usage at 11.6 percent. Copper and copper alloys powders are used for brake linings and bands, bushings, instruments, and filters in the automotive and aerospace industries, for electrical and electronic applications, for anti-fouling paints and coatings, and for various chemical and medical purposes. Copper chemicals, principally copper sulfate and the cupric and cuprous oxides, are widely used as algaecides, fungicides, wood preservatives, copper plating, pigments, electronic applications, and numerous special applications.

IV.A.3. Economic Trends - Copper

Conditions in the U.S. copper industry continued to improve during 1993, and refined copper production increased approximately seven percent by mid-year as compared to the first half of 1992. U.S. copper consumption is estimated to grow by approximately 1.5 to 7 percent through 2000, while global consumption is expected to increase approximately two percent through the same period. The foreign market, particularly the Asian Pacific region, is expected to be a growing market because of its strong automobile, air conditioning, and consumer electronics industries. China is expected to see the largest increase in demand if economic reforms continue.

IV.B. Industrial Process Description - Copper

This section describes the major industrial processes within the Primary and Secondary Copper Processing industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

IV.B.1. Industrial Processes in the Primary and Secondary Copper Processing Industry

The following discussion is based upon materials provided by the International Copper Association, Ltd., and the following documents: "Copper Technology and Competitiveness," Congress of the United States, Office of Technology Assessment and

"Compilation of Air Pollutant Emission Factors (AP42)," the U.S. Environmental Protection Agency.

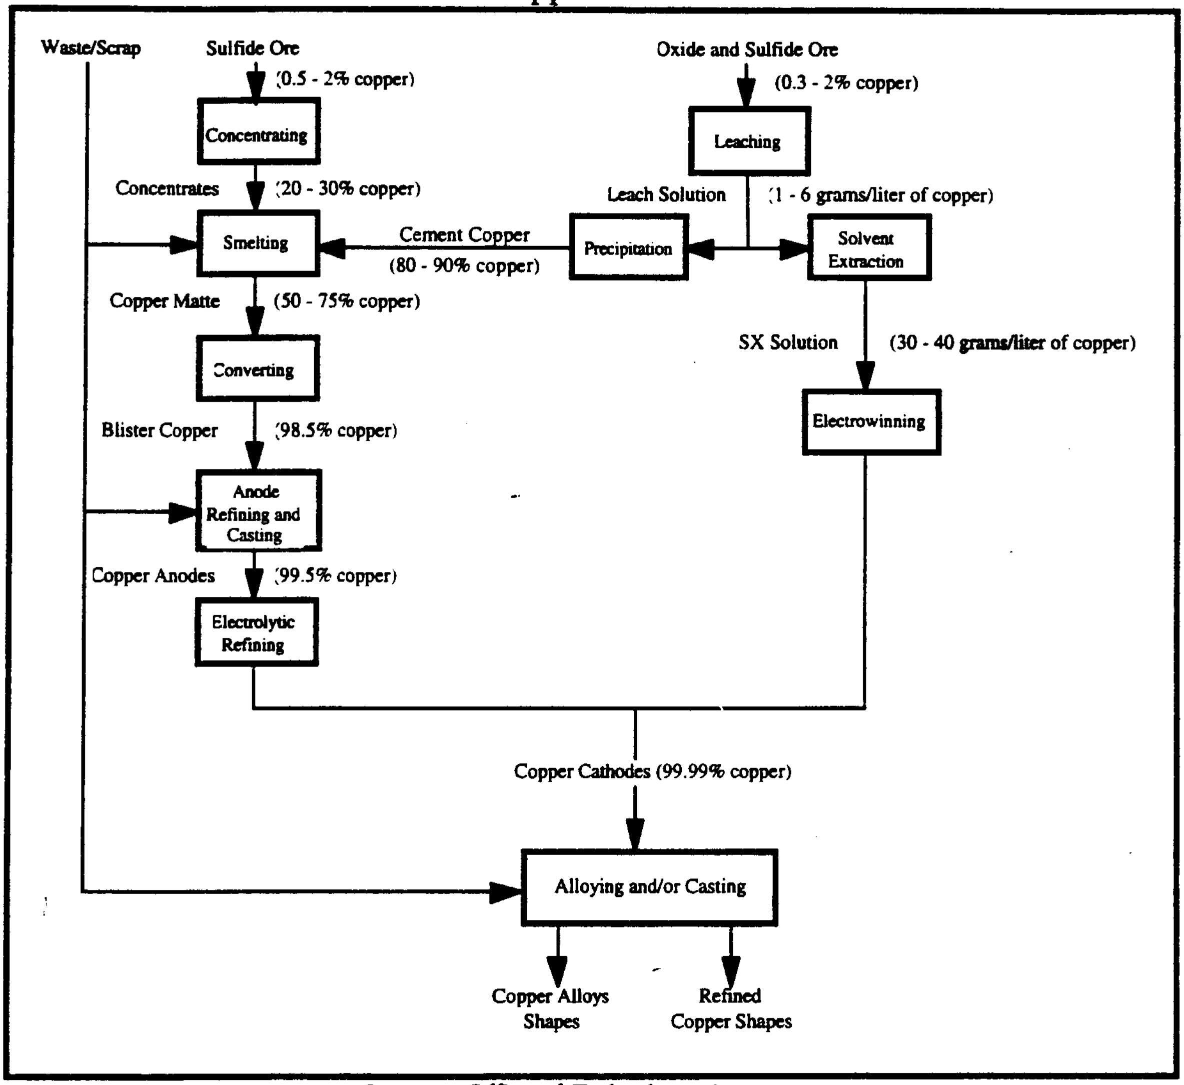
Primary Copper Processing

Copper is mined in both open pits and underground mines, depending upon the ore grade and the nature of the ore deposit. Copper ore typically contains less that one percent copper and is in the form of sulfide minerals. Once the ore is delivered above the ground, it is crushed and ground to a powdery fineness, after which it is concentrated for further processing. In the concentration process, ground ore is slurried with water, chemical reagents are added, and air is blown through the slurry. The air bubbles attach themselves to the copper minerals and are then skimmed off of the top of the flotation cells. The concentrate contains between 20 and 30 percent copper. The "tailings," or gangue minerals, from the ore fall to the bottom of the cells and are removed, dewatered by "thickeners," and transported as a slurry to a tailings pond for disposal. All water used in this operation, from dewatering thickeners and the tailings pond, is recovered and recycled back into the process.

Copper can be produced either pyrometallurgically or hydrometallurgically depending upon the ore-type used as a charge. The ore concentrates, which contain copper sulfide and iron sulfide minerals, are treated by pyrometallurgical processes to yield high purity copper products. Oxide ores, that contain copper oxide minerals which may occur in other parts of the mine, together with other oxidized waste materials, are treated by hydrometallurgical processes to yield high purity copper products. Both processes are illustrated in Exhibit 4.

Copper conversion is accomplished by a pyrometallurgical process known as "smelting." During smelting the concentrates are dried and fed into one of several different types of furnaces. There the sulfide minerals are partially oxidized and melted to yield a layer of "matte," a mixed copper-iron sulfide, and "slag," an upper layer of waste.

Exhibit 4 - Copper Production Process



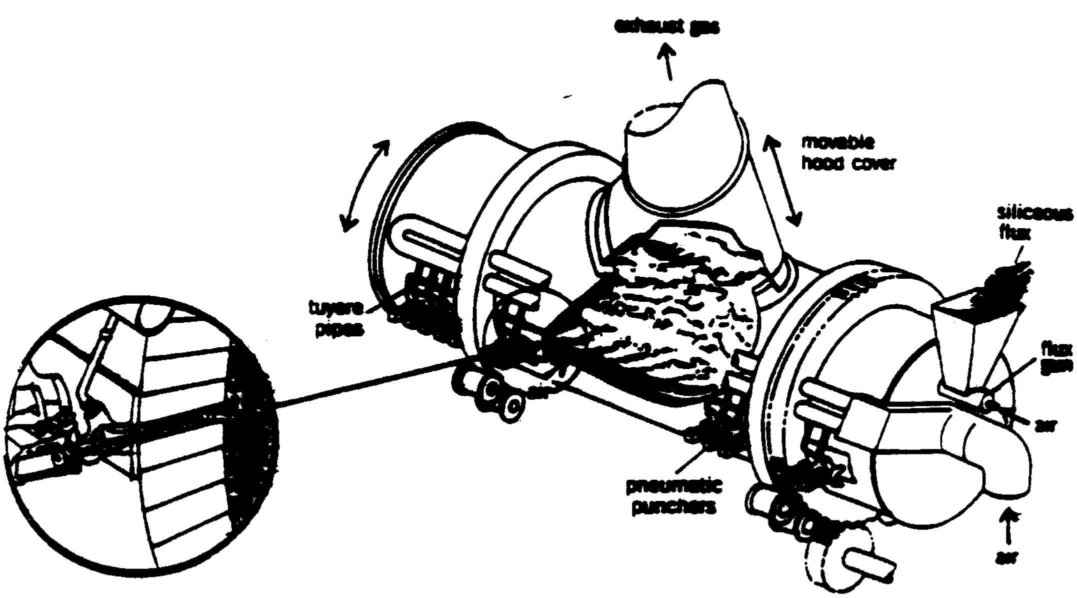
Source: Office of Technology Assessment.

R0076403

The matte is further processed by a process known as "converting." The slag is tapped from the furnace and stored or discarded in slag piles on site. A small amount of slag is sold for railroad ballast and for sand blasting grit. A third product of the smelting process is sulfur dioxide, a gas which is collected, purified, and made into sulfuric acid for sale or for use in hydrometallurgical leaching operations.

Following smelting, the copper matte is fed into a converter. During this process the copper matte is poured into a horizontal cylindrical vessel (approximately 30 x 13 feet) fitted with a row of pipes (See Exhibit 5). The pipes, known as "tuyeres," project into the cylinder and are used to introduce air into the converter. Lime and silica are added to the copper matte to react with the iron oxide produced in the process to form slag. Scrap copper may also be added to the converter. The furnace is rotated so that the tuyeres are submerged, and air is blown into the molten matte causing the remainder of the iron sulfide to react with oxygen to form iron oxide and sulfur dioxide. Following the "blow," the converter is rotated to pour off the iron silicate slag.

Exhibit 5
Cutaway View of a Pierce-Smith Converter for Producing Blister Copper from Matte



Source: *Extractive Metallurgy of Copper, A. K. Biswas and W. D. Davenport, Pergamon Press.*

R0076404

Once all of the iron is removed, the converter is rotated back and given a second blow during which the remainder of the sulfur is oxidized and removed from the copper sulfide. The converter is then rotated to pour off the molten copper, which at this point is called "blister" copper (so named because if allowed to solidify at this point, it will have a bumpy surface due to the presence of gaseous oxygen and sulfur). Sulfur dioxide from the converters is collected and fed into the gas purification system together with that from the smelting furnace and made into sulfuric acid. Due to its residual copper content, slag is recycled back to the smelting furnace.

Blister copper, containing a minimum of 98.5 percent copper, is refined to high purity copper in two steps. The first step is "fire refining," in which the molten blister copper is poured into a cylindrical furnace, similar in appearance to a converter, where first air and then natural gas or propane are blown through the melt to remove the last of the sulfur and any residual oxygen from the copper. The molten copper is then poured into a casting wheel to form anodes pure enough for "electrorefining."

In electrorefining, the copper anodes are loaded into electrolytic cells and interspaced with copper "starting sheets," or cathodes, in a bath of copper sulfate solution. When a DC current is passed through the cell the copper is dissolved from the anode, transported through the electrolyte, and re-deposited on the cathode starting sheets. When the cathodes have built-up to sufficient thickness they are removed from the electrolytic cell and a new set of starting sheets is put in their place. Solid impurities in the anodes fall to the bottom of the cell as a sludge where they are ultimately collected and processed for the recovery of precious metals such as gold and silver. This material is known as "anode slime."

The cathodes removed from the electrolytic cell are the primary product of the copper producer and contain 99.99+ percent copper. These may be sold to wire-rod mills as cathodes or processed further to a product called "rod." In manufacturing rod, cathodes are melted in a shaft furnace and the molten copper is poured onto a casting wheel to form a bar suitable for rolling into a 3/8-inch diameter continuous rod. This rod product is shipped to wire mills where it is extruded into various sizes of copper wire.

In the hydrometallurgical process, the oxidized ores and waste materials are leached with sulfuric acid from the smelting process. Leaching is performed *in situ*, or in specially prepared piles by distributing acid across the top and allowing it to percolate down through the material where it is collected. The ground under the leach pads is lined with an acid proof, impermeable plastic material to prevent leach liquor from contaminating groundwater. Once the copper-rich solutions are collected they can be processed by either of two processes - the "cementation" process or the "solvent extraction/electrowinning" process (SXEW). In the cementation process (which is rarely used today), the copper in the acidic solution is deposited on the surface of scrap iron in exchange for the iron. When sufficient copper has been "cemented out" the copper-rich iron is put into the smelter together with the ore concentrates, for copper recovery via the pyrometallurgical route.

In the SXEW process, the pregnant leach solution (PLS) is concentrated by solvent extraction. In solvent extraction, an organic chemical that extracts copper but not impurity metals (iron and other impurities) is mixed with the PLS. The copper-laden organic solution is then separated from the leachate in a settling tank. Sulfuric acid is added to the pregnant organic mixture, which strips the copper into an electrolytic solution. The stripped leachate, containing the iron and other impurities, is returned to the leaching operation where its acid is used for further leaching. The copper-rich strip solution is passed into an electrolytic cell known as an "electrowinning" cell. An electrowinning cell differs from an electrorefining cell in that it uses a permanent, insoluble anode. The copper in solution is then plated onto a starting sheet cathode in much the same manner as it is on the cathode in an electrorefining cell. The copper-depleted electrolyte is returned to the solvent extraction process where it is used to strip more copper from the organic. The cathodes produced from the electrowinning process are then sold or made into rod in the same manner as those produced from the electrorefining process.

Electrowinning cells are used also for the preparation of starting sheets for both the electrorefining and electrowinning processes. Here copper is plated onto either stainless steel or titanium cathodes. When sufficient thickness has built-up, the cathodes are removed and the copper plating on both sides of the stainless steel or titanium is stripped off. After straightening and flattening, these copper sheets are fabricated into starting sheet cathodes by mechanically attaching copper strips to be used as hangers when they are in the electrolytic cell. Both the starting sheet and the strips become part of the final product. The same care in achieving and maintaining purity must be maintained with these materials as is practiced for the electrodeposited copper.

An activity that is carried out concurrently with the primary copper production is sulfur fixation. As mentioned above, in the pyrometallurgical process most of the sulfur in the ore is transformed into sulfur dioxide (though a portion is discarded in the slag). The copper smelting and converting processes typically generate over half a ton of sulfur dioxide per ton of copper concentrate. In order to meet CAA emission standards, sulfur dioxide releases must be controlled. This is accomplished by elaborate gas collection and filtration systems after which the sulfur dioxide contained in the off-gases is made into sulfuric acid. In general, if the sulfur dioxide concentration exceeds four percent it will be converted into sulfuric acid, an ingredient in fertilizer. Fugitive gases containing less than four percent sulfuric acid are either released to the atmosphere or scrubbed to remove the sulfur dioxide. The sulfur recovery process requires the emissions to flow through a filtering material in the air emissions scrubber to capture the sulfur. A blowdown slurry is formed from the mixture of the filtering material and sulfur emissions. This slurry contains not only sulfur, but cadmium and lead, metals that are present in copper ore. The acid plant blowdown slurry/sludge that results from thickening of blowdown slurry at primary copper facilities is regulated by RCRA as hazardous waste K064.

Secondary Copper Processing

The primary processes involved in secondary copper recovery are scrap metal pretreatment and smelting. Pretreatment includes cleaning and concentration to prepare the material for the smelting furnace. Pretreatment of the feed material can be accomplished using several different procedures, either separately or in combination. Feed scrap is concentrated by manual and mechanical methods such as sorting, stripping, shredding, and magnetic separation. Feed scrap is sometimes briquetted in a hydraulic press. Pyrometallurgical pretreatment may include sweating, burning of insulation (especially from scrap wire), and drying (burning off oil and volatiles) in rotary kilns. Hydrometallurgical methods include flotation and leaching with chemical recovery.

After pretreatment the scrap is ready for smelting. Though the type and quality of the feed material determines the processes the smelter will use, the general fire-refining process is essentially the same as for the primary copper smelting industry.

IV.B.2. <u>Raw Material Inputs and Pollution Outputs</u>

The material inputs and pollution outputs resulting from primary and secondary copper processing are presented by media in Exhibit 6.

Exhibit 6
Process Materials Inputs/Pollution Outputs - Copper

Process	Material Input	Air Emissions	Process Wastes	Other Wastes
Copper Concentration	Copper ore, water, chemical reagents, thickeners		Flotation wastewaters	Tailings containing waste minerals such as limestone, and quartz
Copper Leaching	Copper concentrate, sulfuric acid		Uncontrolled leachate	Heap leach waste
Copper Smelting	Copper concentrate, siliceous flux,	Sulfur dioxide, particulate matter containing arsenic, antimony, cadmium, lead, mercury, and zinc		Acid plant blowdown slurry/sludge (K064), slag containing iron sulfides, silica
Copper Conversion	Copper matte, scrap copper, siliceous flux	Sulfur dioxide, particulate matter containing arsenic, antimony, cadmium, lead, mercury, and zinc		Acid plant blowdown slurry/sludge (K064), slag containing iron sulfides, silica
Electrolytic Copper Refining	Blister copper		Process wastewater	Slimes containing impurities such as gold, silver, antimony, arsenic, bismuth, iron, lead, nickel, selenium, sulfur, and zinc
Secondary Copper Processing		Particulates	Slag granulation waste	Slag

Primary Copper Processing

Primary copper processing results in air emissions, process wastes, and other solid-phase wastes. Particulate matter and sulfur dioxide are the principal air contaminants emitted by primary copper smelters. Copper and iron oxides are the primary constituents of the particulate matter, but other oxides, such as arsenic, antimony, cadmium, lead, mercury and zinc, may also be present, with metallic sulfates and sulfuric acid mist. Single stage electrostatic precipitators are widely used in the primary copper industry to control these particulate emissions. Sulfur oxides contained in the off-gases are collected, filtered, and made into sulfuric acid.

Large amounts of water are used in the copper concentration process though disposal of liquid wastes is rarely a problem because the vast majority of the water is recycled back into the process. Once the wastewater exits the flotation process it is sent to a sediment control pond where it is held long enough for most of the sediment to settle.

The seepage and leaking of sulfuric acid solutions used in leaching can also produce liquid wastes, however this potential is off-set by the copper producer's interest to collect as much of the copper-bearing leachate as possible. Older operations generally do not have protective liners under the piles, and experience some loss of leachate. New leaching operations use impermeable membranes to confine leach solutions and channel them to collection ponds.

Electrolytic refining does produce wastewaters that must be treated and discharged, reused, or disposed in some manner. Many facilities use a wastewater treatment operation to treat these wastes.

Primary copper processing primarily generates two solid-phase wastes; slag and blowdown slurry/sludge. Slag is generated during the smelting, converting, fire refining, and electrolytic refining stages. Slag from smelting furnaces is higher in copper content than the original ores taken from the mines. These slags therefore, may be sent to a concentrator and the concentrate returned to the smelter. This slag processing operation results in slag tailings. Slag resulting from converting and fire refining also is normally returned to the process to capture any remaining mineral values. Blowdown slurry/sludge that results from the sulfur recovery process is regulated by RCRA as hazardous waste K064.

Secondary Copper Processing

Secondary copper processing produces the same types of wastes as primary pyrometallurgical copper processing. One type of secondary processing pollutant that differs from primary processing is the air emissions. Air pollutants are generated during the drying of chips and borings to remove excess oils and cuttings fluids and causes discharges of large amounts of dense smoke containing soot and unburned hydrocarbons. These emissions can be controlled by baghouses and/or direct-flame afterburners.

V. PRIMARY AND SECONDARY LEAD PROCESSING INDUSTRY

V.A. Characterization of the Industry - Lead

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Primary and Secondary Lead Industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes.

V.A.1. Industry Size and Geographic Distribution - Lead

The following discussion is based upon "U.S. Industrial Outlook 1994 - Metals," U.S. Department of Commerce, and information provided by the U.S. Department of the Interior, Bureau of Mines.

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

The U.S. is the world's third largest primary lead producer with 1/7 of all production reserves. Over 80 percent of the lead ore mined domestically comes from Missouri. The mines with the largest ore capacity are owned by Asarco Inc., The Doe Run Co., and Cominco American Inc., the first two of which are also integrated producers of refined lead materials. The majority of lead ores mined in the U.S. are smelted in conventional blast furnaces and are refined using pyrometallurgical methods.

In 1993, the lead industry employed 600 workers at primary smelters and refineries, and 1,700 at secondary smelters and refineries. Primary and secondary smelter and refinery employment was not expected to change in 1994 (U.S. DOI, Bureau of Mines, 1995).

The U.S. is the world's largest recycler of lead scrap and is able to meet about 72 percent of its total refined lead production needs from scrap recycling. At the end of 1991, the secondary lead industry consisted of 16 companies that operated 23 battery breakers-smelters with capacities of between 10,000 and 120,000 metric tons a year (mt/y); five smaller operations with capacities between 6,000 and 10,000 mt/y; and 15 smaller plants that produced mainly specialty alloys for solders, brass and bronze ingots, and miscellaneous uses. Sanders Lead Co., East Penn Mfg. Co., and Schuylkill Metals Corp. are some of the larger secondary lead producers in the United States.

V.A.2. Product Characterization - Lead

Within the U.S., the power storage battery industry is the largest end-user of lead, accounting for 83 percent of the estimated 1.357 Mmt domestically consumed in 1993. Demand for lead by the lead-acid battery industry rose 12 percent to 1.12 Mmt in 1993 due to a significant increase in consumer need for batteries. Industrial demand for batteries rose as well, due both to the growth in demand for stationary batteries used in telecommunications and back-up power systems for computers, lighting, and security systems, as well as an increased need for mobile batteries used in fork lifts and other battery-powered vehicles. Additional lead end-uses and users of consequence are ammunition, consumers of lead oxides used in television glass and computers, construction (including radiation shielding) and protective coatings, and miscellaneous uses such as ballasts, ceramics, and crystal glass.

V.A.3. Economic Trends - Lead

In 1994, domestic consumption of lead is expected to increase seven percent to 1.5 Mmt. This increase is based in part on expected increased demand from the automobile sector for both original and replacement equipment batteries. This increased consumption should continue to be met by the secondary lead industry, which is expected to continue to supply approximately 72 percent of total domestic production. Through 1998, production of unwrought lead is expected to grow 1.4 percent to 1.3 Mmt, while U.S. consumption is estimated to increase 1.4 percent to 1.6 Mmt.

Power storage batteries, both industrial and automotive, will continue to be the largest end-users. Demand for power storage batteries may be greater than initially expected due to several factors. California and nine Northeastern States have recently passed laws requiring the production, but not the consumer use of, electric vehicles. Other innovative uses of lead include lead-acid batteries for load-leveling of electricity. Using batteries for load-leveling reduces the total installed generating capacity needed by charging the battery at times of low demand for electricity, then discharging it to level the power supply at times of peak demand. A pilot facility in Chino, CA has already come on line with a battery which uses 2,000 pounds of lead and has a capacity of 40 megawatt hours. Another potential use for refined lead is the containment of high-level radioactive waste. Argentina and Sweden already employ it for this purpose and this use is being considered elsewhere, including the United States. A final innovative application being tested for lead is its use as a road paving stabilizer.

R0076411

Tests have shown that certain lead compounds can double the life of asphalt while only adding four to five percent to production costs.

V.B. Industrial Process Description - Lead

This section describes the major industrial processes within the Primary and Secondary Lead Processing industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

V.B.1. Industrial Processes in the Primary and Secondary Lead Processing Industry

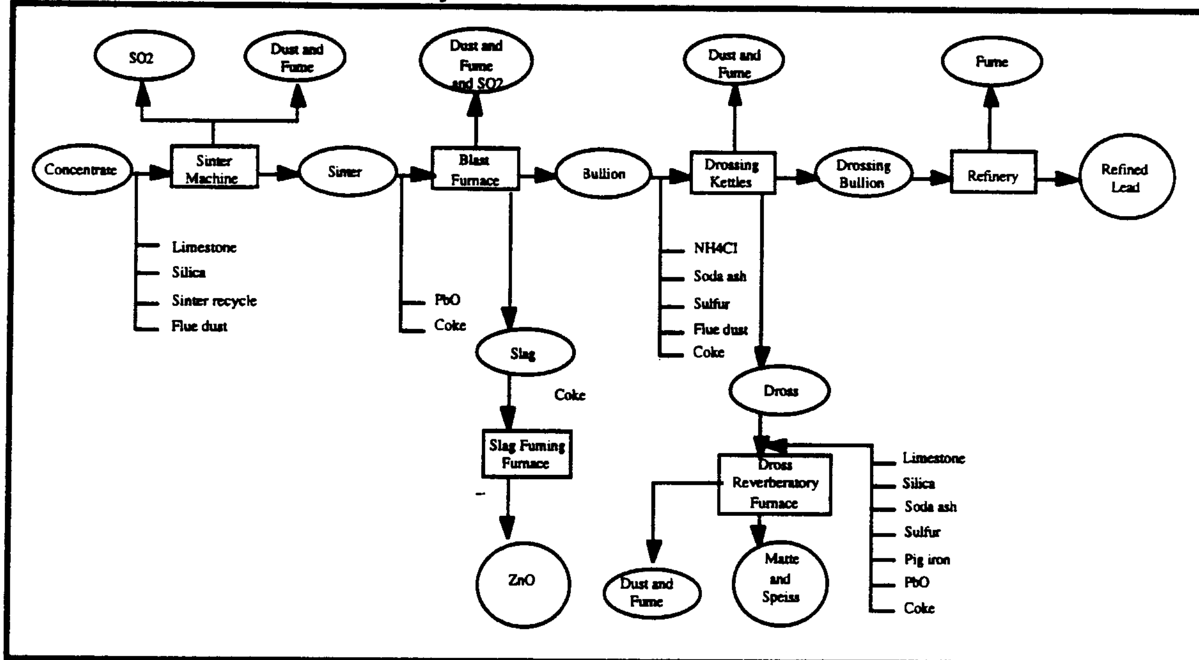
The following discussion is based upon the following documents: "Compilation of Air Pollutant Emission Factors (AP42)," "Background Listing Document for K065," "1990 Report to Congress on Special Wastes From Mineral Processing," published by the U.S. Environmental Protection Agency, and "Recycled Metals in The United States, A Sustainable Resource," published by U.S. Department of the Interior, Bureau of Mines.

Primary Lead Processing

The primary lead production process consists of four steps: sintering, smelting, drossing, and pyrometallurgical refining (See Exhibit 7). To begin, a feedstock comprised mainly of lead concentrate is fed into a sintering machine. Other raw materials may be added including iron, silica, limestone flux, coke, soda, ash, pyrite, zinc, caustic, and particulates gathered from pollution control devices. In the sintering machine the lead feedstock is subjected to blasts of hot air which burn off the sulfur, creating sulfur dioxide. The lead material existing after this process contains about nine percent of its weight in carbon. The sinter is then fed along with coke, various recycled and cleanup materials, limestone, and other fluxing agents into a blast furnace for reducing, where the carbon acts as a fuel and smelts or melts the lead material. The molten lead flows to the bottom of the furnace where four layers form: "speiss" (the lightest material, basically arsenic and antimony); "matte" (copper sulfide and other metal sulfides); blast furnace slag (primarily silicates); and lead bullion (98 weight percent lead). All layers are then drained off. The speiss and matte are sold to copper smelters for recovery of copper and precious metals. The blast furnace slag which contains zinc, iron, silica, and lime is stored in piles and partially recycled. Sulfur oxide emissions are generated in blast furnaces from small quantities of residual lead sulfide and lead sulfates in the sinter feed.

Rough lead bullion from the blast furnace usually requires preliminary treatment in kettles before undergoing refining operations. During drossing the bullion is agitated in a drossing kettle and cooled to just above its freezing point (700 to 800 degrees F). A dross, which is composed of lead oxide, along with copper, antimony, and other elements, floats to the top and solidifies above the molten lead.

Exhibit 7 - Primary Lead Production Process



Source: Air Pollution Engineering Manual, Anthony J. Buonicore and Wayne T. Davis, ed., Air & Waste Management Association, Van Norstrand Reinhold.

The dross is removed and fed into a dross furnace for recovery of the non-lead mineral values. To enhance copper recovery, drossed lead bullion is treated by adding sulfur bearing materials, zinc, and/or aluminum, lowering the copper content to approximately 0.01 percent.

During the fourth step the lead bullion is refined using pyrometallurgical methods to remove any remaining non-lead saleable materials (e.g., gold, silver, bismuth, zinc, and metal oxides such as antimony, arsenic, tin, and copper oxide). The lead is refined in a cast iron kettle during five stages. Antimony, tin, and arsenic are removed first. Then gold and silver are removed by adding zinc. Next, the lead is refined by vacuum removal of zinc. Refining continues with the addition of calcium and magnesium. These two materials combine with bismuth to form an insoluble compound that is skimmed from the kettle. In the final step caustic soda and/or nitrates may be added to the lead to remove any remaining traces of metal impurities. The refined lead will have a purity of 99.90 to 99.99 percent, and may be mixed with other metals to form alloys or it may directly be cast into shapes.

The processes used in the primary production of lead produce several waste streams of concern under different regulatory scenarios. The listed RCRA hazardous wastes include smelting plant wastes that are sent to surface impoundments to settle. The impoundments are used to collect solids from miscellaneous slurries, such as acid plant blowdown, slag granulation water, and plant washings. Acid plant blowdown is generated during the production of lead the same way it is produced at a copper plant; during the recovery of sulfur dioxide emissions. Slag granulation water is produced when hot slag from the process is sprayed with water to be cooled and granulated before transport to a slag pile. Plant washing is a housekeeping process and the washdown normally contains a substantial amount of lead and other process materials. When these materials accumulate in a surface impoundment or are dredged from the surface impoundment they are regulated as hazardous waste K065.

Secondary Lead Processing

The secondary production of lead begins with the recovery of old scrap from worn-out, damaged, or obsolete products and new scrap that is made of product wastes and smelter-refinery drosses, residues, and slags. The chief source of old scrap in the U.S. is lead-acid batteries, though cable coverings, pipe, sheet, and terne bearing metals also serve as a source of scrap. Solder, a tin-based alloy, may also be recovered from the processing of circuit boards for use as lead charge.

While some secondary lead is recovered directly for specialty products like babbitt metal, solder, re-melt, and copper-base alloys, about 97 percent of secondary lead is recovered at secondary lead smelters and refineries as either soft (unalloyed) or antimonial lead, most of which is recycled directly back into the manufacture of new batteries. Unlike copper and zinc, where scrap processing varies tremendously by scrap type and ultimate use, the dominance of lead battery scrap allows for a more standard secondary recovery process. Prior to smelting, batteries must be broken by one of several techniques, and classified into their constituent products. The modern battery breaking process classifies the lead into metallics, oxides and sulfate fragments, and organics into separate casing and plate separator fractions. Cleaned polypropylene case fragments are recycled back into battery cases or other products. The dilute sulfuric acid is either neutralized for disposal, or recycled into the local acid market. One of three main smelting processes is then used to reduce the lead fractions to produce lead bullion.

The majority of domestic battery scrap is processed in blast furnaces or rotary reverberatory furnaces. Used to produce a semisoft lead, a reverberatory furnace is more suitable for processing fine particles and may be operated in conjunction with a blast furnace. The reverberatory furnace is a rectangular shell lined with refractory brick, and is fired directly with oil or gas to a temperature of 2300 degrees F. The material is heated by direct contact with combustion gases. The average furnace can process about 50 tons per day. About 47 percent of the charge is recovered as lead product and is periodically tapped into mold or holding pots. Forty-six percent of the charge is removed as slag and later processed in blast furnaces. The remaining seven percent of the furnace charge escapes as dust or fume. Short (batch) or long (continuous) rotary furnaces may be used. Slags from reverberatory furnaces are processed through the blast furnace for recovery of alloying elements.

Blast furnaces produce hard lead from charges containing siliceous slag from previous runs (about 4.5 percent of the charge), scrap iron (about 4.5 percent), limestone (about 3 percent), and coke (about 5.5 percent). The remaining 82.5 percent of the charge is comprised of oxides, pot furnace refining drosses, and reverberatory slag. The proportions of rerun slags, limestone, and coke, respectively vary to as high as eight percent, ten percent, and eight percent of the charge. Processing capacity of the blast furnace ranges from 20 to 80 tons per day. Similar to iron cupolas, the blast furnace is a vertical steel cylinder lined with refractory brick. Combustion air at 0.5 to 0.75 pounds per square inch is introduced through tuyeres (pipes) at the bottom of the furnace. Some of the coke combusts to melt the charge, while the remainder reduces lead oxides to elemental lead.

As the lead charge melts, limestone and iron float to the top of the molten bath and form a flux that retards oxidation of the product lead. The molten lead flows from the furnace into a holding pot at a nearly continuous rate. The product lead constitutes roughly 70 percent of the charge. From the holding pot, the lead is usually cast into large ingots, called pigs or sows. About 18 percent of the charge is recovered as slag, with about 60 percent of this being matte. Roughly five percent of the charge is retained for reuse, and the remaining seven percent of the charge escapes as dust or fume.

Refining/casting is the use of kettle type furnaces for re-melting, alloying, refining, and oxidizing processes. Materials charged for re-melting are usually lead alloy ingots that require no further processing before casting. Alloying furnaces simply melt and mix ingots of lead and alloy materials. Antimony, tin, arsenic, copper, and nickel are the most common alloying materials. Refining furnaces, as in primary lead production, are used either to remove copper and antimony to produce soft lead, or to remove arsenic, copper, and nickel for hard lead production.

Newer secondary recovery plants use lead paste desulfurization to reduce sulfur dioxide emissions and waste sludge generation during smelting. At the Doe Run Resource Recycling Facility, battery paste containing lead sulfate and lead oxide is desulfurized with soda ash to produce market grade sodium sulfate solution. The desulfurized paste is processed in a reverberatory furnace. The lead carbonate product may then be treated in a short rotary furnace. The battery grids and posts are processed separately in a rotary smelter.

V.B.2. Raw Material Inputs and Pollution Outputs

The material inputs and pollution outputs resulting from primary and secondary lead processing are presented by media in Exhibit 8.

Exhibit 8
Process Materials Inputs/Pollution Outputs - Lead

Process	Material Input -	Air Emissions	Process Wastes	Other Wastes
Lead Sintering	Lead ore, iron, silica, limestone flux, coke, soda, ash, pyrite, zinc, caustic, and baghouse dust	Sulfur dioxide, particulate matter containing cadmium and lead		
Lead Smelting	Lead sinter, coke	Sulfur dioxide, particulate matter containing cadmium and lead	Plant washdown wastewater, slag granulation water	Slag containing impurities such as zinc, iron, silica, and lime, surface impoundment solids (K065)
Lead Drossing	Lead bullion, soda ash, sulfur, baghouse dust, coke			Slag containing such impurities as copper, surface impoundment solids (K065)
Lead Refining	Lead drossing bullion			
Lead-acid Battery Breaking	Lead-acid batteries			Polypropylene case fragments, dilute sulfuric acid
Secondary Lead Smelting	Battery scrap, rerun slag, drosses, oxides, iron, limestone, and coke	Sulfur dioxide, particulate matter containing cadmium and lead		Slag, emission control dust (K069)

Primary Lead Processing

Primary lead processing activities usually result in air emissions, process wastes, and other solid-phase wastes. The primary air emissions from lead processing are substantial quantities of SO_2 and/or particulates. Nearly 85 percent of the sulfur present in the lead ore concentrate is eliminated in the sintering operation. The offgas

R0076417

containing a strong stream of SO_2 (five to seven percent SO_2) is sent to a sulfuric acid plant, while the weak stream (less than 0.5 percent SO_2) is vented to the atmosphere after removal of particulates. Particulate emissions from sinter machines range from five to 20 percent of the concentrated ore feed. Approximately 15 percent of the sulfur in the ore concentrate fed to the sinter machine is eliminated in the blast furnace. However, only half of this amount, about seven percent of the total sulfur in the ore, is emitted as SO_2. Particulate emissions from blast furnaces contain many different kinds of material, including a range of lead oxides, quartz, limestone, iron pyrites, iron-limestone-silicate slag, arsenic, and other metallic compounds associated with lead ores. The emission controls most commonly employed are fabric filters and electrostatic precipitators.

As mentioned above, approximately seven percent of the total sulfur present in lead ore is emitted as SO_2. The remainder is captured by the blast furnace slag. The blast furnace slag is composed primarily of iron and silicon oxides, as well as aluminum and calcium oxides. Other metals may also be present in smaller amounts including antimony, arsenic, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, mercury, molybdenum, silver, and zinc. This blast furnace slag is either recycled back into the process or disposed of in piles on site. About 50-60 percent of the recovery furnace output is slag and residual lead that are both returned to the blast furnace. The remainder of this dross furnace output is sold to copper smelters for recovery of the copper and other precious metals.

Slag from the primary processing of lead that is not recycled was retained within the Bevill exemption and addressed in the 1990 Report to Congress. In the subsequent regulatory determination (56 FR 27300), EPA determined that regulation of this waste under Subtitle C was not warranted.

The smelting of primary lead produces a number of wastewaters and slurries, including acid plant blowdown, slag granulation water, and plant washdown water. Slag granulation water is generated when slag is disposed. It can either be sent directly to a slag pile or granulated in a water jet before being transported to the slag pile. The granulation process cools newly generated hot slag with a water spray. Slag granulation water is often transported to surface impoundments for settling. Plant washdown water results from plant housekeeping and normally contains a substantial amount of lead and other process materials. Acid plant blowdown results from the conversion of SO_2 to sulfuric acid. All of these materials are included in the definition of hazardous waste K065.

Secondary Lead Processing

Secondary lead processing results in the generation of air emissions and solid-phase wastes. As with primary lead processing, reverberatory and blast furnaces used in smelting account for the vast majority of the total lead emissions. Other emissions from secondary smelting include oxides of sulfur and nitrogen, antimony, arsenic, copper, and tin. Smelting emissions are generally controlled with a settling and cooling chamber, followed by a baghouse. Other air emissions are generated during battery breaking. Emissions from battery breaking are mainly sulfuric acid and dusts containing dirt, battery case material, and lead compounds. Emissions from crushing are also mainly dusts.

The solid-phase wastes generated by secondary processing are emission control dust and slag. Slag is generated from smelting, and the emission control dust, when captured and disposed of, is considered to be hazardous waste K069.

VI. PRIMARY AND SECONDARY ZINC PROCESSING

VI.A. Characterization of the Industry - Zinc

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the Primary and Secondary Zinc Industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes.

VI.A.1. Industry Size and Geographic Distribution - Zinc

The following discussion is based upon "U.S. Industrial Outlook 1994 - Metals," U.S. Department of Commerce, and information provided by the U.S. Department of the Interior, Bureau of Mines.

Variation in facility counts occur across data sources due to many factors, including reporting and definitional differences. This document does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

Zinc is the fourth most widely used metal after iron, aluminum, and copper (lead is fifth). In abundant supply world-wide, zinc is mined and produced mainly in Canada, the former Soviet Union, Australia, Peru, Mexico, and the United States. Historically, in the U.S. recoverable zinc has been mined in 19 States: Alaska, Arizona, Colorado, Idaho, Illinois, Kansas, Missouri, Montana, Nevada, New Jersey, New Mexico, New York, Oklahoma, Pennsylvania, Tennessee, Utah, Virginia, Washington, and Wisconsin. In 1993, nearly 50 percent of all domestic zinc was produced in Alaska. Except for Missouri (eight percent) other exact state production figures were withheld to protect company proprietary data. Other top producing states in order of output were Tennessee, New York, and Missouri.

In 1993, the zinc industry employed 22,250 workers at mines and mills and 1,400 at primary smelters. For 1994, mine and mill employment was expected to stay at 2,200 and employment at zinc smelters was expected to decrease to 1,100 (U.S. DOI, Bureau of Mines, 1995). Employment decreases for primary smelters was attributed to the indefinite closures of a smelter in Oklahoma in later 1993. The four primary zinc smelters in the U.S., are located in Illinois, Oklahoma, Tennessee and Pennsylvania. There are currently 10 secondary zinc recovery plants in the U.S. (U.S. EPA, AP42, 1993).

VI.A.2. Product Characterization - Zinc

The U.S. accounts for almost one-quarter of worldwide slab zinc consumption and is the world's single largest market. About 80 percent of zinc is used in metal form while the rest is used in compound form. Ninety percent of zinc metal is used for galvanizing steel (a form of corrosion protection) and for alloys, and is used in a wide variety of materials in the automotive, construction, electrical, and machinery sectors of the economy. Zinc compound use also varies widely, but is mainly found in the agricultural, chemical, paint, pharmaceutical, and rubber sectors of the economy.

VI.A.3. Economic Trends - Zinc

In 1993, both domestic mine and slab zinc production were down, with slab zinc production down 4.75 percent to .381 Mmt. This production slump was off-set by domestic consumption which increased significantly in 1993, up eight percent, to 1.15 Mmt due to a surge in galvanized steel shipments. Strong growth in automobile demand and continued improvement in the construction industry led to increased consumption along with increased zinc die casting consumption. Consumption of zinc compounds also increased, especially of zinc oxide which increased over 27 percent. More than half of domestic zinc oxide production went to the rubber industry, primarily for use in producing tires (zinc is used in the compounding of rubber before it is cured).

In 1994, domestic refined zinc production is expected to continue its downward trend and drop 3.5 percent from .381 to .370 Mmt. However, domestic demand for zinc is expected to grow 4.2 percent in 1994 to 1.22 Mmt due to increases in all end uses except for nonresidential construction. This increased domestic demand should be met in large part by imports from Canada and Mexico. Imports of slab zinc mainly from these two countries in 1993 made up for almost 65 percent of domestic consumption. Zinc alloy was given preferential status in the Generalized System of Preferences 1990, which allows Mexico and member countries to export zinc alloys to the U.S. duty free. Tariffs on zinc from Canada will be phased out by 1998 due to the U.S.-Canada Free Trade Agreement. Zinc from the former Soviet Union is not expected to be used for U.S. consumption though its production is expected to negatively affect the U.S. market. This situation is similar to that for other metals in that over-production by former eastern bloc countries causes world prices to drop as London Metal Exchange warehouse supplies increase.

Domestically, the long-term demand for zinc is expected to increase, with consumption rising about 2.2 percent a year to reach 1.27 Mmt by 1998. Galvanization using zinc is expected to continue as the largest end-user of zinc, and it is predicted that by 1995 virtually all automobiles sold in the U.S. will be made from two-sided steel, enabling these vehicles to last at least ten years without any perforation damage. Zinc die-casting is also expected to increase in use as new applications are put into use.

VI.B. Industrial Process Description

This section describes the major industrial processes within the Primary and Secondary Zinc Processing industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

VI.B.1. Industrial Processes in the Primary and Secondary Zinc Processing Industry

The following discussion is based upon the following documents: "Compilation of Air Pollutant Emission Factors(AP42), " "Background Listing Document for K065," "1990 Report to Congress on Special Wastes from Mineral Processing," published by the U.S. Environmental Protection Agency, and "Recycled Metals in the United States, A Sustainable Resource," published by U.S. Department of the Interior, Bureau of Mines.

Primary Zinc Processing

The primary production of zinc begins with the reduction of zinc concentrates to metal (the zinc concentration process consists of separating the ore, which may be as little as two percent zinc, from waste rock by crushing and flotation, a process normally performed at the mining site and discussed in more detail in the Metal Mining Profile). Zinc reduction is accomplished in one of two ways: either pyrometallurgically by distillation (retorting in a furnace) or hydrometallurgically by electrowinning. Because hydrometallurgical refining accounts for approximately 80 percent of total zinc refining, pyrometallurgical zinc refining will not be discussed in detail in this profile.

Four processing stages are generally used in hydrometallurgic zinc refining: calcining, leaching, purification, and electrowinning. Calcining, or roasting, is common to both pyrometallic and electrolytic (a form of hydrometallurgy) zinc refining, and is performed to eliminate sulfur and form leachable zinc oxide. Roasting is a high-temperature process that converts zinc sulfide concentrate to an impure zinc oxide called calcine. Roaster types include multiple-hearth, suspension, or fluidized-bed. In general, calcining begins with the mixing of zinc-containing materials with coal. This mixture is then heated, or roasted, to vaporize the zinc oxide which is then moved out of the reaction chamber with the resulting gas stream. The gas stream is directed to the bag-house (filter) area where the zinc oxide is captured in bag-house dust.

In a multiple-hearth roaster, the concentrate drops through a series of nine or more hearths stacked inside a brick-lined cylindrical column. As the feed concentrate drops through the furnace, it is first dried by the hot gases passing through the hearths and then oxidized to produce calcine. Multiple hearth roasters are unpressurized and operate at approximately 1,300 degrees F.

In a suspension roaster, the concentrates are blown into a combustion chamber. The roaster consists of a refractory-lined cylindrical shell, with a large combustion space at the top and two to four hearths in the lower portion. Additional grinding, beyond that required for a multiple hearth furnace, is normally required to assure that heat transfer to the material is sufficiently rapid for desulfurization and oxidation reaction to occur in the furnace chamber. Suspension roasters are also unpressurized and operate at about 1,800 degrees F.

Fluidized bed roasters require that the sulfide concentrates be finely ground. The concentrates are then suspended and oxidized on a feedstock bed supported on an air column. As in the suspension bed roaster, the reduction rates for desulfurization are more rapid than in the older multiple-hearth processes. Fluidized-bed roasters operate under a pressure slightly lower than atmospheric and at temperatures averaging 1,800 degrees F. In the fluidized-bed process, no additional fuel is required after ignition has been achieved. The major advantages of this roaster are greater throughput capacities and greater sulfur removal capabilities. All of the above calcining processes generate sulfur dioxide, which is controlled and converted to sulfuric acid as a marketable process by-product.

Electrolytic processing of desulfurized calcine consists of three basic steps; leaching, purification, and electrolysis. Leaching refers to the dissolving of the captured calcine in a solution of sulfuric acid to form a zinc sulfate solution. The calcine may be leached once or twice. In the double-leach method, the calcine is dissolved in a slightly acidic solution to remove the sulfates. The calcine is then leached a second time in a stronger solution which dissolves the zinc. This second leaching step is actually the beginning of the third step of purification because many of the iron impurities (such as goethite and hematite) drop out of the solution as well as the zinc.

After leaching, the solution is purified in two or more stages by adding zinc dust. The solution is purified as the dust forces deleterious elements to precipitate so that they can be filtered out. Purification is usually conducted in large agitation tanks. The process takes place at temperatures ranging from 104 to 185 degrees F, and pressures ranging from atmospheric to 2.4 atmospheres. The elements recovered during purification include copper as a cake and cadmium as a metal. After purification the solution is ready for the final step; electrowinning.

Zinc electrowinning takes place in an electrolytic cell and involves running an electric current from a lead-silver alloy anode through the aqueous zinc solution. This process charges the suspended zinc and forces it to deposit onto an aluminum cathode (a plate with an opposite charge) which is immersed in the solution. Every 24 to 48 hours, each cell is shut down, the zinc-coated cathodes removed and rinsed, and the zinc mechanically stripped from the aluminum plates. The zinc concentrate is then melted and cast into ingots, and is often as high as 99.995 percent pure.

Electrolytic zinc smelters contain as many as several hundred cells. A portion of the electrical energy is converted into heat, which increases the temperature of the electrolyte. Electrolytic cells operate at temperature ranges from 86 to 95 degrees F at atmospheric temperature. During electrowinning a portion of the electrolyte passes through cooling towers to decrease its temperature and to evaporate the water it collects during the process.

Sulfur dioxide is generated in large quantities during the primary zinc refining process and sulfur fixation is carried out concurrently with the primary production process in order to meet CAA emission standards. Concentrations of sulfur dioxide in the off-gas vary with the type of roaster operation. Typical concentrations for multiple hearth, suspension, and fluidized bed roasters are 4.5 to 6.5 percent, 10 to 13 percent, and 7 to 12 percent respectively. This sulfur dioxide is then converted into sulfuric acid.

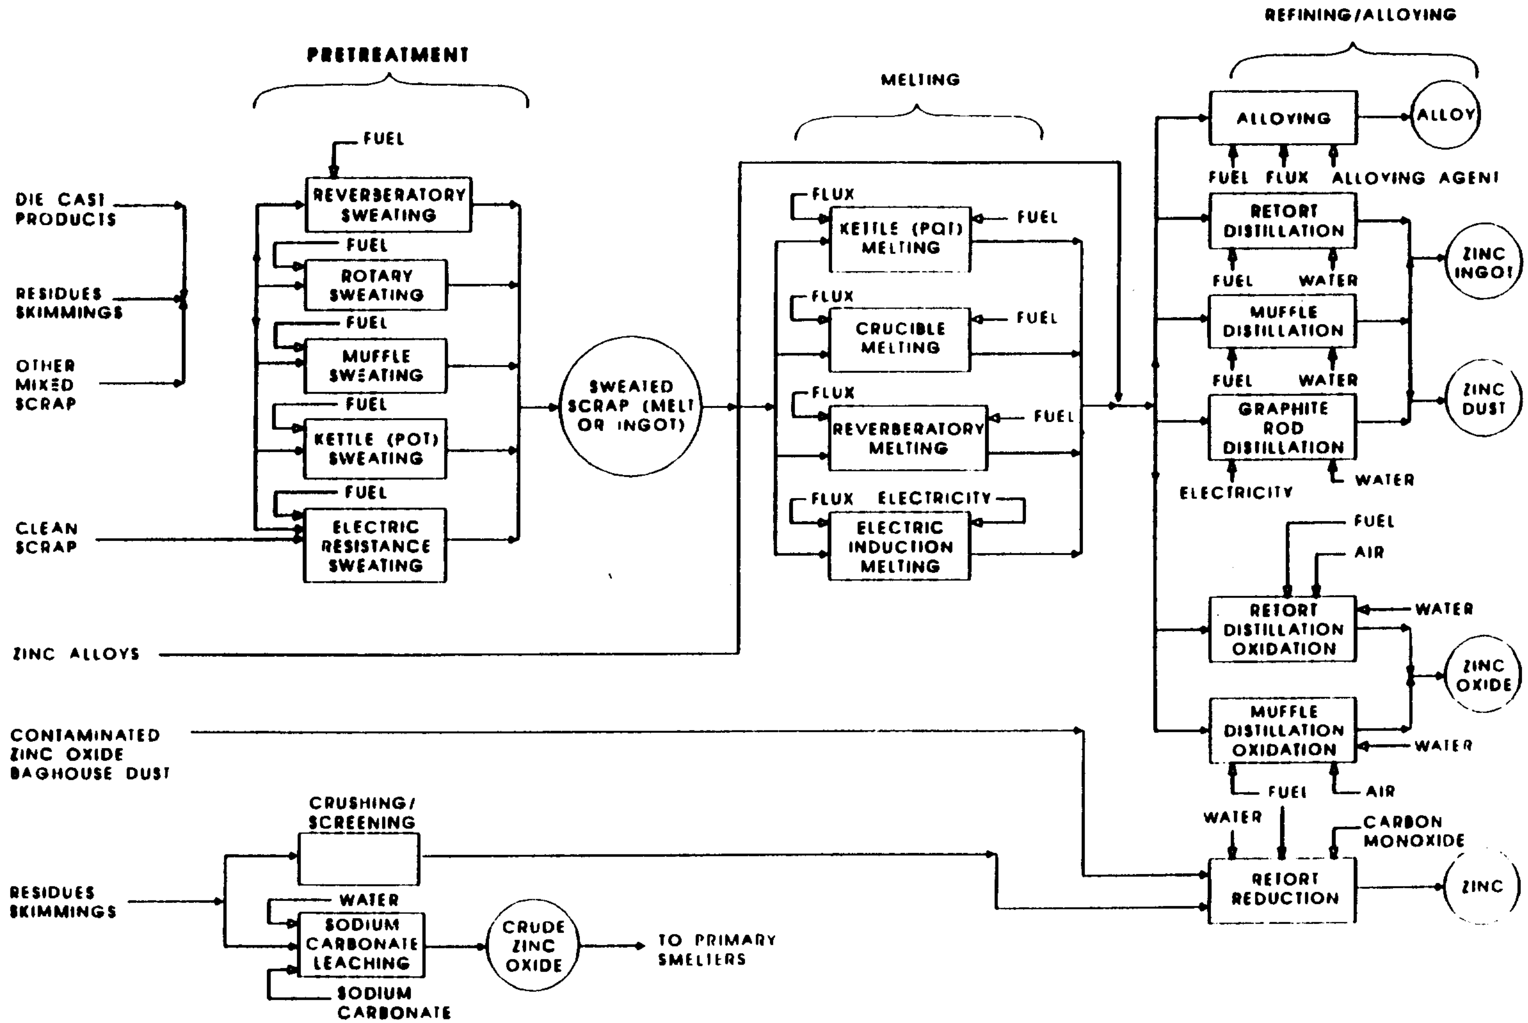
The sulfur recovery process requires that the emissions from the zinc calcining, or roasting process, where over 90 percent of potential sulfur dioxide is generated during primary zinc refining, flow through a filtering material in the air emissions scrubber to capture the sulfur. A blowdown slurry is formed from the mixture of the filtering material and sulfur emissions. This slurry contains not only sulfur, but cadmium and lead, materials that are always present in zinc ore. The acid plant blowdown slurry/sludge that results from thickening of blowdown slurry at primary zinc facilities is regulated by RCRA as hazardous waste K066.

During the electrolytic refining of zinc, solid materials in the electrolytic solution that are not captured previously during purification may precipitate out in the electrolytic cell. When the cells undergo their periodic shutdown to recover zinc, this precipitated waste (known as anode slimes/sludges) is collected during cell cleaning. Once collected it is sent to a waste water treatment plant and the resulting sludges are also regulated by RCRA as hazardous waste K066.

Secondary Zinc Processing

The secondary zinc industry processes scrap metals for the recovery of zinc in the form of zinc slabs, zinc oxide, or zinc dust. Zinc recovery involves three general operations; pretreatment, melting, and refining (see Exhibit 9). Secondary recovery begins with the separation of zinc-containing metals from other materials, usually by magnetics, sink-float, or hand sorting. In situations where nonferrous metals have been mixed in shredder scrap, zinc can be separated from higher-melting metals such as copper and aluminum, by selective melting in a sweating furnace. A sweating furnace (rotary, reverberatory, or muffle furnace) slowly heats the scrap containing zinc and other metals to approximately 787 degrees F. This temperature is sufficient to melt zinc but is still below the melting point of the remaining metals.

Exhibit 9 Secondary Zinc Processing



R0076426

Molten zinc collects at the bottom of the sweat furnace and is subsequently recovered. The remaining scrap is cooled and removed to be sold to other secondary processors. In the case of zinc-galvanized steel, the zinc will be recovered largely in furnace dust after the scrap is charged into a steel making furnace and melted. Almost all of the zinc in electric arc furnace (EAF) dust is first recovered in an upgraded, impure zinc oxide product and is then shipped to primary pyrometallurgical zinc smelter for refinement to metal.

Clean new scrap, mainly brass and rolled zinc clippings and reject diecastings, generally require only re-melting before reuse. During melting, the zinc-containing material is heated in kettle, crucible, reverberatory, and electric induction furnaces. Flux is used to trap impurities from the molten zinc. Facilitated by agitation, flux and impurities float to the surface of the melt as dross, and is skimmed from the surface. The remaining molten zinc may be poured into molds or transferred to the refining operation in a molten state. Drosses, fragmentized diecastings, and mixed high-grade scrap are typically re-melted, followed by zinc distillation with recovery as metal, dust, or oxide. Sometimes, high-purity drosses are simply melted and reacted with various fluxes to release the metallic content; often the recovered metal can be used directly as a galvanizing brightener or master alloy. Zinc alloys are produced from pretreated scrap during sweating and melting processes. The alloys may contain small amounts of copper, aluminum, magnesium, iron, lead, cadmium, and tin. Alloys containing 0.65 to 1.25 percent copper are significantly stronger than unalloyed zinc.

Medium and low-grade skims, oxidic dust, ash, and residues generally undergo an intermediate reduction-distillation pyrometallurgical step to upgrade the zinc product before further treatment; or, they are leached with acid, alkaline, or ammoniacal solutions to extract zinc. For leaching, the zinc containing material is crushed and washed with water, separating contaminants from zinc-containing material. The contaminated aqueous stream is treated with sodium carbonate to convert zinc chloride into sodium chloride and insoluble zinc hydroxide. The sodium chloride is separated from the insoluble residues by filtration and settling. The precipitate zinc hydroxide is dried and calcined (dehydrated into a powder at high temperature) to convert it into crude zinc oxide. The zinc oxide product is usually refined to zinc at primary zinc smelters. The washed zinc-containing metal portion becomes the raw material for the melting process.

Distillation retorts and furnaces are used either to reclaim zinc from alloys or to refine crude zinc. Bottle retort furnaces consist of a pear-shaped ceramic retort (a long-necked vessel used for distillation).

Bottle retorts are filled with zinc alloys and heated until most of the zinc is vaporized, sometimes as long as 24 hours. Distillation involves vaporization of zinc at temperatures from 1800 to 2280 degrees F, and condensation as zinc dust or liquid zinc. Zinc dust is produced by vaporization and rapid cooling, and liquid zinc results when the vaporous product is condensed slowly at moderate temperatures.

A muffle furnace is a continuously charged retort furnace which can operate for several days at a time. Molten zinc is charged through a feed well that also acts as an airlock. Muffle furnaces generally have a much greater vaporization capacity than bottle retort furnaces.

Air pollution control can be an area of concern when pyrometallurgical processes are employed in the secondary recovery of zinc. When the recovery process used is simply an iron pot re-melt operation to produce zinc metal, fumes will not normally be generated. If slab zinc is needed and a rotary furnace is used, any air emissions are captured directly from the venting system (a rotating furnace sweats, or melts, the zinc separating it from drosses with different melting points, which allows it to be poured off separately). Air emissions become more of a concern when more complicated processes are used to produce zinc powder. Retort and muffle furnaces used to produce zinc powder heat the zinc and other charges to such a high temperature that the zinc vaporizes and is captured in the pollution control equipment. It is this zinc oxide dust that is the process' marketable product. Hoods are employed around the furnace openings used to add additional charge. The fumes collected from the hoods are not normally of high quality and will be used for products like fertilizer and animal feed.

For the most part, the zinc materials recovered from secondary materials such as slab zinc, alloys, dusts, and compounds are comparable in quality to primary products. Zinc in brass is the principal form of secondary recovery, although secondary slab zinc has risen substantially over the last few years because it has been the principal zinc product of EAF dust recycling. Impure zinc oxide products and zinc-bearing slags are sometimes used as trace element additives in fertilizers and animal feeds. Currently about 10 percent of the domestic requirement for zinc is satisfied by old scrap.

Due to environmental concerns, both domestic and world-wide secondary recovery of zinc (versus disposal) is expected to increase. However, the prospect for gains higher than 35 to 40 percent of zinc consumption is relatively poor because of the dissipative nature of zinc vapor.

VI.B.2. Raw Material Inputs and Pollution Outputs

The material inputs and pollution outputs resulting from primary and secondary zinc processing are presented by media in Exhibit 10.

Exhibit 10
Process Materials Inputs/Pollution Outputs - Zinc

Process	Material Input	Air Emissions	Process Wastes	Other Wastes
Zinc Calcining	Zinc ore, coke	Sulfur dioxide, particulate matter containing zinc and lead		Acid plant blowdown slurry (K066)
Zinc Leaching	Zinc calcine, sulfuric acid, limestone, spent electrolyte		Wastewaters containing sulfuric acid	
Zinc Purification	Zinc-acid solution, zinc dust		Wastewaters containing sulfuric acid, iron	Copper cake, cadmium
Zinc Electrowinning	Zinc in a sulfuric acid/aqueous solution, lead-silver alloy anodes, aluminum cathodes, barium carbonate, or strontium, colloidal additives		Dilute sulfuric acid	Electrolytic cell slimes/sludges (K066)
Secondary Zinc Smelting	Zinc scrap, electric arc furnace dust, drosses, diecastings, fluxes	Particulates		Slags containing copper, aluminum, iron, lead, and other impurities
Secondary Zinc Reduction Distillation	Medium-grade zinc drosses, oxidic dust, acids, alkalines, or ammoniacal solutions	Zinc oxide fumes		Slags containing copper, aluminum, iron, lead, and other impurities

Primary Zinc Processing

Primary zinc processing activities generate air emissions, process wastes, and other solid-phase wastes. Air emissions are generated during roasting, which is responsible for more than 90 percent of the potential SO_2 emissions. Approximately 93 to 97 percent of the sulfur in the feed is emitted as sulfur oxides. Sulfur dioxide emissions from the roasting process at all four primary zinc processing facilities are recovered at on-site sulfuric acid plants. Much of the particulate matter emitted from primary zinc facilities is also attributable to roasters.

Though the amount and composition of particulate varies with operating parameters, the particulate is likely to contain zinc and lead.

Wastewaters may be generated during the leaching, purification, and electrowinning stages of primary zinc processing when electrolyte and acid solutions become too contaminated to be reused again. This wastewater needs to be treated before discharge.

Solid wastes, some of which are hazardous, are generated at various stages in primary zinc processing. Slurry generated during the operation of sulfuric acid plants is regulated as hazardous waste K066 as is the sludge removed from the bottom of electrolytic cells. The solid copper cake generated during purification is generally sent off-site to recover the copper.

Secondary Zinc Processing

Secondary zinc processing generates air emissions and solid-phase wastes. Air emissions result from sweating and melting and consist of particulate, zinc fumes, other volatile metals, flux fumes, and smoke generated by the incomplete combustion of grease, rubber, and plastics in zinc scrap. Zinc fumes are negligible at low furnace temperatures. Substantial emissions may arise from incomplete combustion of carbonaceous material in the zinc scrap. These contaminants are usually controlled by afterburners, and particulate emissions are most commonly recovered by fabric filters. Emissions from refining operations are mainly metallic fumes. Distillation/oxidations operations emit their entire zinc oxide product in the exhaust dust. Zinc oxide is usually recovered in fabric filters with collection efficiencies of 9 to 99 percent.

The secondary zinc recovery process generates slags that contain metals such as copper, aluminum, iron, and lead. Though slag generated during primary pyrometallurgical processes is exempt from regulation as a hazardous waste under RCRA, slag resulting from secondary processing is not automatically exempt. Therefore if secondary processing slag exhibits a characteristic (e.g., toxicity for lead), it would need to be managed as a hazardous waste.

VII. MANAGEMENT OF CHEMICALS IN WASTESTREAM

The Pollution Prevention Act of 1990 (EPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992-1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The EPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 11 shows that the primary and secondary metals industry managed about 1.9 billion pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, 35 percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 70 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns D, E and F, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns G, H, and I, respectively. The remaining portion of the production-related wastes (12.8 percent), shown in column J, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has increased and the portions treated or managed through energy recovery on-site have remained steady, but are projected to decrease, between 1992 and 1995.

Exhibit 11
Source Reduction and Recycling Activity for SIC 333-334

A	B	C	D	E	F	G	H	I	J
Year	Production Related Waste Volume (10^6lbs.)*	% Reported as Released and Transferred	On-Site			Off-Site			Remaining Releases and Disposal
			% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated	
1992	1,875	28%	42.98%	1.05%	23.93%	17.38%	0.15%	0.89%	12.68%
1993	1,991	35%	44.77%	0.99%	23.75%	17.17%	0.16%	0.33%	12.85%
1994	2,014	—	46.79%	0.88%	23.12%	16.60%	0.14%	0.35%	12.11%
1995	2,023	—	48.42%	1.01%	21.16%	16.39%	0.18%	0.39%	12.45%

VIII. CHEMICAL RELEASE AND TRANSFER PROFILE

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20-39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 42.7% between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotline at 1-800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount, and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds.

Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, the notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by each industry.

Definitions Associated With Section IV Data Tables

General Definitions

SIC Code -- the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20-39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

R0076434

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) - encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for stormwater runoff and non-point losses must also be included.

Releases to Land -- includes disposal of waste to on-site landfills, waste that is land treated or incorporated into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are wastewaters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or landfilled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

VIII.A. EPA Toxics Release Inventory for the Nonferrous Metals Industry

TRI release amounts listed below are not associated with non-compliance with environmental laws. These facilities appear based on self-reported data submitted to the Toxics Release Inventory program.

Exhibits 11-16 illustrate TRI releases and transfers for the primary nonferrous metals smelting and refining industry (SIC 333). For SIC 333 as a whole, chlorine comprises the largest number of TRI releases. This is reflected in the fact that chlorine is a by-product of the magnesium industry and the largest reporter for SIC 333 is a magnesium facility. The other top SIC 333 releases are copper compounds, zinc compounds, lead compounds, and sulfuric acid, all of which are by-products of the processes discussed previously.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below. Facilities that have reported only the SIC codes covered under this notebook appear on the first list. The second list contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations — some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibit 12
Top 10 TRI Releasing Primary Metal Industries Facilities (SIC 333)

SIC Codes	Total TRI Releases in Pounds	Facility Name	City	State

Exhibits 17-20 illustrate the TRI releases and transfers for the secondary nonferrous metals smelting and refining industry (SIC 334). For the industry as a whole, the largest releases were the various metals: aluminum (fume or dust), zinc compounds, lead compounds, copper and zinc (fume or dust).

Exhibit 17

VIII.B. Summary of the Selected Pollutants Released

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section, and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET[1]. The information contained below is based upon exposure assumptions that have been conducted using standard scientific procedures. The effects listed below must be taken in context of these exposure assumptions that are more fully explained within the full chemical profiles in HSDB.

Chlorine

Toxicity. Breathing small amounts of chlorine for short periods of time can affect the respiratory tract in humans, causing symptoms such as coughing and chest pain. It is irritating to the skin, eyes, and respiratory tract. Repeated long-term exposure to chlorine can cause adverse effects on the blood and respiratory systems.

[1] TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 1-800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

Ecologically, chlorine is highly toxic to aquatic organisms at low doses.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Most of the chlorine released to the environment will quickly evaporate.

Physical Properties. Chlorine is a highly reactive gas.

Copper

Toxicity. Metallic copper probably has little or no toxicity, although copper salts are more toxic. Inhalation of copper oxide fumes and dust has been shown to cause metal fume fever: irritation of the upper respiratory tract, nausea, sneezing, coughing, chills, aching muscles, gastric pain, and diarrhea. However, the respiratory symptoms may be due to a non-specific reaction to the inhaled dust as a foreign body in the lung, and the gastrointestinal symptoms may be attributed to the conversion of copper to copper salts in the body.

It is unclear whether long-term copper poisoning exists in humans. Some have related certain central nervous system disorders, such as giddiness, loss of appetite, excessive perspiration, and drowsiness to copper poisoning. Long-term exposure to copper may also cause hair, skin, and teeth discoloration, apparently without other adverse effects.

People at special risk from exposure to copper include those with impaired pulmonary function, especially those with obstructive airway diseases, since the breathing of copper fumes might cause exacerbation of pre-existing symptoms due to its irritant properties.

Ecologically, copper is a trace element essential to many plants and animals. However, high levels of copper in soil can be directly toxic to certain soil microorganisms and can disrupt important microbial processes in soil, such as nitrogen and phosphorus cycling.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Copper is typically found in the environment as a solid metal in soils and soil sediment in surface water. There is no evidence that biotransformation processes have a significant bearing on the fate and transport of copper in water.

Hydrochloric Acid

Toxicity. Hydrochloric acid is primarily a concern in its aerosol form. Acid aerosols have been implicated in causing and exacerbating a variety of respiratory ailments. Dermal exposure and ingestion of highly concentrated hydrochloric acid can result in corrosivity.

Ecologically, accidental releases of solution forms of hydrochloric acid may adversely affect aquatic life by including a transient lowering of the pH (i.e., increasing the acidity) of surface waters.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Releases of hydrochloric acid to surface waters and soils will be neutralized to an extent due to the buffering capacities of both systems. The extent of these reactions will depend on the characteristics of the specific environment.

Physical Properties. Concentrated hydrochloric acid is highly corrosive.

Lead

Toxicity. Short-term lead poisoning is relatively infrequent and occurs from ingestion of acid soluble lead compounds or inhalation of lead vapors. Symptoms include nausea, severe abdominal pain, vomiting, diarrhea or constipation, shock, tingling, pain, and muscle weakness, and kidney damage. Death may occur in one to two days. If the patient survives the acute episode, characteristic signs and symptoms of chronic lead poisoning are likely to appear. Chronic lead poisoning affects the gastrointestinal, neuromuscular, blood, kidney, and central nervous systems. Individuals with chronic lead poisoning appear ashen, with an appearance of "premature aging," with stooped posture, poor muscle tone, and emaciation. Neuromuscular syndrome (muscle weakness, easy fatigue, localized paralysis) and central nervous system syndrome (progressive mental deterioration, decreased intelligence, loss of motor skills and speech, hyperkinetic and aggressive behavior disorders, poorly controlled convulsive disorder, severe learning impairment) usually result from intense exposure, while the abdominal syndrome (anorexia, muscle discomfort, malaise, headache, constipation, severe abdominal pain, persistent metallic taste) is a more common manifestation of a very slowly and insidiously developing intoxication.

In the U.S., the central nervous system syndrome is usually more common among children, while the gastrointestinal syndrome is more prevalent in adults. Exposure to lead is also linked to decreased fertility in men. Lead is a probable human carcinogen, based on sufficient animal evidence and inadequate human evidence. Populations at increased risk of toxicity from exposure to lead include developing fetuses and young children, individuals with decreased kidney function, and children with sickle-cell anemia.

Environmental Fate. If released or deposited on soil, lead will be retained in the upper two to five centimeters of soil. Leaching is not important under normal conditions, nor generally is the uptake of lead from soil into plants. Lead enters water from atmospheric fallout, runoff or wastewater; it is effectively removed from the water column to the sediment predominantly by adsorption to organic matter and clay minerals. Some lead reenters the water column through methylation by microorganisms. Volatilization is negligible. Lead does not appear to bioconcentrate significantly in fish but does in some shellfish such as mussels. When released to the atmosphere, lead will generally be in dust or adsorbed to particulate matter and subject to gravitational settling.

Zinc and Zinc Compounds

Toxicity. Zinc is a nutritional trace element; toxicity from ingestion is low. Severe exposure to zinc might give rise to gastritis with vomiting due to swallowing of zinc dusts. Short-term exposure to very high levels of zinc is linked to lethargy, dizziness, nausea, fever, diarrhea, and reversible pancreatic and neurological damage. Long-term zinc poisoning causes irritability, muscular stiffness and pain, loss of appetite, and nausea.

Zinc chloride fumes cause injury to mucous membranes and to the skin. Ingestion of soluble zinc salts may cause nausea, vomiting, and purging.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Significant zinc contamination of soil is only seen in the vicinity of industrial point sources. Zinc is a relatively stable soft metal, though burns in air. Zinc bioconcentrates in aquatic organisms.

VIII.C. Other Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 21 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 21
Pollutant Releases (Short Tons/Year)

Industry	CO	NO_2	PM_{10}	PT	SO_2	VOC
U.S. Total	97,208,000	23,402,000	45,489,000	7,836,000	21,888,000	23,312,000

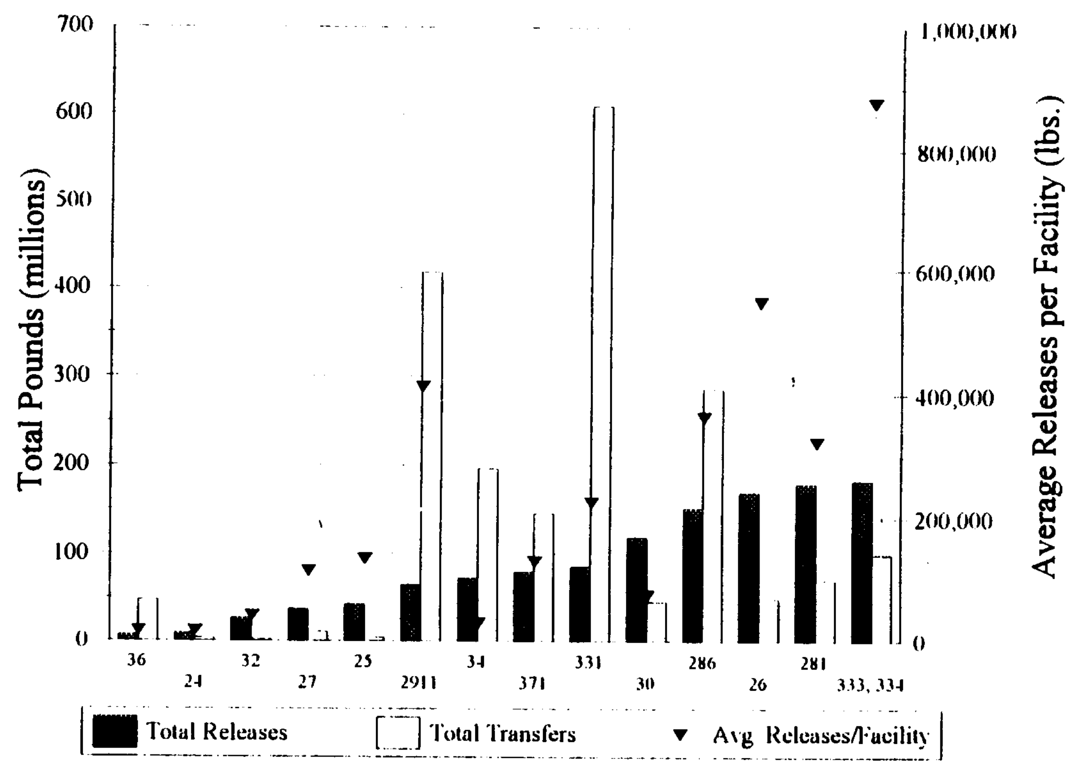
VIII.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following table does not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release book.

Exhibit 22 is a graphical representation of a summary of the 1993 TRI data for the nonferrous metals industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 23 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of nonferrous metals industry, the 1993 TRI data presented here covers 208 facilities. These facilities listed SIC 333-334 nonferrous metals industry as a primary SIC code.

Exhibit 22: Summary of 1993 TRI Data:
Releases and Transfers by Industry



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg.
24	Lumber and Wood Products	34	Fabricated Metals	26	Pulp and Paper
32	Stone, Clay, and Concrete	371	Motor Vehicles, Bodies, Parts, and Accecessories	281	Inorganic Chemical Mfg.
27	Printing	331	Iron and Steel	333, 334	Nonferrous Metals
25	Wood Furniture and Fixtures	30	Rubber and Misc. Plastics

IX. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the Nonferrous Metals Industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

IX.A. Identification of Pollution Prevention Activities in Use

Pollution prevention, whether through source material reduction/reuse, or waste recycling, is practiced in various sectors of the nonferrous metals industry. Pollution prevention techniques and processes currently used by the nonferrous metals industry can be grouped into the following general categories:

- Process equipment modification,
- Raw materials substitution or elimination,
- Solvent recycling, and
- Precious metals recovery.

It is interesting to note that while the stated rationale for the use of many of these techniques or processes is applicable environmental regulations, their use is both fairly universal and profitable.

Process equipment modification is used to reduce the amount of waste generated. Many copper, lead, and zinc refiners have modified their production processes by installing sulfur fixation equipment. This equipment not only captures the sulfur before it enters the atmosphere (helping the refining plant meet CAA sulfur standards), but processes it so that a marketable sulfuric acid is produced. Another example is the use of pre-baked anodes in primary aluminum refining. When a pre-baked anode is used, the electrolytic cell, or pot, can be closed, thereby increasing the efficiency of the collection of fluoride emissions. In addition, new carbon liners have been developed which significantly increase the life of the aluminum reduction cell. This has resulted in large reductions in the amount of spent potliner material (hazardous waste K088) generated by the aluminum industry.

Raw material substitution or elimination is the replacement of raw materials with other materials that produce less waste, or a non-toxic waste. Material substitution is inherent in the secondary nonferrous metals industry primarily by substituting scrap metal, slag, and baghouse dust for ore feedstock. All of these materials, whether in the form of aluminum beverage cans, copper scrap, or lead-acid batteries, are commonly added to other feedstock or charges (usually slag containing residual metals) to produce marketable grades of metal. Primary nonferrous metals refining also uses previously refined metals as feedstock, especially zinc-containing electric arc furnace dust (a by-product of the iron and steel industry).

Precious metals recovery is the modification of a refining process to allow the capture of marketable precious metals such as gold and silver. Like sulfur fixation, precious metals recovery is a common waste minimization practice. During primary copper smelting, appreciable amounts of silver and gold present in copper ore will be concentrated into the anode copper and can be recovered as a by-product in the electrorefining process (as the copper anode is electrochemically dissolved and the copper attaches itself to the cathode, silver and gold drop out and are captured in the slime at the bottom of the tank). In the lead refining process the copper often present in lead ore is removed during the initial lead bullion smelting process as a constituent of dross. Silver and gold are removed from the lead bullion later in the process by adding certain fluxes which cause them to form an impure alloy. The alloy is then refined electrolytically and separated into gold and silver. Precious metals recovery also takes place during zinc refining to separate out copper, a frequent impurity in zinc ore. Copper is removed from the zinc ore during the zinc purification process (after zinc undergoes leaching, zinc dust is added which forces many of the deleterious elements to drop out; copper is recovered in a cake form and sent for refining).

IX.B. Important Pollution Prevention Case Studies

Various pollution prevention case histories have been documented for nonferrous metals refining industries. In particular, the actions of the AMPCO Metal Manufacturing Company, Inc. typify industry efforts to simultaneously lessen the impact of the industrial process on the environment, reduce energy consumption, and lower production costs.

AMPCO Metal Manufacturing Company, Inc., in Ohio is participating in the development of pollution prevention technologies. The project, sponsored by the U.S. DOE and EPA, consists of researching and developing the use of electric induction to replace fossil fuel combustion currently used to heat tundishes. Tundishes are used to contain the heated reservoir of molten alloy in the barstock casting process. The fossil fuel combustion process currently used requires huge amounts of energy and produces tremendous amounts of waste gases, including combustion bases and lead and nickel emissions. According to new OSHA regulations, lead emissions from foundries must be reduced by 80 percent by 1998.

Heating the tundish by electric induction instead of fossil fuel combustion will substantially improve the current process, saving energy and reducing pollution. Energy efficiency will jump to an estimated 98 percent, saving 28.9 billion Btu/yr/unit. Industry-wide energy savings in 2010 are estimated to be 206 billion Btu/yr, assuming a 70 percent adoption at U.S. foundries.

In addition to the energy savings, the new process also has substantial environmental benefits. Along with the elimination of lead and nickel gases, carbon dioxide, carbon monoxide, and nitrogen oxide emissions from combustion will decrease. The consumption of refractory (a heat-resisting ceramic material) will decline by 80 percent, resulting in a similar reduction of refractory waste disposal. In all, prevention of various forms of pollution is estimated to be 147 million lb (66.7 million kg)/yr by 2010.

Economically, the elimination of lead and nickel emissions will result in an improved product because exposure of the metal to combustion gases in the current process results in porosity and entrainment of hydrogen gas in the metal. Overall, AMPCO estimates an annual savings in operations and maintenance expenses of $1.2 million with the use of this technology. Assuming the same 70 percent industry adoption, economic savings by 2010 could reach $5.8 million. Without the new electric induction heating process, the capital costs required for compliance could be $3 million.

X. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section X.A contains a general overview of major statutes
- Section X.B contains a list of regulations specific to this industry
- Section X.C contains a list of pending and proposed regulations

The descriptions within Section X are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

X.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities

that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties

that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the

Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)).

These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

X.B. Industry-Specific Requirements

Clean Water Act (CWA)

The Clean Water Act regulates the amount of chemicals/toxins released by industries via direct and indirect wastewater/effluent discharges. Regulations developed to implement this Act establish effluent guidelines and standards for different industries. These standards usually set concentration-based limits on the discharge of a given chemical by any one facility. If a facility is discharging directly into a body of water, it must obtain a National Pollution Discharge Elimination System (NPDES) permit. If a facility is discharging to a publicly owned treatment works (POTW), it must adhere to specified pretreatment standards. The following regulations are applicable to the nonferrous metals industry.

The Metal Molding and Casting Point Source Category (40 CFR Part 464) is applicable to wastewater from these operations:

- Aluminum Casting
- Copper Casting
- Zinc Casting.

The Aluminum Forming Point Source Category (40 CFR Part 467) is applicable to wastewater from these operations:

- Rolling with Neat Oils
- Rolling with Emulsions
- Extrusion
- Forging
- Drawing with Neat Oils
- Drawing with Emulsions.

The Copper Forming Point Source Category (40 CFR Part 468) is applicable to wastewater from these operations:

- Copper Forming
- Beryllium Copper Forming.

The Nonferrous Metals Forming and Metal Powders Point Source Category (40 CFR Part 471) is applicable to wastewater from these operations:

- Lead-Tin-Bismuth Forming
- Magnesium Forming
- Nickel-Cobalt Forming
- Precious Metals Forming
- Refractory Metals Forming
- Titanium Forming
- Uranium Copper Forming
- Zinc Forming
- Zirconium-Hafnium Forming
- Metals Powders.

Clean Air Act (CAA)

The primary regulatory mechanism used to implement source emission requirements under the CAA is State Implementation Plans (SIPs). SIPs provide the States with the authority and discretion to establish a strategy to attain primary NAAQS levels. These requirements can be uniform for all sources or specifically tailored for individual sources. States are not allowed to adopt less stringent standards than NAAQS. Of particular concern to primary and secondary smelters is the fact that SIPs must include steps to reduce SO_2 source emission levels in nonattainment areas. SIPs must demonstrate that nonattainment areas, designated prior to the 1990 CAA Amendments, will achieve compliance with NAAQS as soon as possible and no later than November 1995. For nonattainment areas designated after the 1990 Amendments, compliance is also required five years after the nonattainment designation. Sections 172(c)(5) or 191 and 192 require the imposition of a construction moratorium on new or modified sources of SO_2 in nonattainment areas without a fully approved SIP until the SIP includes appropriate permit requirements.

- NAAQS for sulfur dioxide, nitrogen dioxide, and hydrocarbons that frequently affect the smelting process are found in 40 CFR Part 50.

Also important to primary and secondary smelters is the list of 189 hazardous air pollutants (HAPs) established in the CAA, as amended in 1990. Under the CAA Amendments, Congress required EPA to identify major and area source categories associated with the emission of one or more listed HAPs. To date, EPA has identified 174 categories of sources. Congress also required EPA to promulgate emission standards for listed source categories within 10 years of the enactment of the CAA Amendments (by November 15, 2000). These standards are known as National Emission Standards for Hazardous Air Pollutants (NESHAPs).

In addition to general CAA requirements, specific standards apply to primary and secondary lead smelters, primary copper smelters, primary zinc smelters, and primary aluminum reduction plants.

The Standards of Performance for Secondary Lead Smelters (40 CFR Part 60, Subpart L) are applicable to pot furnaces of more than 250 kg charging capacity, blast furnaces, and reverberatory furnaces that commence construction after June 11, 1973.

These standards require secondary lead smelters to control discharge to the point that:

- Particulate matter emissions do not exceed 50 mg/dscm, and
- Visible emissions do not exhibit 20 percent opacity or greater.

In addition, these standards require that no owner or operator discharge any gases exhibiting 10 percent opacity or greater from any pot furnace on and after the date of performance testing.

The Standards of Performance for Primary Copper Smelters (40 CFR Part 60, Subpart P) are applicable to dryers, roasters, smelting furnaces, and copper converters that commence construction or modification after October 16, 1974.

These standards require that dryers control discharge to the point that particulate matter emissions do not exceed 50 mg/dscm. With respect to roasters, smelting furnaces, and copper converters, no gases containing sulfur dioxide in excess of 0.065 percent by volume are to be emitted. An exception is made in the case of reverberatory smelting furnaces, which are exempt during periods when the total smelter charge at the primary copper smelter contains a high volume of volatile impurities (more than 0.2 weight percent arsenic, 0.1 weight percent antimony, 4.5 weight percent lead, or 5.5 weight percent zinc, on a dry basis).

In addition, these standards require the owner or operator of a dryer of an affected facility using a sulfuric acid plant to control discharges to the point that visible emissions do not exhibit greater than 20 percent opacity on and after the date of performance testing.

The Standards of Performance for Primary Zinc Smelters (40 CFR Part 60, Subpart Q) are applicable to roaster and sintering machine facilities in primary zinc smelters that commence construction or modification after October 16, 1974.

These standards require sintering machines to control discharges to the point that on and after the date of performance testing:

- No gases containing particulate matter in excess of 50 mg/dscm are emitted, and
- Emissions do not exhibit an opacity of greater than 20 percent.

In addition, no roaster may emit gases containing sulfur dioxide in excess of 0.065 percent by volume. The provision also stipulates that any sintering machine that eliminates more than 10 percent of the sulfur initially contained in the zinc sulfide ore concentrates will be considered a roaster. For affected primary zinc smelting facilities that use a sulfuric acid plant, no emissions greater than 20 percent opacity are allowed on and after the date of performance testing. In addition,

- No gases containing more than 50 mg/dscm may be emitted, and
- Visible emissions may not exhibit greater than 20 percent opacity.

In addition, sintering machines, electric smelting furnaces, and converters must control discharges to the point that no gases containing greater than 0.065 percent sulfur dioxide are emitted on and after the date of performance testing.

For affected primary lead smelting facilities that use a sulfuric acid plant, no visible emissions greater than 20 percent opacity are allowed on and after the date of performance testing.

The Standards of Performance for Primary Aluminum Reduction Plants (40 CFR Part 60, Subpart S) are applicable to potroom groups and anode bake plants that commence construction after October 23, 1974.

The standards require that on and after the date of performance testing affected facilities control discharges to the point that no gases containing total fluorides are emitted on and after the date of performance testing in excess of:

- 1.0 kg/Mg of aluminum produced for potroom groups at Soderberg plants
- 0.95 kg/Mg of aluminum produced for potroom groups at prebake plants
- 0.05 kg/Mg of aluminum equivalent for anode bake plants.

Emissions slightly above these levels from Soderberg and prebake plants may be considered to be in compliance if the owner/operator demonstrates that exemplary operation and maintenance procedures are used.

In addition, on and after the date of performance testing, facilities must control discharges to the point that no emissions are discharged exhibiting greater than:

- 10 percent opacity from any potlines
- 20 percent opacity from any anode bake plant.

All of the above standards (Subparts L, P, Q, R, S) require monitoring and testing methods and procedures specific to the affected facilities.

The National Emission Standards for Hazardous Air Pollutants from Secondary Lead Smelting (40 CFR Part 63, Subpart X) are applicable to secondary lead smelters that use blast, reverberatory, rotary, or electric smelting furnaces to recover lead metal from scrap lead, primarily used lead-acid automotive batteries. These standards limit HAP emissions (lead compounds and total hydrocarbons from secondary lead smelting furnaces, refining kettles, agglomerating furnaces, dryers and fugitive dust sources, but do not affect emissions from lead smelters, lead refiners, or lead remelters.

These standards require secondary lead smelters to control:

- Process Emission sources by limiting lead compounds (metal HAP) and total hydrocarbons (organic HAP) to certain levels depending upon furnace type;
- Process Fugitive Emission Sources by requiring the use of enclosure-type hoods or containment buildings which are ventilated to control devices; and
- Fugitive Dust Sources by requiring the development of facility specific standard operating procedures.

In addition to these standards certain compliance testing, monitoring, and recordkeeping requirements also apply to these facilities. New or reconstructed sources (construction commenced after June 9, 1994) must meet these standards by June 23, 1995 or upon start up of operations. Existing secondary lead smelters have until June 23, 1997 to meet them.

Resource Conservation and Recovery Act (RCRA)

RCRA was passed in 1976, as an amendment to the Solid Waste Disposal Act, to ensure that solid wastes are managed in an environmentally sound manner. A material is classified under RCRA as a hazardous waste if the material meets the definition of solid waste (40 CFR 261.2), and that solid waste material exhibits one of the characteristics of a hazardous waste (40 CFR 261.20-24) or is specifically listed as a hazardous waste (40 CFR 261.31-33). A material defined as a hazardous waste may then be subject to Subtitle C generator (40 CFR 262), transporter (40 CFR 263), and treatment, storage, and disposal facility (40 CFR 254 and 265) requirements. The nonferrous metals industry must be concerned with the regulations addressing all these.

The greatest quantities of RCRA listed waste and characteristically hazardous waste that are generated by nonferrous metal industries are identified in Exhibit 24. For more information on identifying RCRA hazardous waste, refer to 40 CFR Part 261.

Exhibit 24
Hazardous Wastes Relevant to the Nonferrous Metal Industry

EPA Hazardous Waste No.	Hazardous Waste
D004 (arsenic) D005 (barium) D006 (cadmium) D007 (chromium) D008 (lead) D009 (mercury) D010 (selenium) D011 (silver) D035 (methyl ethyl ketone) D039 (tetra-chloroethylene) D040 (trichloro-ethylene)	Wastes which are hazardous due to the characteristic of toxicity for each of the constituents.
F001	Halogenated solvents used in degreasing: tetrachloroethylene, methylene chloride, 1,1,1-trichloroethane, carbon tetrachloride, and chlorinated fluorocarbons; all spent solvent mixtures/blends used in degreasing containing, before use, a total of 10 percent or more (by volume) of one or more of the above halogenated solvents or those solvents listed in F002, F004, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F002	Spent halogenated solvents; tetrachloroethylene, methylene chloride, trichlorethylene, 1,1,1-trichloroethane chlorobenzene, 1,1,2-trichloro-1,2,2-trifluoroethane, ortho-dichlorobenzene, trichlorofluoromethane, and 1,1,2-trichloroethane; all spent solvent mixtures/blends containing, before use, one or more of the above halogenated solvents or those listed in F001, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F003	Spent non-halogenated solvents: xylene, acetone, ethyl acetate, ethyl benzene, ethyl ether, methyl isobutyl ketone, n-butyl alcohol, cyclohexanone, and methanol; all spent solvent mixtures/blends containing, before use, only the above spent non-halogenated solvents; and all spent solvent mixtures/blends containing, before use, one or more of the above non-halogenated solvents, and, a total of 10% or more (by volume) of one of those solvents listed in F001, F002, F004, F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F004	Spent non-halogenated solvents: cresols and cresylic acid, and nitrobenzene; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, and F005; and still bottoms from the recovery of these spent solvents and spent solvent mixtures.
F005	Spent non-halogenated solvents: toluene, methy ethyl ketone, carbon disulfide, isobutanol, pyridine, benzene, 2-ethoxyethanol, and 2-nitropropane; all spent solvent mixtures/blends containing, before use, a total of 10% or more (by volume) of one or more of the above non-halogenated solvents or those solvents listed in F001, F002, or F004; and still bottoms from the recovery of these spent solvents and spent solvents mixtures.

Exhibit 24
Hazardous Wastes Relevant to the Nonferrous Metal Industry

EPA Hazardous Waste No.	Hazardous Waste
K064	Acid plant blowdown slurry/sludge resulting from the thickening of blowdown slurry from primary copper production.
K065	Surface impoundment solids contained in and dredged from surface impoundments at primary lead smelting facilities.
K066	Sludge from treatment of process wastewater and/or acid plant blowdown from primary zinc production.
K088	Spent potliners from primary aluminum reduction.
K069	Emission control dust/sludge from secondary lead smelting. (Note: this listing is stayed administratively for sludge generated from secondary acid scrubber systems. The stay will remain in effect until further administrative action is taken. If EPA takes further action effecting this stay, EPA will publish a notice of the action in the *Federal Register*.)
K100	Waste leaching solution from acid leaching of emission control dust/sludge from secondary lead smelting.

One set of RCRA standards that is of particular relevance to nonferrous metals industries that recycle metals and metal-containing materials is 40 CFR Part 266, Subpart H which lays out the requirements for boilers or industrial furnaces that burn hazardous waste for energy recovery or destruction, or processing for materials recovery or as an ingredient in general.

X.C. Pending and Proposed Regulatory Requirements

Clean Air Act (CAA)

In addition to the CAA requirements discussed above, EPA is currently working on several regulations that will directly affect the nonferrous metals industry. Many proposed standards will limit the air emissions from various industries by proposing Maximum Achievable Control Technology (MACT) based performance standards that will set limits on emissions based upon concentrations in the waste stream. Various potential standards are described below.

Primary Lead Smelting

Primary lead smelters are a major source of hazardous air pollutants (HAPs). Potential emissions include compounds of lead and other metallic HAPs as well as organic HAPs.

The proposed regulation will be a MACT-based performance standard that will set limits on certain emissions based upon concentrations in the waste stream . The legal deadline is November 15, 1997.

When promulgated, these standards will regulate an industry comprised of two companies which operate three facilities in two states.

Primary Copper Smelting

Primary copper smelters are known to emit a number of HAPs listed in Section 112 of the Clean Air Act Amendments of 1990 (CAAA). While most smelters have extensive control systems for oxides of sulfur and HAPs, fugitive emissions may cause smelters to exceed major source standards.

EPA is required to promulgate 50 percent of the source categories listed in Section 112(e) CAAA by November 15, 1997. EPA plans to promulgate emissions standards for several HAPs effecting the primary copper industry by August 30, 1995

Primary Aluminum

Primary aluminum processors may be a major source of one or more HAPs. As a consequence, a MACT-based regulatory program is being developed by EPA.

The MACT based performance standards are expected to be proposed in October 1995 and to be promulgated by November 15, 1997.

Secondary Aluminum

EPA has determined that the secondary aluminum industry may reasonably be anticipated to emit several of the 189 HAPs listed in Section 112(b) of the CAA. As a result, the industry is included on the initial list of HAP emitting categories and will be on the list of categories schedule for the development of a regulatory program.

The standards will be MACT-based performance standards and are expected to be proposed in April 1996. The legal deadline for the promulgation of final standards is November 15, 1997.

Resource Conservation and Recovery Act (RCRA)

As part of EPA's groundwater protection strategy, RCRA prohibits the land disposal of most hazardous wastes until they meet a waste-specific treatment standard. While most hazardous wastes have already been assigned treatment standards, EPA must still promulgate two additional rule makings to address newly listed wastes and to make changes to the land disposal restrictions (LDR) program.

When finalized, the Phase III LDR rulemaking will establish treatment standards for some newly listed wastes and will mandate RCRA equivalent treatment be performed upon certain characteristically hazardous wastes that are injected into UIC wells under the Safe Drinking Water Act (SDWA) or managed in Subtitle D surface impoundments prior to discharge pursuant to the Clean Water Act (CWA). By consent decree, EPA must promulgate the final rule for Phase III by January 1996.

Of particular significance to the nonferrous metals industries, Phase III will restrict the land disposal of spent aluminum potliners, K088. Once the prohibition for these wastes becomes effective, the spent potliners would need to meet numeric treatment levels for at least 27 particular hazardous constituents commonly found in K088.

Phase IV will similarly restrict other newly listed or identified wastes from land disposal and create influent treatment standards to mitigate the impact of sludges, leaks, and air emissions from surface impoundments that have managed decharacterized wastes. Among those wastes that will become subject to prohibitions are characteristically hazardous mining wastes that were once excluded from regulation by the Bevill exemptions of §261.4(b)(10). In addition, Phase IV will also change the treatment standards applicable to those wastes that are prohibited from land disposal because they exhibit the characteristic of toxicity for a metal constituent.

XI. COMPLIANCE AND ENFORCEMENT PROFILE

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[2] This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit,

2 EPA Regions include the following States: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IX KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); 10 (AK, ID, OR, WA).

compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or

R0076481

Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

XI.A. Nonferrous Metals Industry Compliance History

Exhibit 25 presents enforcement and compliance information specific to SIC 33, the nonferrous metals industry (information was not available beyond the two-digit SIC level). As indicated in this exhibit, Region 4 conducted the largest number of inspections in this industry, and nearly all of Regions 4's enforcement actions are also state-lead. The numbers in this exhibit do not necessarily represent the geographic location of the industry's primary and secondary processors. This is because the number facilities and inspections represents all SIC 33 facilities and not just SIC 333 and 334 facilities.

XI.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 26-29 provide enforcement and compliance information for selected industries. The nonferrous metals industry (all of SIC 33) compromises the 4th largest number of facilities tracked by EPA across the selected industries, and the 5th largest number of facilities inspected. However it has the 3rd largest number of inspections and 2nd largest number of enforcement actions. For this industry, RCRA inspections comprise over 39 percent of all inspections conducted, while CWA inspections account for 23 percent and CAA inspections account for 34 percent. The fairly high CWA inspection rate and low CAA inspection rate seem to be in conflict with the importance of air emissions in the primary and secondary nonferrous metals processing industry; however this may be due to the fact that numbers represent the entire SIC 33 and not the more specific three-digit SIC 333 and 334 level.

XI.C. Review of Major Enforcement Actions

XI.C.1. Review of Major Cases

This section provides summary information about major cases that have affected this sector. As indicated in EPA's *Enforcement Accomplishments Report, FY 1991 - FY 1993* publications, 12 significant enforcement cases were resolved between 1991 and 1993 involving the nonferrous metals industry. Five of the cases were comprised of RCRA violations, five of CERCLA violations, and two involved violations of the Clean Water Act (CWA). One case, U.S. v. ILCO (Interstate Lead Company), et. al., settled in 1992 and 1993, involved violations of all three statutes.

Six of the 12 cases resulted in the assessment of a penalty. Civil penalties ranged from $453,750 to $3.5 million. The average penalty was approximately $1.9 million. In U.S. v. Cerro Copper (1991), a consent decree was entered requiring Cerro to recycle its waste waters in order to meet pre-treatment limits for copper and other nonferrous metals at one of its plants. In addition, the company was required to pay a civil penalty of $1.4 million for its CWA violation.

Some of the settlements required defendants to pay only the past or future cleanup costs of the remedial action. In U.S. et. al. v. Alcan Aluminum Corp. et. al. (1991), the District Court granted the government's motion of summary judgment against Alcan Aluminum, a PRP at the Pollution Abatements Services Superfund site. The penalty was $4 million in past costs from this case and $9.1 million in past costs from an unsettled 1987 case. Violations included illegal dumping of PCBs, and about 4.6 million gallons of waste emulsion contaminated with small quantities of metals including lead, cadmium, and chromium.

In U.S. v. Sanders Lead Co. (1993), a consent decree was entered requiring $2 million in civil penalties and the treatment of waste water as a hazardous waste. This consent decree resolved alleged violations involving illegal disposal of lead-bearing hazardous wastes and violations of land disposal restrictions. This was the first civil case that the U.S. filed to enforce land disposal restrictions, and settles a RCRA enforcement action concerning violations at a Troy, Alabama secondary lead smelter.

In the 1993 RCRA case of U.S. v. ILCO et. al., the Court of Appeals held that lead components from spent automobile batteries were discarded and hence could be regulated as "solid waste" under RCRA. The Appeals Court affirmed the district court's award of $3.5 million in

R0076489

civil penalties and $845,033 in CERCLA response costs for violations of RCRA, the CWA, and corresponding Alabama statutes. The action arose from ILCO's operations at its secondary smelter which reprocessed spent-lead acid batteries.

XI.C.2. Supplemental Environmental Projects

Supplementary Environmental Projects (SEPs) are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

In December, 1993, the Regions were asked by EPA's Office of Enforcement and Compliance Assurance to provide information on the number and type of SEPs entered into by the Regions. The following chart contains a representative sample of the Regional responses addressing the primary and secondary nonferrous metals industry. The information contained in Exhibit 30 is not comprehensive and provides only a sample of the types of SEPs developed for the primary and secondary nonferrous metals industry.

Exhibit 30
Supplemental Environmental Projects
Nonferrous Metal (SIC 33)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
Kaiser Aluminum and Chemical Corporation Tacoma, WA	10	TSCA	Pollution Reduction	$ 12,750	Early disposal of PCB-contaminated electrical equipment.	$ 12,750	$ 6,375
Southern Foundry Supply	4	EPCRA	Pollution Reduction	$ 34,000	Assess the feasibility of a process to recover pure nickel from plant wastestreams. Construct a pilot plant to perform the recovery to reduce the quantity of heavy metals entering environment.	$ 15,840	$ 2,376
Aluminum Company of America (ALCOA) Port Lavaca, TX	6	CERCLA (failure to report release)	Equipmment Donation	$ 10,000	Donate equipment to the Local Emergency Planning Committee (LEPC) to assist local officials in emergency responses to chemical emergencies. Develop and submit article on CERCLA compliance to a national trade journal to assist other facilities in reporting duties.	$ 25,000	$ 3,000
Elken Metals Company Alloy, WV	3		Pollution Reduction	$ 449,000	Remove PCB items including PCB transforers and PCB capapcitors, and retrofilling PCB-contaminated transformers to reduce the amount of PCBs which may be released to the environment.	$ 280,000	$ 17,250

Exhibit 30
Supplemental Environmental Projects
Nonferrous Metal (SIC 33) (contd.)

Case Name	EPA Region	Statute/ Type of Action	Type of SEP	Estimated Cost to Company	Expected Environmental Benefits	Final Assessed Penalty	Final Penalty After Mitigation
J.W. Harris, Inc. Cincinnati, OH	5	EPCRA	Pollution Prevention	$189,350	Correct past EPCRA violations and modify industrial processes. Modification will reduce the releases of silver by 713 lbs/yr; copper by 1592 lbs/yr; antimony by 55 lbs/yr; zinc by 5847 lbs/yr; and nickel by 15 lbs/yr.	$109,500	$10,950

XII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

XII.A. Sector Related Environmental Programs and Activities

Voluntary Aluminum Industrial Partnership

The EPA's Voluntary Aluminum Industrial Partnership (VAIP) is an innovative environmental stewardship and pollution prevention program developed jointly by the EPA and the U.S. primary aluminum industry to promote cost-effective reduction in perflurocarbon. Companies joining the VAIP commit to reductions in perfluorocarbon (PFC) emission released during the production of aluminum and to provide data to EPA that tracks their progress toward reduction targets. In turn, EPA provides VAIP Partners with recognition for their pollution prevention initiative, and for their accomplishments in achieving PFC reductions.

The Partnership has been designed with important and unique characteristics that reflect both the diversity within the primary aluminum industry and the differences between this and other industries. These unique characteristics include: flexibility; a joint commitment to finding answers to critical technical questions; and a clear course for achieving substantial pollution prevention goals by the year 2000. EPA estimates that the VAIP will achieve reductions in PFC emissions of 30-60 percent across the U.S. primary aluminum industry — or 1.8 mmt of carbon equivalent — by the year 2000.

XII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of 17 chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given to participants who met their 1992 goals. The list of chemicals includes 17 high-use chemicals reported in the Toxics Release Inventory.

Ninety-three companies listed under SIC 333-334 (primary and secondary metals industry) are currently participating in the 33/50 program. They account for 72 percent of the 129 companies under SIC 333-334, which is higher than the average for all industries of 14 percent participation. (Contact: Mike Burns 202-260-6394 or the 33/50 Program 202-260-6907)

Exhibit 31 lists those companies participating in the 33/50 program that reported under SIC code 333-334 to TRI. Many of the participating companies listed multiple SIC codes (in no particular order), and are therefore likely to conduct operations in addition to primary metals production. The table shows the number of facilities within each company that are participating in the 33/50 program; each company's total 1993 releases and transfers of 33/50 chemicals; and the percent reduction in these chemicals since 1988.

*** = no numerical goal.

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at 202-233-9065 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn, 202-260-0700 or the WasteWi$e Hotline at 1-800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, 202-260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, 303-275-4729)

R0076499

XII.C. Trade Association/Industry Sponsored Activity

Various trade associations represent the interests of the nonferrous metals industry. Some of these organizations are discussed in greater detail below.

Aluminum

The Aluminum Association (AA) 900 19th Street, NW Washington, DC 20006 Phone: (202) 862-5100	Members: 86 Staff: 27 Budget: $4,300,000 Contact: David N. Parker

Founded in 1933, AA represents producers of aluminum and manufacturers of semi-fabricated aluminum products. This association represents members' interest in legislative activity and it also conducts seminars and workshops. Its committees cover such topics as legislative/regulatory affairs, environmental affairs, product standards, technical activities and programs, and health and safety. AA maintains a library of 3000 volumes on aluminum technology and the aluminum industry. Its publications include: *Aluminum Association Report* (10 times per year); *Aluminum Standards and Data* (biennially); *Aluminum Statistical Review* (annually); *World Aluminum Abstracts* (monthly), and a free catalog listing all of its publications, reprints, and audiovisual material. AA also maintains the *World Aluminum Abstracts* data base.

Aluminum Recycling Association (ARA) 1000 16th St. NW, Ste. 603 Washington, DC 20036 Phone: (202) 785-0951	Members: 20 Contact: Richard M. Cooperman

Founded in 1929, ARA represents producers of aluminum specification alloys refined from scrap aluminum. ARA has three committees: Environmental Protection, Government Liaison, and Technical. The association was formerly known separately as the Aluminum Research Institute, the Aluminum Smelters Research Institute, and the Aluminum Smelting and Recycling Institute. ARA publishes *Quarterly Reports on Industry Shipments* as well as a brochure.

Copper

International Copper Association (ICA) 260 Madison Ave. New York, NY 10016 Phone: (212) 251-7240 Fax: (202) 251-7245	Members: 42 Staff: 11 Budget: $ 9,000,000 Contact: Dr. William Drescher

Formerly known as the Copper Products Development Association, ICA represents both copper producing and copper fabricating companies. ICA works in concert with commercial, institutional, and university laboratories to conduct research on, and market development of, new and improved uses of copper. The association along with its committees, Chemical and Environmental Advisory; Corrosion Advisory; Electrical Advisory; Metallurgy Advisory; and Program Review conduct seminars and maintain a 300 volume library. ICA publishes an annual report in addition to a monograph series.

Copper and Brass Fabricators Council (CBFC) 1050 17th St. NW, Ste. 440 Washington, DC 20036 Phone: (202) 833-8575 Fax: (202) 331-8267	Contact: Joseph. L. Mayer

CBFC represents copper and brass fabricators in activities involving foreign trade in copper and brass fabricated products, and Federal regulatory matters including legislation, regulations, rules, controls, and other matter affecting brass and copper fabricators. The association has five committees: Critical Materials; Energy Conservation; EPA Advisory; Foreign Trade; and Government Information. CBFC was formerly known as Copper and Brass Fabricators Foreign Trade Association and was founded in 1966.

Copper Development Association (CDA) 2 Greenwich Office Park Box 1840 Greenwich, CT 06836 Phone: (212) 251-7200 or (800) CDA-DATA	Members: 100 Staff: 20 Contact: M. Payne

CDA represents domestic and foreign copper mining, smelting, and refining companies, and domestic fabricating companies. Functioning in committees divided along principal market areas such as transportation and construction and electronics, CDA seeks to expand the applications and markets of copper. CDA provides technical services to users of copper and its alloys, and also researches market statistics for the entire industry. *Copper Update* and *Copper Topics*, both published quarterly, are the primary publications of CDA in addition to handbooks, technical reports, and bulletins. CDA also operates an *Online Copper Data Center* which contains literature from around the world on copper and its alloys.

Lead

Lead Industries Association (LIA) 295 Madison Ave. New York, NY 10017 Phone: (212) 578-4750 Fax: (212) 684-7714	Members: 70 Staff: 4 Contact: Jerome F. Smith

Founded in 1928, LIA represents mining companies, smelters, refiners, and manufacturers of products containing lead. The association researches and gathers statistics and provides technical services and information to lead consumers. Some of the services LIA provides are a 2000-volume library concerning lead, and association committees focusing on: Battery Manufacturers, Environmental Health, Fabricated Products, Oxide and Chemical, and Solder Manufacturers. LIA publishes a semiannual newsletter, *Lead*, with a circulation of 60,000 that contains articles about the application of lead in architecture, chemicals, and other fields.

Association of Battery Recyclers (ABR) Sanders Lead Co. Corp. Sanders Rd. PO Drawer 707 Troy, AL 36081 Phone: (205) 566-1563	Members: 45 Staff: 1 Contact: N. Kenneth Campbell

ABR represents recyclers of lead, oxide manufacturers, industry equipment suppliers, and consulting services. The association's goals are to provide information services relating to worker safety and environmental controls through continuing industry-wide studies. ABR conducts research in: engineering and administrative controls, respiratory protection, and environmental and biological monitoring. ABR was known as the Secondary Lead Smelters Association until 1990.

Zinc

Independent Zinc Alloyers Association (IZAA) 1000 16th St. NW, Ste. 603 Washington, DC 20036 Phone: (202) 785-0558	Members: 15 Contact: Richard M. Cooperman

Founded in 1959, IZAA represents producers of zinc alloys for the die casting industry. The association has one committee which focuses on International Trade.

XIII. RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the nonferrous metals industry, a list of publications is provided below:

APPENDIX A

INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

ISBN 0-16-048278-X

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be purchased from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
8:00 a.m. to 4:30 p.m., EST, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via Internet on the Enviro$ense World Wide Web. Downloading procedures are described in Appendix A of this document.

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water, and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water, and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, States, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community, and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate, and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project, 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or States may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages State and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested States may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with State and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.

If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

Because this profile was not intended to be a stand-alone document concerning the non-fuel, non-metal mining industry, appended is a full reference of additional EPA documents and reports on this subject, as listed in the March edition of the Federal Register.

II. INTRODUCTION TO THE NON-FUEL, NON-METAL MINING INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the non-fuel, non-metal mining industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of production.

II.A. Introduction, Background and Scope of the Notebook

This profile provides an overview of SIC code 14, which includes mining and quarrying of nonmetallic minerals, except fuels; and establishments engaged primarily in mining or quarrying, developing mines, or exploring for non-fuel, nonmetallic minerals. Also included are certain well and brine operations, and primary preparation plants engaged in crushing, grinding, and washing.

Mining is defined simply as the taking of minerals from the earth. Minerals can be classified as either fuel minerals or non-fuel minerals. Non-fuel minerals can be further divided into metallic and nonmetallic minerals. This industrial profile is concerned only with the mining and quarrying of non-fuel, nonmetallic minerals, although many of the mining activities and processes involved are very similar to those performed in mining metallic minerals. Quarrying is an open-pit mining process designed specifically for the removal of either dimension stone or crushed stone by the cutting and loosening of blocks or blasting.

Establishments engaged primarily in crushing, pulverizing, or otherwise treating non-metal minerals are classified as mining facilities, whether or not they operate in conjunction with mines. However, if the crushing, pulverizing, or other treating activities take place off-site, the establishments are classified under SIC 3295 and are not addressed by this profile.

SIC 14 categorizes the industry according to the types of minerals mined. The following list indicates the three-digit SIC codes used to further distinguish the types of minerals within the industry, and their associated end uses:

SIC 141 - Dimension Stone/End Uses: Construction
SIC 142 - Crushed and Broken Stone, Including Riprap/End Uses: Construction

SIC 144 -	Sand and Gravel/End Uses: Construction, Lime Manufacturing
SIC 145 -	Clay, Ceramic, and Refractory Minerals/End Uses: Bricks, Cement and Paper
SIC 147 -	Chemical and Fertilizer Mineral Mining/End Uses: Glass, Soaps, and Fertilizer
SIC 148 -	Nonmetallic Minerals Services, Except Fuels
SIC 149 -	Miscellaneous Nonmetallic Minerals, Except Fuels/End Uses: Insulation, Textiles, and Abrasives.

Separate profiles have been developed for the metal mining, and stone, clay, glass, and concrete products industries.

II.B. Characterization of the Non-Metal, Non-Fuel Mining Industry

The industry covered in this profile comprises establishments engaged in mining or quarrying, developing mines, or exploring for non-fuel, nonmetallic minerals such as dimension stone; crushed and broken stone; sand and gravel; clay, ceramic, and refractory minerals; chemical and fertilizer minerals, and other miscellaneous non-fuel, nonmetallic minerals. Also included under this SIC code are primary preparation plants, such as those engaged in crushing, grinding, or washing non-fuel, nonmetallic minerals. This section of the profile provides information on industry size and geographic distribution, product characterization, and economic trends. The predominant industries in this SIC code are crushed stone and sand and gravel. This section of the profile concentrates heavily on these two industries.

II.B.1. Industry Size and Geographic Distribution [1]

Crushed Stone Producers

A total freight on board (f.o.b.) of 1.1 billion metric tons of crushed stone, valued at $5.9 billion was reported produced in the United States in 1993 by 1,566 companies with 3,213 operations and 3,915 active quarries through open-pit mining. (See Section III.A. for a discussion of mining processes.) Most of the crushed stone produced in 1993 came from operations with an annual output greater than 300,000 tons; 1,182 operations, representing 37 percent of the total, produced 84 percent of the total tonnage.

In 1993 the ten top producing states, in descending order of tonnage were Texas, Pennsylvania, Florida, Illinois, Missouri, Ohio, Virginia, Georgia, Kentucky, North Carolina, accounting for 51 percent of the total domestic output.

Exhibit 1 lists the ten leading companies that produce crushed stone in the United States. These ten companies, with a total of 507 active operations and 509 quarries, account for 31 percent of the total output of crushed stone in the United States.

Exhibit 1
10 Leading Crushed Stone Producers
(In terms of total output of crushed stone)

Company	Number of Active Operations	States
1. Vulcan Materials Company	158	Alabama, Florida, Georgia, Illinois, Indiana, Iowa, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Texas, Virginia, Wisconsin
2. Beazer USA, Inc./Hanson PLC	98	Alabama, Arizona, California, Georgia, Indiana, Kentucky, Michigan, New Mexico, New York, North Carolina, Ohio, Oregon, Oklahoma, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, Washington
3. Martin Marietta Aggregates	130	Georgia, Indiana, Iowa, Kansas, Maryland, Missouri, Nebraska, North Carolina, Ohio, South Carolina, Virginia, Wisconsin
4. CSR America, Inc.	24	Florida, Georgia, Indiana, Ohio, South Carolina

Source: Directory of Principal Crushed Stone Producers in the United States in 1993, U.S. Department of the Interior, Bureau of Mines.

Exhibit 1 (cont'd)
Leading Crushed Stone Producers
(In terms of total output of crushed stone)

Company	Number of Active Operations	States
5 Rogers Group Inc.	27	Alabama, Indiana, Kentucky, Ohio, Tennessee, Virginia
6. Lafarge Corporation	20	Illinois, Iowa, Kansas, Kentucky, Michigan, Missouri, New York, Ohio, Pennsylvania, Texas
7. Florida Rock Industries, Inc.	18	Florida, Georgia, Maryland, Virginia
8. Tarmac America, Inc.	11	Florida, South Carolina, Texas, Virginia
9. Dravo Corporation	11	Alabama, Florida, Illinois, Kentucky, Louisiana, Ohio
10. Lone Star Industries, Inc.	12	California, Illinois, Indiana, Missouri, New York, Oklahoma, Oregon, Pennsylvania, Texas

Source: Directory of Principal Crushed Stone Producers in the United States in 1993, U.S. Department of the Interior, Bureau of Mines

A total of 93 underground mines produced 65.2 million metric tons of crushed stone in 1993, as opposed to 1.1 billion metric tons produced from open-pit mining. Underground mines were located in 20 states. The leading states in descending order of tonnage were Kentucky, Iowa, Illinois, Missouri, Indiana, Maryland, and Tennessee. Their production represented 76 percent of the total U.S. crushed stone produced from underground mines.

Sand and Gravel Producers

A total of 919 (834 million short tons) of construction sand and gravel valued at 3.3 billion, f.o.b. plant, was reported produced in 1992 by 4,213 companies with 5,999 operations. Some companies produced both construction and industrial sand and gravel from the same operations. In 1992, most of the sand and gravel came from operations that produced more than 200,000 tons per year; 1,290 operations, representing 22 percent of the total, produced 71 percent of the total tonnage.

Exhibit 2 lists the ten leading companies that produce sand and gravel in the United States.

Exhibit 2
10 Leading Companies in Order of Total Output of Sand and Gravel

Company	Number of Active Operations	States
1. Calmat Co.	28	Arizona, California, New Mexico
2. Beazer USA, Inc./Hanson PLC	43	Arkansas, California, Georgia, Indiana, Louisiana, Nevada, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, Texas, Washington
3. CSR America Inc.	39n	Arizona, Georgia, Florida, Indiana, Michigan, Nevada, Ohio, South Carolina, Washington
4. Ashland Oil, Inc./APAC, Inc.	41	Alabama, Arizona, Arkansas, Florida, Georgia, Mississippi, Oklahoma, North Carolina, South Carolina
5. Redland PLC	38	Colorado, Kansas, Maryland, New Mexico, Texas

II.B.2. Product Characterization

Crushed stone and sand and gravel are the two main sources of natural aggregate. Both are used in almost all residential, commercial, and industrial buildings, and in most public works projects such as roads and highways, bridges, railroads, dams, airports, water and sewer systems, and tunnels. Together, crushed stone and sand and gravel make up approximately half the volume of mined minerals in the United States.

Crushed stone and sand and gravel are widely used commodities that are important elements in many national industries. Sand and gravel (or sand alone) can be used for industrial purposes such as foundry operations, in glass manufacturing, as an abrasive, and in filtration beds of water-treatment facilities. Crushed stone is used as a source of calcium for fertilizers, as a metallurgic fluxstone, and as the major resource in the manufacture of cement and lime. It is also used in water and sewer filtration systems and in the manufacture of glass.

Crushed stone and sand and gravel, however, are most commonly used as aggregate in the construction industry. As an example, an average 1,500-square-foot home requires approximately 114 tons of aggregate. If you add each home's proportional share of new streets, schools, churches, municipal projects, and shopping centers, the total aggregate use per home increases to approximately 328 tons (Shumway and Silva, 1993).

Many types of non-fuel, nonmetallic minerals comprise this industry. The major SIC groups of non-fuel, nonmetallic minerals and some of the minerals within each group include: dimension stone (mica schist, granite, limestone, marble, sandstone, slate), crushed and broken stone (limestone, granite, dolomite, cement rock, sandstone, trap rock), sand and gravel (industrial sand, construction sand, gravel, pebble, silica, abrasive sand), clay, ceramic, and refractory minerals (kaolin, ball clay, fire clay, china clay, paper clay, kyanite), chemical and fertilizer minerals (potassium compounds, boron compounds, sodium compounds, phosphate rock, sulfur), and miscellaneous nonmetallic minerals (asbestos, diatomite, gypsum, asphalt rock, graphite, precious stones). Some of the more commonly mined non-fuel, nonmetallic minerals include crushed and broken stone (limestone), sand and gravel (silica sand), and clay (kaolin clay). Non-fuel, nonmetallic minerals are also referred to as industrial minerals.

II.B.3. Economic Trends

According to a Bureau of Mines Study, the demand for crushed stone in 1994 was expected to be about 1.17 billion metric tons (1.29 billion short tons), a 5 percent increase compared with that of 1993. Gradual increases in demand for construction aggregates have occurred after 1994, based on increased volume of work on the infrastructure that is being financed by the Intermodal Surface Transportation Efficiency Act of 1991 and is the result of the recovery of the U.S. economy. The law authorized $151 billion to be spent in the next 6 years on transportation projects, of which $119.5 billion was allocated for highway work and $32.5 billion for mass transit.

It was estimated that the demand for crushed stone will reach 1.3 billion tons in 1995 although the final numbers for 1995 have not been released. The projected increases will be influenced by construction activity primarily in the public as well as the private sector.

Crushed stone f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates will rise over the forecasts. However, the delivered prices of crushed stone are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

The demand for construction sand and gravel in 1993 was expected to be about 940 million tons, a 2.5 percent increase compared with that of 1992. Gradual increases in demand for construction aggregates are anticipated after 1993 as well. The factors that stimulate demand in the construction sand and gravel industry are similar to those that affect the crushed stone industry (i.e., the Intermodal Surface Transportation Efficiency Act of 1991 and the recovery of the U.S. economy). Similarly, construction sand and gravel prices are not expected to rise significantly, except for the delivered prices. It is estimated that the demand for construction sand and gravel will reach 975 million tons in 1995. The projected increases will be influenced by construction activity, primarily in the public construction sector.

Dimension stone production for 1993 was estimated at 1.17 million tons, approximately the same as in 1992. The construction industry, a major consumer of stone and stone products, is expected to boost demand for stone and stone products. Increases in new residential construction should also boost demand for stone and stone products.

The domestic construction industry also provided an impetus for mineral demand in 1994. The construction industry is the largest domestic consumer of brick, clay, cement, sand and gravel, and stone.

Expenditures for road construction and maintenance (which consume large quantities of asphalt, cement, crushed stone, and sand and gravel) continued at a high level in 1994 and are expected to remain strong in 1995 due to continued funding for mass transit projects. In addition, apartment building construction (a major end-use sector for brick clay, cement, sand and gravel, steel, and stone) rose sharply in 1994.

III. Industrial Process Description

This section describes the major industrial processes within the non-fuel, non-metal mining industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of waste outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available to supplement this document.

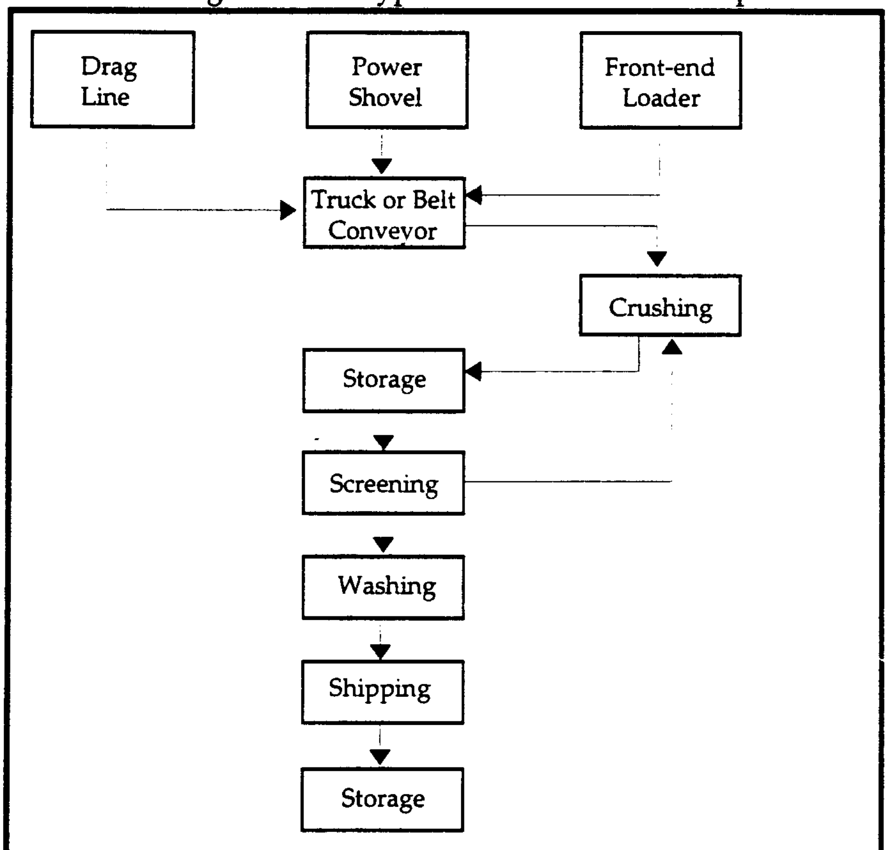
This section specifically contains a description of commonly used production processes, associated raw materials, the byproducts produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provide a concise description of where wastes may be produced in the process. This section also describes the potential fate (air, water, land) of these waste products.

III.A. Industrial Processes in the Non-Fuel, Non-Metal Mining Industry

Minerals extraction is broadly divided into three basic methods: open-pit or surface, underground, and solution mining. The mining method used depends on the particular mineral, the nature of the deposit, and the location of the deposit. Each method is discussed briefly below. For this industry, most mining is open-pit or surface mining.

Surface or open-pit mining requires extensive blasting, as well as rock, soil, and vegetation removal to reach mineral deposits. Waste rock, or overburden, is piled away from the mine. Benches are cut into the walls of the mine to provide access to progressively deeper ore, as upper-level ore is depleted. Ore is removed from the mine and transported to processing plants for concentration.

Exhibit 4
Flow Diagram for a Typical Sand and Gravel Operation



Source : California EPA and the National Stone Association, Aggregate Plants Compliance Assistance Program, September, 1993.

Underground mining involves extraction from beneath the surface at depths as great as 10,000 feet. This requires sinking shafts to reach the main body of deposits. "Drifts," or passages, are then cut from the shaft at various depths to access the ore, which is removed to the surface for processing. Waste rock may be either returned to the mine as fill or put in a disposal area.

Fluid or solution mining entails drilling into intact rock and using chemical solutions to dissolve lode deposits. During solution mining, the leaching solution (usually a dilute acid) penetrates the ore, dissolving soluble minerals. This pregnant leach solution is then retrieved for recovery at a solvent extraction/electrowinning plant.

Historically, the primary mining method has been underground mining. However, with the advent in recent decades of large earth moving equipment, less expensive energy sources, and improved extraction and beneficiation technologies, surface mining now prevails in most industry sectors. It usually costs less to mine a ton of rock from an open-pit mine than from an underground mine. Whether open-pit mining is ultimately less costly than underground mining is closely related to other factors such as stripping ratios, physical properties of the ore body, rates and productivity.

Minerals Extraction

The extraction of minerals from the earth often involves the use of mechanical means such as drilling. Some drill types include rock, diamond, water-jet, and jet flame. Rock and diamond drills involve the rotation of a pipe or rod tipped with a rolling gear-like bit; water-jet drills use a powerful jet of water to blast materials loose; jet flame drills use a high-velocity flame to create holes in hard rock. Other machines unique to mining include mechanical miners and specially adapted materials-handling equipment for use in underground and surface mining. Diesel engines are used for generating small quantities of electric power in remote areas and for transportation units.

Blasting is a method of mineral extraction involving the displacement of solid rock through the use of explosives. Blasting also fragments the deposit into sizes that require a minimum of secondary breakage, and that can be handled by loading and hauling equipment. The explosive charge (usually a mixture of ammonium nitrate and fuel oil) used in blasting must be strategically placed so as to break the solid material efficiently.

Extraction without the use of mechanical methods is also possible if the material surrounding the mine opening is not adequately supported. By removing underlying support, the rock caves into the opening left by the removed supports. If rock needs to be broken down further for transportation, secondary breakage may be required. This involves using drop-ball cranes on the oversized rock to further reduce its size.

Minerals Transportation

The excavation and loading of broken rock is normally performed by mechanical shovels and front-end loaders. The broken rock is either loaded into a haulage vehicle, such as a truck or railroad track-type car for transport to a processing plant, or directly into a primary crusher. At most quarries, large capacity haulage vehicles are used to transport broken rock from the quarry to the primary crusher. Pipelines have also been used successfully to transport many different minerals, such as limestone, phosphates, and sand fills: the dry material is first combined with water to form a slurry and is then pumped to its destination for dewatering. If sufficient dump room or storage capacity exists near the mine, a system of belt conveyors can handle material at high rates and relatively low cost, but only if proper feed control of a sized material allows a continuous, even flow that matches the system design. Other factors that determine the practicality and size of a conveyor system are the rate at which the material must be handled, the material's density and stickiness, the dusting or degradation on transfer, and the need for the system to handle more than one product.

Minerals Processing

Processing minerals after their extraction and transportation to the processing plant involves the use of crushers, grinders, and screens. This equipment is used to separate or scalp larger boulders from the finer rocks that do not need primary crushing, thus minimizing the load to the primary crusher. Following crushing, a variety of mechanical concentration techniques are used to concentrate the desired minerals. Techniques used for non-fuel, nonmetallic minerals include flotation, heavy media separation, and electromagnetic separation.

Flotation is a method of concentrating targeted minerals which uses the physical and chemical properties of the minerals along with process chemicals to separate desired minerals from remaining wastes. Typically, the mineral is entered into an acidic or basic bath of flotation agents. Depending on the type of mineral being concentrated, this bath may consist of such chemicals as sulfuric acid, chromium, phenols, zinc, ammonia, hydrochloric acid, and phosphoric acid. The wastes, including the spent process liquids, are discarded.

Heavy media separation utilizes mainly organic chemicals to separate minerals using the minerals' density differences. Electromagnetic separation uses a magnetic field to remove impurities from the target mineral.

Following are brief descriptions of processes used in mining major non-fuel, nonmetallic minerals.

Dimension Stone

Dimension stone refers to rock that is cut to a certain shape and size. It is commonly used as building material in the construction industry. Common types of dimension stone are limestone, granite, dolomite, sandstone, marble, and slate. Processing the stone begins with sawing the excavated rock into slabs using a rotating diamond or circular saw. Water is used to cool the saws and to remove particles. After the stone has been cut to the desired size, it is finished using natural and synthetic abrasives. Natural abrasives include iron oxide, silica, garnet, and diamond dust. Synthetic abrasives include silicon carbide, boron carbide, and fused alumina.

Crushed and Broken Stone, Including Riprap

Nearly all principal types of stone, including granite, diabase, limestone, sandstone, dolomite, and marble may be used as sources of commercial crushed stone. Stone that breaks in chunky, cubical fragments and is free of surface alteration from weathering is preferred for crushed stone. Such stone should also be free of impurities such as opalescent quartz, which may react with lime in cement and cause disintegration of the concrete in which the stone may be used. Most crushed and broken stone is mined from open quarries; however, in many areas, factors favoring large-scale production by underground mining are becoming more frequent and more prominent.

Surface mining equipment varies with the kind of stone mined, the production capacity needed, the size and shape of the deposit, estimated life of the operation, location of the deposit with respect to urban centers, and other important factors. Ordinarily, drilling is done with tricone rotary drills, long-hole percussion drills, and churn drills. Blasting in smaller operations may still be done with dynamite, but in most medium- to large-size operations, ammonium nitrate fuel oil mixtures (AN-FO), which are much lower in cost, are used.

Other processing activities include conveying, screening, secondary and tertiary crushing, and sizing. Screening is the single most important part of the processing cycle of crushed stone particles. A wide variety of screen types exists, and their selection is a function of the material processed as well as the final product required. Inclined vibratory screens are most commonly used in stationary installations, while horizontal screens are used extensively in portable plants. For screening large sizes of crushed stone, grizzly bars, rod decks, and heavy punched steel or plastic plates are used; for smaller sizes, woven wire, welded wire cloth, rubber, or plastic screens are used. Stone washing is something performed, which consists of processing the crushed stone across sizing screens where it is saturated with water, in order to remove unwanted material.

Underground operations are becoming more common, especially for limestone mining in the central and eastern parts of the United States, as the advantages of such operations are increasingly recognized by the producers. By operating underground, a variety of problems usually connected with surface mining such as environmental impacts and community acceptance are significantly reduced. Underground room-and-pillar mines can be operated on a year-round basis, do not require extensive removal of overburden, and produce a minimum of environmental disturbance.

Of the total crushed stone produced in 1993, about 71 percent was limestone and dolomite; 15 percent granite; and eight percent traprock. The remaining six consisted of sandstone and quartzite, miscellaneous stone, calcareous marl, shell, marble, volcanic cinder and scoria, and slate. Limestone is used in the manufacture of products such as glass, paper, paint, sugar, and cement; of the 1.2 billion tons of crushed stone produced in 1993, approximately 81 percent was used as construction aggregates, mostly for highway and road construction and maintenance; 15 percent for chemical and metallurgical uses including cement and lime manufacture; three percent for agricultural purposes; and one percent for miscellaneous uses and products.

Sand and Gravel

Sand and gravel are the unconsolidated granular materials resulting from the natural disintegration of rock or stone. Sand and gravel deposits are commonly found adjacent to or in river courses or in areas with glaciated or weathered rock. Such deposits often contain the fine alluvial silt that is the primary source of process and fugitive dust from sand and gravel operations.

There are two main types of sand and gravel. Construction sand and gravel are used mainly in concrete, road-base, asphaltic concrete aggregates, and construction fill. Generally, the physical characteristics of construction sand and gravel and their proximity to construction sites is more important than their chemical characteristics. Industrial sand and gravel are used mainly in manufacturing glass, ceramics, and chemicals. The chemical and physical characteristics of industrial sand and gravel are very important to their end uses, and are therefore subject to stricter chemical and physical characterization than construction sand and gravel.

Loose sand and gravel deposits are usually mined without the necessity of drilling and blasting. On rare occasions, blasting with light charges is used to loosen deposits.

Extraction and mining is done by any number of methods, depending on whether the deposit is above or below the water table. Where sand and gravel are above water, extraction is done by power shovels, drag line scrapers, and/or by highly mobile, rubber-tired front-end loaders.

When the sand and gravel deposit is consolidated to the point where digging with a front-end loader or power shovel is too difficult, a bulldozer equipped with a ripper is used to loosen the material. A ripper consists of a large tooth (or series of teeth) which is attached to the rear of the bulldozer and pulled through the material as the bulldozer moves forward. Materials mined below water, in rivers, estuaries, lakes, and oceans must be removed with specialized equipment. This equipment includes dredges, draglines and floating cranes.

Clay, Ceramic, and Refractory Minerals

Common types of clay, ceramic, and refractory minerals include kaolin, ball clay, bentonite, fuller's earth, fire clay, common clay, and shale. Processing of minerals in this category usually entails a combination of crushing, grinding, screening, and shredding to reduce particle size. For kaolin and ball clay, wet and dry processing methods are used. The wet process employs liquid chemical dispersants (phosphates, phosphoric acid, hydroxides) and water to remove impurities. A clay slurry is formed and is made either acidic or basic using sulfuric acid or alum. The slurry is then chemically leached using a reducing agent such as zinc hydrosulfide, ozone, or peroxide to remove unwanted iron and titanium ions. The slurry is dried to remove water and unwanted chemical compounds such as phosphates, phosphoric acids, silicates, iron, and zinc. Clay beads are then formed that are pulverized and calcined (heat treated).

Chemical and Fertilizer Minerals

These minerals include potash and phosphate rock. Potash, a term that describes minerals containing potassium compounds, is used in fertilizers. Processing potash involves mixing crushed potash ore with a brine which is saturated with potassium chloride and sodium chloride. Froth flotation, crystallization, or heavy media separation methods are then used to recover potassium-bearing compounds from the saturated solution.

Processing phosphate rock usually consists of sizing and flotation. Crude ore is pumped and slurried in wells and is transported to a washing plant for sizing. Fine concentrate is sent to flotation, where various flotation methods are used on the concentrate. Typical flotation reagents used include sulfuric acid, which is used in product scrubbing, and soda ash. Additional flotation reagents include fatty acids and amines. Phosphate rock is used mainly in fertilizer manufacturing. Phosphate rock mining involves the movement of huge volumes of soil and other materials in overburden. Phosphate rock preparation involves beneficiation to remove impurities, drying to remove moisture, and grinding to improve reactivity. Usually, direct-fired rotary kilns are used to dry phosphate rock.

Non-fuel, Nonmetallic Minerals Services

This industry code includes facilities which specialize in specific areas of mining operations and which perform services on a contract basis. Specialty areas include exploration and mine development. From a process and chemical use standpoint, activities in this SIC code are similar to other activities conducted in other SIC codes. During the exploration and characterization of a mineral deposit, samples of rock must be collected and analyzed. Drill-based sampling methods are routinely used to characterize a mineral deposit at different depths. These methods include rotary, percussion, auger, and diamond drilling. Diamond drilling will extract a cylindrical core of material, while the former three methods will extract fragmented material. All share the objective of collecting ore material for analysis.

Miscellaneous Non-fuel, Nonmetallic Minerals

Minerals included in this category include lightweight aggregates (pumice, vermiculite), asphaltic minerals (gilsonite, wurtzilite), natural abrasives (millstone, diatomite), gemstones (jade, sapphire), and other minerals, such as asbestos and gypsum. Processing these minerals usually involves crushing, grinding, screening, flotation, heavy media separation, and drying methods similar to those used for other minerals. As in processing other non-fuel, nonmetallic minerals, wet methods are more chemically intensive than dry methods due to the use of various flotation agents to refine the mineral.

III.B. Mining Process Waste Outputs

III.B.1. Process-Specific Wastes

Minerals Extraction

The extraction of minerals requires the removal and disposal of overburden, a layer of soil, vegetation, and rock. Waste rock generated in both surface and underground operations is removed and usually disposed of in impoundment areas or is used to backfill mines. Wastewater is generated from the use of water to suppress dust, wash away waste from the working zone, and cool excavation machinery such as drills. Dusts are generated from the cutting, drilling, sawing, and blasting required to remove the rock. Explosives used in excavation contain mixtures of ammonium nitrate and fuel oil. Hydrocarbons used in machinery as lubricants and fuels can be sources of pollution.

Minerals Processing

Wastes generated from minerals processing include dusts, solid matter, and water effluents. Crushing and screening operations performed to reduce the size of particles are also sources of dust emissions and solid waste. This waste may contain minerals that react with air and water to produce metal ions capable of contaminating water resources such as rivers, streams, and groundwater.

Processes used to remove mineral impurities can be a major source of water contamination. Flotation, a wet method used to refine certain non-fuel, nonmetallic minerals (sand and gravel, kaolin, potash, phosphate rock) is a potential source of water pollution due to the chemicals used to separate impurities from the mineral. Flotation involves placing minerals in an acidic or basic bath of chemicals where pH modifiers such as sulfuric acid, ammonia, and hydrofluoric acid are used to control pH levels in order to separate impurities from the target mineral. Additional materials may be added to the flotation bath to assist in removing impurities, including frothers, conditioning agents, sulfonated oils, and heavy alcohol.

Exhibit 5 summarizes the types of wastes produced at various points in the non-fuel, nonmetal mining industry.

Exhibit 5
Process Waste Materials

Primary	Subprocesses	Air Emissions	Process Waste Water	Other Waste Generated
Minerals Extraction	Drilling, blasting, secondary breakage	Particulates, exhaust from machinery	Surface runoff, groundwater seepage	Overburden (soil, rock)
Minerals Transportation	Loading, conveying, off-road haulage, unloading	Particulates, exhaust from vehicles and machinery	Water for transportation of ore to process plant	
Minerals Processing	Crushing, grinding, screening, washing, drying, calcining, floating	Particulates	Transport water, ore and product wash water, dust suppression water, classification water, heavy media separation water, flotation water, solution water, air emissions control equipment water, equipment, and floor wash down water	Tailings

III.B.2. Mineral-Specific Pollutants

Sand and Gravel

Particulate matter is emitted from sand and gravel operations and is made up principally of inert crustal material (e.g., soil and rock particles). Dust emissions in the form of fugitive dust occur during removal of overburden and sand and gravel from the deposit; from wind-blown dust from storage piles; from traffic on haul roads; from open conveyors exposed to the wind; during material dumping from trucks, front-end loaders, and conveyors; from screening; and from transfer points in conveyor systems. If wet screening is used to produce a washed gravel product, negligible amounts of dust are produced, but effluent water must be clarified by settling before reuse or discharge. The amount of moisture a deposit contains affects the amount of dust emissions that occur. If the deposit is dry and the material and overburden have a high silt content, dust emissions may be significant. If the deposit is wet or is removed by dredging, dust emissions tend to be negligible as long as a high moisture content is maintained in the material.

Methods of controlling dust emissions from sand and gravel operations include using water sprays to keep materials and roads wet, limiting the drop heights of materials, covering trucks and conveyors, using enclosures or hooding material at transfer points and screening operations, and exhausting air from these points to air pollution control systems.

Stone

The source of crushed stone is usually a deposit of relatively solid rock such as limestone, dolomite, trap rock, granite or sandstone. Dust emissions occur from many operations in stone quarrying and processing. Dust is released when rock and crushed stone products are loosened by drilling or blasting them from their deposit beds. Dust is also released when the loosened rock is loaded into trucks by power shovels or front-end loaders. Transporting the quarried material to the processing plant generates dust from the rock inside the truck and from the road. Sources of dust at the processing plant include the dumping of rock into primary crushers; primary, secondary, and tertiary crushing; screening; transferring rock by belt conveyor; loading rock onto storage piles from conveyors; and wind blowing dust from storage piles and open conveyors.

Particulate matter produced during stone quarrying and processing is usually of relatively large particle size. The chemical composition of the dust tends to be homogeneous since its ancestry is the rock formation from which the rock deposit was taken.

Air pollution control techniques for stone quarrying and processing plants include wetting the material and/or surfaces; covering open operations to prevent dust entrainment by the wind; reducing the drop height of dusty material; and using hooding, industrial ventilation systems, and dust collectors (e.g., baghouses) on dusty processes amenable to enclosure. Dust recovered from air pollution control systems is often a valuable product in road building and other construction operations.

Phosphate Rock

Although there are no significant emissions from phosphate rock beneficiation plants, emissions in the form of fine rock dust may be expected from drying and grinding operations. Phosphate rock grinders can be a considerable source of particulates. Because of the extremely fine particle size, baghouse collectors are normally used to reduce emissions. Effluents produced in the mining and beneficiation of phosphate rock are contained in the water suspensions leaving the washer plant. These suspensions are the phosphatic clays and sand tailings. The major effluent is that of the phosphatic clays which contain a suspension of clays and very fine solids. These phosphatic clays are impounded in slime ponds to allow settling and clarification to occur. Clear water is returned from the ponds to the beneficiation plant. When phosphate rock is calcined, fluoride is produced. The fluoride produced is scrubbed with water or dilute hydrofluoric acid.

Because proposed mining activities may also impact aquatic sources, vegetation and wildlife, EPA suggests the following potential mitigation measures for use at mine sites:

Exhibit 6
Ecosystem Mitigation Measures

- Employ sediment retention structures to minimize amount of sediment migrating off-site
- Employ spill prevention and control plans to minimize discharge of toxic/hazardous materials into water bodies
- Site roads, facilities, and structures to minimize extent of physical disturbance
- Avoid construction or new disturbance during critical life stages
- Minimize use of fences or other such obstacles in big game migration corridors; if fences are necessary, use tunnels, gates, or ramps to allow passage of these animals
- Use "raptor proof" designs on power poles to prevent electrocution of raptors
- Use buses to transport employees to and from mine from outer parking areas to minimize animals killed on mine-related roadways
- Limit impacts from habitat fragmentation, minimize number of access roads, and close and restore roads no longer in use
- Prohibit use of firearms on site to minimize poaching.

IV. WASTE RELEASE PROFILE

This section provides a general overview of the waste release activities and issues common to the non-fuel, non-metal mining industry. Unlike facilities covered by SIC codes 20 through 39 (manufacturing facilities), non-fuel, non-metal mining facilities are not required by the Emergency Planning and Community Right-to-Know Act to report to the Toxic Release Inventory (TRI). Because TRI reporting is not required for the non-fuel, non-metal mining industry, other sources of waste release data have been identified for this profile. EPA is considering expanding TRI reporting requirements in the future, which may affect such previously exempt industries such as non-fuel, non-metal mining.

IV.A. Data Sources

The Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry.

AIRS Data

The Aerometric Information Retrieval System (AIRS) is an air pollution data delivery system managed by the Technical Support Division in EPA's Office of Air Quality Planning and Standards, located in Research Triangle Park, North Carolina. AIRS is a national repository of data related to air pollution monitoring and control. It contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. States are the primary suppliers of data to AIRS. Data are used to support monitoring, planning, tracking, and enforcement related to implementation of the Clean Air Act. AIRS users include State environmental agency staff, EPA staff, the scientific community, other countries, and the general public.

Exhibit 7 summarizes AIRS annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulates (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs). This information is compared across industry sectors.

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and industry-specific descriptions of some pollution prevention advances that have been implemented within the non-fuel, non-metallic industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are, being implemented by this sector. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the techniques can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects, air, land, and water pollutant releases.

The use of pollution prevention technologies and environmental controls can reduce substantially the volume and concentration of the contaminants released/discharged into the surrounding environment. In some cases, these pollution prevention approaches may be economically beneficial to mine operators because they may decrease the process chemicals needed, and therefore the cost of producing a given amount of mineral. The approaches actually used depend on many criteria, including the nature of the mine environment, the funds available for enforcement and inspection, the availability of new technological solutions, and the relationships between government and mine operators.

Waste minimization generally encompasses any source reduction or recycling that results in either the reduction of total volume or the toxicity of hazardous waste. Source reduction is a reduction of waste generation at the source, usually within a process. Source reduction can include process modifications, feedstock (raw material) substitution, housekeeping and management processes, and increases in efficiency of machinery and equipment. Source reduction includes any activity that reduces the amount of waste that exits a process. Recycling refers to the use or reuse of a waste as an effective substitute for a commercial product or as an ingredient or feedstock in an industrial process.

Opportunities for waste minimization may include raw material substitutions, though these opportunities are somewhat limited for mining facilities because of the transportation costs involved in using ores or concentrates produced in other regions or countries. In elemental phosphorous production, raw materials substitution generally takes the form of improving the separation of value from the raw ore during beneficiation, so that the furnace operations would begin with a higher grade of ore concentrate. Processing a feedstock with a higher concentration of phosphorous results in decreased slag generation, although presumably increasing the generation of related beneficiation wastes. Other source reduction opportunities may involve process modifications to increase efficiency during the furnace operation.

Utilization of mineral processing wastes can be a viable alternative to disposal. In 1988, Occidental's Columbia, Tennessee plant reported selling all of its slag while three other facilities sold some portion of their slag for off-site use (specific data are confidential). Phosphorous slag can be used as an aggregate in asphalt manufacturing, and elemental phosphorous slag has been used extensively in highway construction for many years in Idaho, Montana, and Tennessee.

The list below summarizes some of the environmental control technologies and regulatory approaches that may serve as effective pollution prevention techniques for this industry.

Water Pollution Prevention

- Reduce the amount of contaminated water produced by using diversion systems to channel runoff away from exposed mine pits and waste dumps.
- Channel contaminated water into containment ponds for treatment or recycling.
- Reuse contaminated water in the extraction process for dust elimination or drilling.
- Utilize subsurface drainage systems and barriers to collect or deflect groundwater prior to contact with exposed mine pits.

Air Pollution Prevention and Control

- Utilize dust elimination technologies such as wet suppression systems to reduce dust created during excavation and transport.
- Use dust suppressant agents such as magnesium chloride to reduce dust in solid piles and tailings.

Closure and Reclamation Approaches

- Use plant cover and landscape alteration to reduce erosion, dust, and runoff contamination; reintroduce native species to the former mine site; and allow alternative uses of the land.

Sample Planning, Monitoring, Enforcement, and Compliance Approaches

- Use company-managed audits, environmental monitoring, and reporting systems to supplement government-run enforcement efforts.
- Prepare detailed environmental impact statements that estimate potential environmental impacts, outline compliance plans, and detail the management of future environmental problems.
- Discuss alternative mine design and extraction/beneficiation approaches prior to issuing mine permits, and explore options for minimizing environmental impacts.

Additional Pollution Prevention Activities

According to 1992 industry information, pollution prevention activities under evaluation in the non-fuel, nonmetallic mineral mining industry include the physical and chemical stabilization of tailings for backfilling, subaqueous disposal of tailings for chemical stabilization, tailings beneficiation to remove toxic and acid components and recover valuable minerals, and procedures for the reclamation and final closure of mines. Each of these methods is discussed briefly below.

Using mine wastes as backfill can minimize surface subsidence by filling in underground voids. It can also minimize the impacts of surface disposal by reducing the volume of waste on the surface. A potential problem with this is that the material used as backfill could contaminate water resources by generating acid mine waters.

A froth flotation process has been developed by the Bureau of Mines to remove heavy-metal-bearing minerals from tailings. This process recovers the mineral components of the tailings while removing acid-forming minerals, rendering the wastes less susceptible to contaminating ground and surface waters. The Bureau is also investigating a new device called the air-sparged hydrocyclone, which provides a portable, compact unit to treat large volumes of tailings on-site without the usual expensive capital requirements.

Bureau researchers are also developing effective methods for reclamation and closure of mining operations. The focus of this work is on controlling hydrology at sites, decontaminating wastes when necessary, and stabilizing wastes for closure. For example, the current practice for sealing mine shafts and portals is to install a concrete plug. This practice is difficult and expensive because it requires drilling into rock walls to provide support for the plug. Access to remote shafts and portals is also a problem. One possible solution is the use of low-density foaming plastics and/or cements. Studies have shown that injecting foaming materials may cost half that of concrete plugs. In addition, the expansion characteristic of the foaming materials may eliminate the need for drilling into intact rock. Another advantage of using foamed plastic or cement plugs is the provision of a resistant seal to acidic mine waters.

Wastes are also generated from maintenance activities associated with the operation of a mine. Exhibit 9 presents some of these activities, along with the wastes generated by each activity and some waste minimization options.

Exhibit 9
Waste Minimization Options

Activity	Waste Generated	Waste Minimization Options
Metal Parts Cleaning	Miscellaneous chlorinated solvents	Switch to semi-aqueous cleaners or water-based cleaning solutions to reduce or eliminate solvent emission and liquid waste generation.
Flotation	Zinc sulfate, sodium cyanide	Use flotation process control equipment that uses sensors, computing elements, and control units to reduce the amount of flotation reagents needed and to improve separation of waste from product.
Blasting	Ammonium	Maintain storage containers properly.
Changing Lubricating Fluids	Lead, cadmium	Do not mix used oil with solvents or other materials; segregate and recycle used oil; use fluid filtration systems to extend fluid life; segregate and recycle antifreeze; use washable rags instead of disposable rags.

Exhibit 9 (cont'd)
Waste Minimization Options

Activity	Waste Generated	Waste Minimization Options
Mining Vehicle Battery Replacement	Lead, acids	Recycle used batteries. Trade in old batteries when buying new batteries.

V.A. Innovative Waste Management Practices

Pipe Recycling/Reuse

IMC operates phosphate rock mines in West Central Florida and has implemented a waste minimization program involving the reuse and recycling of steel pipe used to transport slurry, water, tailings, and other materials. IMC obtains maximum use from its pipe in several ways:

- Pipe used for matrix and clay transport is periodically rotated to ensure that wear is evenly spaced over the full diameter of the pipe
- To the extent possible, pipe no longer suitable for the most demanding use is used in other, less demanding pipelines
- Pipe no longer suitable for use in pipelines is either used for other purposes (such as culverts) or is sold for off-site reuse or scrap.

IMC has developed a computerized model to predict how long a section of pipe can remain in each position and when it needs to be turned. When pipe can no longer be used for materials transport, any undamaged portions of pipe are removed for onsite reuse as culvert or sold to a local scrap dealer as usable pipe. Damaged pipe is sold to a scrap dealer. By reusing pipe onsite, IMC estimates that it saves approximately $1.5 million each year. In 1991, $316,000 was received for pipe that could be reused offsite, and 4,200 tons of scrap piping was sold for an estimated total of $42,000 - $84,000. IMC's program reduces capital expenditures by reducing the amount of new pipe that must be purchased, as well as saving operating costs by avoiding costly shutdowns when pipes fail.

Mine Tire Recycling

Two Federal regulations will increasingly effect the scrap tire industry markets. First, the Clean Air Act Amendments have redefined tire derived fuel (TDF) as a fuel, no longer considering it a waste fuel.

Increased demand for TDF has already occurred as a result: in 1990 about 10 percent of scrap tires were used as TDF, while in 1992 27 percent, or 65 million scrap tires, were used. Projections for 1994 were that 50 to 55 percent of scrap tires, or 141 million tires, would be needed to meet market demand. Second, the Intermodal Surface Transportation Efficiency Act (ISTEA) requires that five percent of all Federally-funded road projects use rubber from scrap tires in 1994; use of scrap tires must increase five percent annually until 1997, when it tops out at 20 percent. By 1995, 17 million scrap tires will be required in Federal road projects; by 1997 the number will increase to 50 million.

Mine representatives have estimated the price of one large tire to range from $10,000 to $16,000, or over $100,000 to fit one large piece of equipment. Several options exist for recycling or reusing whole large tires. One alternative is retreading the tires for reuse; retreading reduces the demand for new tires and conserves resources (retreading a used tire requires less than 40 percent of the fossil fuel to make a new tire). The purchase price for retreaded tires is less than for new tires, providing an additional savings incentive. In addition to retreading, whole scrap tires are used in civil engineering applications, including construction, erosion control, and agriculture (feeding troughs, for example).

Processing scrap tires involves shearing, cutting and/or shredding tires into smaller pieces. The major markets for processed tires are as TDF and in civil engineering applications. Scrap tires are an excellent fuel source, generating about 80 percent as much energy as crude oil per pound. In recent years, there have been major increases in the use of scrap tires as fuel by a number of industries, including power plants, cement kilns, pulp and paper mills, and tire manufacturing facilities.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal statutes and regulations that may apply to this sector. The purpose of this section is to highlight, and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included.

- Section IV.A contains a general overview of major statutes
- Section IV.B contains a list of regulations specific to this industry
- Section IV.C contains a list of pending and proposed regulations

The descriptions within Section IV are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act

The Resource Conservation And Recovery Act (RCRA) of 1976 which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. Facilities

R0076554

that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties

that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the

Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR § 302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §§311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC, and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., EST, excluding Federal holidays.

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants, including various toxic pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has presently authorized forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring and reporting requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from State to State, and site to site, depending on the use classification of the receiving body of water. Most States follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant (40 CFR 122.26(b)(14)). These regulations require that facilities with the following storm water discharges apply for a NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized States enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control (UIC)** program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily State-enforced, since EPA has authorized all but a few States to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding Federal holidays.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding Federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year

2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Regulations

The environmental impacts of the non-fuel, nonmetallic mining industry are regulated primarily by two statutes: the Clean Air Act (CAA) and the Clean Water Act (CWA). Other statutes that might be applied to the non-fuel, non-metal mining industry are the Resource Conservation and Recovery Act (RCRA), the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), the General Mining Law of 1872, and State statutes.

Clean Air Act (CAA)

Although nonmetallic mining operations are not specifically regulated by the CAA, businesses involved in the processing of the minerals are regulated. 40 CFR Part 60 Subpart OOO, Standards of Performance for Nonmetallic Mineral Processing Plants, and 40 CFR Part 60 Subpart UUU, Standards of Performance for Calciners and Dryers in Mineral Industries, require these industries to control or reduce emissions of particulate matter and impose specific monitoring, recordkeeping, and reporting requirements. Under the Clean Air Act, sources are required to obtain construction and operating permits, not only for particulate emissions but also for NOx, SO2, and CO which are often products of combustion from engines for power and also dryers.

40 CFR Part 60 Subpart OOO applies to facilities that process any of the following 18 minerals: crushed and broken stone, sand and gravel, clay, rock salt, gypsum, sodium compounds, pumice, gilsonite, talc and pyrophyllite, boron, barite, fluorspar, feldspar, diatomite, perlite, vermiculite, mica, and kyanite. The affected facilities are: crushers, grinding mills, screening operations, bucket elevators, belt conveyors,

bagging operations, storage bins, and enclosed trucks or railcar loading stations.

40 CFR Part 60 Subpart UUU applies to calciners and dryers used to process the following minerals: aluminum, ball clay, bentonite, diatomite, feldspar, fire clay, fuller's earth, gypsum, industrial sand, kaolin, lightweight aggregate, magnesium compounds, perlite, roofing granules, talc, titanium dioxide, and vermiculite.

Clean Water Act (CWA)

Discharges from mine sites are addressed under two principal regulatory programs: the NPDES permit program (for process water and storm water point source discharges) and the Non-point source program.

NPDES Point Source Program

A point source is defined in Section 502(14) of the CWA as "any discernible, confined and discrete conveyance, included but not limited to, any pipe, ditch, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft from which pollutants are or may be discharged." The Water Quality Act amendments of 1987 added discharges from "landfill leachate collection systems" to this definition. All point source discharges to waters of the U.S. must be addressed by NPDES permits.

Storm water is defined in 40 CFR 122.26(b)(13) as "storm water runoff, snow melt runoff, and surface runoff and drainage." Storm water associated with industrial activity is defined in 40 CFR Section 122.26(b)(14) as the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing, or raw materials storage areas at an industrial plant. Section 402(p) of the CWA generally requires EPA to issue NPDES permits for point source discharges of storm water associated with industrial activity, including active and inactive mines. At mine sites, Section 402(1)(2) specifically limits the permit requirements for storm water that has come into contact with any overburden, raw material, intermediate products, finished products, byproducts, or waste products located on the site of the operation.

EPA is currently developing a storm water program for those point source discharges from active and inactive mines not already permitted. Several States are also currently developing general storm water permits for mine sites.

Non-point Source Program

Non-point sources of pollution are addressed under Sections 304(f)(b) and 319 of the CWA of 1972. Non-point source runoff is caused by runoff from diffuse sources, and is generally caused by rainfall or snow melt. Section 304(f)(b) establishes guidelines for identifying and evaluating the nature and source of non-point sources of pollutants, and processes, procedures, and methods to control pollution resulting from mining activities, including runoff and siltation from new, currently operating, and abandoned surface and underground mines. Non-point source discharges may be to streams, lakes, rivers, wetlands, or to groundwater. Specific best management practices (BMPs) requirements for non-point source control at mine sites have not been promulgated at the national level, nor has any national guidance been issued. However, individual States are currently developing programs for storm water management at mine sites. For example, Idaho recently prepared a document that describes practices to minimize non-point source water quality impacts.

Under Section 319 of the Clean Water Act, States developing plans to address problems and solutions to non-point source pollution, are eligible for grants that are administered by the Regions.

In addition to applicable general CWA requirements, active mineral mining and processing operations are subject to the requirements contained in 40 CFR 436, EPA Effluent Guidelines and Standards for Mineral Mining and Processing. The regulation establishes effluent limitation guidelines and pretreatment standards that limit the discharge of pollutants into navigable waters, and requires the application of best practicable control technologies (BPT). For the purposes of these guidelines and standards of performance, the industry is divided into 38 subcategories consisting of specific mineral types or classes of minerals. Effluent limitations are based on factors such as the type of ore, method of transport, type of processing, use of wet air emissions control devices, type of product, and groundwater seepage and runoff into mine and process wastewater impoundments.

Mine dewatering can invoke environmental regulation under CWA. Dewatering is the removal of water that has infiltrated the mining site. Wells, pumps, or ditches and tunnels are typically used to divert the water away from the site. Dewatering can also lead to the unintentional creation of wetlands, requiring a permit under the CWA. EPA's Office of Water, Office of Wastewater Management/Permits Division is currently developing a mining strategy for hard rock mining which will be completed by the fall of 1995.

Exhibit 10
Mine Discharges Subject to Permitting

Runoff/drainage discharges subject to 40 CFR Part 440 effluent limitation guidelines	Subject to storm water permitting (not subject to 40 CFR Part 440)
Land application area Crusher area Spent ore piles, surge piles, ore stockpiles, waste rock/overburden piles Pumped and unpumped drainage and mine water from pits/underground mines Seeps/French drains On-site haul roads, if constructed of waste rock or spent ore or if wastewater subject to mine drainage limits is used for dust control Tailings dams/dikes when constructed of waste rock/tailings Unreclaimed disturbed areas	Topsoil piles Haul roads not on active mining area On-site haul roads not constructed of waste rock or spent ore (unless wastewater subject to mine drainage limits is used for dust control) Tailings dams, dikes when not constructed of waste rock/tailings Concentration/mill building/site (if discharge is storm water only, with no contact with piles) Reclaimed areas released from reclamation bonds prior to 12/17/90 Partially, inadequately reclaimed areas or areas not released from reclamation bond Most ancillary areas (e.g., chemical and explosives storage, power plant, equipment/truck maintenance and wash areas, etc.)

Resource Conservation and Recovery Act (RCRA)

The Bevill Amendment

In 1980, Congress amended RCRA in the Solid Waste Disposal Act Amendments, adopting what has been dubbed the Bevill Amendment, after Representative Tom Bevill of Alabama. The amendment temporarily exempted from Subtitle C regulation solid waste from ore and mineral extraction, beneficiation, and processing. The Amendment directed EPA either to develop Subtitle C regulations for the waste or determine that the exemption should continue, and to present its findings in a report to Congress.

EPA modified its hazardous waste regulations to reflect the Bevill exclusion and issued a preliminary, and quite broad, interpretation of the exclusion's scope. In particular, it interpreted the exclusion as covering "solid waste from the exploration, mining, milling, smelting and refining of ores and minerals."

In 1985 the U.S. District Court for the District of Columbia awarded judgment to the Environmental Defense Fund and two public interest groups that had sued EPA for failing to submit the required report to Congress and make the regulatory determination by the statutory deadline. The court imposed two schedules, one for completing studies of extraction and beneficiation wastes and submitting them in a report to Congress, and the second for proposing reinterpretation of mineral-processing wastes. In so doing, the court effectively split the wastes that might be eligible for exclusion from regulation into two groups: mineral extraction and beneficiation wastes; and mineral processing wastes.

In December 1985 EPA submitted a report to Congress on mining wastes (*1985 Report to Congress: Wastes from the Extraction and Beneficiation of Metallic Ores, Phosphate Rock, Asbestos, Overburden from Uranium Mining, and Oil Shale*) in which EPA found that some mining wastes exhibit hazardous characteristics, that waste management practices have caused environmental damage, and that the range of risk from mining waste is broad. In July 1986 EPA published a regulatory determination, upheld in subsequent court challenges, that RCRA Subtitle C regulation of extraction and beneficiation wastes was unwarranted because mining wastes tend to be disposed of in arid climates, facilities and wastes are located in sparsely populated areas where human contact is minimal, and waste volumes are high. It also determined that it should develop a risk-based, State-run mining waste program under RCRA Subtitle D.

In keeping with its court-ordered directive to reinterpret the Mining Waste exclusion for mineral processing wastes, EPA proposed to narrow the scope of the exclusion for mineral-processing wastes to include only a few specific waste streams. Unable to articulate criteria for selecting these wastes, EPA later withdrew this proposal and was subsequently sued by the Environmental Defense Fund. The courts ruled against EPA, holding that the Agency's interpretation of Bevill exclusions was overbroad. The court ordered EPA to restrict the scope of the exclusion as it applied to mineral-processing wastes to include only "large volume, low hazard" wastes.

In a series of rulemaking notices, EPA reinterpreted the exclusion for mineral-processing wastes and defined which mineral-processing wastes met the high-volume, low-hazard criteria. The vast majority of mineral-processing wastes did not meet both criteria. EPA published its final regulatory determination in 1991, in compliance with a court-ordered deadline. The final rule permanently retains the Bevill exemption for 20 mineral-processing wastes. EPA determined that regulation under RCRA Subtitle C was inappropriate for these wastes because of the extremely high cost to industry and the technical infeasibility of managing them under Subtitle C requirements; 18 of the

R0076569

wastes are subject to applicable State requirements, while the remaining two (phosphogypsum and phosphoric acid process waste water) are currently being evaluated by EPA.

Wastes from the extraction and beneficiation of ores and minerals remain exempt from Subtitle C requirements, irrespective of their chemical characteristics; EPA may, in the future, evaluate the appropriateness of regulating these wastes under RCRA Subtitle D as an industrial waste. Wastes from mineral processing, however, are not exempt from Subtitle C unless they are one of the 20 specific wastes identified in EPA's final ruling.

In addition, only wastes that are uniquely associated with the extraction and beneficiation of ores and minerals (or one of the 20 listed mineral processing wastes) are excluded from hazardous waste regulation. Non-uniquely associated wastes are typically generated as a result of maintaining mining machinery or as a result of other facility activities, and continue to be subject to Subtitle C regulation. These non-uniquely associated wastes may include used oil, polychlorinated biphenyls, discarded commercial chemicals, cleaning solvents, filters, empty drums, laboratory wastes, and general refuse.

Determining how and under what circumstances the Bevill Amendment exclusions should be interpreted in regulating mining wastes continues to be a subject of discussion and study, at least in part because many beneficiation terms are used to describe activities common to a wide range of nonexempt industries and to describe mineral-processing operations that occur at the same location as the beneficiation operations. Beneficiation and mineral-processing operations are often closely linked; in order to apply Subtitle C regulations at a mine site, a regulator often must prove that the waste is not a beneficiation waste. Because a variety of regulators, at both Federal and State levels, are independently interpreting the Bevill rules, the potential for inconsistent interpretations is significant. Staff in EPA's OSW have suggested the following guidelines for regulators and the regulated community in distinguishing between exempt and nonexempt wastes at mines and mineral-processing sites:

- Determine whether the material is considered a solid waste under RCRA.
- Determine whether the facility is using a primary ore or mineral to produce a final or intermediate product and also whether 50 percent of the feedstocks are from secondary sources.

- Establish whether the material and the operation that generates it are uniquely associated with mineral production.
- Determine where in the sequence of operations beneficiation ends and mineral processing begins.
- If the material is a mineral-processing waste, determine whether it is one of the 20 special wastes from mineral processing.

This sequence will result in one of three determinations: 1) the material is not a solid waste and therefore not subject to RCRA; 2) the material is a solid waste but is exempt from RCRA Subtitle C because of the Mining Waste Exclusion; or 3) the material is a solid waste that is not exempt from RCRA Subtitle C and is subject to regulation.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

Although Bevill wastes are excluded from regulation under RCRA Subtitle C, they can be addressed under CERCLA. Mining companies may be liable under CERCLA for the release or threat of release of hazardous substances, covering releases to air, surface water, groundwater and soils. Many mines, where practices did not incorporate the safeguards now required under the CWA, allowed runoff from mine and tailings sites to flow into nearby streams and lakes. In general, the CERCLA problems associated with mining operations are much more frequent in metal rather than non-metal mining. Even newer mines, which have been subject to CWA regulations, have been targeted for CERCLA enforcement. Mine owners may also be liable for damages to natural resources as a result of mining activity.

National Environmental Policy Act (NEPA)

NEPA requires that all Federal agencies prepare detailed statements assessing the environmental impact of, and alternatives to, major Federal actions that may "significantly affect" the environment. An environmental impact statement (EIS) must provide a fair and full discussion of significant environmental impacts and inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts on the environment; EISs must explore and evaluate all reasonable alternatives, even if they are not within the authority of the lead agency. NEPA authorities are solely procedural; NEPA cannot compel selection of the environmentally preferred alternative.

Federal actions specifically related to mining that may require EISs include Federal land management agency (e.g. BLM and Forest Service) approval of plans of operations for hardrock mining on Federally-managed lands. All effected media (e.g., air, water, soil, geologic, cultural, economic resources, etc.) must be addressed. The EIS provides the basis for the permit decision; for example, an NPDES permit may be issued or denied based on EPA's review of the overall impacts, not just discharge-related impacts, of the proposed project and alternatives. Issues may include the potential for acid rock drainage, aquatic and terrestrial habitat value and losses, sediment production, mitigation, and reclamation.

Endangered Species Act (ESA)

The ESA provides a means to protect threatened or endangered species and the ecosystems that support them. It requires Federal agencies to ensure that activities undertaken on either Federal or non-Federal property do not have adverse impacts on threatened or endangered species or their habitat. In a June 1995 ruling, the U.S. Supreme Court upheld interpretations of the Act that allow agencies to consider impact on habitat as a potential form of prohibited "harm" to endangered species. Agencies undertaking a Federal action (such as a BLM review of proposed mining operations) must consult with the U.S. Fish and Wildlife Service (USFWS); an EIS must be prepared if "any major part of a new source will have significant adverse effect on the habitat" of a Federally or State-listed threatened or endangered species.

State Statutes

In addition to Federal laws, State and common laws also affect waste generation from mining activities. State law generally requires that permits be obtained prior to commencement of mining activities; permits may require design, performance, closure, and reclamation standards, and may impose monitoring requirements. Under common law, a mine owner may be liable for trespassing if wastes migrate into and damage another's property, or if the waste impacts the community as a whole, a miner may be liable for creating a public nuisance. Over the last five years several States have substantially altered their mining regulations to prevent the damage caused by past mining operations. Considerable disagreement remains, however, between mining industry groups and the environmental community regarding the effectiveness of these State regulations in preventing damage to the environment.

Many Western States require mining operations to obtain reclamation bonds and mining permits that are designed to regulate and monitor mining activity. States that require bonding and/or permitting include Alaska, Arizona, California, Idaho, Nevada, New Mexico, Oregon, Utah, Washington, South Dakota, Montana, Wyoming, and Colorado. To regulate mining activity in the State of Colorado, for example, the State requires mining operations to obtain: 1) a performance bond, 2) a reclamation bond, and 3) a permit. The performance bond outlines what the mining operation intends to do on the land, and is simply a promise from the mining operation that it will reclaim the land. This bond gives Colorado the authority to pursue reclamation costs from mining operations that fail to properly reclaim the land. The reclamation bond, also known as a financial warranty, equals the cost the State would incur if it were to hire someone to reclaim the site should the mining operation fail to do so. Although performance bonds are updated periodically, the bonds have not always been adequate to cover closure costs.

VI.C. Pending and Proposed Regulatory Requirements

Emergency Planning and Community Right-to-Know Act of 1986 (EPCRA)

EPCRA Section 313 mandates that owners and operators of facilities that manufacture, process, or otherwise use a listed chemical to report to EPA their annual releases of these chemicals to any environmental medium. EPA makes this information available to the public in the form of the Toxic Release Inventory (TRI). TRI currently requires reporting from facilities in SIC codes 20-39 which meet various threshold requirements.

EPCRA Section 313 gives EPA discretionary authority to modify the coverage of facilities required to report to EPA for inclusion in the TRI. EPA is considering expanding the TRI through the development of reporting requirements for additional facilities. These additional facilities include a list of 25 SIC codes that contribute 99 percent of the non-manufacturing TRI chemical loadings to the environment. SIC 14 is among these 25 SIC codes. EPA anticipates publication of a proposed rule in late 1995 or early 1996 requiring additional facilities to report the use, release, and transfer of TRI chemicals.

Clean Air Act (CAA)

Clean Air Act Amendments (CAAA) of 1990

In 1992, EPA published an initial list of all categories of major and area sources of the hazardous air pollutants (HAPs) listed in Section 112(b) of the CAA. EPA is required to establish dates for the promulgation of emission standards for each of the listed categories of HAP emission sources and develop emission standards for each source of HAPs such that the schedule is met. The standards are to be technology-based and are to require the maximum degree of emission reduction determined to be achievable by the Administrator. Proposed standards for most mineral industries are due by November 1, 1997. The Agency has determined that the phosphoric acid manufacturing industry may be anticipated to emit several of the 189 HAPs listed in Section 112(b) of the CAAA. As a consequence, this source category is included on the initial list of HAP-emitting categories scheduled for standards promulgation.

New Emissions Standards for Hazardous Air Pollutants (NESHAP)

Another proposed rule under the CAA concerns the development of maximum achievable control technology (MACT) or generally achievable control technology (GACT) standards for the asbestos processing source category that is comprised of the milling, manufacturing, and fabrication subcategories of the asbestos NESHAP. Pollutants to be regulated include asbestos and other HAPs emitted in major amounts by these subcategories. Final action on this proposed rule is scheduled for November 1995.

National Ambient Air Quality Standards (NAAQS)

EPA is reviewing and updating the air quality criteria for particulate matter to incorporate new scientific and technical information that has become available since the last review. Based on the revised criteria, EPA will determine whether revisions to the standards are appropriate. This will affect the mining and quarrying of non-fuel, nonmetallic minerals.

Clean Water Act (CWA)

A comprehensive bill was introduced in Congress in 1995 to reauthorize the Clean Water Act. The bill may affect EPA's authority to require changes in production processes, products, or raw materials to control emissions of toxins; may require risk assessments for water quality standards, effluent limitations or other regulatory requirements; and may require social, economic, and environmental benefits to be weighed in establishing regulations. Potentially large sectors of the non-fuel, non-metal mining industry could be affected by this legislation.

Safe Drinking Water Act (SDWA)

Arsenic is one of the non-fuel, nonmetallic minerals covered by SIC 14. A proposed rule will set a maximum contaminant level goal (MCLG) and revised national primary drinking water regulation (NPDWR) for arsenic in drinking water, pursuant to the SDWA amendments of 1986. The SDWA requires EPA to promulgate national primary drinking water regulations for 83 specific contaminants of which arsenic is one.

VII. COMPLIANCE AND ENFORCEMENT PROFILE

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (August 10, 1990 to August 9, 1995) and the other for the most recent twelve-month period (August 10, 1994 to August 9, 1995). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are State/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and States' efforts within each media program. The presented data illustrate the variations across regions for certain sectors. This variation may be attributable to State/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund), and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook Sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected --- indicates the level of EPA and State agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into Federal and State actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (facility with 3 enforcement actions counts as 1). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with 3 enforcement actions counts as 3).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by State and local environmental agencies. Varying levels of use by States of EPA data systems may limit the volume of actions accorded State enforcement activity. Some States extensively report enforcement activities into EPA data systems, while other States may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the U.S. EPA. This value includes referrals from State agencies. Many of these actions result from coordinated or joint State/Federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Related inspections and enforcement actions under the Clean Water Act (PCS), the Clean Air Act (AFS) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and

EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100% because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Non-Fuel, Non-Metal Mining Industry Compliance History

Exhibit 11 presents enforcement and compliance information specific to the non-fuel, non-metal mining industry. As indicated in the chart, Regions III, IV, V, VIII, and X have been the most active in terms of enforcement actions against this sector.

Exhibit 11
Five Year Enforcement and Compliance Summary for the Non-Fuel, Non-Metal Mining Industry

A	B	C	D	E	F	G	H	I	J
Non-Fuel, Non-Metal Mining SIC 14	Facilities in Search	Facilities Inspected	Number of Inspections	Average Number of Months Between Inspections	Facilities w/one or more Enforcement Actions	Total Enforcement Actions	State Lead Actions	Federal Lead Actions	Enforcement to Inspection Rate
Region I	48	22	80	36	1	1	0%	100%	0.01
Region II	52	39	203	15	8	26	100%	0%	0.13
Region III	62	44	396	9	6	13	85%	15%	0.03
Region IV	428	203	1,310	20	32	59	71%	29%	0.05
Region V	164	100	382	26	6	6	100%	0%	0.02

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 12-15 provide enforcement and compliance information for selected industries. The non-fuel, non-metal mineral mining industry has the fourth largest number of facilities tracked by EPA across the selected industries. Of the total number of enforcement actions over five years, 76 percent are State-lead actions and 24 percent are federal-lead actions. For this industry, Clean Air Act inspections comprise 65 percent of all inspections conducted, and Clean Water Act inspections account for 31 percent of all inspections. This inspection pattern seems consistent with the general priority of environmental concerns within this sector. Importantly, the non-fuel, non-metal mining sector exhibits the lowest number of enforcement actions in relations to inspections that any other industry covered under this project over the last five years (see Exhibit 12).

VII.C. Review of Major Legal Actions

VII.C.1. Review of Major Cases

As indicated in EPA's *Enforcement Accomplishments Report, FY 1991* through *FY 1993* publications, two significant enforcement cases were resolved between 1991 and 1993 for the mining and quarrying of non-fuel, nonmetallic minerals. The cases were comprised of CERCLA and the Marine Protection Research and Sanctuaries Act (MAPRSA) violations. Both cases were related to companies in the sand and gravel business.

One of the three cases resulted in the assessment of a penalty. In U.S. v. Petersen Sand & Gravel, Inc. (1993), the defendant failed to furnish accurate and complete information relating to its disposal of hazardous wastes at its site. The defendant mined sand and gravel at the site, during which time several hundred drums of paints, solvents, and other industrial wastes were dumped. The company was required to pay $700,000 and to provide a full response to EPA's original information requests.

In U.S. v. Custom Sand and Gravel (1993), an administrative order was issued under MAPRSA for unauthorized construction of dikes and roadways and for clearing and leveling activities associated with sand and gravel mining operations that impacted wooded swamp. A restoration plan was submitted to restore approximately 65 acres of wetland habitat.

VIII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-Related Environmental Programs and Activities

EPA's Office of Solid Waste (OSW) conducts research into mining waste issues, including engineering studies conducted on innovative methods of mining to reduce mine waste. OSW prepares reports that evaluate current mining designs and how these designs impact the environment. The reports, which are subject to peer review, cover topics such as the design and operation of waste rock piles, subaqueous disposal of tailings, and cyanide detoxification. OSW also provides outreach and technical support to other program and Regional offices to address mine waste problems located on Indian reservations. OSW is currently involved in providing outreach and technical support to approximately six different sites. (Contact: Steve Hoffman, 703-308-8413)

U.S. Bureau of Mines Environmental Research Program

The U.S. Bureau of Mines environmental research program is developing technology to prevent pollution and to maintain a healthy work environment. In the pollution prevention area, the USBM, in conjunction with the Florida phosphate industry and the Florida Institute of Phosphate Research, is researching the environmental pollution associated with phosphogypsum stacks, and the large process/cooling water ponds associated with them. The Bureau is also evaluating the potential for in-situ mining of western phosphate ores, a technique that would significantly reduce gypsum production in the processing of western phosphate rock. (Contact: Frank Lanzetta, Research Staff, (202) 501-9272)

The focus of the environmental health research is the monitoring and control of small airborne dusts that can be inhaled deep into the lungs and cause respiratory diseases. Emphasis is on the monitoring and control of coal and rock dusts and emissions from diesel engines. A continuous monitor to evaluate dust conditions during the extraction process for mineral ores is being developed to provide a means to alert workers to hazardous dust conditions. Dust control techniques are directed primarily towards reducing concentrations through the application of water sprays, more effective use of ventilation air, and modification of mining operating parameters. (Contact: Dr. J. Harrison, Research Staff (202) 501-9309)

Mine Safety and Health Administration (MSHA) Mines Initiative

Electrical transformers or capacitors containing polychlorinated biphenyls (PCBs) are often used as power sources in underground mines. This equipment is regulated by EPA to ensure against environmental release of PCBs, chemicals classified as probable human carcinogens. Abandoned mines often fill with ground water, which can cause PCB-containing equipment to corrode and leak chemicals into the water.

EPA and MSHA launched a joint effort in early 1993 to identify all underground mines using electrical transformers or capacitors that contain PCBs. During 1993, MSHA inspectors completed PCB checklists that identified mines using PCB- or other liquid-filled equipment underground, and whether there were any violations of EPA regulations governing PCB use, marking, storage, or disposal. In total, 85 underground mines that may use PCB-containing equipment were identified. EPA has used the PCB checklists as part of its enforcement efforts. As a result of these efforts, four mining companies have been cited for mismanaging PCBs and face Federal penalties of up to $317,575. EPA has settled one of these cases and filed three additional complaints.

Miscellaneous Activities

Members of several government agencies have been informally meeting over the past five years to share and communicate ideas on mining waste issues. Known as the Federal Land Management Agencies, this group includes EPA, the National Park Service, the Department of Agriculture, the Department of the Interior, the Bureau of Land Management, and the U.S. Forest Service. According to Steve Hoffman of EPA's Office of Solid Waste, a memo of understanding is currently under development to formalize the group's meetings at the senior level.

EPA has provided a multi-year grant to the Southwest Research and Information Center to conduct research and outreach activities regarding mine waste issues. The Center maintains a clearinghouse of technical studies conducted on mine waste topics. (Contact: Paul Robinson, 505-262-1862)

Over the last few years, EPA has enlisted the advice and assistance of the States in developing a Federally-mandated RCRA mine waste program. In order to facilitate the involvement of the States in this effort, EPA has provided funding to the Western Governors' Association (WGA), an independent non-partisan organization of 21 member governors. In 1988, WGA formed a Mine Waste Task Force to coordinate the views of the member States and to work with EPA, the mining industry, the environmental community, and the public in the development of a workable mine waste management program.

Kansas State University's Hazardous Substance Research Center (HSRC) is an EPA-funded center providing research and technology transfer services for pollution prevention and other waste management techniques. HSRC programs include outreach for industry, assistance to government, videos, radio programs, written materials, data bases, and workshops on pollution prevention and hazardous waste remediation. One pollution prevention focus of HSRC is on soils and mining waste.

Contact: Dr. Larry E. Erickson, Director
Hazardous Substance Research Center (HSRC)
Ward Hall, Room 101
Kansas State University
Manhattan, Kansas 66506-5102
(913) 532-6519

The Arizona Department of Environmental Quality (ADEQ) (602-779-0313) has established a multifaceted pollution prevention program to encourage generators of hazardous waste to prepare a pollution prevention plan. ADEQ encourages companies to prepare pollution prevention plans by reducing environmental permit filing fees 50 percent if companies implement a pollution prevention plan. Some mining companies have participated in this program. In addition, a joint partnership between the State and private industry has been formed, called the Arizona Pollution Prevention Partnership. The Partnership consists of 22 of the State's largest hazardous waste generators. These companies, which include some mining companies, have spelled out specific hazardous waste reduction plans for a two to three year period.

The Mineral Policy Center is a non-profit organization that provides technical, legal, and political strategy assistance to deal with mineral threats to sensitive areas. The main goal of the Center is to promote environmentally responsible mining. The organization educates and assists citizens' groups and agency personnel working with conservation problems related to legislation such as the 1872 Mining

Law and RCRA. The Mineral Policy Center provides educational materials such as fact sheets, information packets, videos, and publications that summarize the results of research conducted on the environmental impacts of mining. Its publications include Burden of Guilt, which provides a current assessment of the abandoned mine problem and a proposal to develop and fund an effective nationwide reclamation program. The Center also conducts roundtable discussions with mining companies to discuss environmental issues facing the mining industry. (Contact: Gary Kravis, 202-887-1872)

In 1990, a funding agreement was entered into between EPA and the Interstate Mining Compact Commission (IMCC) (Contact: Greg Conrad 703-709-8654). IMCC is an association that studies and recommends techniques for the protection and restoration of land, water, and other resources affected by mining. The purpose of the funding agreement between EPA and IMCC is to facilitate State involvement in developing and implementing mine waste regulation. Fifteen member States have participated in this effort thus far.

VIII.B. EPA Voluntary Programs

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and State agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and Federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentoring programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects. (Contact: Tai-ming Chang, ELP Director, 202-564-5081 or Robert Fentress, 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project

Agreement, detailing specific objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice, or contact Jon Kessler at EPA's Office of Policy Analysis (202) 260-4034.

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; Federal, State and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Susan Bullard at 202-233-9065 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA in turn provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn, 202-260-0700 or the WasteWi$e Hotline at 1-800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman, 202-260-4407)

$NICE^3$

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics ($NICE^3$). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office, 303-275-4729)

VIII.C. Trade Association/Industry-Sponsored Activity

The Missouri Limestone Producers Association, along with EPA's Region VII developed a voluntary compliance program for Missouri rock crushing companies in violation of the Clean Air Act. Affected rock crusher facilities in Missouri's pilot program must comply with New Source Performance Standards (NSPS) of the Clean Air Act. The EPA regulations, commonly called Subpart OOO, are designed to control air pollution from specific new equipment at nonmetallic mineral processing plants. This includes: rock crushing units, screens, conveyors, and bins. Regulations require owners, who have purchased new equipment since August 31, 1983, to maintain records, conduct performance testing of air emissions, and provide notification to EPA. Many Missouri rock crushers have failed to provide necessary notification and to conduct required performance testing. These failures are violations of Federal regulations and owners are liable for penalties under the Clean Air Act. The maximum penalty can be as much as $25,000 per day, per violation. By participating in the voluntary compliance program, sources are eligible for reduced penalties for notification and testing violations. Forty five companies have taken advantage of this voluntary compliance program and have achieved significant penalty reductions as a result of their participation.

VIII.C.1. Environmental Programs

The National Stone Association produces a Clean Air Management Guide, summarizing provisions of the Clean Air Act, that has been praised by the California Air Resources Board. Additionally, the National Stone Association, along with the Florida Concrete & Products Association and Aggregate Institute produces a course on the Clean Air Act Amendments of 1990 and Title V Operating Permits for the Florida Aggregates Industry. This course has also been taught in other areas of the country i.e. Northern California and Kansas City. The National Stone Association also runs an environmental excellence program for its members with winners receiving Environmental Eagle Awards.

VIII.C.2. Summary of Trade Associations

Trade and professional organizations serving the mining industry in general are divided along mining processes as well as type of mineral mined.

In 1990, a funding agreement was entered into between EPA and the Interstate Mining Compact Commission (IMCC) (Contact: Greg Conrad 703-709-8654). IMCC is an association that studies and recommends techniques for the protection and restoration of land, water, and other resources affected by mining. The purpose of the funding agreement between EPA and IMCC is to facilitate state involvement in developing and implementing mine waste regulation. Fifteen member states have participated in this effort thus far.

National Aggregates Association 900 Spring Street Silver Spring, Maryland 20910 Phone: (301) 587-1400 Fax: (301) 587-9419	Members: 350 Staff: 28 Budget: $1.2 million Contact: Richard A. Morris

The National Aggregates Association (NAA) represents producers of construction aggregates, which include sand, gravel, and crushed and broken stone. For over 75 years, NAA has provided its members with education, training, research, technology, and representation before the Congress and federal regulatory bodies to increase the growth and professionalism of the aggregates industry. NAA is an international trade association with a membership of over 400 companies throughout the United States, Canada, and various foreign countries.

Aggregate Producers Association of Northern California 400 Capitol Mall, Suite 900 Sacramento, CA 95814-4407 Phone: (916) 449-3926 Fax: (916) 443-5369	Members: Staff: 7 Budget: $200,000 Contact: George Cope

The Aggregate Producers Association (APA) is a non-profit trade association comprised of rock, sand and gravel producers, ready-made concrete companies and asphalt companies in Northern California. APA provides its members with a variety of committees that monitor legislation, regulations and other industry issues e.g. environment, safety, product education and promotion, and technical and government affairs. Currently, APA sponsors a Stormwater/NPDES Group Compliance Program for 140 plant locations. APA also meetings regularly with the Mine Safety and Health Administration (MSHA) to address and resolve issues of concern.

The National Stone Association 1415 Elliot Place, NW Washington, DC 20007 Phone: (202) 342-1100 Fax: (202) 342-0702	Members: 579 Staff: 20 Budget: $3.26 million Contact: Bill Ford

The National Stone Association (NSA) is the national trade association representing the many interests and concerns of the crushed stone industry in the United States. NSA, now celebrating its 75th anniversary, is based in Washington, DC. It provides support to member companies, provides technical assistance to universities and schools, and works cooperatively with other national, state and regional groups and associations that help advance the interests of the industry.

National Mining Association 1130 17th Street Washington, DC 20036 Phone: (202) 861-2800 Fax: (202) 861-7535	Contact: Richard L. Lawson

Founded in 1995 as a result of a merger between the American Mining Congress and the National Coal Association, the National Mining Association represents producers of domestic coal, metals, and industrial and agricultural minerals; manufacturers of mining and mineral processing machinery, equipment, and supplies; engineering/consulting firms; and financial institutions that serve the mining industry. It also offers tax, communications, and technical workshops.

Missouri Limestone Producers Association P.O. Box 1725 Jefferson City, Missouri 65102 Phone: (314)-635-0208 Fax: (314)-634-8006	Members: 66 Staff: 2 Budget: $220,000 Contact: Steve Rudloff

The Missouri Limestone Producers Association represents the crushed stone producers for the state of Missouri. This association has taken an active role in voluntary compliance initiatives with EPA's Region VII office.

American Society for Surface Mining and Reclamation (ASSMR) 21 Grandview Dr. Princeton, WV 24740 Phone: (304) 425-8332	Members: 450 Regional Groups: 2 Contact: William T. Plass

Founded in 1973, ASSMR members consist of mining companies and corporations, representatives from Federal agencies and State governments, and individuals from the academic community. It encourages efforts to protect and enhance land disturbed by mining. In addition, ASSMR assists in research and demonstrations and fosters communication among research scientists, regulatory agencies, landowners, and the surface mining industry. Its publications include the Reclamation Newsletter (quarterly).

InterState Mining Compact Commission (IMCC) 459B Carlisle Dr. Herndon, VA 22070 Phone: (703) 709-8654 Fax: (703) 709-8655	Members: 17 Staff: 2 Budget: $150,000 Contact: Gregory E. Conrad

Founded in 1971, IMCC consists of States engaged in surface mining. Its purposes are to study and recommend techniques for the protection and restoration of land, water, and other resources affected by mining; to assist in reducing, eliminating, or counteracting pollution or deterioration of natural resources; to encourage programs of member States that will achieve comparable results in protecting and improving the usefulness of natural resources; and to maintain an efficient and productive mining industry. IMCC also compiles industry statistics, disseminates studies and reports on surface mining and legislative developments, and maintains liaison between State and Federal governments. IMCC publications include The Compact (quarterly).

Society for Mining, Metallurgy, and Exploration, Inc. (SME, Inc.) P.O. Box 625005 Littleton, CO 80162 Phone: (303) 973-9550 Fax: (303) 973-3845	Members: 20,000 Staff: 31 Budget: $3,700,000 Contact: Tom Hendricks

Founded in 1871, SME, Inc. consists of persons engaged in the finding, exploitation, treatment, and marketing of all classes of minerals (metal ores, industrial minerals, and solid fuels) except petroleum. SME, Inc. promotes the arts and sciences connected with the production of useful minerals and metals. Specialized education programs are offered, as well as publications such as Minerals and Metallurgical Processing (quarterly), Mining Engineering (monthly), and handbooks and other materials on mining.

Coalition for Responsible Mining Law (CRML) c/o Coeur D'Alene Mines Corp. P.O. Box 1 Coeur D'Alene, ID 83816-0316 Phone: (208) 667-3511 Fax: (208) 667-2213	Members: 300 Contact: Justin Rice

Founded in 1979, CRML consists of mining company executives, exploration geologists, small miners, and others interested in mining laws. CRML is organized as a means of focusing Western mining interests behind a proposal to preserve the basic provisions of the National Mining Law of 1872. It seeks to raise the level of awareness about the law within the mineral industry, Congress, and the general public through specialized education. Publications include a periodic newsletter.

Clay Minerals Society (CMS) P.O. Box 12210 Boulder, CO 80303 Phone: (303) 444-6405	Members: 950 Contact: Jo Eberl

Founded in 1963, CMS consists of professionals concerned with clay mineralogy and technology in industry, university research, and government. It includes students of mineralogy and other scientific disciplines as well as representatives of clay mining companies. CMS seeks to stimulate research and disseminate information relating to all aspects of clay science and technology. It maintains a store of clay minerals at the Geology Department of the University of Missouri. CMS publications include Clays and Clay Minerals (bimonthly), and Quantitative Mineral Analysis.

Asbestos Information Association/North America (AIA/NA) 1745 Jefferson Davis Hwy., Ste. 509 Arlington, VA 22202 Phone: (703) 979-1150 Fax: (703) 979-1152	Members: 45 Staff: 30 Budget: $300,000 Contact: B.J. Pigg

Founded in 1970, AIA/NA represents manufacturers, processors, and miners/millers of asbestos or products containing asbestos. Its main purposes are: to provide industry-wide information on asbestos and health and on industry efforts to eliminate existing hazards; to cooperate with government agencies in developing and implementing industry-wide standards for exposure to asbestos dust and for the control of asbestos dust emissions into air and water; to exchange information on methods and techniques of asbestos dust control; to assist in solving problems arising from the health effects of asbestos; and to increase public knowledge of the unique benefits and importance of asbestos products. AIA/NA acts as a central information center for collecting and disseminating medical and technical information on asbestos-related disease, asbestos dust control, and other asbestos-related ecological considerations. Publications include News and Notes (monthly) and other technical materials.

Gypsum Association (GA) 810 1st St., N.E., No. 510 Washington, D.C. 20002 Phone: (202) 289-5440	Members: 17 Staff: 30 Budget: $1,000,000 Contact: Jerry A. Walker

Founded in 1930, GA represents miners and manufacturers of gypsum and gypsum products. It sponsors basic and applied research programs at educational institutions and commercial testing laboratories on fire resistant assemblies, structural assemblies, wallboard application techniques, and new uses for gypsum products. GA also compiles market statistics and publishes technical bulletins and data on gypsum products.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.

NOV 18 1997

THE ADMINISTRATOR

Message from the Administrator

Since EPA's founding over 25 years ago, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and those as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper and smarter. As a result, we no longer have rivers catching fire. Our skies are clearer. American environmental technology and expertise are in demand around the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

The Environmental Protection Agency has undertaken its Sector Notebook Project to compile, for major industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with an extensive series covering other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to understand better their regulatory requirements, and learn more about how others in their industry have achieved regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that we together achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

Carol M. Browner

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), Science Applications International Corporation (McLean, VA), and Booz-Allen & Hamilton, Inc. (McLean, VA). A listing of available Sector Notebooks is included on the following page.

Obtaining copies:

Electronic versions of all sector notebooks are available via Internet on the Enviroene World Wide Web at www.epa.gov/oeca/sector. Enviroene is a free, public, environmental exchange system operated by EPA's Office of Enforcement and Compliance Assurance and Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization. Direct technical questions to the "Feedback" button on the bottom of the web page.

Purchase printed bound copies from the **Government Printing Office (GPO)** by consulting the order form at the back of this document or order via the Internet by visiting the on-line GPO Sales Product Catalog at https://orders.access.gpo.gov/su_docs/sale/prf/prf.html. Search using the exact title of the document "Profile of the XXXX Industry" or simply "Sector Notebook." When ordering, use the GPO document number found on the order form at the back of this document.

Complimentary volumes are available to certain groups or subscribers, including public and academic libraries; federal, state, tribal, and local governments; and the media from EPA's National Service Center for Environmental Publications at **(800) 490-9198.** When ordering, use the EPA publication number found on the following page.

The Sector Notebooks were developed by the EPA's Office of Compliance. Direct general questions about the Sector Notebook Project to:

Seth Heminway, Coordinator, Sector Notebook Project
US EPA Office of Compliance
401 M St., SW (2223-A)
Washington, DC 20460
(202) 564-7017

For further information, and for answers to questions pertaining to these documents, please refer to the contact names listed on the following page.

LIST OF FIGURES

LIST OF TABLES

LIST OF ACRONYMS

ACS - Automatic Casing Swab
AFS - AIRS Facility Subsystem (CAA database)
AIRS - Aerometric Information Retrieval System (CAA database)
AOR - Area of Review (SDWA)
AOSC - Association of Oilwell Servicing Contractors
API - American Petroleum Institute
API ES - American Petroleum Institute Environmental Statement
BAT - Best Available Technology Economically Achievable
bbl - Barrel (42 US gallons)
Bcf - Billion Cubic Feet
BCT - Best Conventional Pollutant Control Technology
bpd - Barrels per Day
BIA - Bureau of Indian Affairs (Department of the Interior)
BIFs - Boilers and Industrial Furnaces (RCRA)
BLM - Bureau of Land Management (Department of the Interior)
BMP - Best Management Practice
BOD - Biochemical Oxygen Demand
BOP - Blowout Preventer
BPT - Best Practicable Technology Currently Available
BS&W - Basic Sediment and Water
BTEX - Benzene, Toluene, Ethylbenzene and Xylene
CAA - Clean Air Act
CAAA - Clean Air Act Amendments of 1990
CERCLA - Comprehensive Environmental Response, Compensation and Liability Act
CERCLIS - CERCLA Information System
CFCs - Chlorofluorocarbons
CFR - Code of Federal Regulations
CGP - Construction General Permit (CWA)
CO - Carbon Monoxide
CO_2 - Carbon Dioxide
COE - Army Corps of Engineers (Department of Defense)
CZMA - Coastal Zone Management Act
CWA - Clean Water Act
DOC - United States Department of Commerce
DOE - United States Department of Energy
DOI - United States Department of the Interior
E&P - Exploration and Production
EIA - Energy Information Administration (Department of Energy)
EIS - Environmental Impact Statement
EOR - Enhanced Oil Recovery
EPA - United States Environmental Protection Agency
EPCRA - Emergency Planning and Community Right-to-Know Act
ESA - Endangered Species Act

EST - Eastern Standard Time
FIFRA - Federal Insecticide, Fungicide, and Rodenticide Act
FINDS - Facility Indexing System
FLPMA- Federal Land Policy and Management Act
FPSO- Floating Production, Storage, and Offloading system
FR - Federal Register
FRP - Facility Response Plan
H_2S - Hydrogen Sulfide
HAPs - Hazardous Air Pollutants (CAA)
HSWA - Hazardous and Solid Waste Amendments
IDEA - Integrated Data for Enforcement Analysis
IOGCC - Interstate Oil and Gas Compact Commission
IPAA - Independent Petroleum Association of America
LDR - Land Disposal Restrictions (RCRA)
LEPCs - Local Emergency Planning Committees
MACT - Maximum Achievable Control Technology (CAA)
Mcf - Thousand Cubic Feet
MCLs - Maximum Contaminant Levels
MCLGs - Maximum Contaminant Level Goals
MFC - Magnetic Fluid Conditioner
MIT - Mechanical Integrity Test
MMPA - Marine Mammal Protection Act
MMS - Minerals Management Service (Department of the Interior)
MMTCE - Million Metric Tons of Carbon Equivalent
MPRSA- Marine Protection, Research, and Sanctuaries Act
MSDSs - Material Safety Data Sheets
MSGP - Multi-Sector General Permit (CWA)
NAAQS - National Ambient Air Quality Standards (CAA)
NAICS - North American Industrial Classification System
NCDB - National Compliance Database (for TSCA, FIFRA, EPCRA)
NCP - National Oil and Hazardous Substances Pollution Contingency Plan
NEC - Not Elsewhere Classified
NEPA - National Environmental Policy Act
NESHAP - National Emission Standards for Hazardous Air Pollutants
$NICE^3$ - National Industrial Competitiveness Through Energy, Environment and Economics

UIC - Underground Injection Control (SDWA)
USDW - Underground Sources of Drinking Water (SDWA)
USFS - United States Forest Service (Department of Agriculture)
USFWS - United States Fish and Wildlife Service (Department of the Interior)
UST - Underground Storage Tanks (RCRA)
VOCs - Volatile Organic Compounds
WSPA - Western States Petroleum Association

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution (such as economic sector, and community-based approaches) are becoming an important supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, compliance assurance, education/outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these interrelationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector-based" approach within the EPA Office of Compliance led to the creation of this document.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several interrelated topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references where more in-depth information is available. Text within each profile was researched from a variety of sources, and was usually condensed from more detailed sources pertaining to specific topics. This approach allows for a wide coverage of activities that can be further explored based upon the references listed at the end of this profile. As a check on the information included, each notebook went through an external document review process. The Office of Compliance appreciates the efforts of all those that participated in this process and enabled us to develop more complete, accurate and up-to-date summaries. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project (2223-A), 401 M St., SW, Washington, DC 20460. Comments can also be sent via the web page.

Adapting Notebooks to Particular Needs

The scope of the industry sector described in this notebook approximates the national occurrence of facility types within the sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. The Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume. If you are interested in assisting in the development of new notebooks, please contact the Office of Compliance at (202) 564-2310.

II. INTRODUCTION TO THE OIL AND GAS EXTRACTION INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the oil and gas extraction industry. Facilities described within the document are described in terms of their Standard Industrial Classification (SIC) codes.

II.A. Introduction, Background, and Scope of the Notebook

This industry sector profile provides an overview of the oil and gas industry as listed under SIC code 13. The SIC code 13 encompasses the oil and gas extraction process from the exploration for petroleum deposits up until the transportation of the product from the production site. There are five major groups within SIC code 13:

SIC 1311. Crude petroleum and natural gas. Establishments in this industry are primarily involved in the operation of oil and gas field properties. Establishments under this category might also perform exploration for crude oil and natural gas, drill and complete wells, and separate the crude oil and natural gas components from the natural gas liquids and produced fluids.

SIC 1321. Natural gas liquids. This industry is comprised of establishments that separate natural gas liquids from crude oil and natural gas at the site of production. Examples of these gases are propane and butane. Natural gas liquids producers that remove additional material at petroleum refineries are classified under SIC code 29, and establishments that recover other salable contaminants such as helium are classified under SIC code 28.

SIC 1381. Drilling oil and gas wells. This industry is made up of establishments that drill wells on a contract or fee basis.

SIC 1382. Oil and gas field exploration services. Establishments in this industry perform geological, geophysical and other exploration services for oil and gas on a contract or fee basis.

SIC 1389. Oil and gas field services, not elsewhere classified (NEC). Establishments in this industry perform services on a contract or fee basis that are not elsewhere classified. These include the preparation of drilling sites by building foundations and excavating pits, the completion of wells and preparation for production, and the performing of maintenance.

While this notebook covers all of the SIC codes listed above, the diverse nature of the industries will not allow a detailed description of each. Since the service industries (SIC codes 1381, 1382, and 1389) and natural gas liquids industry (SIC code 1321) are tied to the economic, geographic, and production trends of SIC code 1311, most attention is focused on the crude petroleum and natural gas industry. Although certain products under these SIC codes may not be specifically mentioned, the sector-wide economic, pollutant output, and enforcement and compliance data in this notebook covers all establishments involved with oil and gas extraction.

SIC codes were established by the Office of Management and Budget (OMB) to track the flow of goods and services within the economy. OMB is in the process of changing the SIC code system to a system based on similar production processes called the North American Industrial Classification System (NAICS). In the NAICS, the SIC codes for the oil and gas extraction industry correspond to the following NAICS codes:

1987 SIC	U.S. SIC Description	1997 NAICS	NAICS Description
1311	Crude Petroleum and Natural Gas	211111	Crude Petroleum and Natural Gas Extraction
1321	Natural Gas Liquids	211112	Natural Gas Liquid Extraction
1381	Drilling Oil and Gas Wells	213111	Drilling Oil and Gas Wells
1382	Oil and Gas Field Exploration Services	54136	Geophysical Surveying and Mapping Services
		213112	Support Activities for Oil and Gas Operations
1389	Oil and Gas Field Services, NEC	213112	Support Activities for Oil and Gas Operations

II.B. Characterization of the Oil and Gas Extraction Industry

II.B.1. Product Characterization

The primary products of the industry are crude oil, natural gas liquids, and natural gas. Crude oil is a mixture of many different hydrocarbon compounds that must be processed to produce a wide range of products. U.S. refinery processing of crude oil yields, on average, motor gasoline (approximately 40 percent), diesel fuel and home heating oil (20 percent), jet fuels (10 percent), waxes, asphalts and other nonfuel products (5 percent), feedstocks for the petrochemical industry (3 percent), and other lesser components [U.S.

Department of Energy, Energy Information Administration (EIA), 1999]. Volumes of oil and refined products typically are reported in barrels (bbl), which are equal to 42 gallons.

When crude oil is first brought to the surface, it may contain a mixture of natural gas and produced fluids such as salt water and both dissolved and suspended solids. On land (and at many offshore operations) Natural gas is separated at the well site and is processed for sale if natural gas pipelines (or other transportation vehicles) are nearby, or is flared as a waste (at onshore operations only). Water (which can be more than 90 percent of the fluid extracted in older wells) is separated out, as are solids. Only about one-third of the production platforms offshore in the Gulf of Mexico separate water. The other offshore Gulf platforms transport full well stream, sometimes great distances, to central processing facilities. The crude oil is at least 98 percent free of solids after it passes through this onsite treatment and is prepared for shipment to storage facilities and ultimately refineries (Sittig, 1978).

Natural gas can be produced from oil wells (called *associated gas*), or wells can be drilled with natural gas as the primary objective (called *non-associated gas*). Methane is the predominant component of natural gas (approximately 85 percent), but ethane (10 percent), propane, and butane are also significant components. The heavier components, including propane and butane, exist as liquids when cooled and compressed; these are often separated and processed as natural gas liquids.

Less frequently, oil and gas can be produced by other methods. Oil can be found in tar sands, which are porous rock (sandstone) structures on the surface to 100 meters deep. The material is fairly viscous and also is fairly high in sulfur and metals. Although the Athabasca region in Canada is the primary area of significant tar sand mining, there are some deposits in the western United States.

Oil may also be extracted from oil shale. These deposits may be 10 to 800 feet below the surface and can be removed by surface mining or subsurface excavation. The oil, in a highly viscous form called *kerogen*, is usually heated to allow it to flow. Because only approximately 30 gallons (less than a barrel) are produced per ton of shale, the process is costly, and the oil shale mining industry is currently only a minor contribution to the domestic oil supply.

A small but increasingly significant source of natural gas is coalbed methane. In all coal deposits, methane is found as a byproduct of the coalification process and is loosely bound to coal surface areas. This methane historically was considered a safety hazard in the coal mining process and was vented, but recently it has been recovered in conjunction with mining or produced independently via wells in deposits that are too deep for mining. Generally, coalbed methane is collected by drilling a well similar to those used for conventional oil and gas deposits, but with some adaptations to accommodate mining operations and different rock characteristics (EPA, 1992). In 1997, coalbed methane production accounted for six percent of the total U.S. natural gas production (EIA, 1998).

Methane hydrates are another form of natural gas, for which economically viable recovery methods are still in development. Methane hydrates are structures in which methane molecules are trapped within a lattice of ice. They are found principally in cold and/or pressurized conditions: on land in permafrost regions, or beneath the ocean at depths greater than 1,500 feet below the water surface. These eventually could be an immense resource; estimated amounts of methane in these structures in the United States is 200,000 trillion cubic feet, compared to an estimated 1,400 trillion cubic feet in conventional natural gas deposits. A goal of the U.S. Department of Energy methane hydrates research program is to develop a commercial production system by the year 2015 (U.S. DOE, 1998).

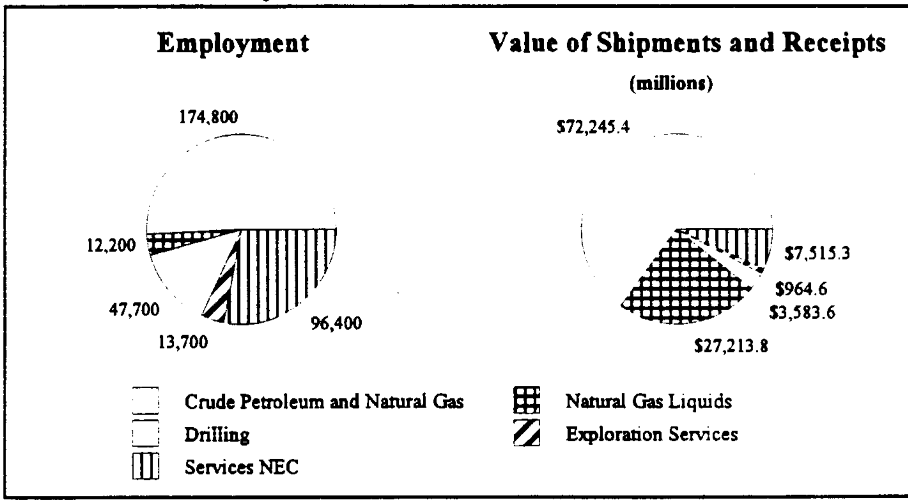
II.B.2. Industry Size and Distribution

The oil and gas extraction industry is an important link in the energy supply of the United States. Petroleum and natural gas supply 65 percent of the energy consumed in the United States, and domestic producers supply approximately 40 percent of the petroleum and 90 percent of the natural gas [EIA and Independent Petroleum Association of America (IPAA), 1999]. According to the 1992 Census of Mining Industries, the industry employed 345,000 people and had yearly revenues of $112 billion.

Several factors influence the size of the industry, including technology development and crude oil prices (which are set in world markets) (EIA, 1999). Employment in the industry is also affected by the recent trend in mergers and consolidation among companies in the industry.

Within the overall oil and gas extraction industry group (SIC code 13), SIC 1311 (crude petroleum and natural gas) is the largest. As shown in Figure 1, this industry employs half of the total workers in this SIC group, and accounts for about 60 percent of the sales. SIC code 1389 (services not elsewhere classified) is the next largest employer, but SIC code 1321 (natural gas liquids) is more significant with respect to sales.

Figure 1: Employment and Value of Shipments and Receipts in the Oil and Gas Industry



Source: *1992 Census of Mineral Industries,* U.S. Department of Commerce, 1995.

The major oil and gas producing areas in the United States are in the Gulf of Mexico region (onshore and offshore), California, and Alaska (see Figure 2). The Gulf of Mexico and surrounding land in particular is the most concentrated area of production; in 1998, Texas (onshore and offshore) produced 23 percent of the nation's crude oil, Louisiana produced 5 percent, and the Federal offshore region produced 14 percent.[1]

The geographic distribution is similar for natural gas; Texas, Louisiana, and the Gulf of Mexico are the major producing locations (Figure 3). New Mexico, Oklahoma, Wyoming, and Kansas are also important gas-producing states, while California and Alaska are less important with respect to natural gas production than they are for crude oil.

[1] The Federal Offshore Region, or Outer Continental Shelf (OCS), is seaward of State jurisdiction (3 nautical miles, or approximately 3.3 statute miles, from an established baseline except for Texas and the Gulf coast of Florida, for which the boundary is 3 marine leagues, or approximately 10 statute miles), and landward of a line defined by international law at a minimum of 200 nautical miles (MMS, 1997) (See p101 for more details).

The oil and gas industry has a unique standing for census purposes because of the sheer number of wells in the country. For the purposes of simplifying reporting procedures under SIC code 1311, the census defines an establishment as all activities of an operating company in an entire state. Therefore, these data give no information on the number of individual wells. Data collected by the Independent Petroleum Association of America, however, indicated that in 1997 there were 573,504 active wells extracting primarily crude oil, and 303,724 wells producing primarily natural gas in the United States (IPAA, 1999).

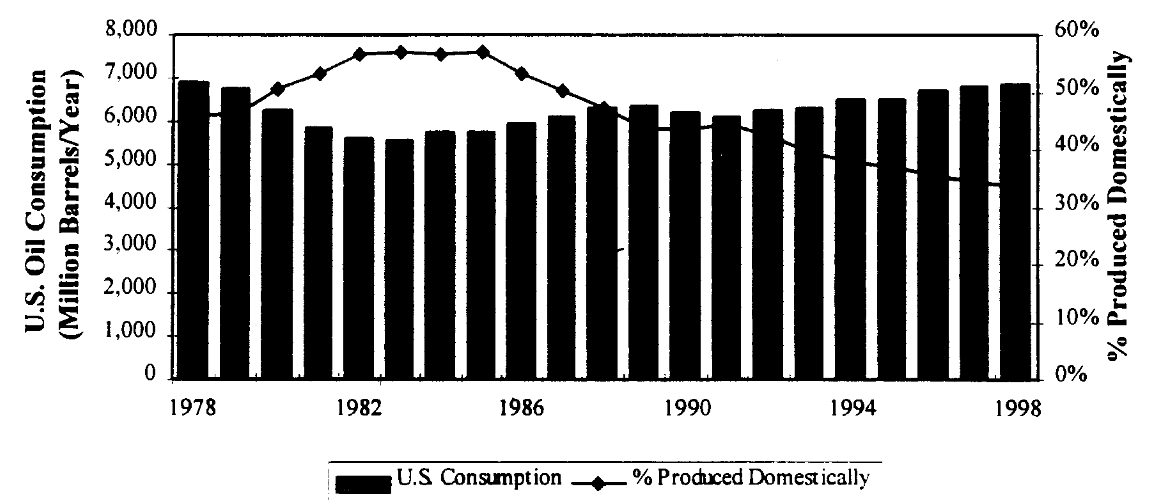
Another unique aspect of the industry is the marginal nature of many operations. Oil and gas wells can have very long lives (20 years or more); some wells drilled in the early years of this century are still producing, but only in small volumes. Wells typically have higher production in the early years, then decline and can level off at a low level of production that can be sustained for a long period (API, 1999). Wells that produce less than 10 barrels of oil per day are called "stripper wells." As of 1997, there were 436,000 active stripper wells (76 percent of all active domestic wells) producing an average of 2.2 barrels each daily. Together stripper wells account for about 15 percent of domestic production (IPAA, 1999).

II.B.3. Economic Trends

Domestic Consumption

The consumption of oil and gas in the United States is closely linked to the overall economy of the country. Between 1990 and 1998, crude oil consumption increased approximately 1.4 percent each year, and natural gas consumption increased at a rate of 2.0 percent per year. The rate of natural gas consumption is expected to continue growing, mostly at the expense of coal. Natural gas is expected to become an important source of energy in the future and will be accelerated by government policies and the development of the natural gas transportation infrastructure. In the past several years, however, the percent of the domestic consumption of both oil and gas met by domestic producers generally has decreased (Figures 4 and 5).

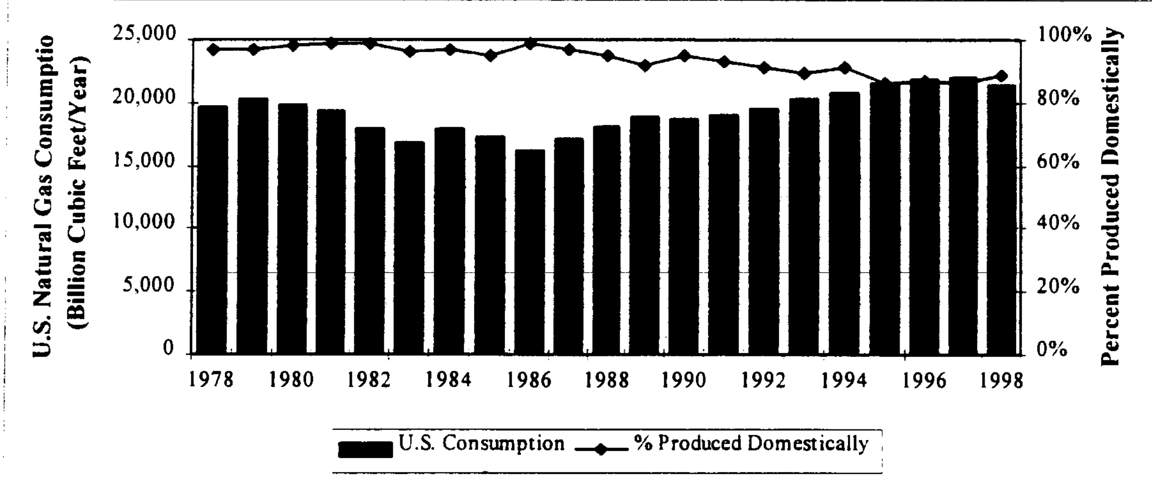
Figure 4: U.S. Oil Consumption and Percent Produced Domestically



Source: EIA and IPAA, 1999.

R0076628

Figure 5: U.S. Natural Gas Consumption and Percent Produced Domestically



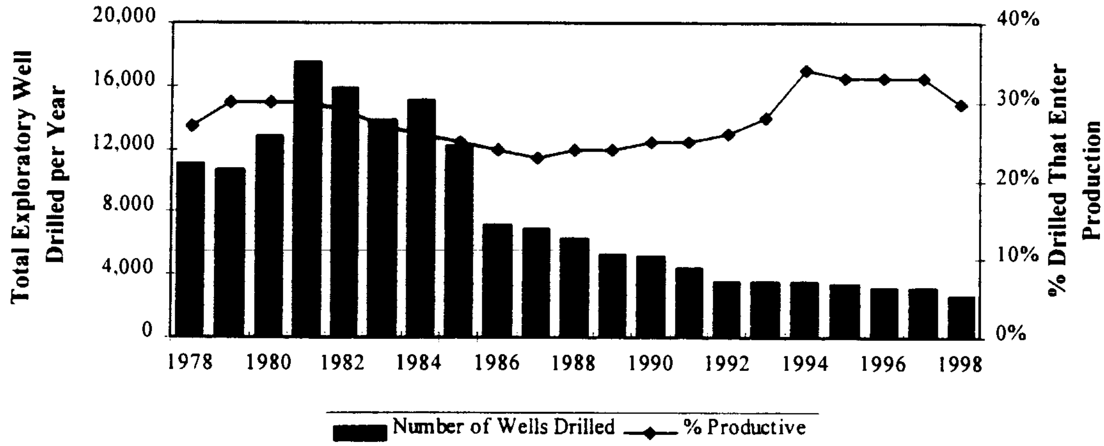
Source: EIA and IPAA, 1999.

Exploration and Reserves

The industry is exhibiting a general trend in exploration from domestic to foreign locations. In 1986, U.S. petroleum companies spent $17 billion on exploration and development within the United States and $7.5 billion abroad. In 1995, these firms spent $12.4 billion in the United States and $13.2 billion abroad (U.S. Department of Commerce (U.S. DOC), 1998). This shift in funds has placed an emphasis on drilling exploratory wells only at the most promising sites in the U.S. The results can be seen in Figure 6; many fewer exploratory wells are being drilled, but the success rate is higher.

R0076629

Figure 6: Number of Exploratory Wells Drilled and Percent That Enter Production



Note: Includes both oil and natural gas wells.
Source: American Petroleum Institute, 1999.

The most active areas of exploration are the Gulf of Mexico and Alaska. In the Gulf of Mexico, the development of technology that facilitates drilling in deeper water (including floating structures, drillships and subsea completions) has made it more feasible to explore deep water sites. Another new source for potential reserves[2] is in Alaska, where roughly 87 percent of the Northeast National Petroleum Reserve was opened in 1998 for exploration and leasing (DOI, 1998). Developments such as these temporarily have boosted hydrocarbon reserves above production levels. In 1997, for the first time in a decade, crude oil reserves were added at a level greater than the amount depleted through production. However, it is expected that in the future reserves will again decline relative to production (EIA, 1998).

Natural gas exploration efforts in the United States have been more successful than crude oil exploration at keeping pace with production. Between 1994 and 1997, the industry added more reserves than it extracted in production. In 1997, about 64 percent of the new reserves of natural gas were found in the Gulf of Mexico Federal Offshore region and Texas (EIA, 1998).

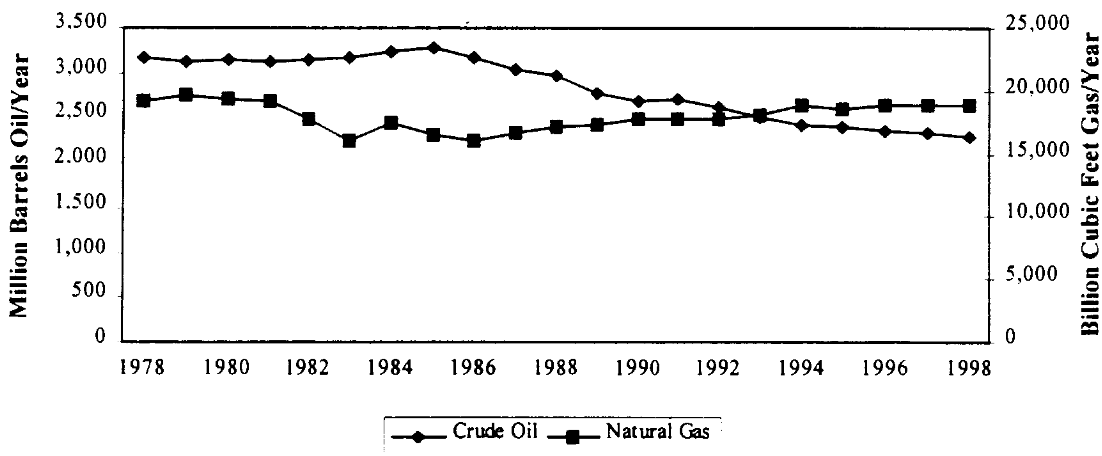
[2] The Energy Information Administration of the U.S. Department of Energy defines proved reserves as those volumes of oil and gas that geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions (EIA, 1998).

Domestic Production and Prices

Production of crude oil is showing a decreasing trend, and natural gas production is showing an increasing trend. As shown in Figure 7, crude oil production is decreasing at an approximate rate of 1.5 percent per year. Leading the decline is Alaska, where production has declined approximately three percent per year in the past decade and six percent in 1997.

The production of natural gas, however, has been increasing steadily. Historically, growth has been about 1 percent per year, and is expected to grow at a rate of 1.6 percent per year through 2002 (U.S. DOC, 1998).

Figure 7: Domestic Crude Oil and Natural Gas Production



Source: EIA and IPAA, 1999.

As shown in Figure 8, the prices of both oil and gas have been quite volatile during the period between 1978 and 1997. In constant 1998 dollars, the wellhead price of crude oil has ranged between $10 and $54 per barrel. In 1998 and early 1999, prices were near $10 per barrel, but by August 1999 the price rebounded to over $20 per barrel (EIA, 1999).

Natural gas prices also have fluctuated. Wellhead prices reached a low point of $1.62 per thousand cubic feet in 1995, but increased in the subsequent two years. Prices of natural gas are expected to increase faster than those of oil through 2002, but still less than the rate of inflation (U.S. DOC, 1998).

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the oil and gas extraction industry, including the materials and equipment used and the processes employed. Specifically, this section contains a description of commonly used drilling and production processes, associated raw materials, the byproducts produced or discharges released, and the materials either recycled or transferred off-site. This discussion also provides a concise description of both the production and the potential fate of wastes produced in each process.

The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections concerning waste outputs, pollution prevention opportunities, and federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available to supplement this document.

III.A. Industrial Processes in the Oil and Gas Extraction Industry

The oil and gas extraction industry can be classified into four major processes: (1) exploration, (2) well development, (3) production, and (4) site abandonment. Exploration involves the search for rock formations associated with oil or natural gas deposits, and involves geophysical prospecting and/or exploratory drilling. Well development occurs after exploration has located an economically recoverable field, and involves the construction of one or more wells from the beginning (called *spudding*) to either abandonment if no hydrocarbons are found, or to well completion if hydrocarbons are found in sufficient quantities.

Production is the process of extracting the hydrocarbons and separating the mixture of liquid hydrocarbons, gas, water, and solids, removing the constituents that are non-saleable, and selling the liquid hydrocarbons and gas. Production sites often handle crude oil from more than one well. Oil is nearly always processed at a refinery; natural gas may be processed to remove impurities either in the field or at a natural gas processing plant.

Finally, site abandonment involves plugging the well(s) and restoring the site when a recently-drilled well lacks the potential to produce economic quantities of oil or gas, or when a production well is no longer economically viable.

R0076633

Two ancillary processes are also discussed in this section because they have significant economic and environmental implications. Maintenance of the well and reservoir is important in sustaining the safety and productivity of the operation and in ensuring protection of the environment. Spill mitigation is important in the oil and gas production industry because spills and other types of accidents can have serious implications for worker safety and the environment.

III.A.1. Exploration

Oil and natural gas deposits are located almost exclusively in sedimentary rock and are often associated with certain geological structures. Geophysical exploration is the process of locating these structures in the subsurface via methods that fall under the category of remote sensing. In particular, common hydrocarbon-containing structures are those where a relatively porous rock has an overlying low-permeability rock that would trap the hydrocarbons (Berger and Anderson, 1992). Two common structural traps are found in Figure 9: anticlines are upward folds in the rock layers, while faults are fractures in the Earth's surface where layers are shifted.

Geophysicists search for these structures by taking advantage of the fact that seismic waves will travel through, bend, absorb, and reflect differently off of various layers of rock (Berger and Anderson, 1992). Geophysicists generate these seismic waves at the earth's surface, and measure the reflected seismic waves with a series of sensors known as geophones. Seismic waves can be generated by a variety of sources ranging from explosives that are detonated in holes drilled below the surface, to land vibroseis and marine airguns. Land vibroseis is typically used near populated areas and near sensitive environmental areas where detonations are not desirable. In the vibroseis process, trucks are used to drop a heavy weight on hard surfaces such as paved roads in order to create seismic waves.

In marine locations, explosives are less effective and have deleterious environmental impacts. In addition, vibroseis is impractical in water that is hundreds of feet deep. Seismic energy is therefore created by an airgun, a large device that can be emptied of air and water to create a vacuum. Seismic waves are created when water is allowed into the device at a very fast rate. It should be stressed that geophysical remote sensing cannot identify oil or gas accumulations directly; it can only indicate the potential for reserves via the presence or absence of certain rock characteristics that may be worthy of exploration.

After a site has been judged to have a reasonable chance of discovering a sufficient amount of hydrocarbons an exploratory well is drilled. It should be noted that although seismic exploration technology is constantly improving, it is not perfect. The only true way to discover the presence and quantity of petroleum is by drilling a well into the formation or structure suspected of containing hydrocarbons.

III.A.2. Well Development

Drilling

During the drilling process, wellsite geologists will augment the remote geophysical data with wireline logs, which are taken by means of devices lowered into the wellbore with wires. Wireline logs include several types of measurements that help to characterize the depths and thickness of subsurface formations and the type of fluids that they may contain. As an example, one type of log analyzes the resistance of the formation to electrical current, which helps to indicate the type of fluid and the porosity of the formation. For exploratory wells, mud logs may also be developed, which document the drill rate, types of rocks encountered, and any hydrocarbons encountered. The range of depths of well holes, or *wellbores,* is anywhere between 1,000 and 30,000 feet, with an average depth of all U.S. wells drilled in 1997 of 5,601 feet (API, 1998a).

For both onshore and offshore sites, the subterranean aspects of the drilling procedure are very similar. The drill bit is the component in direct contact with the rock at the bottom of the hole, and increases the depth of the hole by

R0076635

chipping off pieces of rock. The bit may be anywhere from three and three-fourths inches to two feet in diameter, and is usually studded with hardened steel or diamond. The selection of the drill bit can vary, depending on the type of rock and desired drilling speed. For example, a large-toothed steel bit may be used if the formation is soft and speed is important, while a diamond-studded bit may be used for hard formations or when a long drill life is desired (Kennedy, 1983). The drill bit is connected to the surface by several segments of hollow pipe, which together are called the *drill string*. The drill string is usually about 4 inches in diameter; drilling fluid is pumped down through its center and returns to the surface through the space, called the *annulus*, between the drill string and the rock formations or casing.

Drilling Fluids

Drilling fluid is an important component in the drilling process. A fluid is required in the wellbore to: (1) to cool and lubricate the drill bit; (2) remove the rock fragments, or *drill cuttings*, from the drilling area and transport them to the surface; (3) counterbalance formation pressure to prevent formation fluids (i.e. oil, gas, and water) from entering the well prematurely, and (4) prevent the open (uncased) wellbore from caving in (Berger and Anderson, 1992; Souders, 1998). Different properties may be required of the drilling fluid, depending upon the drilling conditions. For example, a higher-density fluid may be needed in high-pressure zones, and a more temperature-resistant fluid may be desired in high-temperature conditions. While drilling fluid may be a gas or foam, liquid-based fluids (called *drilling muds*) are used for approximately 93 percent of wells (API, 1997). In addition to liquid, drilling muds usually contain bentonite clay that increases the viscosity and alters the density of the fluid. Drilling mud may also contain additional additives that alter the properties of the fluid. The most significant additives are described later in this section. The American Petroleum Institute (API) environmental guidance document "Waste Management in Exploration and Production Operations," (API E5) considers the three general categories of drilling fluid (muds) to be water-based, oil-based, and synthetic-based. Synthetic-based muds are used as substitutes for oil-based muds, but also may be an advantageous replacement for water-based muds in some situations.

Water-based muds are used most frequently. The base may be either fresh or salt water, for onshore and offshore wells, respectively. The primary benefit of water-based muds is cost; they are the least expensive of the major types of drilling fluids, and in general they are less expensive to use since the resultant drilling waste can be discharged onsite provided these wastes pass regulatory requirements (EPA, 1999). The significant drawback with water-based muds is their limited lubricity and reactivity with some shales. In deep holes or high-angle directional drilling, water-based muds are not able to supply sufficient lubricity to avoid sticking of the drill pipe. Reactivity with clay shale can cause the destabilization of the wellbore. In these cases, oil-based and synthetic muds are needed.

In 1993 EPA estimated that about 15 percent of wells drilled deeper than 10,000 feet used some oil-based muds (USEPA, 1993b). Oil-based muds are composed primarily of diesel oil or mineral oil and are therefore more expensive than water-based muds. This higher cost, which includes the added burden of removing the oil from drill cuttings, and the required disposal options make oil-based muds a less frequently used option. Oil-based muds are well suited for the high temperature conditions found in deep wells because oil components have a higher boiling point than water, and oil-based muds can avoid the pore-clogging that may occur with water-based muds. Also oil-based muds are used when drilling through reactive (or high pressure) shales, high-angle directional drilling, and drilling in deep water. These situations encountered while drilling can slow down the drilling rate, increase drilling costs or even be impossible if water-based muds are used. In cases when oil-based muds are necessary, the upper section of a well generally is drilled with water-based muds and the conversion is made to oil-based mud when the situation requires it. It is predicted that since the industry trend is toward deeper wells, oil-based muds may become more prominent. However, because oil-based muds and their cuttings can not be discharged this may not be the case.

Since about 1990, the oil and gas extraction industry has developed many new oleaginous (oil-like) base materials from which to formulate high performance drilling fluids. A general class of these fluids are called synthetic materials, such as the vegetable esters, poly alpha olefins, internal olefins, linear alpha olefins, synthetic paraffins, ethers, linear alkylbenzenes, and others. Other oleaginous materials have also been developed for this purpose, such as enhanced mineral oils and non-synthetic paraffins. Industry developed synthetic-based fluids with these synthetic and non-synthetic oleaginous materials as the base fluid to provide the drilling performance characteristics of traditional oil-based fluids based on diesel and mineral oil, but with the potential for lower environmental impact and greater worker safety through lower toxicity, elimination of Polyaromatic hydrocarbons (PAH), faster biodegradability, lower bioaccumulation potential and in some drilling situations decreased drilling waste volume (FR 66086, December 16, 1996).

On land, air and foam fluids may be used in drilling wells. These fluids are less viscous than drilling muds and can enter smaller pores more easily. They are used when a higher rate of penetration into the formation is desired. Because air is less dense than a liquid, however, these fluids cannot exert the same pressure in the hole as liquid, and their viscosity can be altered if drilling encounters liquid in the formation. For this reason, air and foam fluids are used only in relatively low-pressure and water-free drilling locations, but are preferred in these situations because these fluids are much less expensive than other fluids (Kennedy, 1983; Souders, 1998). Air and foam fluids currently are used in the drilling of about seven percent of the wells in the United States (API, 1997).

Drilling muds typically have several additives. (Air and foam fluids typically do not contain many additives because the additives are either liquid or solid, and will not mix with air and foam drilling fluids.) The following is a list of the more significant additives:

- Weighting materials, primarily barite (barium sulfate), may be used to increase the density of the mud in order to equilibrate the pressure between the wellbore and formation when drilling through particularly pressurized zones. Hematite (Fe_2O_3) sometimes is used as a weighting agent in oil-based muds (Souders, 1998).

- Corrosion inhibitors such as iron oxide, aluminum bisulfate, zinc carbonate, and zinc chromate protect pipes and other metallic components from acidic compounds encountered in the formation.

- Dispersants, including iron lignosulfonates, break up solid clusters into small particles so they can be carried by the fluid.

- Flocculants, primarily acrylic polymers, cause suspended particles to group together so they can be removed from the fluid at the surface.

- Surfactants, like fatty acids and soaps, defoam and emulsify the mud.

- Biocides, typically organic amines, chlorophenols, or formaldehydes, kill bacteria that may produce toxic hydrogen sulfide gas.

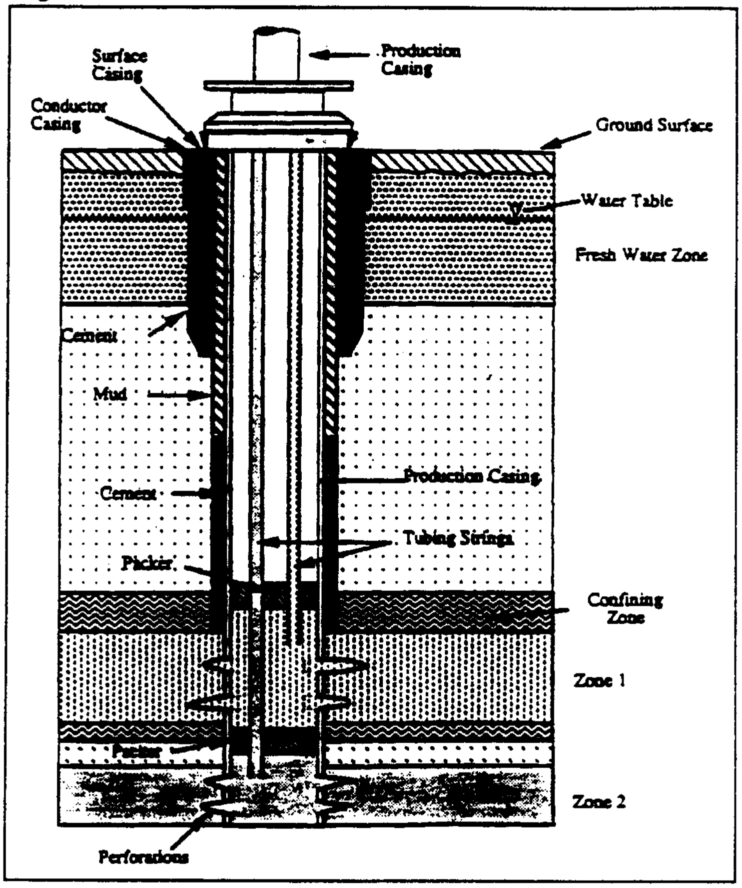
- Fluid loss reducers include starch and organic polymers and limit the loss of drilling mud to under-pressurized or high-permeability formations (EPA, Office of Solid Waste, 1987).

Casing

As the hole is drilled, casing is placed in the well to stabilize the hole and prevent caving. The casing also isolates water bearing and hydrocarbon bearing zones. As shown in Figure 10, three or four separate casing "strings" (lengths of tubing of a given diameter) may be used in intermediate-depth wells. In locations where surface soils may cave in during drilling, a "conductor" casing may be placed at the surface, extending only twenty to one hundred feet from the surface. This string is often placed prior to the commencement of drilling with a pile driver (Berger and Anderson, 1992). The next string, or "surface" casing, begins at the surface and may penetrate two thousand to three thousand feet. Its primary purpose is to protect the surrounding fresh-water aquifer(s) from the incursion of oil or brine from greater depths. The "intermediate" string begins at the surface and ends within a couple thousand feet of the bottom of the wellbore. This section prevents the hole from caving in and facilitates the movement of equipment used in the hole, e.g., drill strings and logging tools. The final "production" string extends the full length of the wellbore and encases the downhole production equipment. Shallow wells may have only two casing strings, and deeper wells may have multiple intermediate casings. After each casing string has been installed, cement is forced out through the bottom of the casing up the annulus to hold it in place and surface casing is cemented to the surface. Casing is cemented to prevent migration of fluids behind the casing and to prevent communication of higher pressure productive formations with lower pressure non-productive formations. Additional features and equipment shown in Figure 10 will be installed during the completion process for production: perforations will allow reservoir fluid to enter the wellbore; tubing strings will carry the fluid to the surface; and packers (removable plugs) may be installed to isolate producing zones.

Casing is important for both the drilling and production phases of operation, and must therefore be designed properly. It prevents natural gas, oil, and associated brine from leaking out into the surrounding fresh-water aquifer(s), limits sediment from entering the wellbore, and facilitates the movement of equipment up and down the hole. Several considerations are involved in planning the casing. First, the bottom of the wellbore must be large enough to accommodate any pumping equipment that will be needed either upon commencement of pumping, or in the later years of production. Also, unusually pressurized zones will require thicker casing in that immediate area. Any casing strings that must fit within this string must then be smaller, but must still accommodate the downhole equipment. Finally, the driller is encouraged to keep the hole size to a minimum; as size increases, so does cost and waste.

Figure 10: Cross Section of a Cased Well



Source: EPA, 1992.

Drilling Infrastructure

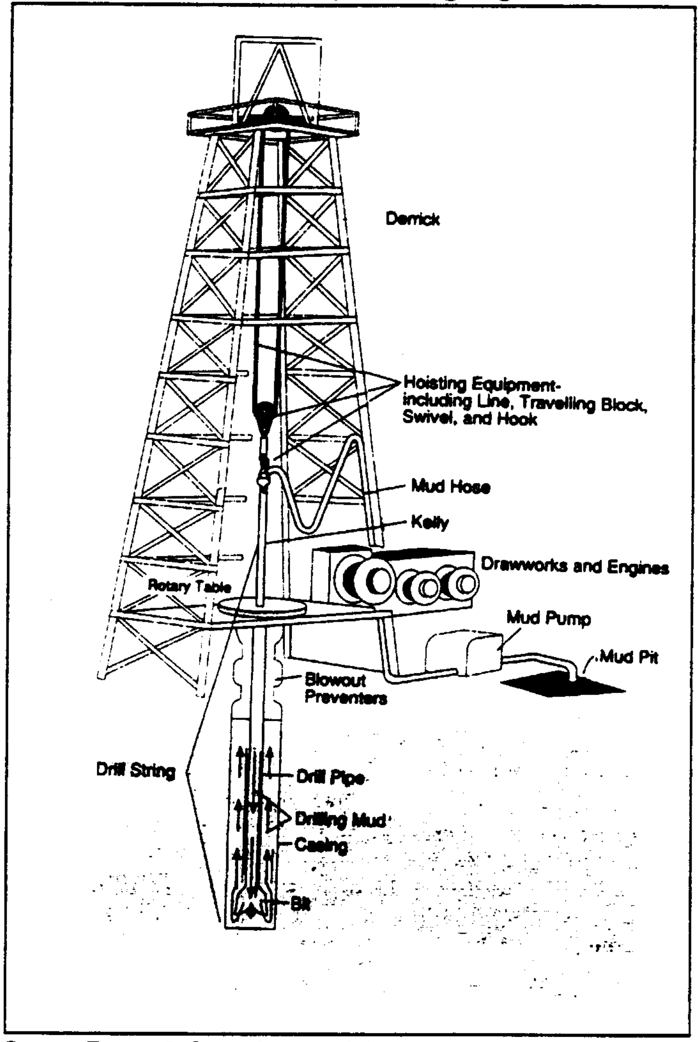
In addition to the well and its accouterments, infrastructure including construction and equipment is necessary at the surface. Roads and a pad are built at onshore sites; a ship, floating structure, or a fixed platform is needed for offshore operations. In addition, devices are needed to lift and lower the drilling equipment, filter rock cuttings from the drilling fluid, and store excess fluid and waste. The following sections describe the equipment required for onshore and offshore sites, respectively.

<u>Onshore Drilling</u>
Because the majority of onshore drilling sites are accessed by road, the equipment is geared toward mobility. First, an access road is built. In many locations the building of an access road is not difficult, but some areas present complications. On the North Slope of Alaska, for example, building a road that does not melt the permafrost can be both challenging and expensive. Board roads are used in some locations where soil conditions are not stable. Next, a footing for the equipment, usually gravel, is created in

areas where the ground may be either unstable or subject to freeze/thaw cycles. Finally, the drilling rig is brought in. For shallow wells, the drill rig may be self-contained on a single truck; for deeper wells, the rig may be brought to the site in several pieces and assembled at the site.

A basic arrangement of the actual drilling equipment, or *rig*, is shown in Figure 11. The derrick (sometimes referred to as the mast) is the centerpiece of the operation, and is the frame from which the drill string is lifted, lowered, and turned. The hoisting equipment, kelly, and drill pipe connect the bit to the derrick. The drawworks and engines next to the derrick lift and drive the drill string, by turning the rotary table. The drilling mud is circulated through the wellbore via the mud hose (also called a gooseneck), down through the rotary hose (not shown), kelly, and drillpipe, out nozzles in the drill bit, and back up to the surface between the drill string and the wellbore. The mud is pumped by the mud pump, and is stored in the mud (or reserve) pit or in mud tanks. Finally, blowout preventers, which are described later in this section, are installed as a safety measure to prevent the drill pipe and subsurface fluids from being blown out of the hole if a high-pressure formation is encountered during drilling. Rigs will often have much more equipment, including a shale shaker which separates rock cuttings, a desander and desilter, which remove smaller particles, and a vacuum degasser, which removes entrained gas (Berger and Anderson, 1992).

Figure 11: Typical Rotary Drilling Rig



Source: Energy Information Administration, Department of Energy, 1991.

Offshore Drilling

For offshore sites, selecting the type of drilling rig needed is very important. Two primary considerations in rig selection are: (1) the size of the rig needed for the depth drilled, and (2) the depth of the water. Exploratory wells (called wildcat wells) may be located far from established oil and natural gas fields, and the rig must be transported over a significant distance. Mobility is therefore a primary concern in these situations. The depth of water at the drilling site is also important. If the water is fairly shallow, a ground-supported rig may be used. If the water is deep (typically over 400 feet), a floating rig may be necessary. The following is a description of the significant offshore rig types:

R0076642

Drillships are a popular choice for drilling in deep water, because they are the most mobile of the rig types and have a large capacity for drill strings, casing, and similar supplies. A drillship has a standard ship hull, with the derrick extending from its center. The ship is kept in place by anchors or by dynamic positioning, a system in which propellers on each side of the ship are coordinated to keep the ship in the same location despite wind, currents, and the torsion caused by drill activities.

Semi-submersible drilling rigs are another option at deep water sites. The rig is usually a rectangular structure that holds the drilling equipment, with ballast containers underneath. These containers can be filled with air to float the rig when moving it. The rig is held in place by anchors or dynamic positioning. The semi-submersible rig is more stable than a drillship, but it is also more cumbersome to move from site to site.

Jack-up rigs float and are very mobile, but rest on the sea floor when drilling. For this reason, they are used in relatively shallow water (i.e., under 400 feet). The rig is towed into place floating, and legs, previously raised for transportation, are lowered to the ocean bottom so that the rig is raised above the water and supported on the ocean floor. The legs may be raised and lowered independently to compensate for an uneven sea floor. In an alternative footing method, mat support, the legs are attached to a mat on the sea floor; this mat distributes the weight over a larger area and minimizes the risk of the rig sinking into the soft ocean floor.

Fixed structures are commonly used after exploratory or developmental drilling prove a site has economically recoverable hydrocarbons. In these cases, offshore drilling rigs are mounted onto the production platform, which are securely pinned to the sea floor by concrete, steel, or tension legs. Tension legs are hollow steel tendons that allow no vertical movement, but some horizontal movement. They are the largest and most complex offshore structures and can be used in water in depths of over 500 feet (usually less than 1,000 feet). Platforms are very stable and can withstand waves greater than 60 feet high, and winds in excess of 90 knots. Assembling a fixed platform is a sizeable investment; some platforms have been reported to cost over $1 billion (Berger and Anderson, 1992). For this reason, multiple wells are usually drilled at outward angles from a single platform. The centralizing of pumps and separation equipment also make this a convenient arrangement for production (Kennedy, 1983).

<u>Lake and Wetland Drilling</u>

Inland regions of water often require additional engineering techniques and special adaptations other than the onshore and offshore practices mentioned above. In places of deeper and more open water, barge rigs may be used for drilling. In shallow areas or wetlands, stationary rigs can be constructed or the area can be backfilled and drilled with a land-based rig. Canals may also be dredged to bring in floating or submergible drilling rigs. It is common while drilling in wetlands to use the directional drilling technique in order to disrupt as little of the wetland as possible while developing a field. Often supplies and equipment must be transported by helicopter, or dredging is required for access by barge rigs. Regardless of the approach used, these areas often pose challenges for erecting the rig and transporting materials and personnel to and from the site, and involves compliance with Clean Water Act wetlands regulations (See Section VI.B for additional information) (Kennedy, 1983, and EPA, 1995).

Well Completion

When drilling has been completed, several steps may be needed before production begins. First, testing is performed to verify whether the hydrocarbon-bearing formations are capable of producing enough hydrocarbons to warrant well completion and production. As many as three types of tests may be performed before the final (production) string of casing is installed. These tests are coring, wireline logging, and drill stem testing.

Coring is typically performed only in exploratory wells. and not in fields where several wells have already been drilled. A special drill removes an intact sample, or *core*, of rock at the depth where oil or gas is most likely to be. The core can be as short as 15 feet or as long as 90 feet. Special side-wall coring techniques may be employed in some wells. Unlike the more indirect testing methods described below, a core allows a geologist to observe the rock type directly, and measure its *porosity*, or the volume of fluid-occupying space relative to the volume of rock. and *permeability*, the ease with which fluids can flow through a porous rock.

Wireline logging refers to the recording of acoustical, electrical resistivity, and other geophysical measurements within a wellbore. These measurements provide detailed information on the geologic formations encountered by the well, and augment the seismic data recorded prior to the well drilling and the mud log for that well. These data often help to determine more precisely the depth at which oil and gas could be produced. A logging of electrical resistivity takes advantage of the fact that some compounds are better insulators of electrical charge than others. For example, oil, gas, and consolidated rock resist electrical current better than water and unconsolidated rock. Additional tests may be used; radioactivity logs can differentiate between types of rock, and neutron logs can measure the amount of liquid in the formation (but not differentiate between oil and water). Logging is performed on nearly all wells, and multiple forms of logging may be used in conjunction with each other to attain a more complete analysis. For example, a neutron log will indicate the amount of liquid in a formation.

and a resistivity log may help to determine what percentage of that liquid is oil. Certain types of logs may be conducted during drilling with a special tool located on the drillstring above the bit.

Drill stem testing may be the most important and definitive test. Equipment attached to the bottom of a drill string traps a sample of formation fluid. Measuring the pressure at which the fluid enters the chamber and the pressure required to expel that fluid back into the formation yields an estimate of the flow rate of formation fluid to be expected during production. If the flow rate is expected to be too low, procedures such as stimulation (see below) may be required to increase the flow before production equipment is installed.

Perforation

When the production casing is cemented in the wellbore, the casing is sealed between the casing and the walls of the well. For formation fluid (oil, gas, and water) to enter the well, the casing must be perforated. The depth of the producing zone is determined by analyzing the logging data; small, directed explosive charges are detonated at this depth, thereby perforating the casing, cement, and formation. The result is that formation fluid enters the well, yet the rest of the well's casing remains intact.

Stimulation

Some formations may have a large amount of oil as indicated by coring and logging, but may have a poor flow rate. This may be because the production zone is not have sufficient permeability, or because the formation was damaged or clogged during drilling operations. In these cases, pores are opened in the formation to allow fluid to flow more easily into the well. The hydraulic fracturing method involves introducing liquid at high pressure into the formation, thereby causing the formation to crack. Sand or a similar porous substance is then emplaced into the cracks to prop the fractures open. Another method, acidizing, involves pumping acid, most frequently hydrochloric acid, to the formation, which dissolves soluble material so that pores open and fluid flows more quickly into the well. Both fracturing and acidizing may be performed simultaneously if desired, in an acid fracture treatment. Stimulation may be performed during well completion, or later during maintenance, or *workover*, operations, if the oil-carrying channels become clogged with time (EPA, 1992).

Production equipment installation

When drilling, casing, and testing operations are completed, the drilling rig is removed and the production rig is installed. In most cases, tubing is installed in the well which carries the liquids and gas to the surface. At the surface, a series of valves, collectively called the Christmas tree because of its appearance, is installed to control the flow of fluid from the well. Pumps are added if the formation pressure is not sufficient to force the formation fluid to the surface. Different types of pumps are available; the most common is the rod pump. The rod pump is suspended on a string of rods from a pumping unit, and the prime mover for pumping units can be an electric motor, or a gas engine. Equipment is usually installed onsite to separate natural gas and liquid phases of the production and remove impurities. Finally, a pipeline connection or storage container (tank) is connected to the well to facilitate transport or store the product. In the case of natural gas, which cannot be stored easily, a pipeline connection is necessary before the well can be placed on production.

Although the practice is becoming less common, one or more pits may be constructed for onshore facilities. These may include a skimming pit, which reclaims residual oil removed with water that has been removed from the product stream; a sediment pit, which stores solids that have settled out in storage tanks; or an evaporation or percolation pit, which disposes of produced water (EPA, 1992).

III.A.3. Petroleum Production

The major activities of petroleum production are bringing the fluid to the surface, separating the liquid and gas components, and removing impurities. Frequently, oil and natural gas are produced from the same reservoir. As wells deplete the reservoirs into which they are drilled, the gas to oil ratio increases (as well as the ratio of water to hydrocarbons). This increase of gas over oil occurs because natural gas usually is in the top of the oil formation, while the well usually is drilled into the bottom portion to recover most of the liquid. Although the following discussion is geared toward wells producing both oil and gas, the majority of the discussion also applies to wells producing exclusively one or the other.

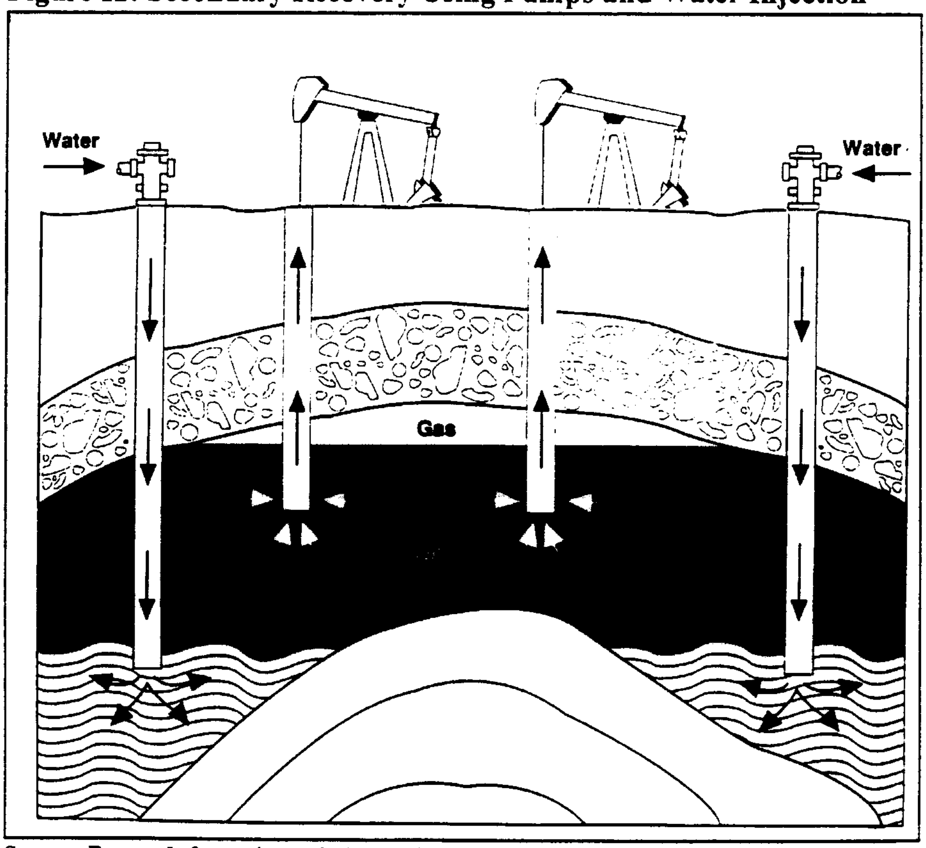
Primary Production

Primary recovery is the first stage of hydrocarbon production, and natural reservoir pressure is often used to recover oil. When natural pressure is not sufficiently capable of forcing oil to the surface, artificial lift equipment is then employed. This includes various types of pumps, gas lift valves, and may occasionally include oil stimulation. When pumping is employed, motors may be used at the surface or inside the wellbore to assist in lifting the fluid to the surface. Primary production accounts for less than 25 percent of the original oil in place.

Secondary Recovery

Secondary recovery enhances the recovery of liquid hydrocarbons by repressurizing the reservoir and reestablishing or supporting the natural water drive. Usually water which is produced with the oil is reinjected, but other sources of water may also be used. This type of secondary recovery is generally called a "waterflood" (See Figure 12). Produced water injection for enhanced recovery of crude oil and natural gas is recognized as a form of recycling of this waste. Furthermore, produced water is more commonly injected for the purpose of secondary recovery than in an injection well that is only used for disposal (in Texas, approximately 61 percent of injected produced water is for enhanced recovery) (Texas Railroad Commission, 1999). This procedure is described further in Section III.C., Management of Wastestreams. Gas is injected to enhance gas cap drive in some reservoirs.

Figure 12: Secondary Recovery Using Pumps and Water Injection



Source: Energy Information Administration, Department of Energy, 1991.

R0076647

Tertiary Recovery

A final method for removing the last extractable oil and gas is tertiary recovery. In contrast to primary and secondary recovery techniques, tertiary recovery involves the addition of materials not normally found in the reservoir (Lake, 1989). These methods are often expensive and energy-intensive (Sittig, 1978). In most cases, a substance is injected into the reservoir, mobilizes the oil or gas, and is removed with the product. Examples include:

- Thermal recovery, in which the reservoir fluid is heated either with the injection of steam or by controlled burning in the reservoir, which makes the fluid less viscous and more conducive to flow;
- Miscible injection, in which an oil-miscible fluid, such as carbon dioxide or an alcohol, is injected to reduce the oil density and cause it to rise to the surface more easily;
- Surfactants, which essentially wash the oil from the reservoir; and
- Microbial enhanced recovery, in which special organic-digesting microbes are injected along with oxygen into the formation to digest heavy oil and asphalt, thereby allowing lighter oil to flow (Lake, 1989; EPA, 1992)

Crude Oil Separation

When the formation fluid is brought to the surface, it may contain a spectrum of substances including natural gas, water, sand, silt, and any additives used to enhance extraction. The general order of separation with respect to oil is the following: the separation of gaseous components, the removal of solids and water, and the breaking up of oil-water emulsions. (The conditioning of the natural gas that is removed in the first step will be discussed in the next subsection.)

The removal of gaseous components primarily is intended to remove natural gas from the liquid; however, gaseous contaminants such as hydrogen sulfide (H_2S) also may be produced in some fields during this process. The gases are removed by passing the pressurized fluid through one or two decreasing pressure chambers; less and less gas will remain dissolved in the solution as the pressure is lowered.

The liquids and solids that remain are usually a complex mix of water, oil, and sand. Water and oil are generally immiscible; however, the extraction process is usually very turbulent and may cause the water and oil to form an emulsion, in which the oil forms tiny droplets in the water (or vice versa). Fluid separation often produces a layer of sand, a layer of relatively oil-free water, a layer of emulsion, and a (small) layer of relatively pure oil. The free water and sand, or basic sediment and water (BS&W) are generally removed by a process called free water knockout, in which the BS&W are removed primarily by gravity. Finally, emulsions are broken by heating the fluid in a heater-treater to a temperature of 100-160 degrees fahrenheit, or by treating it with emulsion-breaking chemicals (Arnold and Stewart, 1998). Following the emulsion breaking, the oil is about 98 percent pure, which is sufficient for storage or transportation to the refinery (Sittig, 1978).

Natural Gas Conditioning

Natural gas conditioning is the process of removing impurities from the gas stream so that it is of high enough quality to pass through transportation systems. It should be noted that conditioning is not always required; natural gas from some formations emerges from the well sufficiently pure that it can pass directly to the pipeline. As the natural gas is separated from the liquid components, it may contain impurities that pose potential hazards or problems. The most significant is hydrogen sulfide (H_2S), which may or may not be contained in natural gas. Hydrogen sulfide is toxic (and potentially fatal at certain concentrations) to humans and corrosive for pipes; it is therefore desirable to remove it as soon as possible in the conditioning process. Another concern is that posed by water vapor. At high pressures, water can react with components in the gas to form gas hydrates, which are solids that can clog pipes, valves, and gauges (Manning and Thompson, 1991). Nitrogen and other gases may also be mixed with the natural gas (methane) in the subsurface. These other gases must be separated from the methane prior to sale. At cold temperatures the water can freeze, also clogging pipes, valves, and gauges. High vapor pressure hydrocarbons that are found to be liquids at surface temperature and pressure (benzene, toluene, ethylbenzene, and xylene, or BTEX) are removed and processed separately. Two significant natural gas conditioning processes are dehydration and sweetening.

Dehydration is performed to remove water from the gas stream. Three main approaches toward dehydration are the use of a liquid or solid desiccant, and refrigeration. When using a liquid desiccant, the gas is exposed to a glycol that absorbs the water. The water can be evaporated from the glycol by a process called heat regeneration, and the glycol can then be reused. Solid desiccants, often materials called molecular sieves, are crystals with high surface areas that attract the water molecules. The solids can be regenerated simply by heating them above the boiling point of water. Finally, particularly for gas extracted from deep, hot wells, simply cooling the gas to a temperature below the condensation point of water can remove enough water to transport the gas. Of the three approaches mentioned above, glycol dehydration is the most common when processing occurs in the field (at or near the well). At natural gas plants, solid desiccants are most commonly used (Smith, 1999).

Sweetening is the procedure in which H_2S and sometimes CO_2 are removed from the gas stream. The most common method is amine treatment. In this process, the gas stream is exposed to an amine solution, which will react with the H_2S and separate them from the natural gas. The contaminant gas solution is then heated, thereby separating the gases and regenerating the amine. The sulfur gas may be disposed of by flaring, incinerating, or when a market exists, sending it to a sulfur-recovery facility to generate elemental sulfur as a salable product. Another method of sweetening involves the use of iron sponge, which reacts with H_2S to form iron sulfide and later is oxidized, then buried or incinerated (EPA, 1992).

III.A.4. Maintenance

Production wells periodically require significant maintenance sessions, called *workovers*. During a workover, several tasks may be undertaken: repairing leaks in the casing or tubing, replacing motors or other downhole equipment, stimulating the well, perforating a different section of casing to produce from a different formation in the well, and painting and cleaning the equipment. The procedure often requires bringing in a rig for the downhole work. This rig can be smaller than those used for initially drilling a well.

Two procedures performed to improve the flow of fluid during workovers are removing accumulated salts (called *scale*) and paraffin, and treating production tubing, gathering lines, and valves for corrosion with corrosion-prevention compounds. As fluids are withdrawn from the formation, the salts that are dissolved in the produced water precipitate out of solution as the solution approaches the surface and cools. The resulting scale buildup can significantly reduce the flow of fluid through the tubing, gathering lines, and valves. Examples of scale removal chemicals are hydrochloric and hydrofluoric acids, organic acids, and phosphates (EPA, 1994). These solvents are added to the bottom of the wellbore and pumped through the tubing through which extracted fluid passes. In a similar fashion, corrosion inhibitors may be passed through the system to mitigate and prevent the effects of acidic components of the formation fluid, such as H_2S and CO_2. These corrosion inhibitors, such as ammonium bisulfite or several forms of zinc, may serve to neutralize acid or form a corrosion-resistant coating along the production tubing and gathering lines. Corrosion control activities can be continuous, not just at workover.

III.A.5. Well Shut-in/Well Abandonment

Production may be stopped for several reasons. If it is a temporary stoppage, the well is shut-in. If the closure is to be permanent, the well is either converted to a UIC Class II injection well, or it is plugged and abandoned.

A temporary shut-in is an option when the conditions causing the interruption in production are anticipated to be short-term. Examples include situations when the well may be awaiting a workover crew or a connection to a pipeline, or there may be a (temporary) lack of a market (Williams and Meyers, 1997). A well is shut in by closing the valves on the Christmas tree. Depending on the duration, the stoppage may be called a temporary abandonment, and regulatory approval and testing, including a mechanical integrity test (MIT), may be required in order to be idle (IOGCC, 1996). It is much more desirable to shut-in a well rather than plug it if production is still viable, because once the well is permanently plugged and abandoned, it is highly impractical to re-access the remaining oil in the reservoir.

If the well is part of a production field with many nearby wells still in production, the well may be converted to a UIC Class II injection well, which is regulated under the Safe Drinking Water Act (see Section VI.B, Sector-Specific Requirements for more information). Such a well can be used either for disposal of the produced water from these other wells, or may be part of a coordinated Enhanced Oil Recovery (EOR) effort in the field.

The final option is to plug and abandon the well. The goal of this procedure is to prevent fluid migration within the wellbore, which could contaminate aquifers or surface water. Oil and gas producing states all have specific regulations governing the plugging and abandonment of wells (see Section VI.B.4., State Regulations). When a well is plugged, the downhole equipment is removed and the perforated parts of the wellbore are cleaned of fill, scale and other debris. A minimum of three cement plugs are then placed, each of which are 100 to 200 feet long. The first is pumped into the perforated (production) zone of the well, in order to prevent the inflow of fluid. A second is placed in the middle of the wellbore. A third plug is placed within a couple hundred feet of the surface. Additional plugs may be placed anywhere within the wellbore when necessary. Fluid with an appropriate density is placed between the cement plugs in order to maintain adequate pressure. During this process, the plugs are tested to verify plug placement and integrity (Fields and Martin, 1998). Finally, the casing is cut off below the surface, capped with a steel plate welded to the casing, and at onshore sites, surface reclamation is undertaken to restore natural soil consistency and plant cover (EPA, 1992).

Problems are sometimes encountered with wells that have stopped production, yet neither have government approval nor have been plugged. These are generally called idle wells, or when the owners are not known or are insolvent, are called orphan wells. Please see Section III.B for the possible environmental impacts of such wells.

Offshore Platform Decommissioning
For offshore, the structure itself must be decommissioned in addition to plugging the well. Several options exist:

- Complete removal of the structure and disposing of the structure onshore
- Removing the structure and placing it in an approved location in the ocean
- Reuse of the structure elsewhere (National Research Council, 1996).

The method used will vary with the type of structure and water depth, but the most common approach is the complete removal of the structure, with removal at a minimum of 15 feet below the mudline (seafloor). Other approaches are less expensive and less intrusive to the existing environment, but can be more dangerous for commercial ships, military submarines, fishing trawlers, and recreational boaters. In Texas and Louisiana, however, it may be possible to participate in the states' "rigs-to-reefs" programs, which under the National Fishing Enhancement Act of 1984 seek to convert offshore structures to permanent artificial reefs (MMS, 1999).

When removing the structure, the most common approach is to sever the leg piles with explosives. Explosives must be placed at least five feet below the mud line (sea floor). Explosives are less expensive and are less risky to divers than alternatives such as manual or mechanical cutting, but concern has been raised about the use of explosives and their effect on marine life (National Research Council, 1996).

III.A.6. Spill and Blowout Mitigation

Accidental releases at oil and gas production facilities may come in two forms: spills or blowouts. Oil spills (usually consisting of crude oil or condensate) may come from several sources at production sites (and in some cases at drilling sites): leaking tanks, during transfers, or from leaking flowlines, valves, joints, or gauges. Other spills of oil have occurred such as diesel from drilling operations, oily drilling muds while being offloaded, and production chemicals (MMS, 1998). Spills are the most common type of accident and are often small in quantity.

Well blowouts are rare, but can be quite serious. They are most likely to occur during drilling and workovers, but can occur during any phase of well development including production operations. When the drill encounters an unusually pressurized zone or when equipment is being removed from the hole, the pressure exerted by the formation may become considerably higher than that exerted by the drilling or workover fluid. When this happens, the formation fluid and drilling or workover fluid may rise uncontrollably through the well to the surface. Downhole equipment may also be thrust to the surface. Especially if there is a significant quantity of associated natural gas, the fluid may ignite from an engine spark or other source of flame. Blowouts have been known to completely destroy rigs and kill nearby workers. Some blowouts can be controlled in a matter of days, but some -- particularly offshore -- may take months to cap and control (Kennedy, 1983).

Drilled wells and many workover wells are equipped with a blowout preventer. These blowout preventers (BOPs) are hydraulically operated, and serve to close off the drill pipe. BOPs can be operated manually, or can be automatically triggered. Most rigs have regular blowout drills and training sessions so that workers can operate the BOPs and escape as safely as possible.

Should a spill occur despite precautions, established responses should be undertaken. If the facility is subject to Spill Prevention Control and Countermeasure (SPCC) regulation (see Section VI.B for additional information), the facility will be equipped with secondary containment and diversionary structures to prevent the spill from reaching drains, ditches, rivers, and navigable waters. These structures may be berms, retention ponds, absorbent material, weirs, booms, or other barriers or equivalent preventive systems. Should these secondary containment devices not be adequate, the response will be different for onshore and offshore spills (EPA, 1999). In both cases, the goals are to stop the flow of oil, recover as much as possible of the material as a salable product, then minimize the impact on navigable waterways or groundwater.

<u>Onshore Spills</u>

For onshore spills, concern is for both surface runoff to streams, and for seepage into groundwater. The first considerations are to stop the source of the leakage and to contain the spill. Containment may either be achieved with pre-existing structures, or by using bulldozers at the time of response (Blaikley, 1979). Pooled oil would then be collected, pumped out, and whenever possible, processed for sale. When treating the contaminated soil, the remediation approach taken may vary considerably depending on the porosity of the soil and composition of the spilled fluid. If the spill has permeated less than about 6-10 inches of soil, bioremediation may be the most appropriate approach. With bioremediation, hydrocarbon-digesting microbes found naturally in soil are enhanced with fertilizers and moisture to degrade the material. The site would be tilled periodically and watered to maintain proper amounts of air and moisture. Should the temperature at the site be too cold or should the spill be too deep for bioremediation to be fully effective, approaches such as composting, or soil excavation with landspreading or landfilling, may be used either exclusively or in combination (Deuel and Holliday, 1997). Another option in remote locations or in situations when other options have not been successful is in-situ burning. In these situations, primarily when there is little surrounding vegetation, calm winds, and difficulty in transporting the equipment required for other methods, the oil is concentrated as much as possible and ignited by any of a variety of methods (Zengel, et al., 1998; Fingas, 1998). Application of in situ burning is still being refined.

Offshore Spills

The conditions for an offshore spill cleanup can vary substantially; from deep-water to coastal, from calm water to very choppy seas. As with onshore spills, initial priorities are to contain spilled oil and prevent further leakage. The oil is usually contained by booms, or floating devices that block the movement of surface oil. The booms may then be moved to concentrate the oil, at which point skimmers collect the oil. Booms may also be placed along a shoreline to minimize the amount of oil that reaches shore. For the oil that cannot be collected in this fashion, other approaches are used to minimize environmental impact, including sorbents, dispersants, or oil-digesting bacteria (EPA, 1993). In-situ burning also may be an option for offshore spills. This option may be best suited to arctic conditions, where cold temperatures keep the oil relatively concentrated and where ice may hinder the use of other methods. Depending on the thickness of the oil, the calmness of the seas, and other factors, the destruction rate can be over 90 percent (Fingas, 1998; Buist, 1998). This technique has not been widely used and is still considered experimental.

III.B. Raw Material Inputs and Pollution Outputs

This section describes the impacts that individual steps in the extraction process may have on adding contaminants to the environment. Relevant inputs and significant output wastes are presented, with outputs summarized in Table 2. The management techniques used to handle the wastes are discussed in Section III.C, and more information on the magnitude and qualities of the releases are found in Section IV.

Oil and gas extraction generates a substantial volume of byproducts and wastes that must be managed. Relatively small volumes of chemicals may be used as additives to facilitate drilling and alter the characteristics of the hydrocarbon flow. For example, acids may be used to increase rock permeability, or biocides may be added to wells to prevent the growth of harmful bacteria. The industry also contends with many naturally occurring chemical substances. Byproducts and wastes result from the separation of impurities found in the extracted hydrocarbons or from accidents when oil is spilled. In addition, most processes involving machinery will produce relatively small quantities of waste lubricating oils and emissions from fossil fuel combustion, and inhabited facilities will produce sanitary wastes. Finally, formation oil contamination may be present in the spent drilling fluids and cuttings.

Drilling

There are a number of possible environmental impacts from the wastes generated during the well drilling and completion/stimulation processes. In the drilling process, rock fragments (cuttings) are brought to the surface in the drilling fluid. These cuttings pose a problem both in the large volume produced and the muds that coat the cuttings as they are extracted. Oil-based fluids have the added stigma of having oil frequently coating the cuttings. The volume of rock cuttings produced from drilling is primarily a function of the depth of the well and the diameter of the wellbore. It has been estimated that between 0.2 barrels and 2.0 barrels (8.4 and 84.0 gallons) of total drilling waste are produced for each vertical foot drilled (EPA, 1987).

Drilling mud disposal generally becomes an issue at the end of the drilling process. However, sometimes drilling mud is disposed of during the drilling process when the mud viscosity or density needs to be changed to meet the demands of formation pressures. This can create special concerns for offshore operations where the disposal of a large volume of mud over a short period can create a mud blanket on the seafloor that can have an impact on benthic organisms. Industry is limited to using barite stock for the making of drilling mud, which passes 40 CFR 435 requirements (less than or equal to 1 ug/kg dry weight maximum mercury and 3 mg/kg dry weight maximum cadmium). The muds are combined, however, with dissolved and suspended contaminants including mercury, cadmium, arsenic and hydrocarbons (typically found in trace amounts). The additives listed in Section III.A may be found in waste mud, and components from the formation, such as hydrogen sulfide and natural gas, may also be dissolved in the mud. Rock cuttings from the formations overlying the target formation may contribute contaminants to the drilling mud such as arsenic or metals. Also rock cuttings create a large volume of waste and for water-based fluids the rock cuttings may be discharged to surface waters offshore. Oil-based mud will also contain diesel oil that must be disposed of properly, or more typically, conditioned for reuse. Oil-based muds and cuttings cannot be discharged to surface waters. Both oil-based and synthetic-based fluid are conditioned and reused, which reduces waste volume from drilling operations.

Drilling operations also produce air emissions, such as exhaust from diesel engines and turbines that power the drilling equipment. The air pollutants from these devices will be those traditionally associated with combustion sources, including nitrogen oxides, particulates, ozone, and carbon monoxide. Additionally, hydrogen sulfide may be released during the drilling process (EPA, 1992).

Some steps in the well completion process may produce waste. The most prominent is stimulation. Unused hydrochloric acid must be neutralized if acid stimulation is being used, and paraffins and any other dissolved materials brought to the surface from the formation must be disposed of as well. In addition, solid wastes such as waste cement and metal casing may remain from the casing process.

Production

The primary byproduct from the production process (and the dominant one on a volume basis in the industry) is produced water. Other wastes that may be generated during production include the residual wastes that remain after separation of the oil and natural gas.

Produced Water

The largest volume byproduct by far in the extraction process is water extracted with oil. In wells nearing the end of their productive lives, water can comprise 98 percent of the material brought to the surface (Wiedeman, 1996). The American Petroleum Institute estimates that over 15 billion barrels of water are produced annually. This is nearly eight barrels of water for every barrel of oil produced. Natural gas wells typically produce much lower volumes of water than oil wells, with the exception of certain types of gas resources such as coalbed methane or Devonian/Antrim shales (API, 1997).

Although many petroleum components are separated from the water easily, some components and impurities are water-soluble and difficult to remove. Some substances may be found in high concentrations, including chloride, sodium, calcium, magnesium and potassium. Others found are:

- Organic compounds: benzene, naphthalene, toluene, phenanthrene, bromodichloromethane, and pentachlorophenol;
- Inorganics: lead, arsenic, barium, antimony, sulfur, and zinc;
- Radionuclides: uranium, radon, and radium (EPA, 1992).

It should be noted that concentrations of these pollutants will vary considerably depending on the location of the well and the extent of treatment of the water. Geography can be a key factor in whether a substance may exist in produced water. For example, radionuclides are found only in some areas of the country.

The risks of water pollution due to produced water management differ for onshore and offshore operations, and are discussed separately.

Onshore operations, and coastal and shallow offshore areas, may pose a risk to the environment if produced water with high saline concentrations is not properly managed. The saline concentration of produced water varies widely. In some locations, the produced water can have salt concentrations of 200,000 mg/L (Stephenson, 1992). However, in some areas west of the 98th Meridian, produced water may contain low enough levels of salt that it may be used (upon meeting regulatory limits for oil and grease) for beneficial use for irrigation or livestock watering (EPA, 1992; Railroad Commission of Texas, 1999).

The discharge of produced water inappropriately onto soil can result in salinity levels too high to sustain plant growth. If introduced to a water supply, the water can be unusable for human consumption. The introduction of metals and organic compounds from produced water are also a concern. (See Section IV for more details on contaminants in produced water.) However, over 90 percent of onshore produced water is injected for enhanced recovery or disposal (Smith, 1999). This injection involves a closed system from the producing wellbore to the injection wellbore, so the potential for release to the soil is minimized.

Offshore operations may impact the area immediately surrounding the platform if produced water effluents are not properly treated and discharged. The concentration of metals, radionuclides, residual oily materials and high BOD in the produced water may be higher than the surrounding water. However, the impact is reduced significantly at greater distances from the well; research in the Gulf of Mexico has indicated that produced water can be diluted 100-fold within 100 meters of the discharge (Neff and Sauer, 1996).

Natural Gas Processing

Wastes are generated when natural gas undergoes dehydration and sweetening. For dehydration, triethylene glycol is the most common desiccant. Although glycol is reused, it becomes less effective over time and must be replaced periodically. Glycols are volatile and can be hazardous if inhaled as a vapor. At larger natural gas processing plants, the solid molecular sieves that are used also require periodic replacement.

The wastes from gas sweetening will vary depending on the method used. Possible wastes include spent amine solution, iron sponge, and elemental sulfur. When there is a market for sulfur, it is sold.

Air Emissions

There are several sources of air emissions in the production process. Leaking tubing, valves, tanks, or open pits will release volatile organic compounds (VOCs). When natural gas produced from the well is not sold or used on-site, it is usually flared, thereby releasing carbon monoxide, nitrogen oxides, and possible sulfur dioxide if the gas is sour (see Section III.C. for more information on flaring). Finally, production involves the use of machinery including pumps, heater-treaters, and motors which require fuel combustion. Emissions from these include nitrogen oxides, sulfur oxides, ozone, carbon monoxide, and particulates (EPA, 1992). Where electricity is available, electric-powered equipment may be used. Emissions from natural gas processing plants (SIC 1321) are larger than field production operations due to the greater scale and concentration of equipment. Even at gas plants most engines are powered by natural gas or electricity.

Other Wastes

The sand that is separated from produced water must be disposed of properly. Similar to the sand removed during the drilling process, this sand is often contaminated with oil and trace amounts of metals or other naturally occurring constituents.

Most oil and gas operations include tanks for the temporary storage of oil, natural gas liquids, and/or produced water. While stored, small solid particles that were entrained in the liquids can settle out, forming a sludge on the bottom of the tank. These "tank bottoms," or "basic sediment and water" (BS&W) wastes, may be periodically removed from the tank and disposed of. Some tanks may require cleaning a few times per year; others may require cleaning once every 10 years. The need for tank cleaning, and therefore the generation of these wastes, is dependent upon the characteristics of the fluids being handled and the operation. Because they are removed from hydrocarbon storage tanks, tank bottoms are likely to contain oil and smaller amounts of other constituents (see Section IV for an example of concentrations of contaminants in these sediments.)

Maintenance

The workover process requires many of the same inputs and produces similar outputs as the drilling process. In particular, workover fluid, which is similar to drilling fluid, is required to control downhole pressure. Also, emissions will result from the combustion of fuels to power the rig.

Workovers also use additional inputs and produce other pollutants, some of which are toxic. The compounds usually appear in the produced water when production resumes, or in the case of cleaning fluids, may be spilled from equipment at the surface.

Scale removal requires strong acids, such as hydrochloric or hydrofluoric acids. When carried to the surface in produced water, any acids not neutralized during use must be neutralized before being disposed, usually in a Class II injection well. Scale is primarily comprised of sodium, calcium, chloride and carbonate; however, trace contaminants such as barium, strontium, and radium may be present.

Also, corrosion inhibitors and stimulation compounds are flushed through the well. Corrosion-resistant compounds of concern include zinc carbonate and aluminum bisulfate. Stimulation may require acidic fluids.

In addition, painting- and cleaning-related wastes may be generated during workovers. Paint fumes and cleaning solvent vapor may produce gaseous emissions, paint and cleaning solvents with suspended oil and grease must be disposed of properly, and paint containers will require disposal as a solid.

Collectively, wastes produced by the industry other than drilling wastes and produced water are called associated wastes. The volume is usually small, about one barrel per well per year (DOE, 1993). Because associated wastes are those associated with chemical treatment or wells or produced fluids, post-treatment materials, and residual waste streams, they are more likely to have higher hydrocarbon or chemical constituent content than produced water or waste drilling fluids.

In 1985, API estimated that approximately 12 billion barrels of associated wastes were generated annually (Wakim, 1987). API estimates that in 1995, the annual volume of associated wastes is 22 millions barrels (API, 1997). The higher volume is attributed primarily to a difference in definitions between the two studies (i.e., the 1995 study includes wastes form gas plants that were not included in 1985). On a comparable basis, there has been only a slight increase in associated waste volumes over the past decade. This increase can be attributed primarily to aging wells requiring more stimulation or workover treatments to remain on production. Table 1 summarizes the types of associated wastes and their relative volume based on a 1985 API industry survey.

Table 1: Types of Associated Waste

Material	Process	Percent of Total Associated Waste Volume
Workover wastes (mud and other completion fluids, oil, chemicals, acid water, cement, sand)	Maintenance	34%
Produced sand, separator sludges	Production	21%
Other production fluid waste	Production	14%
Oily debris, filters, contaminated soils	All	12%
Cooling water, engine and other waste water	All	8%
Dehydration and sweetening unit wastes	Production	4%
Untreatable emulsions	Production	2%
Used solvents and cleaners	Maintenance	2%
Other production solid waste	Production	1%
Used lubricating or hydraulic oils	All	1%

Idle/Orphan Wells

Idle wells are wells that have ceased production (either temporarily or permanently) but have not been plugged. Generally the state regulatory agency knows the operator who is responsible for these wells, and in most states, wells require regulatory approval to be idle. However, a small percentage of these are orphan wells, for which no responsible party exists. This may be because the operator is unknown (in the case of wells drilled in the early part of the century) or because the operator has gone bankrupt and has no assets available.

Wells that have stopped production yet neither have state government approval nor have been plugged are uncommon. Approximately 134,000 of the nearly 2.7 million total wells drilled by 1995 in the United States are in this category (IOGCC, 1996). These wells may pose problems with respect to migrating reservoir fluid. With these wells, the mechanical integrity of the casing is not known, and therefore it may be possible for reservoir fluid to migrate to fresh water aquifers. In such cases, the primary contaminant would be saline formation water that could pollute fresh water aquifers and possibly surface waters.

It should be noted that not all of these wells will necessarily cause pollution; rather, the concern is that the risk posed by these wells is variable. Currently, most oil- and gas-producing states are handling the issue by prioritizing among these wells, and have established programs to plug dangerous orphan wells and clean up any contamination that may have already occurred. One way in which this prioritization is achieved is through area of review (AOR) studies that are required for the approval of new UIC wells. Under this requirement, the operator of the new well must study all active, idle and abandoned wells within an area (often a 1/4 mile radius) to determine whether they pose a risk of contamination (IOGCC, 1996).

Spills and Blowouts

Based on data from the U.S. Coast Guard and other sources, the American Petroleum Institute reported that in 1996, 1,276 onshore facilities reported spills of crude oil for a total of 131,000 gallons. This total would include spills from field operations, but also would include spills of crude oil at refineries, terminals, and other types of facilities. Spill volumes specifically for crude oil are not available. According to the Coast Guard, 78 percent of spills in 1996 were less than 10 gallons (API, 1998b).

Production facilities often have systems in place for handling larger accidents such as blowouts, and many onshore oil and gas operations must have a Spill Prevention Control and Countermeasures (SPCC) Plan in place for addressing spills. Under the CWA only spills above a certain threshold must be reported (see Section IV for more details on SPCC and CWA regulations). However, smaller spills appear to account for most reported crude oil releases. These are most likely to occur due to poor connections in filling or removing materials from tanks (Smith, 1999).

Offshore, the Marine Minerals Service collects data on oil spills. According to MMS, in 1995 there were 34 spills from production operations in the Gulf of Mexico, totaling 773 barrels. There was also one spill of one barrel of oil on the Pacific Coast (MMS, 1995).

In addition to oil spills, well blowouts can result in accidental releases of material. In a blowout, the pollutant can be produced water and oil, or drilling fluids and workover fluids, such that possible components of concern are salt, heavy metals, and oil. The produced water and oil mixture can be spread in a wide area around the rig possibly leaching through the soil to a fresh water aquifer or running off into nearby surface waters. Onshore, statistics on the number of blowouts annually are not available. Offshore, according to data from MMS, there was only one blowout in 1995, and 15 blowouts between 1991 and 1995. The total amount of oil spilled as a result of those blowouts was 100 barrels, all in 1992. It is assumed from the historical distribution that 14 percent of all blowouts could result in the spillage of crude oil or condensate, with 4 percent of the blowouts resulting in spills greater than 50 barrels. Since 1992, all blowouts have been controlled without any spills (MMS, 1995).

Accidental releases can also include air emissions. Crude oil contains organic compounds that may volatilize and be emitted before the spill can be cleaned up. In-situ burning of crude oil is one approach for cleaning up spills. Use of burning can result in emissions from the combustion, including particulates and carbon monoxide. Blowouts can result in the emission of methane (natural gas). If the well ignites, combustion outputs would be expected. In rare cases, process upsets at facilities that process sour natural gas could result in the release of hydrogen sulfide.

Table 2: Potential Material Outputs from Selected Oil and Gas Extraction Processes

Process	Air Emissions	Process Waste Water	Residual Wastes Generated
Well Development	fugitive natural gas, other volatile organic compounds (VOCs), Polyaromatic hydrocarbons (PAHs), carbon dioxide, carbon monoxide, hydrogen sulfide	drilling muds, organic acids, alkalis, diesel oil, crankcase oils, acidic stimulation fluids (hydrochloric and hydrofluoric acids)	drill cuttings (some oil-coated), drilling mud solids, weighting agents, dispersants, corrosion inhibitors, surfactants, flocculating agents, concrete, casing, paraffins
Production	fugitive natural gas, other VOCs, PAHs, carbon dioxide, carbon monoxide, hydrogen sulfide, fugitive BTEX (benzene, toluene, ethylbenzene, and xylene) from natural gas conditioning	produced water possibly containing heavy metals, radionuclides, dissolved solids, oxygen-demanding organic compounds, and high levels of salts. also may contain additives including biocides, lubricants, corrosion inhibitors. wastewater containing glycol, amines, salts, and untreatable emulsions	produced sand, elemental sulfur, spent catalysts, separator sludge, tank bottoms, used filters, sanitary wastes
Maintenance	volatile cleaning agents, paints, other VOCs, hydrochloric acid gas	completion fluid, wastewater containing well-cleaning solvents (detergents and degreasers), paint, stimulation agents	pipe scale, waste paints, paraffins, cement, sand
Abandoned Wells, Spills and Blowouts	fugitive natural gas and other VOCs, PAHs, particulate matter, sulfur compounds, carbon dioxide, carbon monoxide	escaping oil and brine	contaminated soils, sorbents

III.C. Management of Wastestreams

The primary wastestreams are those associated with drilling wastes and produced water. As a result, most disposal options are oriented toward these two waste categories. The management of associated wastes and of gases is also briefly described.

Liquids

Underground Injection

Underground injection is the most common disposal method of produced water; over 90 percent of onshore produced water is disposed of through injection wells (API, 1997), but it is rare at offshore facilities. For disposal of produced water by underground injection, two options are available: to inject the water as a waste disposal method, or to use the produced water as part of a waterflooding effort for enhanced recovery. Water being disposed of typically is injected into known formations, such as a former producing formation. In a few Appalachian states, annular injection of produced water may be used, in which case the fluid is pumped into the space between tubing and casing (or uncased formation) within the well (EPA, 1992).

The second option, implemented especially in locations where formation pressure may be relatively low, is reinjecting produced water into the oil- and gas-producing formation. (See Figure 12 on page 29 for an illustration.) The volume of produced water used for enhanced recovery is approximately 57 percent of total produced water volumes (API, 1997). This method increases pressure in the formation to force oil toward the well and contributes to secondary recovery efforts. It requires that water be more thoroughly treated before injection; the water should be free of solids, bacteria, and oxygen, all of which could potentially contaminate the oil reservoir and, in the case of sulfur-reducing bacteria, could lead to increased hydrogen sulfide concentrations in the extracted oil. Please see Section VI.B, Sector-Specific Requirements for UIC regulations that apply to produced water underground injection.

Liquid wastes bought onshore may include produced water that fails NPDES toxicity requirements; water extracted from sludge; or treatment, workover, and completion fluids. At commercial waste treatment facilities liquid wastes are usually injected into disposal wells. As of February 1997, there are 94 disposal wells located in the Texas coastal zone and 17 in the Louisiana coastal zone. These wells could be used for disposal of OCS-generated liquid wastes (MMS, 1998).

Roadspreading

If the fluid has the characteristics of materials used for dust suppressants, road oils, deicing materials, or road compaction, the fluid may be used for roadspreading. In this procedure, water is applied to roads at approved rates, in order to prevent pooling or runoff and to minimize the risk of surface water or groundwater contamination. This practice may be subject to testing to ensure that the fluid is similar to the conventional road materials mentioned above, and also to ensure that the level of radioactive material is not above regulatory action levels (IOGCC, 1994). Roadspreading is declining as a disposal option, and accounts for less than 1 percent of produced water volumes (API, 1997).

Use of Produced Water for Irrigation

In areas west of the 98th meridian, produced water from onshore wells that are in the Agricultural and Wildlife Beneficial Use Subcategory may be used as a beneficial use with agriculture. In these cases, treated water that meets water quality standards may be released directly to agricultural canals for use in irrigation or livestock watering (EPA, 1992; Texas Railroad Commission, 1999). Beneficial use of produced water currently accounts for around 4 percent of onshore produced water volumes in the United States (API, 1997).

Evaporation or Percolation Pits

In this approach, produced water is placed in the pit and allowed to either evaporate to the air or percolate into the surrounding soil. These pits can only be used when the fluid will not adversely impact groundwater or surface water, and restrictions may be imposed on water salinity, hydrocarbon content, pH, and radionuclide content. This approach is declining because of potential environmental contamination of groundwater and the potential hazard posed to birds and waterfowl by residual oil in these open pits (IOGCC, 1994; Buckner, 1998). About 2 percent of produced water is currently disposed of using evaporation or percolation pits (API, 1997). Most of this volume is disposed of in percolation pits in arid portions of California.

Treat and Discharge

For this disposal method the water must meet standards for oil and grease content and pass a toxicity test prior to discharge. In 1997, 1 percent of onshore produced water was disposed of in this manner (API, 1997). Until recently, this method was also used at coastal facilities, but has been largely phased out since 1995. The only coastal area where discharge of produced water is currently allowed is Cook Inlet, Alaska.

Treatment and discharge is the primary method for disposing of produced water at offshore operations. Produced water discharges are not expected to take place at every platform or well. The trend in the Gulf of Mexico is for water treatment and separation of the well stream to occur only at designated locations. An industry survey of 1992 discharge monitoring reports submitted annually to USEPA (Shell Oil Company, 1994) found that only 29 percent of existing platforms contain water treatment systems and discharge their produced waters. As industry uses more sophisticated methods of developing shallow oil and gas fields and is required to conduct more complex treatment protocols, it is likely that operators will increasingly use central processing facilities (MMS, 1998).

Industry's projections (Deepstar, 1994) for deepwater are that the oil and gas produced in deepwater will most likely be piped from subsea completions through mixed line pipelines to large processing facilities primarily operating at the shelf break. These processing facilities will separate and process the production streams into oil, gas and water, and then discharge the treated water. The exception to this process would be whenever a floating production, storage and offloading system (FPSO) is chosen as the surface facility receiving oil and gas from subsea completions. An FPSO is a converted tanker used for a production and storage base, usually at a deepwater (greater than 400 meters) production site. These FPSO's, able to operate at any depth, would process the well stream prior to the transport of the products to shallower locations (MMS, 1998).

Table 3: Summary of 1995 Disposal Practices for Onshore Produced Water

Method	Percent of Onshore Produced Water
Injected for Enhanced Recovery	57%
Injection for Disposal	36%
Beneficial Use	4%
Evaporation and Percolation Ponds	2%
Treat and Discharge	1%
Roadspreading	<1%

Source: API, 1997.

Solids

The primary solid waste-generating process is drilling, and therefore the solid waste disposal processes are geared toward drilling waste. However, solid waste is also generated during production and maintenance. Production and maintenance wastes are usually transported offsite. Offshore, solids are often treated and discharged in accordance with Clean Water Act regulations.

In the Gulf of Mexico, offshore oil field wastes that are not discharged or disposed of onsite are brought onshore for disposal and taken to specifically designated commercial oil field waste disposal facilities. In Texas there are ten existing commercial oil field waste disposal facilities that receive all of the types of wastes that would come from the OCS operations (4 stationary treatment, 5 landfarms, and 1 commercial pit); in Louisiana there are seven facilities (5 land treatment, 1 incinerator, and 1 chemical stabilization facility); and in Alabama there are two landfarm/landtreatment facilities. Included in these numbers are one site in Texas and two sites in Louisiana that process naturally occurring radioactive material (NORM)-contaminated oil field wastes (MMS, 1998).

Reserve Pit

During drilling on land, a pit is usually constructed onsite to hold drill cuttings and extra drilling fluid. Depending on geology and hydrogeology, states might require reserve pits to be lined with geosynthetic or synthetic liners. Often the pit is intended only as a temporary holding vessel for drilling waste before being moved offsite for treatment and disposal; however, at some sites the reserve pit is used as the final disposal site. When used as a disposal method after drilling is completed, the liquid is removed (by suction or by evaporation if in a dry climate) and the solid remnants covered over with dirt. The liquids account for 62 percent of drilling waste by volume. Over two-thirds of the remaining drilling waste solids are disposed of by burying them onsite in the reserve pit (API, 1997).

Solidification

This is a modification of the reserve pit disposal method. When drilling is completed, a mixture of cement, flyash (from coal-fired utility boilers), and/or lime or cement kiln dust is added to the contents of the pit. The liquid in the pit does not necessarily need to be removed. The contents of the pit solidify into a concrete-like block, which immobilizes the heavy metal components. The process adds significantly to the bulk of the waste, but it prevents the mobilization of potential pollutants. In API's 1995 survey, less than 1 percent of drilling waste volumes were disposed of in this manner (API, 1997).

Landfarming or Landspreading

In this procedure, solids from the reserve pit (and potentially other solids from production) are broken up and thinly applied to soil, and tilled to mix the waste and soil. In theory, Volatile components evaporate off, metal ions bind to the clay, and heavy organic components are broken down by biological activity. State agencies do not use consistent terminology in referring to this process: some call it landfarming, others landspreading, and others use different terms. The disposal of solid wastes by spreading them on the land surface can occur either as a one-time application or in multiple applications. One-time application is most likely to be near the well site, and would most likely involve application of material from the reserve pit. Multiple applications of waste are often approved for centralized or commercial operations. In these cases, monitoring of soil constituents (e.g., pH, chlorides, and total hydrocarbons) is required by state agencies and once certain levels are reached, no more wastes may be applied on that site. In either one-time or multiple application operations, fertilizer may be added to enhance biodegradation of hydrocarbons. Land farming operations must be controlled to ensure that the hydrocarbons, salts and metals do not present a threat to groundwater or surface water, and that the hydrocarbon concentration does not inhibit biological activity. Approximately 10 percent of drilling waste solids are disposed of in landfarming operations (API, 1997; Smith, 1999).

Commercial Disposal
Offsite disposal of drilling wastes by commercial enterprises accounts for around 15 percent of drilling waste solids (API, 1997). This commercial disposal takes two formats. In major oil and gas producing areas of the country, dedicated facilities for managing exploration and production wastes exist. These facilities manage drilling waste and some associated waste streams using a range of processes from landfarming to slurry injection of solids to disposal in salt caverns. Drilling wastes from offshore that cannot be discharged (e.g., from oil-based muds) typically are barged to shore and disposed of in these commercial facilities. In areas of the country with less oil and gas activity, municipal or commercial landfills may accept drilling waste and certain other waste streams.

Reuse/Recycling
A growing share of drilling wastes are reused or recycled. It is currently estimated that around 10 percent of total drilling waste volume (solids and liquids) are reused or recycled. The liquids (mud) are reconditioned, with solids and other impurities removed, then used in the drilling of other wells. Because of the high cost of the base material, reuse of oil-based and synthetic-based muds is more common. Drilling waste is also used as landfill cover, roadbed construction, dike stabilization, and plugging and abandonment of other wells.

Associated Waste Disposal

Because associated wastes encompass such a diverse set of waste streams, generalizing about disposal options is difficult. What is appropriate for one stream may not be appropriate for another. Associated waste may be disposed of onsite or offsite. Some waste streams (e.g., waste solvents, unused acids, and painting wastes) are not unique to oil and gas exploration and production. These waste streams must be segregated from other wastes and managed the same as they would be at other industrial facilities. If these wastes exhibit hazardous characteristics they must be disposed of as RCRA hazardous wastes. (See Section VI.B. for more information on whether specific waste streams are exempt or non-exempt from RCRA hazardous waste requirements). Table 4 summarizes the general management of associated wastes across all waste streams.

Table 4: Management of Associated Wastes in 1995

Management Technique	Percent
Underground Injection	58%
Commercial Facility	9%
Evaporation	8%
Recycling/Beneficial Use	8%
Municipal or Commercial Facility	4%
Landspreading	4%
Roadspreading	3%
Crude Oil Reclaimer	2%
Incineration	2%
Other (including hazardous waste disposal)	3%

Gases

Flaring

Although most gas emissions are minimized through prevention, flaring can be used to reduce the impact of gaseous releases that are unavoidable or are too small to warrant the cost of capture. Nearly all drilling rigs and production wells are equipped with a vent and flare to release unusual pressure, and some wells that produce only a small amount of natural gas will flare it when there is no on-site use for the gas (e.g., to power engines) and no pipeline nearby to transport the gas to market. Since natural gas has economic value, flaring it is usually a last resort. Approval of state regulatory agencies is required prior to flaring.

When a gas is flared, it passes through the vent away from the well, and is burned in the presence of a pilot light. Although it is preferable to prevent the emission in the first place, flaring has benefits over simple venting of unburned material. First, by burning the gas, the health and safety risks in the vicinity of the well posed by combustible and poisonous gases like methane and hydrogen sulfide are reduced. Second, flaring reduces the potential contribution to climate change; methane is a much more potent greenhouse gas than carbon dioxide, the primary product of the combustion.

V. WASTE RELEASE PROFILE

This section provides estimates and reported quantities of wastes released from oil and gas extraction industries. Unlike facilities covered by SIC codes 20-39 (manufacturing facilities), oil and gas extraction facilities are not required by the Emergency Planning and Community Right-to-Know Act to report to the Toxic Release Inventory (TRI). Because TRI reporting is not required for the oil and gas extraction industry, other sources of waste release data have been identified for this profile. EPA is considering expanding TRI reporting requirements in the future which may affect industries that are currently not required to report to TRI, such as oil and gas extraction.

Much of the published data on wastes generated at oil and gas extraction facilities is specific to the various oil producing regions of the United States, including onshore and offshore sites. In 1996, EPA developed effluent limitation guidelines for the Coastal Subcategory of the Oil and Gas Extraction Point Source Category. Much of the information presented below was collected as supporting technical information for the guidelines. Additional data reflecting the releases of onshore wells were provided by the Pennsylvania Department of Environmental Protection.

IV.A. Available Data on Produced Water

Produced water is the largest volume waste generated in oil and gas extraction operations. In 1985, the American Petroleum Institute (API) estimated that 20.8 billion barrels of produced water were generated per year by the U.S. onshore oil and gas production industry (Souders, 1998). API conducted an updated survey of the industry in 1995. Based on preliminary results, API estimates current produced water volumes at over 15 billion barrels annually (API, 1997). The decline can be attributed primarily to a 32 percent decrease in oil production over the decade. While natural gas production has risen, natural gas wells produce much less water than do oil wells.

The concentration of contaminants in produced water varies from region to region and depends on the depth of the production zone and the age of the well, among other factors. Since most contaminants found in produced water are naturally occurring, they will vary based on what is present in the subsurface at a particular location. Three tables are presented below that indicate both the relative concentrations of pollutants and the variation that can occur among samples from different locations and product streams. Table 5 presents the results of analyses performed on produced water from **-XX-** Venango County, Pennsylvania. Table 7 presents data from natural gas wells in the Devonian formation of Pennsylvania.

IV.B. Available Data on Drilling Waste for the Oil and Gas Extraction Industry

According to API, 361 million barrels of drilling waste were produced in 1985. Due to a reduction in the number of wells drilled, for 1995 API preliminary findings indicate an estimated 146 million barrels of drilling waste (API, 1997). Drilling fluids (muds and rock cuttings) are the largest sources of drilling wastes. For offshore Gulf of Mexico, EPA estimates from 1993 assumed that 7,861 barrels of drilling fluids and 2,681 barrels of cuttings are discharged overboard per exploratory well, and 5,808 barrels of drilling fluids and 1,628 barrels of cuttings are discharged per development well (USEPA, 1993b). The different volumes are based on the average depths for the two types of wells. These volumes exclude the volumes of any drilling wastes not discharged offshore but transported to shore for disposal. Historically, on average, about 12 percent of the mud and 2 percent of the cuttings fail permit limits (USEPA, 1993b) and thus cannot be discharged. Table 8 below summarizes some of the characteristics of drilling waste in Cook Inlet, Alaska as reported in the *Development Document for Final Effluent Limitations Guidelines and Standards for the Coastal Subcategory of the Oil and Gas Extraction Point Source Category*. Table 9 presents the characteristics of drilling fluids used in the drilling of gas wells into the Devonian formation of Pennsylvania.

Table 8: Cook Inlet Drilling Waste Characteristics	
Waste Characteristics	**Value**
Percent of cuttings in waste drilling fluid	19%
Average density of dry cuttings	980 pounds per barrel
Average density of waste drilling fluid	420 pounds per barrel
Percent of dry solids in waste drilling fluid, by volume	11%
Average density of dry solids in waste drilling fluids	1,025 pounds per barrel

IV.C. Available Data on Miscellaneous and Minor Wastes (Associated Wastes)

Associated wastes are a relatively small but significant category of waste from the oil and gas extraction industry. The term "associated wastes" encompasses a wide range of small volume waste streams essential to oil and gas extraction. Because of their nature, these waste streams are the most likely to contain constituents of concern. Preliminary data from a 1995 survey estimate that 22 million barrels of associated wastes are generated annually (API, 1997). Four particular associated waste streams are discussed below.

IV.C.1. Workover, Treatment, and Completion Fluids

Well maintenance, including workover, treatment, and completion, requires the use of fluids similar to drilling fluid and is the largest miscellaneous source of waste. These fluids may contain a range of chemicals (depending on the maintenance activity undertaken) and naturally occurring materials (i.e., trace metals). Because of the presence of these constituents, the wastes require proper disposal. Onshore, most of these wastes are disposed of through Class II injection wells. Offshore, they may be discharged if they meet the standards in applicable NPDES permits. Otherwise, they are barged to shore and typically disposed of in an injection well. Table 10 presents the relative amounts of liquid and solid wastes from well maintenance operations. Table 11 contains the range and average pollutant concentrations from workover, treatment and completion fluid samples collected from wells in Texas, New Mexico, and Oklahoma.

Table 10: Typical Volumes from Well Treatment, Workover, and Completion Operations

Operation	Type of Material	Estimated Waste Volume (barrels)
Completion and Workover	Completion/Workover Fluids	200 to 1000
	Formation Sand	1 to 50
	Filtration Solids	10 to 50

IV.C.2. Minor Wastes

Smaller waste streams of concern for the oil and gas extraction industry that are discussed below are drainage from drilling and production sites, solids brought to the surface with oil and gas (produced sand, also referred to as tank bottoms), and domestic and sanitary wastes at coastal and offshore sites.

Deck Drainage

Drainage from the production site, or *deck drainage*, is a concern particularly in areas with high precipitation. When water from rainfall or from equipment cleaning comes in contact with oil-coated surfaces, the water becomes contaminated and must be treated and disposed of. The fluids can contain oil from leaking equipment, wastes from cleaning operations, and spilled chemicals from treatment processes. Some locations will collect deck drainage, treat it separately in a skim tank, and discharge it, while others might combine the water with produced water and dispose of the fluids together. In the coastal areas of the Gulf of Mexico, the average facility generates approximately 12,000 barrels of deck drainage each year, but this figure would be significantly lower for facilities in drier climates (EPA, 1996).

Produced Sand

Produced sand consists of the accumulated formation sands and other particles generated during production as well as the slurried particles used in hydraulic fracturing. The waste stream also includes sludges produced from chemical flocculation procedures during produced water treatment. Produced sand typically contains crude oil. The amount will vary based on the handling and separation processes used, but can comprise as much as 19 percent by volume (EPA, 1996). Table 12 presents an analysis of samples of basic sediment taken from pits containing produced water in Pennsylvania. Like for produced water, it should be noted that concentrations will vary for different locations, particularly with respect to Naturally Occurring Radioactive Material (NORM).

Table 12: Pollutant Concentrations in Produced Water Pit Sediments in Pennsylvania

Material	Range (mg/L)	Average (mg/L)	# Samples Above Detection Limits	# Samples Below Detection Limits
Oil and Grease (mg/kg)	640 - 540,000	68,056	49	0

Domestic and Sanitary Wastes

Domestic and sanitary wastes are issues at coastal and offshore sites. Domestic wastes are water from sinks, showers, laundry, and food preparation areas. Domestic waste also includes solid materials such as paper and cardboard which must be disposed of properly. Because domestic waste does not contain fecal coliform bacteria, most NPDES permits allow untreated discharge so long as floating solids are not produced. Sanitary wastes are generated from toilets, and must be either treated or stored for disposal on land. Most offshore facilities treat the wastes through a combination of chlorination and biological digesters or physical maceration, and discharge the waste at the site. Offshore facilities discharge an average of approximately 2,050 barrels of domestic/sanitary waste per facility per year (EPA, 1996).

IV.D. Other Data Sources

The Aerometric Retrieval System (AIRS) is an air pollution data delivery system managed by the Technical Support Division in EPA's Office of Air Quality Planning and Standards (OAQPS), located in Research Triangle Park, North Carolina. The AIRS is a national repository of data related to air pollution monitoring and control. The AIRS contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. Table 13 summarizes annual releases (from the industries for which Sector Notebook Profiles have been prepared) of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), particulate matter, all sizes reported in lieu of PM10 (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Table 13: Air Pollutant Releases by Industry Sector (tons/year)

Industry Sector	CO	NO_2	PM10	PT	SO_2	VOC

POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and employing substitution of toxic chemicals. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

The Pollution Prevention Act of 1990 established a national policy of managing waste through source reduction, which means preventing the generation of waste. The Pollution Prevention Act also established as national policy a hierarchy of waste management options for situations in which source reduction cannot be implemented feasiblely. In the waste management hierarchy, if source reduction is not feasible, the next alternative is recycling of wastes, followed by energy recovery, with waste treatment as a last alternative.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the oil and gas extraction industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be used effectively. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

Waste Management Plans

Pollution prevention opportunities are most effective when they are coordinated in a facility-wide waste management plan. The American Petroleum Institute (API) has published guidelines for waste management plans, in which pollution prevention is an integral part (API, 1991). The ten-step plan involves the following:

1. Company management approval: Management should establish goals for the waste management plan, identify key personnel and resources that are

committed to the plan, and develop a mission statement for its environmental policies.

2. Area Definition: The waste management plan should be designed for a specific area to account for differing regulations and conditions; in most cases, the area would be limited to within one state.

3. Regulatory Analysis: Federal, state and local laws, and landowner and lease agreements, should be evaluated. Based on these evaluations, operating conditions and requirements should be defined.

4. Waste Identification: The source, nature, and quantity of generated wastes within the plan's area should be identified, and a brief description of each type of waste should be written.

5. Waste Classification: Each waste stream should be classified according to its regulatory status, including whether it is a hazardous waste subject to regulation under the Resource Conservation and Recovery Act (RCRA).

6. List and Evaluate Waste Management and Disposal Options: List all waste management practices and determine the environmental acceptability of each option. Consider regulatory restrictions, engineering limitations, economics, and intangible benefits when determining their feasibility.

7. Waste Minimization: Analyze each waste-generating process for opportunities to reduce the volume generated or ways to reuse or recycle wastes. Note that the waste minimization or pollution prevention opportunities that are presented in this section can be used for this step.

8. Select Preferred Waste Management Practices: Choose the preferred management practices identified in Step 6 and incorporate waste minimization options from Step 7 wherever feasible. Specific instructions for implementation should be developed.

9. Prepare and Implement an Area Waste Management Plan: Compile all preferred waste management and minimization practices and write waste management summaries for each waste. Implement the plan on a field level.

10. Review and Update Waste Management Plan: Establish a procedure to periodically review and revise the plan.

V.A. Exploration

Several approaches or technologies can be used by exploration companies to drill more efficiently and to maximize the recovery of oil and natural gas. Oil and gas Exploration is not a waste-intensive activity per se, but efforts made by those involved with exploration can assist in minimizing the number of dry wells that are later drilled.

Drill Site Selection

The volume of drilling waste is directly related to the number of wells drilled. Thus, if fewer wells can be drilled to efficiently produce a discovered reservoir, and if the number of dry holes (wells drilled that do not find commercial quantities of oil or gas) can be minimized, then the total volume of drilling wastes will be reduced. Site selection is a key component of this reduction.

Modeling Software
New computer software is available that converts seismic data into models of subterranean formations. Until 15 years ago, modeling software was limited to large mainframe computers and was inaccessible for small-scale projects. In recent years, software has been created for use on personal computers that can incorporate the various components of remote sensing and logging. Three-dimensional models can now be produced from data that geophysicists previously would have had to analyze manually.

> The U.S. Department of Energy has created several significant computer programs for the oil and gas exploration industry. KINETICS models the chemical reactions that take place over millions of years that lead to the creation of oil and gas, and therefore assists in interpreting whether conditions at a site are favorable for oil. Programs like BOAST and MASTER can be used in wells already in production to model flow patterns to determine the best approach for secondary or tertiary recovery efforts. It is estimated that computer programs such as these can result in an increase of three billion barrels of domestic reserves, generate increased tax revenue for thc government, and reduce the drilling of unnecessary or unproductive wells (U.S. Department of Energy, 1998).

Iodine Sensing
Empirical evidence indicates that unusual concentrations of iodine on the earth's surface are nearly always associated with petroleum that seeps from subsurface formations. Although the process is still in the experimental stage, surface geochemical analyses can be performed to test for the presence of unusually high concentrations of iodine, which in turn indicates the presence of oil or gas. The iodine test can be used in conjunction with

traditional seismic processes to determine favorable drilling sites. Seismic tests measure for geological formations that can potentially contain large amounts of oil or gas, but can't directly detect these products. Conversely, high iodine levels may indicate that petroleum is present, but not that the geological structures are favorable for petroleum extraction. These two processes therefore can be used in conjunction with each other to better determine the probability of being able to produce oil at a given site before a well is drilled.

Drill Site Construction

Storm Water Runoff Impact Reduction

Measures that can be taken to reduce the impacts associated with storm water runoff can apply to all aspects of oil and gas exploration and production. The following are a few examples of such measures.

- Reduce exposure of materials such as drilling fluids and other chemicals stored on-site to rainfall and storm water runoff. This can be accomplished by storing drums and other materials under cover (such as in a trailer, in a shed or covering with tarps).
- Utilize best management practices (BMPs) such as diversion dikes, containment diking, and curbing to reduce exposure of storm water runoff to cuttings and other waste storage areas.
- Utilize BMPs such as sediment traps, swales, and mulching during construction activities (such as during road building or construction of buildings) to reduce loss of sediment and contamination of runoff.
- Insure that adequate materials and equipment are available to contain and control spills in order to prevent contamination of runoff. An effort should be made here to go beyond any SPCC requirements and be prepared to contain and control all spills (of any waste) on site.

Two references that may be useful for oil and gas exploration and production operations to prevent contamination of storm water runoff are 1) Storm Water Management for Industrial Activities - Developing Pollution Prevention Plans and Best Management Practices (EPA 832-R-92-006) and 2) Storm Water Management for Construction Activities - Developing Pollution Prevention Plans and Best Management Practices (EPA 832-R-92-005).

Downhole Analysis

Recently, several technologies have emerged that allow for more accurate analysis of an oil or gas-bearing formation via equipment lowered into the wellbore of producing wells. These either can lead to improvements in production of the well in question, or assist in determining the best location for an additional well. In either case, the technology helps to reduce the number of wells drilled that do not produce.

Formation Analysis Through Old Well Casings
Some of the geophysical logging procedures and tools now in use for new wells were not available for wells drilled 30 years ago. Therefore, data for the zones between the surface and the production zone of the well may be incomplete. Typically the metal casing limits analysis of the formations in these sealed-off zones. New tools have been developed that allow surveying through casing and that may lead to the discovery of production zones that were missed during the original drilling. The procedure can extend the life of old wells and reduce the need for drilling new ones.

Crosswell Seismic Imaging
Geological imaging techniques via the surface are limited by the thousands of feet of rock between the equipment and the potential production zone. As a result, the best resolution obtainable is approximately 50 feet. With crosswell seismic imaging, sound wave generators and receivers are lowered into several wellbores in a production field. Because the waves need to travel a shorter distance between the generator and receivers, the resolution can be as accurate as five feet. This process can be useful in ensuring that additional wells drilled in a producing field are placed accurately.

V.B. Well Development

Drilling

Closed Loop Drilling Fluid System
When drilling a well that will be shallow and likely will not encounter unusual zones of pressure, a closed system for drilling fluids can be used. At a conventional drilling site, drilling fluid is circulated through the wellbore, then deposited in a reserve pit dug next to the well. This pit is open to the atmosphere, and serves to store excess fluid and to separate out contaminants. While the large storage capacity is important for wells that encounter high pressure and therefore might experience fluctuations in the amount of fluid needed, a reserve pit can be the source of considerable costs at a drilling site. The pit itself must be constructed at the beginning of drilling, and must be closed properly when drilling is completed. Also, because the pit may release higher levels of VOCs and can leak liquids into surface or groundwater, there are increased health, environmental, and financial risks.

In a closed-loop drilling fluid system, the reserve pit is replaced with a series of storage tanks. The tanks represent an additional cost, but because they preclude the need for constructing a pit, reduce the amount of environmental releases, and result in more efficient use of drilling fluid, the technology can save the operator money when conditions allow its use.

A small independent operator in Texas was concerned that reserve pits for drilling fluid were increasing waste management costs and exposing it to liability for surface and ground water contamination. Because the wells to be drilled were relatively shallow and few complications were expected, the operator negotiated with the drilling contractors to use a closed-loop fluid system. The operator realized savings of about $10,000 per well because reserve pits were not constructed and waste management costs were reduced. The operator's liability was also reduced (Texas Railroad Commission, 1997).

Pit Design

If the closed-loop drilling system is not used for drilling fluids, another approach may be to use a V-shaped pit instead of the traditional rectangular pit. The open end of the "V" faces the drilling rig and the cross-sectional view resembles a squared-off funnel (about 10 feet deep with the upper 5 feet having slanted walls to a width of about 20 feet). Because the fluid must travel the full length of the pit, this design prevents mud from channeling between the discharge point and the suction point, and reduces the amount of water that needs to be added to maintain the desired fluid characteristics. In addition, because the V-shaped pit is long and narrow, it is easier to construct and leaves a smaller "footprint" at the site.

A company installed a V-shaped reserve pit and compared the costs with those incurred at similar-sized wells using a traditional pit. The company determined that pit construction time was reduced by about 40 percent, water costs for the well were reduced by about 38 percent, and pit liner costs were reduced by about 43 percent. The total cost savings were about $10,800 per well (Texas Railroad Commission, 1999).

Substitution of Drilling Fluid Additives

Some traditional drilling fluid additives are toxic and require extra care in disposal. In response, the drilling fluid industry has developed replacements for some of the more toxic compounds. These include:

- Replacement of chrome lignosulfonate dispersants with chrome-free lignosulfonates and polysaccharide polymers.

- Use of amines instead of pentachlorophenols and paraformaldehyde as biocides.

- Lubrication with mineral oil and lubra-beads instead of diesel oil.

Substitutions such as those described above can minimize the toxicity of drilling wastes and reduce the risks and costs associated with drilling fluid disposal.

Material Balance and Mud System Monitoring
Monitoring devices used at various points in the drilling fluid circulation system may be used to check for the decrease of fluid levels or other changes in fluid characteristics. Such devices may reduce the need for the addition of water and additives to the fluid, thereby reducing the costs and waste associated with drilling fluid.

Removal of Solids from Drilling Fluid
Careful removal of drill cuttings and other contaminating solids can reduce the need to dilute or replace drilling fluid. Furthermore, if the separated solids are treated thoroughly to remove moisture, the weight of waste can be significantly reduced. In addition to using shale shakers, which are always used to remove rocks and larger fragments, drilling rigs can reduce waste by including several optional components in their mud treatment systems. Desanders and desilters separate increasingly smaller particles. Centrifuges remove the smallest suspended pieces. Finally, mud cleaners break oil-water emulsions and remove many dissolved components. If these devices are in optimal working condition, the drilling mud can be nearly free of suspended materials, and the solid waste can be less than 30 percent moisture by weight.

Polycrystalline Diamond Compact (PDC) Drill Bit
Pulling the drill string to replace the drill bit is one of the more inefficient and potentially dangerous procedures in drilling. Quite a bit of time and energy can be wasted in pulling the entire drill string to the surface and lowering it back into the wellbore. In addition, it is when the drill string is being raised and lowered that well blowouts are an increased risk if not properly done. It is therefore desirable for both efficiency and blowout prevention to minimize drill bit replacement.

PDC bits have been viable commercially for about a decade, and are the most durable bits available. The bit is primarily steel with interlocked diamond studs. The bits typically last between 230 and 260 drilling hours, but have lasted over 1,000 hours without replacement. Because of their durability, diamond bits account for one-third of the drill bit market, and can save drilling companies as much as $1 million per well (U.S. Department of Energy, 1998).

Downhole Drilling Telemetry
Traditionally, drillers have determined the position of the drill bit by removing the drill string from the well, lowering an instrument into the

wellbore, retrieving the instrument, then lowering the drill string back into the wellbore. This process is inefficient and increases the risk of a blowout.

The Department of Energy has helped to develop a wireless system that sends pulses through the drilling mud from the drill bit to the surface, in a process called *mudpulse telemetry*. The technology presents several benefits for wells in which its use is practical: data can be collected during drilling, the data are more complete than those from periodic measurements because the pulsing can occur continuously, and advance warnings can be received of impending drill hazards. Without considering the benefit of decreased environmental and health risks, mudpulse technology saves the industry over $400 million per year.

Horizontal Drilling

Oil and natural gas bearing formations typically have a small vertical profile (i.e., are confined to a narrow range of depth), but are spread over a large horizontal area. As a result, wellbores that intersect the oil-producing formation at an angle can drain more of the formation and reduce the need to drill additional wells compared to purely vertical wells.

Horizontal drilling is costly, because it requires advanced geological sensing equipment and constant attention to the placement of the drill bit. However, the increased cost is often more than offset by increased production and the reduced need for drilling multiple wells.

In the Dundee Formation of Michigan, as much as 85 percent of the known oil remained in the formation after many years of production. Many wells were on the verge of being plugged, with production near five barrels of oil per day per well. A DOE co-sponsored project drilled a horizontal well in the formation, which produced 100 barrels per day, and had estimated recoverable reserves of 200,000 barrels of oil. The program attracted other well developers, and 20 to 30 additional horizontal wells are being drilled in the formation. It is estimated that the application of horizontal drilling to this formation may yield an additional 80 to 100 million barrels of oil (Department of Energy, 1998).

Reuse of Drilling Fluids

Drilling fluid is often disposed of when a well is completed, and fresh fluid used for any adjacent wells. Filtration processes have allowed drilling fluid to be reconditioned, so that it can be used for multiple wells before being discarded. Other possible uses for used drilling fluids are to plug unproductive wells or to spud in new wells. Reuse of oil-based and synthetic-based drilling fluids to drill additional wells is common because of the high cost of the base fluids.

One drilling company in Alaska sought to filter and recondition its drilling fluid in order to use it for several wells. The fluid was used on average over two times, resulting in a decrease of fluid used from 50,000 barrels of fluid to 22,000 barrels. Because the cost of filtering is only six percent of the cost of purchasing new fluid, the fluid treatment system reduced the fluid costs for this operator from $7 million to $3.25 million (SAIC, 1997).

Preventive Maintenance and Leak Containment

Engines, tanks, pumps and other equipment used in the drilling process may leak lubricating oil or fuel. Soil contamination and waste generation may be avoided and valuable chemicals may be recovered by performing regular preventive maintenance and installing leak containment devices. Examples of preventive maintenance include routine checks and replacement of leaking valves, hoses, or connections, while containment measures may include the installation of drip pans underneath engines, containers, valves, and other potential sources of leaks. These practices and devices are important pollution prevention options at production and maintenance operations as well as at drilling sites.

Inventory Control

Facilities may maintain an excess on-site volume of chemicals and materials. This may lead to unnecessary regulatory compliance concerns, operating costs, and waste generation. By tracking the inventory of chemicals and materials, particularly with the use of computer programs, an operator may use materials more efficiently and reduce waste generation. In addition, an operator may negotiate with vendors to accept empty and partially-filled containers for reclamation and reuse, because commercial chemical products that are returned to a vendor or manufacturer may not be considered solid wastes.

An operation encompassing drilling, gas production, and compression activities determined that its on-site supply of chemicals was excessive and that much of its hazardous waste generation was unnecessary. The company made several changes: it identified alternative, less toxic chemicals; eliminated the use of organic solvents; identified processes for which individual chemicals could be used in multiple situations; established a purchasing procedure in which a new chemical is purchased only after evaluating information including material safety data sheets (MSDSs) and other information sources supplied by vendors; and tracked all purchased chemicals to ensure efficient usage. As a result of the program, the company eliminated the use of 32 unnecessary chemicals and products, reduced regulatory concerns, minimized waste disposal costs, and achieved the cooperation of vendors, who worked to supply the company with satisfactory chemicals (Texas Railroad Commission, 1999).

Completion

Lead-Free Pipe Dope

Pipe dope is used in drill string connections. The American Petroleum Institute (API)-specified pipe dope contains approximately 30 percent lead, which raises human health and environmental concerns. New lead-free, biodegradable pipe dopes are now available, however, which may be used when conditions do not require the use of the API-specified material. In particular, the use of pipe dope on thread protectors may allow for the recycling of thread protectors with fewer regulatory concerns.

Cementing "On-the-Fly"

When well casing is cemented in, the cement used is often pre-mixed with additives to specification. There may be a substantial surplus of unused, pre-mixed cement if the quantity required for the project was overestimated. One solution used by some service companies is to mix neat (concentrated) cement with additives on-the-fly, through the use of automatic density control systems. The mixing process can be stopped as soon as the cementing job is complete, and the unused raw materials can be used at a later cementing job rather than disposed of as waste. Cementing on-the-fly is becoming common practice.

V.C. Petroleum Production

Produced Water Management

Produced water constitutes the vast majority of oil and gas extraction waste, and traditionally the volume has been fixed and unavoidable. However, there have been developments that might help to reduce the amount of produced water that is brought to the surface, and reduce the wastes associated with treating produced water that does reach the surface.

Downhole Produced Water Separation

A new procedure made possible by the miniaturization of motors is the separating and pumping of produced water downhole, without bringing it to the surface. There are three significant variations, but in each case excess water is separated from the desired product in the wellbore and injected into another geological formation, typically below the production zone.

In formations where oil and water are mostly separate, two perforations in the well can be made; oil is removed through one and transported to the surface, and water is removed through the other perforation and injected in the disposal zone. It should be noted that the water disposal system must be monitored to ensure that oil is not lost.

In another method, a hydrocyclone is used downhole to separate free water from any oil- or gas-containing fluid by centrifugal force. The water is injected into a disposal zone, and the product is pumped to the surface.

Finally, in gas wells, simple gravity can be used to remove a substantial amount of water. Gas rises to the surface of the separation device, and water is injected from the bottom into a lower disposal zone.

With these methods, some water is always still brought to the surface. Also, the technology is still in development. Nevertheless, downhole separation can be an effective and economically attractive method of reducing produced water volumes.

Produced Water Filter Management

Many wells employ filters to remove some waste from produced water before the water is injected into an underground well. Because the water may contain varying amounts of filterable components, the filters must be changed regularly in order to prevent the system from backing up. Many wells replace the filters at fixed intervals; for example, twice a month. However, it is possible to reduce the frequency of filter changes by measuring the difference in pressure between the input and output sides of the filter, and only changing the filter when a certain pressure is reached. Costs are incurred when valves are installed, but the savings involved in labor, filters, and filter disposal often offset the cost of valve installation.

> A small independent operator wanted to reduce the number of filters used for its produced water injection system. Previously, the operator had changed the filters twice a month at its 36 injection wells, at a cost of $4,148 per year (1,700 filters at $2.44 per filter). The operator installed valves on the filter units, at a total cost of $1,800. The following year, the operator only generated 28 waste filters, and saved about $4,000 per year in filter purchases, plus additional labor time and waste management costs (Texas Railroad Commission, 1997).

Natural Gas Conditioning

Reducing Glycol Circulation Rates

Glycol is used to remove water from natural gas. However, methane and VOCs are removed as well, in proportion to the amount of glycol circulated through the system. These methane and VOC components are removed from the glycol during a reconditioning process, and may be either returned to the production stream or vented to the atmosphere.

Research by the EPA voluntary industry partnership Natural Gas STAR has indicated that operators often maintain a circulation rate that is at least two times higher than is needed to attain mandated water content levels. Therefore, it is desirable to perform calculations to determine the minimum circulation rate needed. Savings can be realized on several fronts:

- Less salable methane lost to the atmosphere
- Less glycol needed
- Improved dehydrator unit efficiency
- Lower fuel pump use.

The potential savings for a dehydrator unit can range from $260 to $26,280 per year (Natural Gas STAR, 1997).

Adjusting Pneumatic Devices

For both oil and gas field operations pressurized natural gas is used regularly in pneumatic devices to regulate pressure, control valves, and equilibrate liquid levels. Leaks and releases from this practice, particularly from inefficient or "high-bleed" devices, are the single largest source of methane emissions by the industry. Methane is released at the estimated rate of 31 billion cubic feet (Bcf) per year from pneumatic devices. Several strategies exist to reduce such emissions, including the replacement of high-bleed devices with equivalent low-bleed ones and maintenance of existing devices to replace leaking seals and tune valves. Natural Gas STAR estimates that partners of the program have saved 11.2 Bcf to date through improvements to pneumatic devices, saving approximately $22.4 million. For most of the improvements, the payback period is between six months and a year (Natural Gas STAR, 1997).

Energy-Efficient Production

Automatic Casing Swab

In wells where natural formation pressure is insufficient to lift the product to the surface, it might be possible to install a small device downhole to delay the purchase of costly pumping or injection equipment. The Automatic Casing Swab (ACS) seals off the production zone of the well, which causes pressure to build up in the formation. At a threshold pressure, the ACS opens, and product flows to the surface without mechanical assistance. When the flow slows and pressure decreases, the ACS closes until pressure increases again. The device was created by the Sandia National Laboratories under a grant from DOE, and as of the end of 1997 has been applied to 350 wells. These wells are producing more than 3.5 million cubic feet of natural gas per year that otherwise would have been uneconomical to extract. The device may also lead to decreased energy consumption in other wells in situations where it reduces the need for energy-intensive mechanical pumps.

Solid Waste Reduction

Oily Sludge Minimization

When oil first is brought to the surface, fine particles, oil, and water form a stable sludge that settles out in storage tanks and separation equipment. There are two approaches to minimizing the loss of product that occurs when oil becomes entrained in the sludge: preventing the formation of sludge and treating the sludge to recover the oil.

Two significant methods can minimize the formation of sludge in a storage tank at a production site. First, recirculating pumps can be installed in tanks. By increasing circulation, heavier components remain in suspension longer and do not collect on the bottom of the tanks as quickly. Second, eliminating air contact with oil in the tanks can reduce the formation of sludge. Oxygen can play a role in the formation of sludge, so minimizing the introduction of atmospheric oxygen can reduce sludge levels. Furthermore, reducing contact to the atmosphere can minimize emissions of VOCs.

In many locations, recyclers can treat sludge to remove oil at a crude oil reclamation plant. Crude oil reclamation serves two purposes; the extracted oil can be sold, and disposal costs for sludge is minimized because much of the liquid component is removed. In addition, salable material that has solidified, e.g., paraffin, may be reclaimed during this process. The separation process typically is performed with the use of centrifuges, heat, or filters. One example is a filter press, which presses solids into a cake and extracts oil and water as an aqueous filtrate. The water and oil are then separated further.

A facility on the West Coast installed a filter press to retrieve oil from sludge and reduce disposal costs. The press reduced the volume of waste from 44,900 to 13,500 barrels per year, a reduction of 70 percent. Disposal costs were reduced by $564,200 per year. Approximately 81 percent of the oil in the sludge was recovered, so that at a price of $15 per barrel, the recovered oil represented additional revenues of $108,000 per year. Based on a capital cost for the press of approximately $3,000,000 and operating costs of $400,000 per year, the system is saving approximately $272,000 per year and the capital cost has a payoff period of about 3.5 years.

V.D. Maintenance

Maintenance procedures, particularly workovers, may be a source of potential pollutants for industry including acids, VOCs, and solutions with high concentrations of salts and metals. The following opportunities describe steps that can minimize the need for workovers, or help notify operators when maintenance is necessary to limit releases.

Preplanning

Careful preplanning efforts undertaken prior to a workover may reduce the amount of materials necessary at the site, and therefore may reduce waste and the chance of spilling. For example, by estimating the amount of acid required for acid stimulation based on the known reservoir conditions, the transportation, storage, and disposal of excess acid may be reduced.

Paraffin and Scale Accumulation Prevention

The buildup of paraffins in production equipment, particularly in older wells, is a serious concern, and when untreated, paraffin buildups can damage pumping equipment and rupture flowlines. Therefore, it is desirable to minimize the buildup of paraffins. One possible solution is the installation of a magnetic fluid conditioner (MFC), which creates a strong permanent magnetic field around the pump. This magnetic field alters the solubility and viscosity of crude oil, so that paraffin, scale, and other contaminants do not precipitate in the flowlines. The device requires a significant capital investment, must be custom-made for each well, and is not always successful. but the reduced frequency of maintenance and the reduced risk of flowline rupture (and the associated mitigation costs) can make an MFC a wise choice for wells with paraffin and scale buildup problems.

A small independent operator was suffering from damaged pumping equipment and ruptured flowlines as a result of paraffin buildup, and had to treat the well every ten days with solvent/hot oil to remove the deposits. The operator installed an MFC in the well for $5,000. Seven weeks later for an unrelated reason, the operator pulled the tubing from the well, and minimal paraffin deposition was observed. The investment was recovered in six months due to reduced maintenance costs, and because flow had improved, revenue increased as well (Texas Railroad Commission, 1997).

High-level alarm

A helpful device for preventing releases and loss of product is an alarm and automatic shut-off that shuts-in production equipment when an irregularity is detected. The equipment can only be restarted manually, to ensure that the problem is addressed. A facility-wide alarm is particularly important when the operator is offsite and the well is only monitored periodically.

Microbially-Treated Produced Water

The separation of oil from produced water is not completely efficient; oil concentrations in produced water can be at least 10 ppm. This oil can clog disposal wells and increase electricity costs because injection pumps must contend with increased pressure in these clogged wells. If oil-eating microbes are introduced to the produced water, oil content can be reduced. injection wells may become clogged less frequently (thereby reducing workover costs), and electricity costs are reduced because the pump can work more efficiently.

> A small operator wanted to reduce the frequency of workovers and trim electricity costs due to oil clogging in two injection wells. For approximately $150 per month for the two wells, the company added oil-scavenging microbes to the produced water. The operator realized a reduction of $400 per month in electricity costs due to the reduced pressure in the injection well, for a net savings of $250 per month. The procedure also has helped to minimize the number of injection well workovers.

Coiled Tubing Units

As mentioned in previous sections, pulling the drill string or production tubing can increase the chance of a blowout or other spills. Coiled tubing units allow workovers to be performed while keeping production tubing in place. By using coiled tubing units during workovers, the use of a workover rig and the pulling of production tubing are avoided.

Product Substitution

Many materials used in the workover process, particularly solvents used for cleaning and for paints, are classified as hazardous wastes when spent. Alternatives are available that are not classified as hazardous waste, and which are safer for the environment and present fewer regulatory concerns. Alternatives for cleaning solvents include citrus-based cleaning compounds and steam, or a substitute for the solvent Varsol (also called petroleum spirits or Stoddard solvent) is available as a "high flash point Varsol," thereby sufficiently reducing the solution's ignitability hazardous waste characteristic. For solvent-based paints, a common substitution is the use of water-based paints, which reduce or eliminate the need for solvents and organic thinners.

Chemical Metering or Dosing Systems

The dispensing of some workover fluids, such as corrosion inhibitors, by an occasional bulk addition can result in the inefficient use of the chemical and an inadequate workover job. As an alternative, an automatic dosing system that releases a small, continuous stream of fluid can reduce the amount of needed fluid and may improve workover results.

VI. SUMMARY OF FEDERAL STATUTES AND REGULATIONS

This section discusses the federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section VI.A contains a general overview of major statutes
- Section VI.B contains a list of regulations specific to this industry
- Section VI.C contains a list of pending and proposed regulatory requirements.

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information, readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Clean Water Act

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act (CWA), is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA are classified as either "toxic" pollutants; "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; or "non-conventional" pollutants, including any pollutant not identified as either conventional or priority.

The CWA regulates both direct and "indirect" dischargers (those who discharge to publicly owned treatment works). The National Pollutant Discharge Elimination System (NPDES) permitting program (CWA section 402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized state (EPA has authorized 43 states and 1 territory to administer the NPDES program), contain industry-specific, technology-based and water quality-based limits and establish pollutant monitoring and reporting requirements. A facility that proposes to discharge into the nation's waters must obtain a permit prior to initiating a discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

Water quality-based discharge limits are based on federal or state water quality criteria or standards, that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technology-based standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from state to state, and site to site, depending on the use classification of the receiving body of water. Most states follow EPA guidelines which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges
In 1987 the CWA was amended to require EPA to establish a program to address storm water discharges. In response, EPA promulgated NPDES permitting regulations for storm water discharges. These regulations require that facilities with the following types of storm water discharges, among others, apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the state determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR Part 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 29-petroleum refining; SIC 311-leather tanning and finishing; SIC 32 (except 323)-stone, clay, glass, and concrete; SIC 33-primary metals; SIC 3441-fabricated structural metal; and SIC 373-ship and boat building and repairing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels. and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment: SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly owned treatment works (POTW). The national pretreatment program (CWA section 307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under section 307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a state is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than federal standards.

Wetlands

Wetlands, commonly called swamps, marshes, fens, bogs, vernal pools, playas, and prairie potholes, are a subset of "waters of the United States," as defined in Section 404 of the CWA. The placement of dredge and fill material into wetlands and other water bodies (i.e., waters of the United States) is regulated by the U.S. Army Corps of Engineers (Corps) under 33 CFR Part 328. The Corps regulates wetlands by administering the CWA Section 404 permit program for activities that impact wetlands. EPA's authority under Section 404 includes veto power of Corps permits, authority to interpret statutory exemptions and jurisdiction, enforcement actions, and delegating the Section 404 program to the states.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water Resource Center, at (202) 260-7786.

Oil Pollution Prevention Regulation

Section 311(b) of the CWA prohibits the discharge of oil. in such quantities as may be harmful, into the navigable waters of the United States and adjoining shorelines. The EPA Discharge of Oil regulation, 40 CFR Part 110, provides information regarding these discharges. The Oil Pollution Prevention regulation, 40 CFR Part 112, under the authority of Section 311(j) of the CWA, requires regulated facilities to prepare and implement Spill Prevention Control and Countermeasure (SPCC) plans. The intent of a SPCC plan is to prevent the discharge of oil from onshore and offshore non-transportation-related facilities. In 1990 Congress passed the Oil Pollution Act which amended Section 311(j) of the CWA to require facilities that because of their location could reasonably be expected to cause "substantial harm" to the environment by a discharge of oil to develop and implement Facility Response Plans (FRP). The intent of a FRP is to provide for planned responses to discharges of oil.

A facility is SPCC-regulated if the facility, due to its location, could reasonably be expected to discharge oil into or upon the navigable waters of the United States or adjoining shorelines, and the facility meets one of the following criteria regarding oil storage: (1) the capacity of any aboveground storage tank exceeds 660 gallons, or (2) the total aboveground storage capacity exceeds 1,320 gallons, or (3) the underground storage capacity exceeds 42,000 gallons. 40 CFR Part 112.7 contains the format and content requirements for a SPCC plan. In New Jersey, SPCC plans can be combined with DPCC plans, required by the state, provided there is an appropriate cross-reference index to the requirements of both regulations at the front of the plan.

According to the FRP regulation, a facility can cause "substantial harm" if it meets one of the following criteria: (1) the facility has a total oil storage capacity greater than or equal to 42,000 gallons and transfers oil over water to or from vessels; or (2) the facility has a total oil storage capacity greater than or equal to 1 million gallons and meets any one of the following conditions: (i) does not have adequate secondary containment, (ii) a discharge could cause "injury" to fish and wildlife and sensitive environments, (iii) shut down a public drinking water intake, or (iv) has had a reportable oil spill greater than or equal to 10,000 gallons in the past 5 years. Appendix F of 40 CFR Part 112 contains the format and content requirements for a FRP. FRPs that meet EPA's requirements can be combined with U.S. Coast Guard FRPs or other contingency plans, provided there is an appropriate cross-reference index to the requirements of all applicable regulations at the front of the plan.

For additional information regarding SPCC plans, contact EPA's RCRA, Superfund, and EPCRA Hotline, at (800) 424-9346. Additional documents *and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.*

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint federal-state system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of fluid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized states enforce the primary drinking water standards, which are contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set generally as close to MCLGs as possible, considering cost and feasibility of attainment.

Part C of the SDWA mandates EPA to protect underground sources of drinking water from inadequate injection practices. EPA has published regulations codified in 40 CFR Parts 144 to 148 to comply with this mandate. The Underground Injection Control (UIC) regulations break down injection wells into five different types, depending on the fluid injected and the formation that receives it. The regulations also include construction. monitoring, testing, and operating requirements for injection well operators. All injection wells have to be authorized by permit or by rule depending on their potential to threaten Underground Sources of Drinking Water (USDW). RCRA also regulates hazardous waste injection wells and a UIC permit is considered to meet the requirements of a RCRA permit. EPA has authorized delegation of the UIC for all wells in 35 states, implements the program in 10 states and all Indian lands, and shares responsibility with 5 states.

The SDWA also provides for a federally-implemented Sole Source Aquifer program, which prohibits federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area. and for a state-implemented Wellhead Protection program. designed to protect drinking water wells and drinking water recharge areas.

The SDWA Amendments of 1996 require states to develop and implement source water assessment programs (SWAPs) to analyze existing and potential threats to the quality of the public drinking water throughout the state. Every state is required to submit a program to EPA and to complete all assessments within 3 ½ years of EPA approval of the program. SWAPs include: (1) delineating the source water protection area, (2) conducting a contaminant source inventory, (3) determining the susceptibility of the public water supply to contamination from the inventories sources, and (4) releasing the results of the assessments to the public.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., EST, excluding federal holidays. Visit the website at www.epa.gov/ogwdw for additional material.

Resource Conservation and Recovery Act

The Solid Waste Disposal Act (SWDA), as amended by the Resource Conservation and Recovery Act (RCRA) of 1976, addresses solid and hazardous waste management activities. The Act is commonly referred to as RCRA. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (discarded commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitability, corrosivity, reactivity, or toxicity and designated with the code "D").

Entities that generate hazardous waste are subject to waste accumulation, manifesting, and recordkeeping standards. A hazardous waste facility may accumulate hazardous waste for up to 90 days (or 180 days depending on the amount generated per month) without a permit or interim status. Generators may also treat hazardous waste in accumulation tanks or containers (in accordance with the requirements of 40 CFR Part 262.34) without a permit or interim status. Facilities that treat, store, or dispose of hazardous waste are generally required to obtain a RCRA permit.

Subtitle C permits are required for treatment, storage, or disposal facilities. These permits contain general facility standards such as contingency plans, emergency procedures, recordkeeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Subparts I and S) for conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA treatment, storage, or disposal facilities.

Although RCRA is a federal statute, many states implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 47 of the 50 states and two U.S. territories. Delegation has not been given to Alaska, Hawaii, or Iowa.

Most RCRA requirements are not industry specific but apply to any company that generates, transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Criteria for Classification of Solid Waste Disposal Facilities and Practices** (40 CFR Part 257) establishes the criteria for determining which solid waste disposal facilities and practices pose a reasonable probability of adverse effects on health or the environment. The criteria were adopted to ensure non-municipal, non-hazardous waste disposal units that receive conditionally exempt small quantity generator waste do not present risks to human health and environment.

- **Criteria for Municipal Solid Waste Landfills** (40 CFR Part 258) establishes minimum national criteria for all municipal solid waste landfill units, including those that are used to dispose of sewage sludge.

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) establishes the standard to determine whether the material in question is considered a solid waste and, if so, whether it is a hazardous waste or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an EPA identification number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and recordkeeping and reporting requirements. Generators can accumulate hazardous waste on-site for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) (40 CFR Part 268) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs program, materials must meet treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil Management Standards** (40 CFR Part 279) impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil processor, re-refiner, burner, or marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- RCRA contains unit-specific standards for all units used to store, treat, or dispose of hazardous waste, including **Tanks and Containers**. Tanks and containers used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including large quantity generators accumulating waste prior to shipment offsite.

- **Underground Storage Tanks** (USTs) containing petroleum products (including gasoline, diesel, and used oil) and hazardous substances are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also includes upgrade requirements for existing tanks that were to be met by December 22, 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and, in some cases, restrict the type of waste that may be burned.

EPA's RCRA, Superfund, and EPCRA Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. Additional documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The RCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response or remediation costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for the Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA hazardous substance release reporting regulations (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which equals or exceeds a reportable quantity. Reportable quantities are listed in 40 CFR Part 302.4. A release report may trigger a response by EPA or by one or more federal or state emergency response authorities.

EPA implements hazardous substance responses according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for cleanups. The National Priorities List (NPL) currently includes approximately 1,300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct cleanups and encourages community involvement throughout the Superfund response process.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. Documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The Superfund Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Emergency Planning And Community Right-To-Know Act

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created the Emergency Planning and Community Right-to-Know Act (EPCRA, also known as SARA Title III), a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by state and local governments. Under EPCRA, states establish State Emergency Response Commissions (SERCs), responsible for coordinating certain emergency

response activities and for appointing Local Emergency Planning Committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA section 302** requires facilities to notify the SERC and LEPC of the presence of any extremely hazardous substance at the facility in an amount in excess of the established threshold planning quantity. The list of extremely hazardous substances and their threshold planning quantities is found at 40 CFR Part 355, Appendices A and B.

- **EPCRA section 303** requires that each LEPC develop an emergency plan. The plan must contain (but is not limited to) the identification of facilities within the planning district, likely routes for transporting extremely hazardous substances, a description of the methods and procedures to be followed by facility owners and operators, and the designation of community and facility emergency response coordinators.

- **EPCRA section 304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance (defined at 40 CFR Part 302) or an EPCRA extremely hazardous substance.

- **EPCRA sections 311 and 312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDSs and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA section 313** requires certain covered facilities, including SIC codes 20 through 39 and, the seven industry groups added in 1997 (including metal mining (SIC code 10, except for SIC codes 1011, 1081, and 1094), coal mining (SIC code 12, except for SIC code 1241 and extraction activities), electrical utilities that combust coal and/or oil (SIC codes 4911, 4931, and 4939), RCRA Subtitle C hazardous waste treatment and disposal facilities (SIC code 4953), chemicals and allied products wholesale distributors (SIC code 5169), petroleum bulk plants and terminals (SIC code 5171), and solvent recovery services (SIC code 7389)), which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media. EPA maintains the data reported in a publically accessible database known as the Toxics Release Inventory (TRI).

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's RCRA, Superfund and EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. Documents and resources can be obtained from the hotline's homepage at www.epa.gov/epaoswer/hotline. The EPCRA Hotline operates weekdays from 9:00 a.m. to 6:00 p.m., EST, excluding federal holidays.

Clean Air Act

The Clean Air Act (CAA) and its amendments are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the states to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAA, many facilities are required to obtain operating permits that consolidate their air emission requirements. State and local governments oversee, manage, and enforce many of the requirements of the CAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are designated as attainment areas; those that do not meet NAAQSs are designated as non-attainment areas. Under section 110 and other provisions of the CAA, each state must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet federal air quality standards. Revised NAAQSs for particulates and ozone were proposed in 1996 and will become effective in 2001.

Title I also authorizes EPA to establish New Source Performance Standards (NSPS), which are nationally uniform emission standards for new and modified stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source (see 40 CFR Part 60).

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented toward controlling specific hazardous air pollutants (HAPs). Section 112(c) of the CAA further directs EPA to develop a list of sources that emit any of 188 HAPs, and to develop regulations for these categories of sources. To date EPA has listed 185 source categories and developed a schedule for the establishment of emission standards. The emission standards are being developed for both new and existing sources based on "maximum achievable control technology" (MACT). The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV-A establishes a sulfur dioxide and nitrogen oxides emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances that are set below previous levels of sulfur dioxide releases.

Title V of the CAA establishes an operating permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States have developed the permit programs in accordance with guidance and regulations from EPA. Once a state program is approved by EPA, permits are issued and monitored by that state.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restricting their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), were phased out (except for essential uses) in 1996.

EPA's Clean Air Technology Center, at (919) 541-0800 or www.epa.gov/ttn/catc, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996 *or www.epa.gov/ozone, provides general information about regulations promulgated under Title VI of the CAA; EPA's EPCRA Hotline, at (800) 535-0202 or www.epa.gov/epaoswer/hotline, answers questions about accidental release prevention under CAA section112(r); and information on air toxics can be accessed through the Unified Air Toxics website at www.epa.gov/ttn/uatw. In addition, the Clean Air Technology Center's website includes recent CAA rules, EPA guidance documents, and updates of EPA activities.*

Federal Insecticide, Fungicide, and Rodenticide Act

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) was first passed in 1947, and amended numerous times, most recently by the Food Quality Protection Act (FQPA) of 1996. FIFRA provides EPA with the authority to oversee, among other things, the registration, distribution, sale and use of pesticides. The Act applies to all types of pesticides, including insecticides, herbicides, fungicides, rodenticides and antimicrobials. FIFRA covers both intrastate and interstate commerce.

Establishment Registration
Section 7 of FIFRA requires that establishments producing pesticides, or active ingredients used in producing a pesticide subject to FIFRA, register with EPA. Registered establishments must report the types and amounts of pesticides and active ingredients they produce. The Act also provides EPA inspection authority and enables the agency to take enforcement actions against facilities that are not in compliance with FIFRA.

Product Registration
Under section 3 of FIFRA, all pesticides (with few exceptions) sold or distributed in the U.S. must be registered by EPA. Pesticide registration is very specific and generally allows use of the product only as specified on the label. Each registration specifies the use site i.e., where the product may be used and the amount that may be applied. The person who seeks to register the pesticide must file an application for registration. The application process often requires either the citation or submission of extensive environmental, health and safety data.

To register a pesticide, the EPA Administrator must make a number of findings, one of which is that the pesticide, when used in accordance with widespread and commonly recognized practice, will not generally cause unreasonable adverse effects on the environment.

FIFRA defines "unreasonable adverse effects on the environment" as "(1) any unreasonable risk to man or the environment, taking into account the economic, social, and environmental costs and benefits of the use of the pesticide, or (2) a human dietary risk from residues that result from a use of

R0076712

a pesticide in or on any food inconsistent with the standard under section 408 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 346a)."

Under FIFRA section 6(a)(2), after a pesticide is registered, the registrant must also notify EPA of any additional facts and information concerning unreasonable adverse environmental effects of the pesticide. Also, if EPA determines that additional data are needed to support a registered pesticide, registrants may be requested to provide additional data. If EPA determines that the registrant(s) did not comply with their request for more information, the registration can be suspended under FIFRA section 3(c)(2)(B).

Use Restrictions

As a part of the pesticide registration, EPA must classify the product for general use, restricted use, or general for some uses and restricted for others (Miller, 1993). For pesticides that may cause unreasonable adverse effects on the environment, including injury to the applicator, EPA may require that the pesticide be applied either by or under the direct supervision of a certified applicator.

Reregistration

Due to concerns that much of the safety data underlying pesticide registrations becomes outdated and inadequate, in addition to providing that registrations be reviewed every 15 years, FIFRA requires EPA to reregister all pesticides that were registered prior to 1984 (section 4). After reviewing existing data, EPA may approve the reregistration, request additional data to support the registration, cancel, or suspend the pesticide.

Tolerances and Exemptions

A tolerance is the maximum amount of pesticide residue that can be on a raw product and still be considered safe. Before EPA can register a pesticide that is used on raw agricultural products, it must grant a tolerance or exemption from a tolerance (40 CFR Parts 163.10 through 163.12). Under the Federal Food, Drug, and Cosmetic Act (FFDCA), a raw agricultural product is deemed unsafe if it contains a pesticide residue, unless the residue is within the limits of a tolerance established by EPA or is exempt from the requirement.

Cancellation and Suspension

EPA can cancel a registration if it is determined that the pesticide or its labeling does not comply with the requirements of FIFRA or causes unreasonable adverse effects on the environment (Haugrud, 1993).

In cases where EPA believes that an "imminent hazard" would exist if a pesticide were to continue to be used through the cancellation proceedings, EPA may suspend the pesticide registration through an order and thereby halt the sale, distribution, and usage of the pesticide. An "imminent hazard" is defined as an unreasonable adverse effect on the environment or an unreasonable hazard to the survival of a threatened or endangered species that would be the likely result of allowing continued use of a pesticide during a cancellation process.

When EPA believes an emergency exists that does not permit a hearing to be held prior to suspending, EPA can issue an emergency order which makes the suspension immediately effective.

Imports and Exports

Under FIFRA section 17(a), pesticides not registered in the U.S. and intended solely for export are not required to be registered provided that the exporter obtains and submits to EPA, prior to export, a statement from the foreign purchaser acknowledging that the purchaser is aware that the product is not registered in the United States and cannot be sold for use there. EPA sends these statements to the government of the importing country. FIFRA sets forth additional requirements that must be met by pesticides intended solely for export. The enforcement policy for exports is codified at 40 CFR Parts 168.65, 168.75, and 168.85.

Under FIFRA section 17(c), imported pesticides and devices must comply with U.S. pesticide law. Except where exempted by regulation or statute, imported pesticides must be registered. FIFRA section 17(c) requires that EPA be notified of the arrival of imported pesticides and devices. This is accomplished through the Notice of Arrival (NOA) (EPA Form 3540-1), which is filled out by the importer prior to importation and submitted to the EPA regional office applicable to the intended port of entry. U.S. Customs regulations prohibit the importation of pesticides without a completed NOA. The EPA-reviewed and signed form is returned to the importer for presentation to U.S. Customs when the shipment arrives in the U.S. NOA forms can be obtained from contacts in the EPA Regional Offices or *www.epa.gov/oppfead1/international/noalist.htm*.

Additional information on FIFRA and the regulation of pesticides can be obtained from a variety of sources, including EPA's Office of Pesticide Programs www.epa.gov/pesticides, EPA's Office of Compliance, Agriculture and Ecosystem Division es.epa.gov/oeca/agecodiv.htm, or The National Agriculture Compliance Assistance Center, (888) 663-2155 or es.epa.gov/oeca/ag. Other sources include the National Pesticide Telecommunications Network, (800) 858-7378, and the National Antimicrobial Information Network, (800) 447-6349.

Toxic Substances Control Act

The Toxic Substances Control Act (TSCA) granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk. It is important to note that pesticides as defined in FIFRA are not included in the definition of a "chemical substance" when manufactured, processed, or distributed in commerce for use as a pesticide.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA section 5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemical's effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA section 6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under section 6 authority are asbestos, chlorofluorocarbons (CFCs), lead, and polychlorinated biphenyls (PCBs).

Under TSCA section 8(e), EPA requires the producers and importers (and others) of chemicals to report information on a chemicals' production, use, exposure, and risks. Companies producing and importing chemicals can be required to report unpublished health and safety studies on listed chemicals and to collect and record any allegations of adverse reactions or any information indicating that a substance may pose a substantial risk to humans or the environment.

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., EST, excluding federal holidays.

Coastal Zone Management Act

The Coastal Zone Management Act (CZMA) encourages states/tribes to preserve, protect, develop, and where possible, restore or enhance valuable natural coastal resources such as wetlands, floodplains, estuaries, beaches, dunes, barrier islands, and coral reefs, as well as the fish and wildlife using those habitats. It includes areas bordering the Atlantic, Pacific, and Arctic Oceans, Gulf of Mexico, Long Island Sound, and Great Lakes. A unique feature of this law is that participation by states/tribes is voluntary.

In the Coastal Zone Management Act Reauthorization Amendments (CZARA) of 1990, Congress identified nonpoint source pollution as a major factor in the continuing degradation of coastal waters. Congress also recognized that effective solutions to nonpoint source pollution could be implemented at the state/tribe and local levels. In CZARA, Congress added Section 6217 (16 U.S.C. section 1455b), which calls upon states/tribes with federally-approved coastal zone management programs to develop and implement coastal nonpoint pollution control programs. The Section 6217 program is administered at the federal level jointly by EPA and the National Oceanic and Atmospheric Agency (NOAA).

Section 6217(g) called for EPA, in consultation with other agencies, to develop guidance on "management measures" for sources of nonpoint source pollution in coastal waters. Under Section 6217, EPA is responsible for developing technical guidance to assist states/tribes in designing coastal nonpoint pollution control programs. On January 19, 1993, EPA issued its *Guidance Specifying Management Measures For Sources of Nonpoint Pollution in Coastal Waters*, which addresses five major source categories of nonpoint pollution: (1) urban runoff, (2) agriculture runoff, (3) forestry runoff, (4) marinas and recreational boating, and (5) hydromodification.

Additional information on coastal zone management may be obtained from EPA's Office of Wetlands, Oceans, and Watersheds, www.epa.gov/owow, or from the Watershed Information Network www.epa.gov/win. The NOAA website, www.nos.noaa.gov/ocrm/czm/, also contains additional information on coastal zone management.

VI.B. Industry Specific Requirements

The onshore and offshore segments of the oil and gas extraction industry are subject to different sets of regulations. Onshore, releases primarily are under the authority of EPA. Federal land leases are managed by the Bureau of Land Management (BLM) in the Department of the Interior (DOI). States also impose regulations and play a crucial role in exploration and production solid waste regulation because of the RCRA exemption. Offshore, on the Outer Continental Shelf (OCS), the Minerals Management Service (MMS) of DOI is the designated regulatory agency. MMS oversees leasing operations and shares responsibility for environmental regulation with EPA.

Because of these differences, onshore and offshore regulations are discussed in separate sections. In addition, regulatory differences associated with stripper wells (wells that produce less than 10 barrels of oil per day) and selected state regulations are presented.

VI.B.1. Onshore Requirements

Laws Regulating Oil and Gas Exploration and Production on Federal Lands

Many regulations controlling the location of onshore oil and gas production stem from the Federal Land Policy and Management Act (FLPMA) of 1976. Production is barred at national monuments, national rivers, and areas of critical environmental concern. On Federal land where oil production is allowed, the Bureau of Land Management (BLM), under the Department of the Interior (DOI), is authorized under 43 CFR Parts 3160-92 to regulate the siting, drilling and production activities; an exception is on lands within the National Forest System, where BLM must obtain the consent of the Secretary of Agriculture. Oil and gas production regulation is achieved through the distribution of leases and the issuance of drilling permits. Most procedures are established under the Federal Oil and Gas Leasing Reform Act of 1987. Included in this Act are bonding regulations, presented in 43 CFR Part 3104, that require submission of a surety or personal bond to ensure compliance with requirements for the plugging of wells, reclamation of the leased areas, and restoration of any lands or surface waters adversely affected by lease operations. The BLM is revising its regulations. A proposed rule was promulgated in early 1999.

National Environmental Policy Act (NEPA)
NEPA requires that all Federal agencies prepare detailed statements assessing the environmental impact of, and alternatives to, major Federal actions that may "significantly affect" the environment. An environmental impact statement (EIS) must provide a fair and full discussion of significant environmental impacts and inform both decision-makers and the public about

the reasonable alternatives that would avoid or minimize adverse impacts on the environment; EISs must explore and evaluate all reasonable alternatives, even if they are not within the authority of the lead agency. NEPA authorities are solely procedural; NEPA cannot compel selection of the environmentally preferred alternative. For offshore operations new sources require NEPA analysis.

Federal actions specifically related to oil and gas exploration and production that may require EISs include Federal land management agency (e.g., BLM and Forest Service) approval of plans of operations for exploration or production on Federally-managed lands. All affected media (e.g., air, water, soil, geologic, cultural, economic resources, etc.) must be addressed. The EIS provides the basis for the permit decision; for example, an NPDES permit may be issued or denied based on EPA's review of the overall impacts, not just discharge-related impacts, of the proposed project and alternatives. Issues may include the potential for surface or groundwater contamination, aquatic and terrestrial habitat value and losses, sediment production, mitigation, and reclamation.

Clean Air Act (CAA)

The oil and gas production industry is subject to recently-promulgated National Emission Standards for Hazardous Air Pollutants (NESHAP) (Federal Register, Vol. 64, No. 116, June 17, 1999). The regulation calls for the application of maximum achievable control technology (MACT) in order to reduce the emissions of hazardous air pollutants (HAP) at facilities classified as major sources. The primary HAPs released by the industry are benzene, toluene, ethyl benzene, and mixed xylenes (BTEX) and n-heptane. The technology requirements involve the following emission points: process vents on glycol dehydration units, storage vessels with flash emissions, and equipment leaks at natural gas processing plants. Additional requirements include the installation of air emission control devices, and adherence to test methods and procedures, monitoring and inspection requirements, and recordkeeping and reporting requirements.

In addition, New Source Performance Standards (NSPS) may affect exploration and production facilities. Standards apply to devices used at these facilities, including gas turbines, steam generators, storage vessels for petroleum liquids, volatile organic liquid storage vessels, and gas processing plants (see 40 CFR Part 60). Requirements will depend on whether the region in which the particular facility is located is in compliance with the National Ambient Air Quality Standards (NAAQS) and whether Prevention of Significant Deterioration (PSD) requirements apply (EPA, 1992).

Clean Water Act

Onshore exploration and production facilities may be subject to four aspects of the CWA: national effluent limitation guidelines, stormwater regulations, and wetlands regulations, and Spill Prevention Control and Countermeasure (SPCC) requirements.

National effluent limitation guidelines have been issued for two subcategories of onshore (non-stripper) wells. The Onshore Subcategory guidelines prohibit the discharge of water pollutants from any source associated with production, field exploration, drilling, well completion, or well treatment (40 CFR Part 435.30). Agriculture and Wildlife Water Use Subcategory guidelines apply to facilities in the continental United States west of the 98th meridian for which produced water may be used beneficially for irrigation or wildlife propagation. For facilities in this subcategory, produced water may be discharged into navigable waters so long as it does not exceed limitations for oil and grease, and is put to use for agricultural purposes. Discharge of waste pollutants excluding produced water is prohibited (40 CFR Part 435.50).

Oil and gas exploration and production facilities are exempt from CWA stormwater Phase I regulations under most conditions, but there are two exceptions: (1) if the facility has a reportable quantity spill that could be carried to waters of the United States via a storm event, or (2) if the stormwater runoff violates a water quality standard. (See 40 CFR Parts 117 and/or 302 for reportable quantities of hazardous substances or Part 110 for the reportable quantity of spilled oil.) If either of these two scenarios should happen, the facility would be required to apply for a Multi-Sector General Permit (MSGP) stormwater permit and develop a pollution prevention plan. However, if a reportable quantity spill were to be cleaned up quickly or containment were so total that there would be no threat of a product release as a result of storm water event, there would be no permit requirement. In addition, coverage is mandatory under the Construction General Permit (CGP) for earth-disturbing activities of five acres or more. This is relevant during exploration or site expansion efforts (EPA Region VI Stormwater Hotline, 1999; Rittenhouse, 1999). See Section VI.C. for proposed Phase II regulations that may impact the industry.

Wetlands

During the course of petroleum exploration wetlands may be encountered. Under the CWA wetlands are defined by the frequency and length of time they are saturated with water, by the type of vegetation they support, and by soil characteristics. Also by definition wetlands are part of the "waters of the United States" and as such all discharges of pollutants to wetlands require a CWA permit. However, the CWA regulates not only the discharges of dissolved pollutants but also the discharge of solids, dredge and fill materials or dirt to waters of the United States. Permits are required for the filling of wetlands (dredging is regulated under the 1899 Rivers and Harbors Act). Permits are of two types: general (a standard permit for certain classes of activities) or site-specific.

Enforcement of the CWA provisions for wetlands is overseen by the Army Corps of Engineers, EPA and in some cases the States. Most of the day to day administration of the program is implemented by the Corps of Engineers (COE). The COE issues and enforces permits, and is also responsible for delineating wetlands. EPA regions comment on permits and can enforce the provisions of the Act. EPA also helps to develop environmental criteria for wetlands. The COE can approve a state to operate the CWA wetlands program (only Maryland and New Jersey are currently approved). If a state is authorized to operate the CWA wetlands program it may issue a permit in addition to the COE issued permit. Any state can comment on wetland permits prior to issuance.

Spill Prevention Control and Countermeasure Plans

An oil and gas production, drilling, or workover facility will be subject to Spill Prevention Control and Countermeasure (SPCC) requirements if it meets the following specifications: the facility could reasonably be expected to discharge oil into or upon the navigable waters of the United States or adjoining shorelines, and have (1) a total underground buried storage capacity of more than 42,000 gallons; (2) a total aboveground oil storage capacity of more than 1,320 gallons; or (3) an aboveground oil storage capacity of more than 660 gallons in a single container. SPCC applicability is dependent on the tank's maximum design storage volume and not "safe" operating or other lesser operational volumes. For purposes of the regulation, an onshore production facility may include all wells, flowlines, separation equipment, storage facilities, gathering lines, and auxiliary non-transportation-related equipment and facilities in a single geographical oil or gas field operated by a single operator.

All facilities subject to SPCC requirements must prepare a site-specific spill prevention plan that incorporates requirements specified in 40 CFR Part 112.7. For production facilities, these include considerations for the following processes and procedures:

- Drainage
- Tank materials
- Secondary containment
- Visual inspection of tanks
- Fail-safe engineering methods for tank battery installations
- Tank repair and maintenance

- Facility transfer operations
- Inspection and testing measures
- Record-keeping
- Security
- Personnel training.

In addition, the plan must discuss spill history and spill prediction (i.e., the anticipated direction of flow). The SPCC plan must be approved by a Registered Professional Engineer who is familiar with SPCC requirements, be fully implemented, and be modified when changes are made to the facility (e.g., installation of a new tank). Regardless of whether changes have been made to the facility, the plan must be reviewed at least once every three years, and amended if new, field-proven technology may reduce the likelihood of a spill.

The SPCC plan must also address oil drilling and workover facility equipment. This portion of the plan requires that the equipment be positioned or located so as to prevent spilled oil from reaching navigable waters, that catchment basins or diversionary structures be in place, and that blowout preventers (BOPs) are installed according to state regulatory requirements.

A portion of SPCC-regulated facilities may also be subject to Facility Response Planning (FRP) requirements if they pose a threat of "substantial harm" to navigable waters. The determination of a "substantial harm" facility is made on the basis of meeting either of two sets of criteria – one involving transfer over water, and the other involving oil storage capacity or other factors. If the facility were subject to FRP requirements, it would be required to develop a facility response plan which would involve, among other requirements, identification of small, medium and worst-case discharge scenarios and response actions; a description of discharge detection procedures and equipment; detailed implementation plans for containment and disposal; diagrams of facility and surrounding layout, topography, and evacuation paths; and employee training, exercises, and drills.

Safe Drinking Water Act (SDWA)

The Underground Injection Control (UIC) program of the SDWA regulates injection wells used in the oil and gas production process for produced water disposal or for enhanced recovery. Wells used in this industry for produced water are classified as Class II. Minimum UIC Class II well requirements, as outlined in 40 CFR Part 144, involve specific construction, operation, and closure standards, as well as provisions for ensuring that the owner, operator and/or transferor of the well maintain financial responsibility and resources to plug and abandon the well. Included are casing and cementing requirements based on the depth to the injection zone, location of aquifers, and estimated injection pressures as well as other possible considerations. Operational standards involve regular (at least once every five years) mechanical integrity tests (MITs); monitoring of injection pressure, flow rate, and volume; monitoring of the nature of injected fluid as needed; and annual reporting of monitoring results. Finally, closure procedures must be performed in accordance with an approved plugging and abandonment plan, which includes the placement and composition of cement plugs, the amount of casing to be left in the hole, the estimated cost of plugging, and any proposed tests or measurements. Additional requirements may be imposed in states that have been delegated implementation of the UIC program.

Comprehensive Environmental Response, Compensation and Liability Act (CERCLA)

The "petroleum exclusion" is an important exemption under CERCLA requirements for the oil and gas extraction industry. Under the "hazardous substance" definition, "petroleum, including crude oil or any fraction thereof," is exempted unless specifically listed or designated under CERCLA (CERCLA section 101 (14)). Subsequent interpretation has concluded that listed hazardous substances that are normally found in crude oil, such as benzene, do not invalidate the exemption unless the concentration of these substances is increased by contamination or by addition after refining. However, specifically listed waste oils (e.g., F010, and K042 through K048) are subject to reporting requirements if spilled in excess of their established Reportable Quantities (RQs) (EPA, 1998).

Emergency Planning and Community Right-to-Know Act (EPCRA)

The oil and gas extraction industry is currently not required to report to TRI under EPCRA section 313, which requires facilities under certain SIC codes to submit annual reports of toxic chemical releases to the Toxic Release Inventory (TRI). (Please see Section VI.C., Pending and Proposed Regulatory Requirements, of this document, however, for possible future changes to this status.) However, oil and gas extraction facilities are generally responsible for other reporting obligations of EPCRA if the facility stores or manages threshold levels of specified chemicals.

Resource Conservation and Recovery Act (RCRA)

Under the 1980 Amendments to RCRA, Congress conditionally exempted certain categories of solid waste from regulation as hazardous wastes under RCRA Subtitle C including drilling fluids, produced waters, and other wastes associated with the exploration, development, or production of crude oil or natural gas. The Amendments required EPA to study these wastes to determine whether their regulation as hazardous wastes was warranted and to submit a report to Congress. In its report to Congress and in a July 1988 regulatory determination (53 FR 25446, July 6, 1988), the Agency stated that regulation as hazardous wastes under Subtitle C was not warranted and that these wastes could be controlled under other federal and state regulatory programs including a tailored RCRA Subtitle D program.

Specifically, EPA's regulatory determination for exploration and production (E&P) wastes found that the following wastes are exempt from RCRA hazardous waste management requirements. The list below identifies many, but not all, exempt wastes. In general, E&P exempt wastes are generated in "primary field operations," and not as a result of maintenance or transportation activities. Exempt wastes are typically limited to those that are intrinsically related to the production of oil or natural gas.

- Produced water;
- Drilling fluids;
- Drill cuttings;
- Rigwash;
- Drilling fluids and cuttings from offshore operations disposed of onshore;
- Well completion, treatment, and stimulation fluids;
- Basic sediment and water, and other tank bottoms from storage facilities that hold product and exempt waste;
- Accumulated materials such as hydrocarbons, solids, sand, and emulsion from production separators, fluid treating vessels, and production impoundments;
- Pit sludges and contaminated bottoms from storage or disposal of exempt wastes;
- Workover wastes;
- Gas plant sweetening wastes for sulfur removal, including amine, amine filters, amine filter media, backwash, precipitated amine sludge, iron sponge, and hydrogen sulfide scrubber liquid and sludge;
- Cooling tower blowdown;
- Spent filters, filter media, and backwash (assuming the filter itself is not hazardous and the residue in it is from an exempt waste stream);
- Packing fluids;
- Produced sand;
- Pipe scale, hydrocarbon solids, hydrates, and other deposits removed from piping and equipment prior to transportation;
- Hydrocarbon-bearing soil;
- Pigging wastes from gathering lines;
- Wastes from subsurface gas storage and retrieval, except for the listed non-exempt wastes;
- Constituents removed from produced water before it is injected or otherwise disposed of;

- Liquid hydrocarbons removed from the production stream but not from oil refining;
- Gases removed from the production stream, such as hydrogen sulfide and carbon dioxide, and volatilized hydrocarbons;
- Materials ejected from a producing well during the process known as blowdown;
- Waste crude oil from primary field operations and production; and
- Light organics volatilized from exempt wastes in reserve pits or impoundments or production equipment.

On March 22, 1993, EPA provided "clarification" regarding the scope of the E&P waste exemption for waste streams generated by crude oil and tank bottom reclaimers, oil and gas service companies, crude oil pipelines, and gas processing plants and their associated field gathering lines. (See 58 FR 15284-15287.) EPA stated that certain waste streams from these operations are "uniquely associated" with primary field operations and as such are within the scope of the RCRA Subtitle C exemption. EPA's clarification cautioned, however, that these wastes may not be exempt if they are mixed with non-exempt materials or wastes.

EPA's 1988 regulatory determination lists the following wastes as non-exempt. The list below identifies many, but not all non-exempt wastes, as well as transportation (pipeline and trucking) activities. While the following wastes are non-exempt, their regulatory status as "hazardous wastes" is dependent upon a determination of their characteristics or whether they are specifically listed as RCRA hazardous waste.

- Unused fracturing fluids or acids;
- Gas plant cooling tower cleaning wastes;
- Painting wastes;
- Oil and gas service company wastes, such as empty drums, drum rinsate, vacuum truck rinsate, sandblast media, painting wastes, spent solvents, spilled chemicals, and waste acids;
- Vacuum truck and drum rinsate from trucks and drums transporting or containing non-exempt waste;
- Refinery wastes;
- Liquid and solid wastes generated by crude oil and tank bottom reclaimers;
- Used equipment lubrication oils;
- Waste compressor oil, filters, and blowdown;
- Used hydraulic fluids;
- Waste solvents;
- Waste in transportation pipeline-related pits;
- Caustic or acid cleaners;
- Boiler cleaning wastes;

- Boiler refractory bricks;
- Incinerator ash;
- Laboratory wastes;
- Sanitary wastes;
- Pesticide wastes;
- Radioactive tracer wastes; and
- Drums, insulation, and miscellaneous solids.

EPA did not specifically address, in its 1988 regulatory determination, the status of hydrocarbon-bearing material that is recycled or reclaimed by reinjection into a crude stream. However, under existing EPA regulations, recycled oil, even if it were otherwise hazardous, could be reintroduced into the crude stream, if it is from normal operations and is to be refined along with normal process streams at a petroleum refinery facility (40 CFR Part 261.6 (a)(3)(vi).).

The Agency also determined that produced water injected for enhanced recovery is not a waste for purposes of RCRA regulation and therefore is not subject to control under RCRA Subtitle C or Subtitle D. Produced water used in this manner is considered beneficially recycled and is an integral part of some crude oil and natural gas production processes. Produced water injected in this manner is already regulated by the Underground Injection Control program under the SDWA. However, if produced water is stored in surface impoundments prior to injection, it may be subject to RCRA Subtitle D regulations.

It is important to note that some states have adopted hazardous waste regulations which differ from those that EPA has promulgated. While different in many specific areas, those state programs, by law, still must be at least as stringent as the federal programs.

Endangered Species Act (ESA)

The ESA provides a means to protect threatened or endangered species and the ecosystems that support them. It requires Federal agencies to ensure that activities undertaken on either Federal or non-Federal property do not have adverse impacts on threatened or endangered species or their habitat. In a 1995 ruling, the U.S. Supreme Court upheld interpretations of the Act that allow agencies to consider impact on habitat as a potential form of prohibited "harm" to endangered species. Agencies undertaking a Federal action (such as a BLM or MMS review of proposed oil and gas extraction production operations) must consult with the U.S. Fish and Wildlife Service, and an EIS must be prepared if "any major part of a new source will have significant adverse effect on the habitat" of a Federally- or State-listed threatened or endangered species.

VI.B.2. Offshore Requirements

This section describes laws and regulations applying to offshore production facilities that differ from those presented above for onshore facilities. It should be noted that several regulations presented in the onshore section will apply to offshore sites as well. Offshore facilities are: 1) those which are found within the Federal jurisdiction of the Outer Continental Shelf and are operated under Minerals Management Service (MMS) leases, and 2) those that are found in territorial seas and are operated under state leases. Facilities in the territorial seas are operated under both state and federal regulations and therefore some regulations discussed below may not be applicable. In addition, coastal facilities, which are generally landward of the inner boundary of the territorial seas (approximated by the shoreline) are operated under state regulations and therefore some regulations discussed below may not be applicable.

Offshore Jurisdictions

The Outer Continental Shelf (OCS) consists of the submerged lands, subsoil, and seabed, lying between the seaward extent of the states' jurisdiction and the seaward extent of federal jurisdiction. The continental shelf is the gently sloping undersea plain between a continent and the deep ocean. The United States OCS has been divided into four leasing regions. They are the Gulf of Mexico Region, the Atlantic OCS Region, the Pacific OCS Region, and the Alaska OCS Region. State jurisdiction is defined as follows. Texas and the Gulf Coast of Florida are extended 3 marine leagues (approximately 9 nautical miles) seaward from the baseline from which the breadth of the territorial sea is measured. Louisiana is extended 3 imperial nautical miles (imperial nautical miles are 6,080.2 feet) seaward of the baseline from which the breadth of the territorial sea is measured. All other states' seaward limits are extended 3 nautical miles (approximately 3.3 statute miles) seaward of the baseline from which the breadth of the territorial sea is measured. Federal jurisdiction is defined under accepted principals of international law. The seaward limit is defined as the farthest of 200 nautical miles seaward of the baseline from which the breadth of the territorial sea is measured.

Outer Continental Shelf Lands Act (OSCLA)

OCSLA establishes Federal jurisdiction over submerged lands on the Outer Continental Shelf (OCS) and requires the Secretary of the Interior to administer mineral leasing, exploration, and development on the OCS. Under the Act, leases are granted to the highest qualified responsible bidder(s), on the basis of sealed competitive bids. Objectives of the OCSLA include allowing for expeditious and orderly development of OCS resources, encouraging the development of new technology to minimize the likelihood of accidents or events that might damage the environment or endanger life or health, and ensuring that a State's regulatory protection for land, air, and water uses are considered within its jurisdiction (MMS, 1999; National Research Council, 1996).

In offshore locations, the production is limited under Title III of the Marine Protection, Research, and Sanctuaries Act (MPRSA), which provides for the designation of sanctuaries for areas of conservation, recreational, ecological, or aesthetic value. The Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA) prohibit the taking of species, and can also limit the placement of offshore wells.

Clean Air Act

In offshore areas, both the CAA and regulations of the MMS govern air quality. Coastal areas and the offshore regions of the Pacific, Atlantic, and Arctic Oceans, as well as the region of the Gulf of Mexico adjacent to Florida, are subject to the CAA. Important regulations include the NESHAP and NSPS standards described above for onshore facilities.

The sections of the Gulf of Mexico adjacent to Texas, Louisiana, Mississippi, and Alabama are exempt from the 1990 CAA amendments, and instead must adhere to MMS air quality standards. These standards set limits for VOC, CO, NO_2, SO_2, and Total Suspended Particulate (TSP) pollutants, and require limits for sources that significantly affect the quality of a nonattainment area (30 CFR Part 250.45).

Additional MMS air regulations apply to offshore sites. Blowout prevention regulations (in the form of safety practices and equipment requirements) attempt to reduce accidental releases. The venting and flaring of natural gas is limited under MMS rules so that natural gas may be released only when required for safety or when the volume is small (Sustainable Environmental Law and 30 CFR Part 250.175).

Clean Water Act

In offshore locations, facilities must acquire National Pollutant Discharge Elimination System (NPDES) permits before any pollutant can be discharged from a point source in U.S. waters. Standards differ for the offshore and coastal subcategories. For offshore facilities, permits require the use of best available technology economically achievable (BAT) or best conventional pollutant control technology (BCT). Discharges from coastal facilities, which are landward of the inner boundary of the territorial seas, are mostly prohibited (Jordan, 1998; note that the definition of the coastal category for the purposes of the CWA is different than that for mineral rights, presented in Section II). An exception to the coastal discharge prohibition is for facilities in Cook Inlet, Alaska, where discharges may be made in accordance with BPT, BAT, or BCT effluent limitations.

Facilities located offshore of EPA Region 6 (and some in Regions 9 and 10) are subject to a general CWA permit that covers all facilities in certain geographic locations. Offshore exploration and production facilities in Regions 4, 9 and 10 are also permitted individually in some cases. EPA Regions 6 and 9 have an MOA with MMS whereby MMS agrees to conduct CWA preliminary inspections for EPA.

In addition to NPDES permitting requirements, offshore facilities may be subject to CWA Section 403. This section is intended to ensure that no unreasonable degradation of the marine environment occurs as a result of permitted discharges, and to ensure that sensitive ecological communities are protected. Requirements may involve ambient monitoring programs to determine degradation of marine waters, alternative assessments designed to further evaluate the consequences of various disposal options, and pollution prevention techniques designed to further reduce the quantities of pollutants requiring disposal and thereby reduce the potential for harm to the marine environment. If section 403 requirements for protection of the ecological health of marine waters are not met, an NPDES permit will not be issued.

Spill Prevention Control and Countermeasure Plans

Many aspects of SPCC rule described above for onshore facilities apply to offshore facilities as well. 40 CFR Part 112.7(e)(7) provides additional spill prevention and control measures to be addressed in SPCC plans for offshore facilities. These include:

- Oil drainage collection equipment around pumps, joints, valves, separators, tanks, etc.
- Adequately-sized sump systems
- Dump valves installed with oil-water separators and treaters
- High-level sensing devices for atmospheric storage tanks and corrosion protection for all tanks
- High pressure sensing device and shut-in valve for pipelines appurtenant to the facility.

Oil Spill Contingency Plans

Pursuant to 30 CFR 250.203, 250.204 and 254, a lessee is required to submit an Oil Spill Contingency Plan (OSCP) to MMS for approval. This plan identifies the response capabilities of lease and pipeline operators in the event an accidental oil spill occurs during drilling or production activities.

Additionally, the Oil Pollution Act of 1990 authorizes the MMS to require Oil Spill Contingency Plans from oil and gas lessees operating in state waters seaward of the coastline. Operators must join a cooperative with oil spill equipment available to members, or obtain a letter of agreement for rental of oil spill equipment. Oil Spill Coordinators must be trained. The entire Oil Spill Response Team must attend annual drills. The Plan requires annual review and update.

VI.B.3. Stripper Well Requirements

Stripper wells are identified as an individual subcategory in Clean Water Act NPDES requirements. In addition, stripper wells may be exempt from requirements under other statutes or regulations by virtue of their low production volume. For example, they may not meet the threshold of a major source of HAP for NESHAP requirements, or they may have less than the specified storage volume for SPCC rules. States and Federal agencies may also provide incentives to stripper well operators to maximize the number of these marginally profitable wells that remain operational. Reductions of severance taxes are available in some states, and BLM offers royalty rate reductions for qualifying stripper wells (Williams and Meyers, 1997; 43 CFR Part 3103.4-2).

Clean Water Act

Stripper wells are defined as onshore wells that produce less than 10 barrels of oil per day, are operating at the maximum feasible rate of production, and operate in accordance with recognized conservation practices (40 CFR Part 435.60) They are currently exempt from onshore point source discharge restrictions discussed above in Section VI.B.1. As a result, technology-based limitations instead are developed on a case-by-case basis or in a state-wide general permit.

VI.B.4. State Statutes

In addition to the federal laws described above, most oil-producing states develop other laws affecting oil and gas extraction and production. These include permitting, bonding, temporary abandonment, and plans for plugging orphan wells. Each oil-producing state has a regulatory body, and most require operators to obtain a well permit before drilling. Historically, permitting has been required in these places in order to ensure an efficient and safe mechanism for withdrawing oil from reservoirs by preventing wells from being drilled too close together (Williams and Meyers, 1997).

Nearly all oil-producing states require some form of security or financial assurance for those operators seeking a permit, in order to ensure proper plugging and abandonment. The form of assurance varies from state to state, but the most commonly accepted are surety bonds, certificates of deposit, and cash. The amount of money required for security can vary as well; the amounts range from $10,000 in Kentucky and Tennessee to a minimum of $200,000 in Alaska (IOGCC, 1996).

Laws for temporary abandonment of wells differ among states. (See Section III.B. for a discussion of temporary abandonment.) In general, States are reluctant to require plugging of wells that have significant potential for oil production (and state revenues), yet they seek to avoid problems associated with inactive and unattended wells. As a result, most states require inactive wells to gain state approval for temporary abandonment. (The term temporary abandonment is used for wells that are inactive with state approval.) Most states allow some period of time of inactivity (usually six months to one year) without approval. At this point, however, states may require a statement of future use from the operator; this statement might include extensive geological and engineering information and a schedule for returning the well to production. As part of a temporary abandonment permit, a state may require periodical mechanical integrity tests (MITs) to ensure that the temporarily abandoned well does not pose a threat to the environment (IOGCC, 1996).

Finally, many states have established plugging funds to ensure that wells that pose a threat to the environment but are without financial assurance are properly plugged. These wells, often called orphan wells (see Section III.C.), are identified and prioritized by any number of methods, and are plugged as funds become available and procurement issues are settled. Funding sources vary among states; in some states, such as Arkansas, California, and Mississippi, funding comes directly from the government's general fund or from the regulatory body's budget, while in others the programs are funded through permit fees, portions of oil taxes, bond forfeitures, or penalties (IOGCC, 1996).

In 1990, the Interstate Oil and Gas Compact Commission (IOGCC) developed guidelines for state oil and gas exploration and production waste management program. In 1991, IOGCC began reviewing state programs against the guidelines. State reviews were conducted by stakeholder teams. Review teams wrote reports of their findings, including strengths and weaknesses, and made recommendations for program improvements. Seventeen state programs were reviewed between 1991 and 1997. These reports are an excellent source of state-specific regulations and programs. State reviews can be obtained from IOGCC by calling (405) 525-3556 and from the IOGCC Website at *www.iogcc.oklaosf.state.ok.us/.* The state review program has subsequently been managed by STRONGER, Inc., a non-profit corporation. For more information on IOGCC and STRONGER, Inc., see Section VIII.A.2., State Activities.

VI.C. Pending and Proposed Regulatory Requirements

Clean Water Act (CWA)

Proposed Phase II NPDES Storm Water Regulations
Under this proposal, construction sites between one and five acres would be regulated under the NPDES storm water program. The oil and gas exploration and production industry might be impacted by this rule during onshore drilling site preparations. Possible requirements include: the submission of a Notice of Intent (NOI) that would include general information and a-certification that the activity will not impact endangered or threatened species, development and implementation of a Storm Water Pollution Prevention Plan (SWPPP) and use of best management practices (BMP) to minimize the discharge of pollutants from the site, and submission of a Notice of Termination (NOT) when final stabilization of the site has been achieved as defined in the permit. Finalization of the rule is anticipated in November 1999 (George Utting, EPA, Office of Water, (202) 260-9530 or John Kosco, EPA, Office of Water, (202) 260-6385).

Proposed Effluent Limitations Guidelines and Standards for Synthetic-Based Drilling Fluids
This proposed rule would amend the technology-based effluent limitations guidelines and standards for the discharge of pollutants from oil and gas drilling operations associated with the use of synthetic-based drilling fluids (SBFs) and other non-aqueous drilling fluids into the waters of the United States. This proposed rule would apply to existing and new facilities in the offshore subcategory and the Cook Inlet portion of the coastal subcategory of the oil and gas extraction point source category. The final rule is scheduled for December 2000. (Carey A. Johnston, EPA, Office of Water, (202) 260-7186).

Revisions to the Oil Pollution Prevention Regulation
Three separate proposals, in 1991, 1993, and 1997, had been offered to amend the text of 40 CFR Part 112, which includes requirements for sites to develop spill prevention control and countermeasures (SPCC) plans. The current proposed rule is a consolidation of the three proposals. The goals of the new rule are to give more flexibility with paperwork and to reduce the burden of information collection for some facilities. Two considerations will be emphasized during the rule development: the importance of good engineering practices and the value of site-specific flexibility. A final rule is

R0076731

expected during Spring, 2000. (Hugo Fleischman, EPA, Office of Solid Waste and Emergency Response, (703) 603-8769).

Emergency Planning and Community Right-To-Know Act (EPCRA)

Addition of Oil and Gas Exploration and Production to the Toxic Release Inventory

A long-term consideration is the addition of the oil and gas extraction industry to regulation under EPCRA section 313, which requires reporting to the Toxics Release Inventory (TRI). The possible addition of the industry was considered carefully in 1996, but was not added at that time. The proposal may enter the proposed rule stage in December, 2000, but no definite schedule had been set at the time of the publication of this document. (Tim Crawford, EPA, Office of Prevention, Pesticides, and Toxic Substances. (202) 260-1715).

VII. COMPLIANCE AND ENFORCEMENT HISTORY

Background

Until recently, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small

businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general make-up.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and reflect solely EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the past five calendar years (April 1, 1992 to March 31, 1997) and the other for the most recent twelve-month period (April 1, 1996 to March 31, 1997). The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across EPA Regions for certain sectors.[3] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to link separate data

[3] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

R0076734

records from EPA's databases. This allows retrieval of records from across media or statutes for any given facility, thus creating a "master list" of records for that facility. Some of the data systems accessible through IDEA are: AFS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental Response, Compensation, and Liability Information System, Office of Solid Waste and Emergency Response), and TRIS (Toxics Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of Toxic Release Inventory (TRI) reporters within the listed SIC code range. For industries not covered under TRI reporting requirements (oil and gas extraction, metal mining, nonmetallic mineral mining, electric power generation, ground transportation, water transportation, and dry cleaning), or industries in which only a very small fraction of facilities report to TRI (e.g., printing), the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a one-year or five-year period.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time, expressed in months, between compliance inspections at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were the subject of at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. A facility with multiple enforcement actions is only counted once in this column, e.g., a facility with 3 enforcement actions counts as 1 facility.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times, e.g., a facility with 3 enforcement actions counts as 3.

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use by states of EPA data systems may limit the volume of actions recorded as state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This ratio is a rough indicator of the relationship between inspections and enforcement. It relates the number of enforcement actions and the number of inspections that occurred within the one-year or five-year period. This ratio includes the inspections and enforcement actions reported under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA). Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. Also, this ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Violation

R0076736

status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Oil and Gas Extraction Industry Compliance History

Table 14 provides an overview of the reported compliance and enforcement data for the oil and gas extraction industry over the past five years (April 1992 to April 1997). These data are also broken out by EPA Regions thereby permitting geographical comparisons. A few points evident from the data are listed below.

- Over half of the inspections (3,094) and a majority of the enforcement actions (175) during the five year period were conducted in Region VI, which comprises Texas, Oklahoma, Louisiana, New Mexico, and Arkansas. More than half of the oil and gas production activity for the nation is centered in these states.

- Region II has among the fewest facilities, but held the most inspections per facility (an average of an inspection per 12 months at each facility) and had the highest enforcement to inspection ratio (0.17).

- Region VIII had the least frequent inspections (an average of 69 months between inspections) and one of the lowest enforcement to inspection ratios (0.04).

- Nearly 80 percent of the enforcement actions were state-led. The only Region where the majority of actions were federally-led was Region X, in which many oil fields are on Federal land in Alaska.

VII.B. Comparison of Enforcement Activity Between Selected Industries

Tables 15 and 16 allow the compliance history of the oil and gas sector to be compared to the other industries covered by the industry sector notebooks. Comparisons between Tables 15 and 16 permit the identification of trends in compliance and enforcement records of the various industries by comparing data covering the last five years (April 1992 to April 1997) to that of the past year (April 1996 to April 1997). Some points evident from the data are listed below.

- Oil and gas extraction facilities are inspected much less frequently (46 months between inspections on average) than facilities in most other industries included in the following tables, and the enforcement to inspection ratio (0.05) is among the lowest of the included industries.

- Oil and gas extraction facilities have the lowest percentage of facilities with one or more violations (15 percent) and have one of the lowest percentages of facilities with enforcement actions (three percent).

- The one-year enforcement to inspection ratio (0.03) is significantly less than the five-year ratio (0.05), indicating that enforcement actions may be becoming less frequent per given number of inspections.

Tables 17 and 18 provide a more in-depth comparison between the oil and gas extraction industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in the previous Tables (Tables 15 and 16), the data cover the last five years (Table 17) and last one year (Table 18) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- The vast majority of both inspections and actions were performed under the Clean Air Act, much more so than in other industries.

- RCRA accounted for a relatively low percentage of the industry's inspections and enforcement actions compared to other industries.

- The inspections performed under RCRA yielded proportionately more actions than those performed under either CAA or CWA.

Table 15: Five-Year Enforcement and Compliance Summary for Selected Industries

VII.C. Review of Major Legal Actions

Major Cases/Supplemental Environmental Projects

This section provides summary information about major cases that have affected this sector, and a list of Supplemental Environmental Projects (SEPs).

VII.C.1. Review of Major Cases

As indicated in EPA's *Enforcement Accomplishments Report* publications for FY 1996, FY 1997, and FY 1998 and a U.S. Department of Justice press release, seven significant enforcement actions have been resolved recently for the oil and gas extraction industry.

Three cases involved violations of the Clean Water Act. Two cases involved violations of National Pollution Discharge Elimination System (NPDES) discharge limits. The Cook Inlet Oil and Gas Platforms (owned by Marathon. Shell, and Unocal) agreed to pay $212,000 for allegedly violating NPDES permits for 18 offshore platforms in Cook Inlet, Alaska. In a separate settlement, BP Exploration, Inc. agreed to pay $59,900 in response to an administrative complaint that the levels of fecal coliform bacteria, BOD, TRC, pH and flow were beyond its NPDES permit levels between January 1992 and October 1995.

The CWA violation settled in U.S. v. Berry Petroleum was part of a multi-agency (federal and state) case relating to a crude oil spill of 2,000 barrels from an oil production facility in a wetland area located adjacent to a California state beach. The spill contaminated the wetlands, adjacent ocean, and nearby beaches. It was determined that the spill occurred, in large part, because the facility failed to implement its EPA-mandated SPCC plan. Berry Petroleum paid $800,000 to EPA for the CWA violation in addition to $1.06 million in penalties to the California Regional Water Quality Control Board, the U.S. Fish and Wildlife Service, and other federal and state agencies. Berry also transferred $1,315,000 to a trust fund administered by the National Fish and Wildlife Foundation that will be used for long term restoration of the site.

A settlement in U.S. (Sac and Fox Nation) v. Tenneco Oil Company was reached over an alleged SDWA violation. Surface and groundwater on land of the Sac and Fox Nation was contaminated near areas of oil leases maintained by Tenneco between 1924 and 1989. Tenneco is required to provide the Sac and Fox Nation with a potable water supply of 207 sustainable gallons per minute and $1.16 million in cash. The overall dollar value of the settlement is over $3.5 million.

An alleged CAA violation was settled with Vastar Resources, Inc. and ARCO, regarding their facility on the Southern Ute Indian Reservation in La Plata County, CO. Vastar (the current owner) and ARCO (the previous owner) failed to install pollution control equipment on gas production engines at the facility. The results were large emissions of carbon monoxide (CO) and savings of $657,412 on the part of Vastar by operating the equipment without the required air emission controls. Vastar complied with EPA self-policing policies, and as a result the company only paid $137,949 plus $247,000 for the pollution control equipment. Although ARCO came forward at the same time as Vastar, it did not report the emissions while it owned the facility, and as a result did not meet EPA's self-disclosure standards. ARCO did not admit to the allegations, but settled for $519,463, which includes money saved from not using the equipment plus a penalty.

In September 1999, the Department of Justice announced that BP Exploration (Alaska) Inc. pleaded guilty to one felony count related to the illegal disposal of hazardous waste on Alaska's North Slope in violation of CERCLA. BP Exploration had contracted with Doyan Drilling Inc. to drill production wells on Endicott Island. Between 1993 and 1995 Doylan employees illegally injected wastes down the outer rim, or annuli, of the oil wells. BP Exploration failed to report the illegal injections as soon as it learned of the conduct. The wastes included paint thinner and toxic solvents containing lead and chemicals such as benzene, toluene, and methyl chloride. BP Exploration was fined $500,000 and agreed to spend a total of $22 million to resolve the criminal case and related civil claims. The civil settlement requires BP Exploration to pay $6.5 million in penalties to resolve allegations that BP illegally disposed of the hazardous waste and violated the Safe Drinking Water Act. Also under the terms of the agreement, BP Exploration will establish an environmental management system at all of BP Amoco's facilities in the U.S. and Gulf of Mexico that are engaged in the exploration, drilling, or production of oil (U.S. Department of Justice, September 23, 1999).

VII.C.2. Supplementary Environmental Projects (SEPs)

SEPs are compliance agreements that reduce a facility's non-compliance penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can reduce the future pollutant loadings of a facility. Information on SEP cases can be accessed via the internet at the SEP National Database, es.epa.gov/oeca/sep/. This information is not comprehensive and provides only a sample of the types of SEPs developed for the oil and gas extraction industry.

One agreement was listed for SIC code 13. George Perry Exploration and Production, in Oceana County, MI, performed a SEP in response to violations of sections 1421 and 1422 of SDWA, in which the company violated the state underground injection control (UIC) program regulations and failed to submit an application for implementation of a UIC program. As a pollution reduction SEP, the company plugged three abandoned production wells to prevent the possible contamination of underground sources of drinking water. The cost of the project was valued at $6,000.

VIII. COMPLIANCE ASSURANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those initiated independently by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

VIII.A.1. Federal Activities

EPA Regional Compliance and Enforcement Activities

Several significant regional activities relating to the oil and gas extraction industry were reported in the 1997 Enforcement and Compliance Assurance Reports. Region VI provided assistance to offshore oil and gas exploration and production facilities with regard to NPDES permits. Region VI sent reporting forms to more than 2,000 facilities for compliance monitoring and reporting of the effluent quality of wastewater discharges from offshore platforms to the Gulf of Mexico. General permitting and reporting questions were explained to increase compliance through approximately 300 telephone conversations with facility operators, consultant, and state and federal agencies. Finally, a presentation on NPDES Offshore General Permit compliance and enforcement was given to approximately 100 permittees in Dallas. Partially as a result of these efforts, the compliance reporting rate is approximately 98 percent.

Region VI also created a work group that addressed the compliance and reporting of over 3,000 injection wells operated by 500 to 600 oil producers in the Osage Mineral Reserve. The group created *Osage Operators' Environmental Handbook* and *Osage Operators' Environmental Manual*, in order to assist small oil producers in complying with Bureau of Indian Affairs (BIA) and EPA requirements.

Region VIII, the U.S. Fish and Wildlife Service (USFWS) and associated states implemented a pilot program regarding problem oil pits (POPs). POPs are open-air pits along with tanks and associated spills at drilling and production sites that lack devices (such as proper netting) to prevent birds from landing on (and becoming stuck in) the layer of oil. This program seeks to address impacts to ground water and surface water as well as impacts to wildlife. The program cooperated with federal and state regulators (Bureau of Land Management, state environmental agencies, and state oil and gas commissions) to perform aerial surveys and ground surveys of oil pits in Colorado, Montana, and Wyoming. The states had the lead whenever possible. It was found that a large number of the pits would be considered POPs and were in noncompliance with applicable federal and state statutes or regulations. To address the high rate of noncompliance, the relevant agencies are mobilizing to offer compliance assistance, informal enforcement, or formal enforcement. All EPA Region VIII states have been completed for this POP effort except Utah, which is planned for completion in 1999 and EPA regions 5 and 7 are pursuing POP programs.

U.S. Department of Energy Oil and Gas Environmental Research and Analysis Program

The Office of Fossil Energy of the Department of Energy (DOE) has initiated several programs that address environmental and regulatory issues in the oil and gas industry. The efforts primarily center around streamlining regulatory procedures that affect the industry and performing research on cost-effective environmental compliance technologies.

The regulatory streamlining efforts attempt three major tasks: coordinating the many federal and state agencies involved with oil and gas regulation, including EPA, the Bureau of Land Management (BLM), and relevant state agencies; incorporating more risk-based decision making into regulatory, enforcement, and compliance decisions; and reducing impediments to technology implementation.

In its efforts to coordinate regulatory agencies, DOE worked with a group including the Interstate Oil and Gas Compact Commission (IOGCC), BLM, industry, and environmental groups to standardize permit applications in different states and on federal lands. The group also identified seven areas of regulatory responsibility that could be transferred from federal to state agencies to reduce overlapping activities within states.

DOE is also attempting to broaden the use of risk-based decision making. In one project, DOE is working with California, Kansas, and Oklahoma to expand exemptions for costly Area of Review (AOR) analyses of surrounding areas prior to the permitting of a disposal or injection well. AOR analyses investigate the potential of aquifer contamination by a proposed disposal well; new DOE methodology would limit the necessity of AOR studies in areas predetermined to have little risk.

The DOE environmental program also works to remove impediments to technology implementation. An example is shown in the case of newly developed synthetic drilling fluids, which show promise in increasing drilling efficiency and safety, particularly in deepwater drilling. Existing EPA regulations, however, limit their use. In 1994, DOE worked with industry and EPA to re-evaluate the regulations that affect these synthetic fluids. Consequently, EPA is in the process of revising regulations to clarify the terms under which industry may be allowed to use the technology. The use of these fluids could save the industry over $50 million annually.

Finally, DOE is assisting in the development of pollution prevention and waste management technologies. DOE's Sandia National Laboratories are developing a laser-equipped camera that can detect methane leaks in pipes. Argonne National Laboratory is undertaking a study to determine whether naturally occurring radioactive material (NORM), which may be found in well fluids, can be disposed of on-site in some locations, in order to reduce disposal costs. DOE also performs or funds research on produced water disposal; this includes further investigation into underground injection systems and development of a treatment for produced water into potable water in arid regions such as California. (Contact: *www.fe.doe.gov/oil_gas/oilgas7.html* or William Hochheiser, Environmental Scientist, at (202) 586-5614 or e-mail william.hochheiser@hq.doe.gov.)

U.S. EPA Voluntary Self-Disclosure Policy

In 1996, EPA adopted its final policy on incentives for self-evaluation and self-disclosure of violations. Through this policy, the Agency aims to protect public health and the environment by reducing civil penalties and not recommending criminal prosecution for regulated entities that voluntarily discover, disclose and correct violations under the environmental laws that EPA administers.

Under the final policy, where violations are found through voluntary environmental audits or efforts that reflect a regulated entity's due diligence (i.e., systematic efforts to prevent, detect and correct violations, as defined in the policy), and all of the policy's conditions are met, EPA will not seek gravity-based penalties and will generally not recommend criminal prosecution against the company if the violation results from the unauthorized criminal conduct of an employee. Where violations are discovered by means other than environmental audits or due diligence efforts, but are promptly disclosed and expeditiously corrected, EPA will reduce gravity-based penalties by 75 percent provided that all of the other conditions of the policy are met. EPA retains its discretion to recover economic benefit gained as a result of noncompliance, so that companies won't be able to obtain an economic advantage over their competitors by delaying their investment in compliance.

In addition to prompt disclosure and correction, the policy requires companies to prevent recurrence of the violation and to remedy any environmental harm. Repeated violations or those which may have presented an imminent and substantial endangerment or resulted in serious harm are excluded from the policy's coverage. Corporations remain criminally liable for violations resulting from conscious disregard of their legal duties, and individuals remain liable for criminal wrongdoing.

Although the final policy restates EPA's practice of not routinely requesting environmental audit reports, it does contain two provisions ensuring public access to information. First, EPA may require as a condition of penalty mitigation that a description of the regulated entity's due diligence efforts be made publicly available. Second, where EPA requires that a regulated entity enter into a written agreement, administrative consent order or judicial consent decree to satisfy the policy's conditions, those agreements will be made publicly available.

VIII.A.2. State Activities

The oil and gas industry is primarily regulated at the state level. Four organizations are discussed in this section that strongly influence state compliance assurance and waste minimization initiatives. Interstate Oil and Gas Compact Commission (IOGCC) coordinates oil and gas issues among oil and gas producing states, including environmental concerns. State Review of Oil and Natural Gas Environmental Regulations, Inc. (STRONGER, Inc.) is a non-profit corporation that develops guidelines for state oil and gas production waste regulatory programs and coordinates state reviews. The Ground Water Protection Council (GWPC) brings together state and federal regulators, industry, and others to address both underground injection control and groundwater protection issues. Finally, the Waste Minimization Program of the Texas Railroad Commission is in many ways a model for other states in disseminating cost-effective waste minimization solutions. While many states have waste minimization programs for underground injection wells, the Texas Railroad Commission has a unique structure among state governments of oil producing states as the regulator of nearly every aspect of the oil and gas extraction industry. The Waste Minimization Program therefore has a wider reach over the industry in the state.

Interstate Oil and Gas Compact Commission (IOGCC)

The IOGCC is an organization of the governors of 30 member states and seven associate states concerned with many aspects of the oil and gas industry. The primary purpose of the compact is to conserve oil and gas by the prevention of physical waste. IOGCC advocates for the rights of the states to govern oil and gas issues within their own borders, and coordinates regulatory efforts among the states to protect oil and gas resources and protect the environment. The organization serves as a forum for government, industry, environmentalists and others to share information and voice opinions on a wide range of topics.

Specifically relating to environmental issues, IOGCC is active in developing state regulatory standards, guidelines, and models for many aspects of the oil and gas industry, including bioremediation, waste disposal, waste minimization, beneficial use of waste, water and air quality, and abandoned sites. One of the most prominent of the IOGCC's efforts with respect to environmental issues has been the development of guidelines and reviews of state extraction and production waste management regulatory programs. Seventeen states representing over 90 percent of the onshore production in the United States have undergone these reviews, and summaries of the reviews are published in individual reports. These reports, in addition to other IOGCC publications, are an excellent source of state-specific regulations and programs. State reviews can be obtained from IOGCC by calling (405) 525-3556, and from the IOGCC Website at: www.iogcc.oklaosf.state.ok.us/. Since mid-1999, the state review program has been managed by STRONGER, Inc., a non-profit organization. Also, the IOGCC, through its annual Environmental Stewardship Awards recognizes major and independent operators that are performing environmentally beneficial projects.

State Review of Oil and Natural Gas Environmental Regulations, Inc. (STRONGER, Inc.)

The state review process described above, established by IOGCC, developed guidelines for state oil and gas exploration and production waste regulatory programs and coordinated reviews of state programs until 1997, when the process was terminated. During 1998, several meetings of interested stakeholders were conducted to determine how the process could be revitalized. In early 1999, the IOGCC proposed to EPA that the program be managed by a separate group of stakeholders equally representing the states, industry, and environmental organizations. Such a group was formed, and in June, 1999, was incorporated as a non-profit corporation, State Review of Oil and Natural Gas Environmental Regulations, Inc. (STRONGER, Inc.). STRONGER, Inc. develops updated and revised guidelines for adoption by IOGCC and coordinates state reviews. Guidelines, documents and state review reports are published and distributed by IOGCC. State participation in STRONGER, Inc. is coordinated through the IOGCC State Review Committee.

Ground Water Protection Council (GWPC)

The Ground Water Protection Council (GWPC) is a nonprofit organization whose members consist of state and federal ground water agencies, industry representatives, environmentalists, and concerned citizens. The council seeks to promote and ensure the use of best management practices and fair but effective laws regarding comprehensive ground water protection. The

GWPC works with the oil and gas industry via its UIC Class II Division. GWPC can be contacted by calling (405) 516-4972 or visiting their website at http://gwpc.site.net/.

Texas Waste Minimization Program

The Waste Minimization Program, run by the Texas Railroad Commission, is a voluntary program intended to provide oil and gas well operators with cost effective waste minimization solutions. The program serves as a technology transfer clearinghouse for information on specific waste streams, such as fugitive VOCs or produced water. The program also performs several forms of outreach:

- A manual outlining general techniques, *Waste Minimization in the Oil Field.*
- One-day workshops.
- A *Waste Minimization Newsletter*, which illustrates case studies of cost-effective programs implemented by operators (the newsletter is published two or three times a year).
- On-site assistance to help operators assess their operations and to develop individualized waste minimization programs.
- WasteMin, an easy-to-use waste minimization planning software package.

The program focuses on discovering and spreading innovative techniques that will add revenue for operators in addition to reducing environmental impacts. (Contact: Jack Ward, (512) 475-4580, or *www.rrc.state.tx.us/divisions/og/key-programs/ogkwast.html*.)

VIII.B. EPA Voluntary Programs

Natural Gas STAR

Natural Gas STAR is a voluntary partnership between EPA and the natural gas industry that was formed to find cost-effective ways of reducing emissions of methane. Methane is a significant concern with regard to the climate change issue; it is second only to carbon dioxide as a component of so-called "greenhouse gases."

Fugitive emissions from the natural gas industry are a substantial source of anthropogenic methane. Natural Gas STAR has two programs: one focusing on production and the other concentrating on distribution and transmission. The program for producers was launched in 1995, and participants represent approximately 35 percent of the U.S. natural gas production. The primary goals of the producers program are to promote technology transfer and implement best management practices (BMPs) that are cost-effective and that reduce methane emissions. Partners perform the following:

- Submit and execute BMP implementation plans
- Assist in the testing of emerging technologies
- Design new facilities to include BMPs when cost effective.

EPA serves to facilitate the transfer of new technology between members, perform outreach to inform and attract non-members, and address regulatory barriers that may threaten BMP implementation.

By mid-1998, partners had prevented the release of roughly 50 billion cubic feet (Bcf) of methane, worth approximately $100 million. The program has achieved this mark and plans to continue improvements by holding workshops for satellite offices of both member and non-member companies and updating members on new developments through newsletters and reports, among other activities. (Contact: www.epa.gov/gasstar or Paul Gunning at (202) 564-9736).

33/50 Program

The 33/50 Program is a groundbreaking program that has focused on reducing pollution from seventeen high-priority chemicals through voluntary partnerships with industry. The program's name stems from its goals: a 33% reduction in toxic releases by 1992, and a 50% reduction by 1995, against a baseline of 1.5 billion pounds of releases and transfers in 1988. The results have been impressive: 1,300 companies joined the 33/50 Program (representing over 6,000 facilities) and reached the national targets a year ahead of schedule. The 33% goal was reached in 1991, and the 50% goal -- a reduction of 745 million pounds of toxic wastes -- was reached in 1994.

Table 19 lists those companies participating in the 33/50 program that reported four-digit SIC codes within 13 to TRI. Some of the companies shown also listed facilities that are not producing oil and gas. The number of facilities within each company that are participating in the 33/50 program and that report oil and gas extraction SIC codes is shown.

Since oil and gas facilities are not currently required to report to TRI under EPCRA section 313 reporting requirements (TRI), only a few oil and gas extraction companies participated in the 33/50 program. Where available and quantifiable against 1988 releases and transfers, each company's 33/50 goals

R0076753

for 1995 and the actual total releases and transfers and percent reduction between 1988 and 1995 are presented. In each case, the participating oil and gas extraction operations of the partner companies performed significantly better than the company-wide goals, and nearly all facilities attained greater than 50 percent reductions in 33/50 chemicals.

Table 19 shows that six companies comprised of 80 facilities reporting SIC 13 participated in the 33/50 program. For those companies shown with more than one oil and gas facility, all facilities may not have participated in 33/50. The 33/50 goals shown for companies with multiple oil and gas facilities, however, are company-wide, potentially aggregating more than one facility and facilities not carrying out oil and gas extraction operations. In addition to company-wide goals, individual facilities within a company may have had their own 33/50 goals or may be specifically listed as not participating in the 33/50 program. Since the actual percent reductions shown in the last column apply to all of the companies' oil and gas facilities and only oil and gas facilities, direct comparisons to those company goals incorporating non-oil and gas facilities may not be possible. For information on specific facilities participating in 33/50, or to review case studies on corporate accomplishments in reducing waste contact David Sarokin, (202) 260-6907, at the 33/50 Program Office.

With the completion of the 33/50 program, several lessons were learned. Industry and the environment benefitted by this program for several reasons. Companies were willing to participate because cost savings and risk reduction were measurable and no additional record keeping and reporting was required. The goals of the program were clear and simple and EPA allowed industry to achieve the goals in whatever manner they could. Therefore, when companies can see the benefits of environmental programs and be an active part of the decision-making process, they are more likely to participate.

Table 19: Oil and Gas Industry Participation in the 33/50 Program

Parent Company (Headquarters Location)	Company-Owned Oil and Gas Facilities Reporting 33/50 Chemicals	Company-Wide % Reduction Goal[1] (1988-1995)	1988 TRI Releases and Transfers of 33/50 Chemicals (pounds)	1995 TRI Releases and Transfers of 33/50 Chemicals (pounds)	Actual % Reduction for Oil and Gas Facilities (1988-1995)
Amerada Hess Corp. New York, NY	4	50%	2,241,601	567,251	75%
Atlantic Richfield Co. Los Angeles, CA	11	23%	835,443	451,818	46%
Dresser Industries, Inc. Dallas, TX	10	47%	230,202	17,578	92%
Exxon Corp. Irving, TX	17	50%	5,155,264	2,159,535	58%
Texaco, Inc. White Plains, NY	14	49%	713,136	251,152	65%
USX Corp. Pittsburgh, PA	24	25%	9,873,833	1,246,246	87%
TOTAL	80	--	19,049,479	4,693,580	75%

Source: U.S. EPA, OPPTS, 33/50 Program 1998
[1] Company-Wide Reduction Goals aggregate all company-owned facilities which may include facilities not involved with oil and gas production.

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by providing participants regulatory flexibility on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specific environmental objectives that the regulated entity shall satisfy. EPA will provide regulatory flexibility as an incentive for the participants' superior environmental performance. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories, including industrial facilities, communities, and government facilities regulated by EPA. Applications will be accepted on a rolling basis. For additional information regarding XL projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Fax-on-Demand Hotline (202) 260-8590, Web: www.epa.gov/ProjectXL, or Christopher Knopes in EPA's Office of Reinvention, (202) 260-9298).

Energy Star® Buildings and Green Lights® Partnership

In 1991, EPA introduced Green Lights®, a program designed for businesses and organizations to proactively combat pollution by installing energy-efficient lighting technologies in their commercial and industrial buildings. In April 1995, Green Lights® expanded into Energy Star® Buildings-- a strategy that optimizes whole-building energy-efficiency opportunities.

The energy needed to run commercial and industrial buildings in the United States produces 19 percent of U.S. carbon dioxide emissions, 12 percent of nitrogen oxides, and 25 percent of sulfur dioxide, at a cost of 110 billion dollars a year. If implemented in every U.S. commercial and industrial building, Energy Star® Buildings' upgrade approach could prevent up to 35 percent of the emissions associated with these buildings and cut the nation's energy bill by up to 25 billion dollars annually.

The over 2,500 participants include corporations, small businesses, universities, health care facilities, nonprofit organizations, school districts, and federal and local governments. As of January 1, 1998, Energy Star®Buildings and Green Lights® Program participants have reduced their annual energy use by 7 billion kilowatt hours and annually save more than 517 million dollars. By joining, participants agree to upgrade 90 percent of their owned facilities with energy-efficient lighting and 50 percent of their owned facilities with whole-building upgrades, where profitable, over a seven-year period. Energy Star participants first reduce their energy loads with the Green Lights approach to building tune-ups, then focus on "right sizing" their heating and cooling equipment to match their new energy needs. EPA predicts this strategy will prevent more than 5.5 MMTCE of carbon dioxide by the year 2000. EPA's Office of Air and Radiation is responsible for operating the Energy Star Buildings and Green Lights Program. (Contact the Energy Star Hotline number, (888) STAR-YES ((888) 872-7937) or Maria Tikoff Vargas, Co-Director at (202) 564-9178 or visit the website at www.epa.gov/buildings.)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste prevention, recycling collection and the manufacturing and purchase of recycled products. As of 1998, the program had about 700 business, government, and institutional partners. Partners agree to identify and implement actions to reduce their solid wastes setting waste reduction goals and providing EPA with yearly progress reports for a three year period. EPA, in turn, provides partners with technical assistance, publications, networking opportunities, and national and regional recognition. (Contact: WasteWi$e Hotline at (800) 372-9473).

NICE^3

The U.S. Department of Energy sponsors a grant program called *National Industrial Competitiveness through Energy, Environment, and Economics* (NICE^3). The NICE^3 program provides funding to state and industry partnerships (large and small business) for projects demonstrating advances in energy efficiency and clean production technologies. The goal of the NICE^3 program is to demonstrate the performance and economics of innovative technologies in the U.S., leading to the commercialization of improved industrial manufacturing processes. These processes should conserve energy, reduce waste, and improve industrial cost-competitiveness. Industry applicants must submit project proposals through a state energy, pollution prevention, or business development office. The following focus industries, which represent the dominant energy users and waste generators in the U.S. manufacturing sector, are of particular interest to the program: Aluminum, Chemicals, Forest Products, Glass, Metal-casting, and Steel. Awardees receive a one-time, three-year grant of up to $400,000, representing up to 50 percent of a project's total cost. In addition, up to $25,000 is available to support the state applicant's cost share. (Contact: www.oit.doe.gov/Access/nice3, Steve Blazek, DOE, (303) 275-4723 or Eric Hass, DOE, (303) 275-4728)

Design for the Environment (DfE) Program

DfE is working with several industries to identify cost-effective pollution prevention strategies that reduce risks to workers and the environment. DfE helps businesses compare and evaluate the performance, cost, pollution prevention benefits, and human health and environmental risks associated with existing and alternative technologies. The goal of these projects is to encourage businesses to consider and use cleaner products, processes, and technologies. For more information about the DfE Program, call (202) 260-1678. To obtain copies of DfE materials or for general information about DfE, contact EPA's Pollution Prevention Information Clearinghouse at (202) 260-1023 or visit the DfE Website at www.epa.gov/dfe.

Small Business Compliance Assistance Centers

The Office of Compliance, in partnership with industry, academic institutions, environmental groups, and other federal and state agencies, has established national Compliance Assistance Centers for nine specific industry sectors heavily populated with small businesses that face substantial federal regulation. These sectors are printing, metal finishing, automotive services and repair, agriculture, commercial transportation, paint and coating applications, the printed wiring board industry, municipalities and small chemical manufacturers.

The purpose of the Centers is to improve compliance of the customers they serve by increasing their awareness of the pertinent federal regulatory requirements and by providing the information that will enable them to achieve compliance. The Centers accomplish this by offering the following:

- "First-Stop Shopping" - serve as the first place that small businesses and technical assistance providers go to get comprehensive, easy to understand compliance information targeted specifically to industry sectors.

- "Improved Information Transfer" - via the Internet and other means, create linkages between the small business community and providers of technical and regulatory assistance and among the providers themselves to share tools and knowledge and prevent duplication of efforts.

- "Compliance Assistance Tools" - develop and disseminate plain-English guides, consolidated checklists, fact sheets, and other tools where needed by small businesses and their information providers.

- "Links Between Pollution Prevention and Compliance Goals" - provide easy access to information and technical assistance on technologies to help minimize waste generation and maximize environmental performance.

- "Information on Ways to Reduce the Costs of Compliance" - identify technologies and best management practices that reduce pollution while saving money.

For general information regarding EPA's compliance assistance centers, contact Tracy Back at (202) 564-7076.

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Industry Research Programs

American Petroleum Institute- Strategies for Today's Environmental Partnership (STEP)

The STEP (Strategies for Today's Environmental Partnership) program was developed by API member companies to address public environmental concerns by improving the industry's environmental, health, and safety performance; documenting performance improvements; and communicating them to the public. The foundation for STEP is the API Environmental Mission and the API Guiding Environmental Principles. The program also includes a series of environmental strategic plans; a review and revision of existing industry standards; documentation of industry environmental, health, and safety performance; and mechanisms for obtaining public input. In 1992, API endorsed, as part of STEP, adoption of management practices as an API recommended practice. The management practices contain the following elements: pollution prevention, operating and process safety, community awareness, crisis readiness, product stewardship, proactive government interaction, and resource conservation. The management practices are an outline of actions to help companies incorporate environmental health and safety concerns into their planning and decision making. Each company will make its own decisions on how and whether to change its operations. API has developed a compilation of resources that provide recommendations and guidance on various operational areas of the oil industry to assist API members with their implementation of the management practices.

STEP is a program of the American Petroleum Institute (API) that strives to improve and promote the industry's commitment to environmental, health, and safety issues. The program encompasses many projects performed by member companies, plus research performed by API. STEP is involved with environmental issues on two fronts: research, and communications with both member companies and external entities.

STEP sponsors a wide range of research on environmental issues, including studies on releases, exposure assessments, and pollution prevention assessments. In many cases, the data leads toward the setting of API industry standards, which are often cited in EPA regulations.

The program also serves to disseminate information about environmental and health issues to the public. An example is the *Petroleum Industry Environmental Performance Annual Report*, which presents statistics on the progress of the industry in reducing its environmental impacts.

API's Upstream Department undertakes a range of activities focused on environmental issues facing the oil and gas extraction industry. Sponsored research may identify available, cost-effective techniques for control of emissions or remediation of a spill. Workshops are sponsored to assist companies (both members and nonmembers) in complying with new regulations or applying new technologies. As an example, API sponsored research on the remediation of soils affected by salt resulting from decades-old discharges or more recent spills of produced water. From this research has grown a series of workshops to transfer this information to companies and state agencies working to address these sites.

Gas Research Institute (GRI)

The Gas Research Institute is headquartered in Chicago and manages a cooperative research, development, and commercialization program for the mutual benefit of the natural gas industry. GRI works with research organizations, manufacturers and its member companies to develop gas technologies and to transfer new products and information to the marketplace.

GRI has published studies of waste generation and management in the natural gas industry. "Waste Minimization in the Natural Gas Industry: Regulations, Methodology, and Assessment of Alternatives" is of particular interest. The publication provides a thorough overview of waste generation in the industry and methods for minimizing many of the waste streams. (Contact: www.gri.org/ or (773) 399-8100.)

VIII.C.2. Trade Associations

American Petroleum Institute (API) 1220 L Street, NW Washington, DC 20005 Phone: (202) 682-8000 Fax: (202) 962-4797	Members: 500 Staff: 300 Budget: $40,000,000 Contact: Mark Rubin www.api.org/

The American Petroleum Institute (API) is the largest trade group for the oil and gas industry, with the largest membership and budget. API represents major oil companies, and independent oil producers, refiners, marketers, and transporters of crude oil, lubricating oil, gasoline, and natural gas. API conducts and promotes research in the oil and gas industry and collects data and publishes statistical reports on oil production and refining. Numerous manuals, booklets, and other materials are published on oil and gas exploration and production.

Independent Petroleum Association of America (IPAA) 1101 16th St., NW Washington, DC 20036 Phone: (202) 857-4722 Fax: (202) 857-4799	Members: 6,000 Staff: 25 Contact: Gil Thrum www.ipaa.org/

IPAA was founded in 1929 to represent small oil and natural gas producers in legislative and regulatory issues at the federal level. Its members are principally well operators and royalty owners, plus others involved in the industry such as suppliers, and drilling contractors. IPAA collects production, consumption, and economic data on the industry and publishes documents including *The Oil and Natural Gas Producing Industry in Your State.*

Society of Petroleum Engineers (SPE) PO Box 833836 Richardson, TX 75083-3836 Phone: (214) 952-9393 Fax: (214) 952-9435	Members: 53,000 Staff: 92 Budget: $15,000,000 Regional Groups: 13 Local Groups: 137 Contact: Dan K. Adamson www.spe.org/

SPE was founded in 1922 to serve petroleum engineers involved with oil and gas exploration and production. The organization has 53,000 members and a budget of $15 million. SPE publishes several journals and books, including the monthly *Journal of Petroleum Technology,* that report on reservoir characterization and management methods and industry statistics.

Association of Oilwell Servicing Contractors (AOSC) 6060 N. Central Expy., Ste. 428 Dallas, TX 75206 Phone: (214) 692-0771 Fax: (214) 692-0162	Members: 600 Staff: 4 Budget: $500,000 Regional Groups: 16 Contact: M.L. Clark

AOSC was founded in 1956, and represents oil well servicing and workover contractors, equipment manufacturers, and others related to the well servicing industry. The organization publishes the monthly *AOSC Newsletter*, which includes industry news, rig activity information, and legislative updates, and

Well Servicing, a bimonthly journal that includes articles on new technology, equipment and products.

Mid-Continent Oil and Gas Association (MCOGA) 801 Pennsylvania Ave NW, Ste. 840 Washington, DC 20004-2604 Phone: (202) 638-4400 Fax: (202) 638-5967	Members: 7,500 Staff: 6 State Groups: 4 Contact: Albert Modiano

The Mid-Continent Oil and Gas Association was founded in 1917 and represents oil and gas producers, royalty owners, refiners, gasoline manufacturers, transporters, drilling contractors, supply and equipment dealers and wholesalers, bankers, and other individuals interested in oil business.

Western States Petroleum Association (WSPA) 505 N. Brand Blvd., Ste. 1400 Glendale, CA 91203-1925 Phone: (818) 545-4105 Fax: (818) 545-0954	Members: 35 Staff: 32 Regional Groups: 4 Contact: Douglas Henderson www.wspa.org/

The Western States Petroleum Association was founded in 1907 and represents companies involved with petroleum exploration, production, refining, transportation, and wholesale marketing in Arizona, California, Hawaii, Nevada, Oregon, and Washington. WSPA offers advisory services for industry members.

Offshore Operators Committee (OOC) P.O. Box 50751 New Orleans, LA 70150 Phone: (504) 593-7443 Fax: (504) 593-7544	Members: 110 Staff: 1 Contact: Mr. Virgil Harris e-mail: virgil_a_harris@cngp.cng.com

OOC is an industry cooperative representing nearly all of the operators in the Gulf of Mexico. They sponsor research on the effects of oil and gas operations offshore and work with EPA on updates to offshore NPDES permits.

Petroleum Technology Transfer Council (PTTC) 1101 16th Street, NW, Suite 1-C Washington, DC 20036 Phone: (202) 785-2225 or (800)THE-PTTC Fax: (202) 785-2240	Regional Centers: 10 Contact: Deborah Rowell www.pttc.org/

The Petroleum Technology Transfer Council (PTTC) was formed in 1994 by the U.S. oil and natural gas exploration and production industry to identify and transfer upstream technologies to domestic producers. PTTC's technology programs help producers reduce costs, improve operating efficiency, increase ultimate recovery, enhance environmental compliance, and add new oil and gas reserves. Through its 10 regional resource centers located at universities around the country, PTTC offers expert assistance, information resources, inter-disciplinary referrals, and demonstrations of E&P software solutions.

EPA Office Of Compliance Sector Notebook Project

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

THE ADMINISTRATOR

Message from the Administrator

Over the past 25 years, our nation has made tremendous progress in protecting public health and our environment while promoting economic prosperity. Businesses as large as iron and steel plants and businesses as small as the dry cleaner on the corner have worked with EPA to find ways to operate cleaner, cheaper, and smarter. As a result, we no longer have rivers catching on fire. Our skies are clearer. American environmental technology and expertise are in demand throughout the world.

The Clinton Administration recognizes that to continue this progress, we must move beyond the pollutant-by-pollutant approaches of the past to comprehensive, facility-wide approaches for the future. Industry by industry and community by community, we must build a new generation of environmental protection.

Within the past two years, the Environmental Protection Agency undertook its Sector Notebook Project to compile, for a number of key industries, information about environmental problems and solutions, case studies and tips about complying with regulations. We called on industry leaders, state regulators, and EPA staff with many years of experience in these industries and with their unique environmental issues. Together with notebooks for 17 other industries, the notebook you hold in your hand is the result.

These notebooks will help business managers to better understand their regulatory requirements, learn more about how others in their industry have undertaken regulatory compliance and the innovative methods some have found to prevent pollution in the first instance. These notebooks will give useful information to state regulatory agencies moving toward industry-based programs. Across EPA we will use this manual to better integrate our programs and improve our compliance assistance efforts.

I encourage you to use this notebook to evaluate and improve the way that together we achieve our important environmental protection goals. I am confident that these notebooks will help us to move forward in ensuring that -- in industry after industry, community after community -- environmental protection and economic prosperity go hand in hand.

ISBN 0-16-048279-8

This report is one in a series of volumes published by the U.S. Environmental Protection Agency (EPA) to provide information of general interest regarding environmental issues associated with specific industrial sectors. The documents were developed under contract by Abt Associates (Cambridge, MA), and Booz-Allen & Hamilton, Inc. (McLean, VA). This publication may be **purchased** from the Superintendent of Documents, U.S. Government Printing Office. A listing of available Sector Notebooks and document numbers is included at the end of this document.

All telephone orders should be directed to:

Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
(202) 512-1800
FAX (202) 512-2250
9:00 a.m. to 4:30 p.m., Eastern Time, M-F

Using the form provided at the end of this document, all mail orders should be directed to:

U.S. Government Printing Office
P.O. Box 371954
Pittsburgh, PA 15250-7954

Complimentary volumes are available to certain groups or subscribers, such as public and academic libraries, Federal, State, local, and foreign governments, and the media. For further information, and for answers to questions pertaining to these documents, please refer to the contact names and numbers provided within this volume.

Electronic versions of all Sector Notebooks are available on the EPA Enviroene Bulletin Board and via the Internet on the Enviroene World Wide Web. Downloading procedures are described in Appendix A of this document.

UST -	Underground Storage Tanks (RCRA)
VOCs -	Volatile Organic Compounds

I. INTRODUCTION TO THE SECTOR NOTEBOOK PROJECT

I.A. Summary of the Sector Notebook Project

Environmental policies based upon comprehensive analysis of air, water and land pollution are an inevitable and logical supplement to traditional single-media approaches to environmental protection. Environmental regulatory agencies are beginning to embrace comprehensive, multi-statute solutions to facility permitting, enforcement and compliance assurance, education/ outreach, research, and regulatory development issues. The central concepts driving the new policy direction are that pollutant releases to each environmental medium (air, water and land) affect each other, and that environmental strategies must actively identify and address these inter-relationships by designing policies for the "whole" facility. One way to achieve a whole facility focus is to design environmental policies for similar industrial facilities. By doing so, environmental concerns that are common to the manufacturing of similar products can be addressed in a comprehensive manner. Recognition of the need to develop the industrial "sector based" approach within the EPA Office of Compliance led to the creation of this document. Many of those who reviewed this notebook are listed as contacts in Section IX and may be sources of additional information. The individuals and groups on this list do not necessarily concur with all statements within this notebook.

The Sector Notebook Project was initiated by the Office of Compliance within the Office of Enforcement and Compliance Assurance (OECA) to provide its staff and managers with summary information for eighteen specific industrial sectors. As other EPA offices, states, the regulated community, environmental groups, and the public became interested in this project, the scope of the original project was expanded. The ability to design comprehensive, common sense environmental protection measures for specific industries is dependent on knowledge of several inter-related topics. For the purposes of this project, the key elements chosen for inclusion are: general industry information (economic and geographic); a description of industrial processes; pollution outputs; pollution prevention opportunities; Federal statutory and regulatory framework; compliance history; and a description of partnerships that have been formed between regulatory agencies, the regulated community and the public.

For any given industry, each topic listed above could alone be the subject of a lengthy volume. However, in order to produce a manageable document, this project focuses on providing summary information for each topic. This format provides the reader with a synopsis of each issue, and references if more in-depth information is available. The contents of each profile were researched from a variety of sources, and were usually condensed from more detailed sources. This approach allowed for a wide coverage of activities that can be further explored based upon the citations and references listed at the end of this profile. As a check on the information included, each notebook went through an external review process. The Office of Compliance appreciates the efforts of all those that participated in this process which enabled us to develop more complete, accurate and up-to-date summaries.

I.B. Additional Information

Providing Comments

OECA's Office of Compliance plans to periodically review and update the notebooks and will make these updates available both in hard copy and electronically. If you have any comments on the existing notebook, or if you would like to provide additional information, please send a hard copy and computer disk to the EPA Office of Compliance, Sector Notebook Project. 401 M St., SW (2223-A), Washington, DC 20460. Comments can also be uploaded to the Enviroene Bulletin Board or the Enviroene World Wide Web for general access to all users of the system. Follow instructions in Appendix A for accessing these data systems. Once you have logged in, procedures for uploading text are available from the on-line Enviroene Help System.

Adapting Notebooks to Particular Needs

The scope of the existing notebooks reflect an approximation of the relative national occurrence of facility types that occur within each sector. In many instances, industries within specific geographic regions or states may have unique characteristics that are not fully captured in these profiles. For this reason, the Office of Compliance encourages state and local environmental agencies and other groups to supplement or re-package the information included in this notebook to include more specific industrial and regulatory information that may be available. Additionally, interested states may want to supplement the "Summary of Applicable Federal Statutes and Regulations" section with state and local requirements. Compliance or technical assistance providers may also want to develop the "Pollution Prevention" section in more detail. Please contact the appropriate specialist listed on the opening page of this notebook if your office is interested in assisting us in the further development of the information or policies addressed within this volume.
If you are interested in assisting in the development of new notebooks for sectors not covered in the original eighteen, please contact the Office of Compliance at 202-564-2395.

II. INTRODUCTION TO THE ORGANIC CHEMICALS INDUSTRY

This section provides background information on the size, geographic distribution, employment, production, sales, and economic condition of the organic chemical industry. The type of facilities described within the document are also described in terms of their Standard Industrial Classification (SIC) codes. Additionally, this section contains a list of the largest companies in terms of sales.

II.A. Introduction, Background, and Scope of the Notebook

The industrial organic chemical sector produces organic chemicals (those containing carbon) used as either chemical intermediates or end-products. This categorization corresponds to Standard Industrial Classification (SIC) code 286 established by the Bureau of Census to track the flow of goods and services within the economy. The 286 category includes gum and wood chemicals (SIC 2861), cyclic organic crudes and intermediates, organic dyes and pigments (SIC 2865), and industrial organic chemicals not elsewhere classified (SIC 2869). By this definition, the industry does not include plastics, drugs, soaps and detergents, agricultural chemicals or paints, and allied products which are typical end-products manufactured from industrial organic chemicals. In 1993, there were 987 establishments in SIC 286 of which the largest 53 firms (by employment) accounted for more than 50 percent of the industry's value of shipments. The SIC 286 may include a small number of integrated firms that are also engaged in petroleum refining and manufacturing of other types of chemicals at the same site although firms primarily engaged in manufacturing coal tar crudes or petroleum refining are classified elsewhere.[a]

The industrial organic chemical market has two broadly defined categories, commodity and specialty. Commodity chemical manufacturers compete on price and produce large volumes of small sets of chemicals using dedicated equipment with continuous and efficient processing. Specialty chemical manufacturers cater to custom markets, manufacture a diverse set of chemicals, use two or three different reaction steps to produce a product, tend to use batch processes, compete on technological expertise and have a greater value added to their products. Commodity chemical manufacturers have lower labor requirements per volume and require less professional labor per volume.

[a] Variations in facility counts occur across data sources due to many factors including reporting and definitional differences. This notebook does not attempt to reconcile these differences, but rather reports the data as they are maintained by each source.

The *1992 Census of Manufactures for Industrial Organic Chemicals* reports employment of 124,800 and a 1992 value of shipments of $64.6 billion. This value of shipments does not include organic chemicals manufactured for captive use within a facility or the value of other non-industrial organic chemical products manufactured by the same facility. It does, however, include intra-company transfers which are significant in this industry. By comparison, the 1992 value of shipments for inorganic chemicals totaled $27.3 billion with employment of 103,400 people. The 1992 value of shipments for the entire chemical industry (SIC 28) was $292.3 billion and employment totaled 850,000. According to *Chemical and Engineering News*, the production of industrial organic chemicals has increased by three percent per year between 1983 and 1993 while employment has fallen by one percent per year over the same period indicating an overall increase in productivity for the sector. The same source reports the industry employed 153,000 people in 1993 while shipping products valued at $60.9 billion.

The Department of Commerce reported that output in the industrial organic chemical market grew five percent between 1992 and 1993 and is expected to continue to grow at the same rate partially on the strength of increased demand and production of methyl tert-butyl ether, a fuel oxygenate.

II.B. Characterization of the Organic Chemicals Industry

II.B.1. Industry size and geographic distribution

Industrial organic chemical facilities have an unusual distribution when compared to downstream manufacturing facilities. Most significantly, a small number of very large facilities account for the majority of the industry's value of shipments. The *1992 Census of Manufactures* (Exhibit 1) showed that only 113 of the 986 industrial organic chemical facilities (11 percent) had more than 250 employees. However, these facilities accounted for almost 70 percent of the value of shipments for the industry; the largest 16 plants (greater than 1,000 employees) accounted for about 25 percent of the total value of shipments.

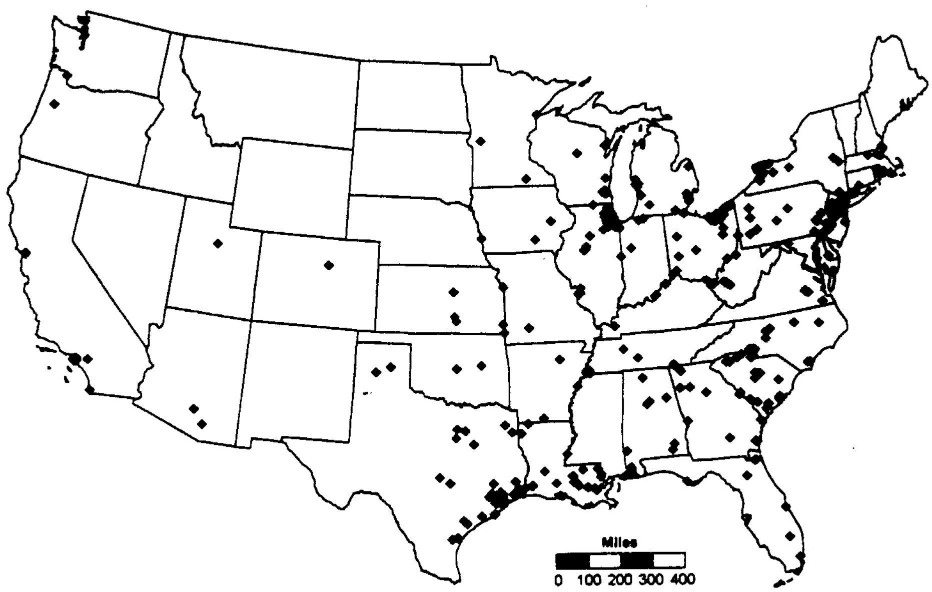
Exhibit 1: Small Number of Large Facilities Account for Majority of Shipments

Number of Employees	Number of Facilities	Percent of Facilities	Percent of Shipment Value
fewer than 10	259	26%	1%
10 to 49	301	30%	5%
50 to 249	313	32%	27%
250 to 499	60	6%	16%
500 to 999	37	4%	26%
1,000 or more	16	2%	25%
Total	986	100%	100%

Source: *1992 Census of Manufactures*

The industrial organic chemical sector is geographically diverse (Exhibit 2). Gum and wood chemical manufacture (SIC 2861) is concentrated in Missouri, Florida and Virginia. Cyclic crudes and intermediates (SIC 2865) and unclassified industrial organic chemicals (SIC 2869) are concentrated in Texas, Louisiana, New Jersey, Ohio, Illinois and West Virginia. Facility sites are typically chosen for their access to raw materials (petroleum and coal products for SICs 2865 and 2869 and wood for SIC 2861) and to transportation routes. In addition, because much of the market for industrial organic chemicals is the chemical industry, facilities tend to cluster near such end-users.

Exhibit 2: Organic Chemical Manufacturing Facilities (SIC 286)



(Source: U.S. EPA, Toxics Release Inventory Database, 1993)

Ward's Business Directory of U.S. Private and Public Companies, produced by Gale Research Inc., compiles financial data on U.S. companies including those operating within the organic chemical industry. Ward's ranks U.S. companies, whether they are a parent company, subsidiary or division, by sales volume within their assigned 4-digit SIC code. Readers should note that: (1) companies are assigned a 4-digit SIC that most closely resembles their principal industry; and (2) sales figures include total company sales, including subsidiaries and operations (not related to organic chemicals). Additional sources of company specific financial information include Standard & Poor's *Stock Report Services*, Dun & Bradstreet's *Million Dollar Directory*, Moody's Manuals, and annual reports.

Exhibit 3: Top U.S. Companies with Organic Chemical Operations

Rank[a]	Company[b]	1993 Sales (millions of dollars)
1	Exxon Corp., Exxon Chemical Co. - S. Darien, CT	9,591
2	Dow Chemical USA - Midland, MI	9,000
3	Miles, Inc. - Pittsburgh, PA	5,130
4	Union Carbide Corp. - Danbury, CT	4,877
5	Amoco Chemical Co. - Chicago, IL	4,031
6	Chevron Chemical Co. - San Ramon, CA	3,354
7	Quantum Chemical Corp. - New York, NY	2,532
8	Witco Corp. - New York, NY	1,631
9	Ethyl Corp. - Baton Rouge, LA	1,600
10	Texaco Chemical Co. - Houston, TX	1,600

Note: [a] When Ward's Business Directory lists both a parent and subsidiary in the top ten, only the parent company is presented above to avoid double counting. Not all sales can be attributed to the companies' organic chemical operations.
[b] Companies shown listed SIC 286 as primary activity.

Source: Ward's Business Directory of U.S. Private and Public Companies - 1993.

II.B.2. Product Characterization

The two-digit SIC code 28, Chemicals and Allied Products, includes facilities classified as industrial organic chemical manufacturers under the three-digit SIC code 286. This includes gum and wood chemicals, cyclic crudes and intermediates and industrial organic chemical not elsewhere classified. The last category is by far the largest and most diverse of the three; however, its size distribution and industry structure are similar to those of the cyclic crudes and intermediates because both use primarily petroleum and coal derived feedstocks. In addition to industrial organic chemicals, seven separate types of product establishments are identified under Chemicals and Allied Products (SIC 28). Many of the other industry sectors within the two-digit SIC code 28, such as plastics materials and synthetics (SIC 282), are downstream users of the products manufactured by the industrial organic chemical industry. Others, such as the inorganic chemical sector, utilize unrelated feedstocks.

The following list includes industrial organic chemicals (italicized) as well as other chemicals and allied product SIC codes included within SIC code 28.

SIC	Industry Sector	SIC	Industry Sector
281	Inorganic Chemicals	*2861*	*Gum and Wood Chemicals*
282	Plastics Materials and Synthetics	*2865*	*Cyclic Organic Chemicals*
283	Drugs	*2869*	*Industrial Organic Chemicals, n.e.c.*
284	Soaps, Cleaners, and Toilet Goods	287	Agricultural Chemicals
285	Paints and Allied Products	289	Miscellaneous Chemical Products

The industrial organic chemical industry uses feedstocks derived from petroleum and natural gas (about 90 percent) and from recovered coal tar condensates generated by coke production (about 10 percent). The chemical industry produces raw materials and intermediates, as well as a wide variety of finished products for industry, business and individual consumers. The important classes of products within SIC code 2861 are hardwood and softwood distillation products, wood and gum naval stores, charcoal, natural dyestuffs, and natural tanning materials.

The important classes of products within SIC code 2865 are: (1) derivatives of benzene, toluene, naphthalene, anthracene, pyridene, carbazole, and other cyclic chemical products, (2) synthetic organic dyes, (3) synthetic organic pigments, (4) cyclic (coal tar) crudes, such as light oils and light oil products; coal tar acids; and products of medium and heavy oil such as creosote oil, naphthalene, anthracene and their high homologues.

Important classes of chemicals produced by organic chemical industry facilities within SIC code 2869 include: (1) non-cyclic organic chemicals such as acetic, chloroacetic, adipic, formic, oxalic acids and their metallic salts, chloral, formaldehyde, and methylamine; (2) solvents such as amyl, butyl and ethyl alcohols; methanol; amyl, butyl, and ethyl acetates; ethyl ether, ethylene glycol ether and diethylene glycol ether; acetone, carbon disulfide, and chlorinated solvents such as carbon tetrachloride, tetrachloroethene, and trichloroethene; (3) polyhydric alcohols such as ethylene glycol, sorbitol, pentaerythritol, and synthetic glycerin; (4) synthetic perfumes and flavoring materials such as coumarin, methyl salicylate, saccharin, citral, citronellal, synthetic geraniol, ionone, terpineol, and synthetic vanillin; (5) rubber processing chemicals such as accelerators and antioxidants, both cyclic and acyclic; (6) plasticizers, both cyclic and acyclic, such as esters of phosphoric acid, phthalic anhydride, adipic acid, lauric acid, oleic acid, sebacic acid, and stearic acid; (7) synthetic tanning agents such as sulfonic acid condensates; and (8) esters and amines of polyhydric alcohols and fatty and other acids.

II.B.3. Economic trends

With organic chemicals as the single largest segment of chemical exports (accounting for nearly one-half of total chemical shipments to foreign markets), the industrial organic sector faces a market similar to the petrochemical industry. While the U.S. production is expected to continue to grow at two to four percent annually, there is increasing competition in the export market despite growing demand. World petrochemical demand is projected to increase from 320 million metric tons in 1992 to 575 million metric tons in 2010. The share accounted for by the United States, Western Europe and Japan is expected to drop from 71 to 63 percent. Products from the Gulf Cooperation Council and Pacific Rim countries, including China and Korea, will begin to compete with U.S. products in current export markets as new facilities are brought on-line. The U.S. is expected to maintain a positive trade balance in organic chemicals. Chemical imports of organic chemicals (some representing intra-company transfers) have been steady over the last five years. The reduced trade barriers due to the North American Free Trade Agreement (NAFTA) and the Uruguay Round of the General Agreement on Tariffs and Trade (GATT) have increased competition. Firms are adapting to the increased competition by emphasizing specialty chemicals and higher value-added products.

III. INDUSTRIAL PROCESS DESCRIPTION

This section describes the major industrial processes within the organic chemical industry, including the materials and equipment used, and the processes employed. The section is designed for those interested in gaining a general understanding of the industry, and for those interested in the inter-relationship between the industrial process and the topics described in subsequent sections of this profile -- pollutant outputs, pollution prevention opportunities, and Federal regulations. This section does not attempt to replicate published engineering information that is available for this industry. Refer to Section IX for a list of reference documents that are available.

This section specifically contains a description of commonly used production processes, associated raw materials, the by-products produced or released, and the materials either recycled or transferred off-site. This discussion, coupled with schematic drawings of the identified processes, provides a concise description of where wastes may be produced in the process. This section also describes the potential fate (via air, water, and soil pathways) of these waste products.

III.A. Industrial Processes in the Organic Chemicals Industry

Industrial Organic Chemicals - Overview

The industrial organic chemical sector includes thousands of chemicals and hundreds of processes. In general, a set of building blocks (feedstocks) is combined in a series of reaction steps to produce both intermediates and end-products. The chart and flow diagram below (Exhibits 4 and 5) show the primary organic chemical building blocks (generated principally from petroleum refining), a key subset of the large volume secondary building blocks and a set of large volume tertiary building blocks. The subsequent chart (Exhibit 6) shows the reaction types used to manufacture a sample of organic chemicals, and illustrates the large variety of processes used by the industry.

Exhibit 4: High Volume Organic Chemical Building Blocks

Primary Building Block	Secondary Building Block	Tertiary Building Block
Ethylene	Ethylene dichloride Ethylene oxide Ethylbenzene	Vinyl chloride Ethylene glycol Vinyl acetate
Propylene	Propylene oxide Acrylonitrile Isopropyl alcohol	 Acetone
Benzene	Ethylbenzene Cumene Cyclohexane	Styrene Phenol Acetone Adipic acid
Methanol	Acetic acid Formaldehyde Methyl t-butyl ether	Vinyl acetate
Toluene		
Xylenes p-isomer	 Terephthalic acid	
Butadiene		
Butylene

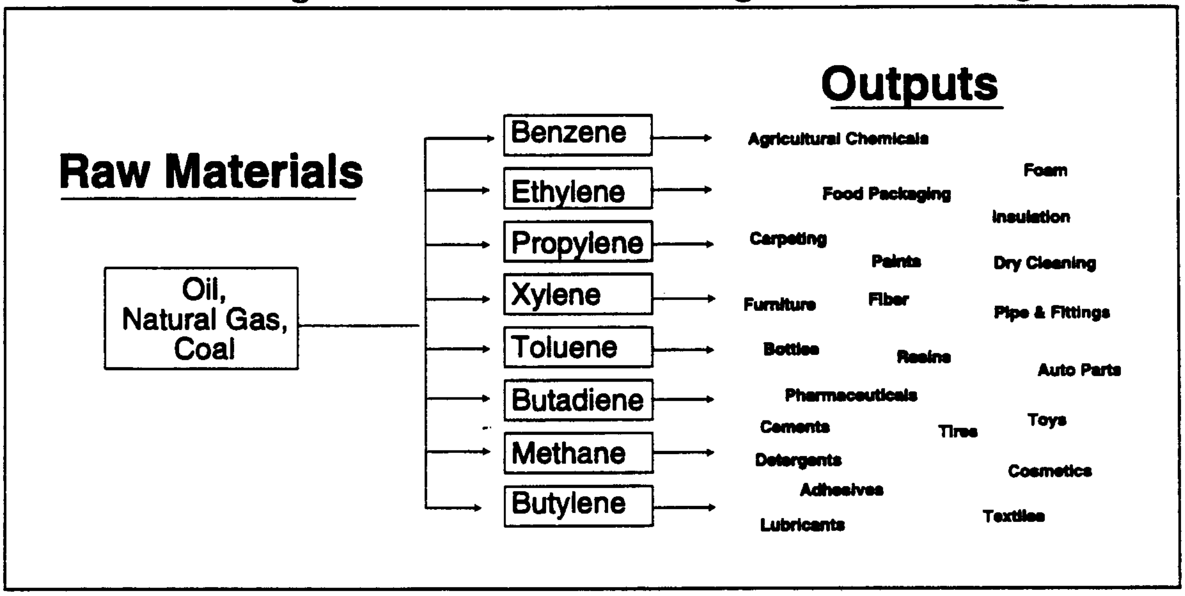
Exhibit 5: Organic Chemicals and Building Blocks Flow Diagram



The typical chemical synthesis process involves combining multiple feedstocks in a series of unit operations. The first unit operation is a chemical reaction. Commodity chemicals tend to be synthesized in a continuous reactor while specialty chemicals usually are produced in batches. Most reactions take place at high temperatures, involve metal catalysts, and include one or two additional reaction components. The yield of the reaction will partially determine the kind and quantity of by-products and releases. Many specialty chemicals require a series of two or three reaction steps. Once the reaction is complete, the desired product must be separated from the by-products by a second unit operation. A number of separation techniques such as settling, distillation or refrigeration may be used. The final product may be further processed, by spray drying or pelletizing for example, to produce the saleable item. Frequently by-products are also sold and their value may alter the process economics.

R0076798

The separation technology employed depends on many factors including the phases of the substances being separated, the number of components in the mixture, and whether recovery of by-products is important. Numerous techniques such as distillation, extraction, filtration, and settling can be used singly or in combination to accomplish separations and are summarized in publications such as *Perry's Chemical Engineers' Handbook* or basic texts on chemical plant design.

Relatively few organic chemical manufacturing facilities are single product/process plants. Additionally, many process units are designed so that production levels of related products can be varied over wide ranges. This flexibility is required to accommodate variations in feedstock and product prices which can change the production rate and processes used, even on a short-term (less than a year) basis. A 1983 survey showed that 59 percent of industrial organic plants had more than one product or process and that seven percent had more than 20 (USEPA Development Document for Effluent Limitations Guidelines and Standards for the Organic Chemicals, Plastics and Synthetic Fibers Point Source Category).

The type of reaction process used to manufacture chemicals depends on the intended product; however, several types of reactions are common: polymerization, oxidation, and addition. Polymerization is a chemical reaction usually carried out with a catalyst, heat or light (often under high pressure) in which a large number of relatively simple molecules combine to form a chain-like macromolecule. Oxidation, in the strict sense, means combining oxygen chemically with another substance although this name is also applied to reactions where electrons are transferred. Addition covers a wide range of reactions where a double or triple bond is broken and a component added to the structure. Alkylation can be considered an addition, as can some oxidation reactions. The following charts list the reactions used to produce a subset of organic chemical products.

Four Specific Industrial Organic Chemicals

This profile examines the reactions of four high-volume chemicals (ethylene, propylene, benzene and vinyl chloride) chosen to illustrate the use of typical chemical feedstocks based on several factors, including the quantity of chemical produced, and the health and environmental impacts of the chemical. Ethylene, propylene, and benzene are all primary building blocks and their reaction products are used to produce still other chemicals. Vinyl chloride is an important tertiary building block.

The four chemicals described below illustrate several key points. First, primary building blocks are typically used in more reactions than the building blocks further down the chain. Second, most feedstocks can participate in more than one reaction and third, there is typically more than one reaction route to an end-product. The end-products of all of these chemicals can be used in numerous commercial applications; *Riegel's Handbook of Industrial Chemistry*, listed in the reference section, describes many uses.

Ethylene

The major uses for ethylene are in the synthesis of polymers (polyethylene) and in ethylene dichloride, a precursor to vinyl chloride. Other important products are ethylene oxide (a precursor to ethylene glycol) and ethylbenzene (a precursor to styrene). While ethylene itself is not generally considered a health threat, several of its derivatives, such as ethylene oxide and vinyl chloride, have been shown to cause cancer. The distribution of uses is shown below.

The manufacturing processes that use ethylene as a feedstock are summarized in the table below along with reaction conditions and components. In 1993, 18.8 million metric tons of ethylene were produced in the United States making ethylene the fourth largest production volume organic chemical in the United States. Ethylene dichloride, ethylbenzene, and ethylene oxide (products of ethylene reactions) are all among the top 50 high production volume organic chemicals in the United States (*Chemical and Engineering News*).

Exhibit 7: Distribution of Uses for Ethylene

Product	Percent of Ethylene Use
Polyethylene	54
Ethylene dichloride	16
Ethylbenzene-styrene	7
Ethylene oxide-glycol	13
Ethanol	1
Linear olefins-alcohol	3
Vinyl acetate	2

Propylene

Over half of the U.S. propylene supplies (10.2 million metric tons produced in 1993) are used in the production of chemicals. The primary products are polypropylene, acrylonitrile, propylene oxide, and isopropyl alcohol. Of these, propylene, acrylonitrile and propylene oxide are among the top fifty high-volume chemicals produced in the United States. Acrylonitrile and propylene oxide have both been shown to cause cancer, while propylene itself is not generally considered a health threat. The table below shows the use distribution of propylene.

Exhibit 9: Distribution of Propylene Use

Product	Percent of Propylene Use
Polypropylene	36
Acrylonitrile	16
Propylene oxide	11
Cumene	9
Butyraldehydes	7
Oligomers	6
Isopropyl alcohol	6
Other	9

Source: Szmant, *Organic Building Blocks of the Chemical Industry*

The important propylene reactions are shown below. The products of the reactions are the feedstocks for numerous additional products.

R0076802

Exhibit 10: Manufacturing Processes Using Propylene

Process	Target Product	Process Conditions			Reaction Components	Other Characteristics
		Pressure (MPa)	Temperature	Catalyst		
Polymerization	Polypropylene			Aluminum alkyls/Titanium oxide		
Oxidation	Acrylonitrile		400	Phosphomolybdate	Ammonia Oxygen	Commercially valuable by-products are acetonitrile and hydrogen cyanide
	Propylene oxide				Oxygen Ethylbenzene	Commercially valuable by-product is *tert*-butyl alcohol
Addition Chlorohydrination	Propylene oxide	25	37	Tungsten	Hypochlorous acid	
Hydrolysis	Isopropyl alcohol		267		Water	

Source: *Kirk-Othmer Encyclopedia of Chemical Technology*

Benzene

Benzene is an important intermediate in the manufacture of industrial chemicals and over 5.5 million metric tons were produced in the U.S. in 1993 (*Chemical and Engineering News*). Over 95 percent of U.S. consumption of benzene is for the preparation of ethylbenzene, cumene, cyclohexane, nitrobenzene, and various chlorobenzenes as shown in the table below.

Exhibit 11: Distribution of Benzene Use

Product	Percent of Benzene Use
Ethylbenzene	52
Cumene	22
Cyclohexane	14
Nitrobenzene	5
Chlorobenzenes	2
Linear detergent alkylate	2
Other	3

Source: *Kirk-Othmer Encyclopedia of Chemical Technology*

The following table summarizes the primary benzene reactions. The products are frequently feedstocks in the synthesis of additional chemicals. Benzene is considered a human carcinogen by the Agency.

Exhibit 12: Manufacturing Processes Using Benzene

Process	Target product	Process Conditions			Reaction components	Other characteristics
		Pressure (MPa)	Temperature (°C)	Catalyst		
Oxidation	Phenol	0.6	90-100		Cumene, Oxygen	Most important phenol synthesis
	Maleic anhydride	0.1-0.2	350-400	Vanadium oxide	Butane Oxygen	
	Styrene	0.1	580-590	Iron oxide	Ethylene benzene	
Addition Alkylation	Ethylbenzene	0.2-0.4	125-140	Aluminum chloride	Benzene, Ethylene	Precursor to styrene
	Ethylbenzene	2.0	420-430	Zeolite	Benzene, Ethylene	Precursor to styrene
	Cumene	0.3-1.0	250-350	Phosphoric acid/silicate	Benzene, Propylene	
	2,6-Xylenol	0.1-0.2	300-400	Aluminum oxide	Phenol, Methanol	
Hydrogenation	Cyclohexanone	0.1	140-170	Palladium	Phenol, Hydrogen	
	Cyclohexanol	1.0-2.0	120-200	Nickel/silicon oxide and aluminum oxide	Phenol Hydrogen	
	Cyclohexane	2.0-5.0	150-200	Nickel	Benzene, Hydrogen	
	Aniline	.18	270	Copper	Nitrobenzene, Hydrogen	
Nitration	Nitrobenzene	0.1	60		Benzene, sulfuric acid, nitric acid	
Sulfonation	Surfactants	0.1	40-50		Alkylbenezenes/ Sulfur trioxide	
Chlorination	Chlorobenzene	0.1	30-40	Aluminum chloride/ Iron chloride	Benzene, Chlorine	
Condensation	Biphenol A	0.1	50-90	HCl	Phenol, Acetone	

Source: *Franck and Stadelhofer, "Industrial Aromatic Chemistry"*

Vinyl Chloride

Vinyl chloride is one of the largest commodity chemicals in the U.S. with over 6.25 million metric tons produced in 1993. It is also considered a human carcinogen by the EPA. Vinyl chloride polymers are the primary end use but various vinyl ethers, esters, and halogen products can also be made as shown in the table below.

Exhibit 13: Manufacturing Processes Using Vinyl Chloride

Process	Target Product	Process Conditions			Reaction components	Other characteristics
		Pressure (MPa)	Temperature (°C)	Catalyst		
Polymerization	Polyvinylchloride		50	Peroxides		
Substitution at the Carbon-Chlorine Bond	Vinyl acetates, alcholates, vinyl esters and vinyl ethers			Palladium	Alkyl halides	
Addition	Various halogen addition products					

Source: *Kirk-Othmer Encyclopedia of Chemical Technology*

III.B. Raw Material Inputs and Pollution Outputs

Industrial organic chemical manufacturers use and generate both large numbers and quantities of chemicals. The industry emits chemicals to all media including air (through both fugitive and direct emissions), water (direct discharge and runoff) and land. The types of pollutants a single facility will release depend on the feedstocks, processes, equipment in use and maintenance practices. These can vary from hour to hour and can also vary with the part of the process that is underway. For example, for batch reactions in a closed vessel, the chemicals are more likely to be emitted at the beginning and end of a reaction step (associated with vessel loading and product transfer operations), than during the reaction. The potential sources of pollutant outputs by media are shown below.

Exhibit 14: Potential Releases During Organic Chemical Manufacturing

Media	Potential Sources of Emissions
Air	Point source emissions: stack, vent (e.g. laboratory hood, distillation unit, reactor, storage tank vent), material loading/unloading operations (including rail cars, tank trucks, and marine vessels) Fugitive emissions: pumps, valves, flanges, sample collection, mechanical seals, relief devices, tanks Secondary emissions: waste and wastewater treatment units, cooling tower, process sewer, sump, spill/leak areas
Liquid wastes (Organic or Aqueous)	Equipment wash solvent/water, lab samples, surplus chemicals, product washes/purifications, seal flushes, scrubber blowdown, cooling water, steam jets, vacuum pumps, leaks, spills, spent/used solvents, housekeeping (pad washdown), waste oils/lubricants from maintenance
Solid Wastes	Spent catalysts, spent filters, sludges, wastewater treatment biological sludge, contaminated soil, old equipment/insulation, packaging material, reaction by-products, spent carbon/resins, drying aids
Ground Water Contamination	Unlined ditches, process trenches, sumps, pumps/valves/fittings, wastewater treatment ponds, product storage areas, tanks and tank farms, aboveground and underground piping, loading/unloading areas/racks, manufacturing maintenance facilities

III.C. Management of Chemicals in the Production Process

The Pollution Prevention Act of 1990 (PPA) requires facilities to report information about the management of TRI chemicals in waste and efforts made to eliminate or reduce those quantities. These data have been collected annually in Section 8 of the TRI reporting Form R beginning with the 1991 reporting year. The data summarized below cover the years 1992 through 1995 and is meant to provide a basic understanding of the quantities of waste handled by the industry, the methods typically used to manage this waste, and recent trends in these methods. TRI waste management data can be used to assess trends in source reduction within individual industries and facilities, and for specific TRI chemicals. This information could then be used as a tool in identifying opportunities for pollution prevention compliance assistance activities.

From the yearly data presented below it is apparent that the portion of TRI wastes reported as recycled on-site has remained reasonably constant between 1992 and 1995 (projected). While the quantities reported for 1992 and 1993 are estimates of quantities already managed, the quantities reported for 1994 and 1995 are projections only. The PPA requires these projections to encourage facilities to consider future waste generation and source reduction of those quantities as well as movement up the waste management hierarchy. Future-year estimates are not commitments that facilities reporting under TRI are required to meet.

Exhibit 15 shows that the organic chemical industry managed about 6.3 trillion pounds of production-related waste (total quantity of TRI chemicals in the waste from routine production operations) in 1993 (column B). Column C reveals that of this production-related waste, seven percent was either transferred off-site or released to the environment. Column C is calculated by dividing the total TRI transfers and releases by the total quantity of production-related waste. In other words, about 90 percent of the industry's TRI wastes were managed on-site through recycling, energy recovery, or treatment as shown in columns E, F and G, respectively. The majority of waste that is released or transferred off-site can be divided into portions that are recycled off-site, recovered for energy off-site, or treated off-site as shown in columns H, I and J, respectively. The remaining portion of the production related wastes (three percent), shown in column D, is either released to the environment through direct discharges to air, land, water, and underground injection, or it is disposed off-site.

Exhibit 15: Source Reduction and Recycling Activity for the Organic Chemical Industry (SIC 286) as Reported within TRI

A	B	C	D	On-Site			Off-Site		
				E	F	G	H	I	J
Year	Quantity of Production-Related Waste (10^6 lbs.)[a]	% Released and Transferred[b]	% Released and Disposed[c] Off-site	% Recycled	% Energy Recovery	% Treated	% Recycled	% Energy Recovery	% Treated
1992	6,313	7%	3%	71%	7%	15%	2%	1%	2%
1993	6,325	7%	3%	71%	7%	15%	2%	1%	1%
1994	6,712	---	2%	71%	8%	15%	2%	1%	1%
1995	6,645	---	2%	72%	7%	15%	2%	1%	<1%

[a] Within this industry sector, non-production related waste < 1% of production related wastes for 1993.
[b] Total TRI transfers and releases as reported in Section 5 and 6 of Form R as a percentage of production related wastes.
[c] Percentage of production related waste released to the environment and transferred off-site for disposal.

IV. CHEMICAL RELEASE AND TRANSFER PROFILE

The following is a synopsis of current scientific toxicity and fate information for the top chemicals (by weight) that facilities within this sector self-reported as released to the environment based upon 1993 TRI data. Because this section is based upon self-reported release data, it does not attempt to provide information on management practices employed by the sector to reduce the release of these chemicals. Information regarding pollutant release reductions over time may be available from EPA's TRI and 33/50 programs, or directly from the industrial trade associations that are listed in Section IX of this document. Since these descriptions are cursory, please consult the sources referenced below for a more detailed description of both the chemicals described in this section and the chemicals that appear on the full list of TRI chemicals appearing in Section IV.A.

This section is designed to provide background information on the pollutant releases that are reported by this industry. The best source of comparative pollutant release information is the Toxic Release Inventory System (TRI). Pursuant to the Emergency Planning and Community Right-to-Know Act, TRI includes self-reported facility release and transfer data for over 600 toxic chemicals. Facilities within SIC Codes 20 through 39 (manufacturing industries) that have more than 10 employees, and that are above weight-based reporting thresholds are required to report TRI on-site releases and off-site transfers. The information presented within the sector notebooks is derived from the most recently available (1993) TRI reporting year (which then included 316 chemicals), and focuses primarily on the on-site releases reported by each sector. Because TRI requires consistent reporting regardless of sector, it is an excellent tool for drawing comparisons across industries. TRI data provide the type, amount and media receptor of each chemical released or transferred.

Although this sector notebook does not present historical information regarding TRI chemical releases over time, please note that in general, toxic chemical releases have been declining. In fact, according to the 1993 Toxic Release Inventory Data Book, reported releases dropped by 43 percent between 1988 and 1993. Although on-site releases have decreased, the total amount of reported toxic waste has not declined because the amount of toxic chemicals transferred off-site has increased. Transfers have increased from 3.7 billion pounds in 1991 to 4.7 billion pounds in 1993. Better management practices have led to increases in off-site transfers of toxic chemicals for recycling. More detailed information can be obtained from EPA's annual Toxics Release Inventory Public Data Release book (which is available through the EPCRA Hotlines at 800-535-0202), or directly from the Toxic Release Inventory System database (for user support call 202-260-1531).

Wherever possible, the sector notebooks present TRI data as the primary indicator of chemical release within each industrial category. TRI data provide the type, amount and media receptor of each chemical released or transferred. When other sources of pollutant release data have been obtained, these data have been included to augment the TRI information.

TRI Data Limitations

The reader should keep in mind the following limitations regarding TRI data. Within some sectors, the majority of facilities are not subject to TRI reporting because they are not considered manufacturing industries, or because they are below TRI reporting thresholds. Examples are the mining, dry cleaning, printing, and transportation equipment cleaning sectors. For these sectors, release information from other sources has been included.

The reader should also be aware that TRI "pounds released" data presented within the notebooks is not equivalent to a "risk" ranking for each industry. Weighting each pound of release equally does not factor in the relative toxicity of each chemical that is released. The Agency is in the process of developing an approach to assign toxicological weightings to each chemical released so that one can differentiate between pollutants with significant differences in toxicity. As a preliminary indicator of the environmental impact of the industry's most commonly released chemicals, this notebook briefly summarizes the toxicological properties of the top five chemicals (by weight) reported by the organic chemical industry.

Definitions Associated with Section IV Data Tables

General Definitions

SIC Code -- is the Standard Industrial Classification (SIC) is a statistical classification standard used for all establishment-based Federal economic statistics. The SIC codes facilitate comparisons between facility and industry data.

TRI Facilities -- are manufacturing facilities that have 10 or more full-time employees and are above established chemical throughput thresholds. Manufacturing facilities are defined as facilities in Standard Industrial Classification primary codes 20 through 39. Facilities must submit estimates for all chemicals that are on the EPA's defined list and are above throughput thresholds.

Data Table Column Heading Definitions

The following definitions are based upon standard definitions developed by EPA's Toxic Release Inventory Program. The categories below represent the possible pollutant destinations that can be reported.

RELEASES -- are an on-site discharge of a toxic chemical to the environment. This includes emissions to the air, discharges to bodies of water, releases at the facility to land, as well as contained disposal into underground injection wells.

Releases to Air (Point and Fugitive Air Emissions) -- Include all air emissions from industry activity. Point emissions occur through confined air streams as found in stacks, ducts, or pipes. Fugitive emissions include losses from equipment leaks, or evaporative losses from impoundments, spills, or leaks.

Releases to Water (Surface Water Discharges) -- encompass any releases going directly to streams, rivers, lakes, oceans, or other bodies of water. Any estimates for storm water runoff and non-point losses must also be included.

Releases to Land -- includes disposal of toxic chemicals in waste to on-site landfills, land treated or incorporation into soil, surface impoundments, spills, leaks, or waste piles. These activities must occur within the facility's boundaries for inclusion in this category.

Underground Injection -- is a contained release of a fluid into a subsurface well for the purpose of waste disposal.

TRANSFERS -- is a transfer of toxic chemicals in wastes to a facility that is geographically or physically separate from the facility reporting under TRI. The quantities reported represent a movement of the chemical away from the reporting facility. Except for off-site transfers for disposal, these quantities do not necessarily represent entry of the chemical into the environment.

Transfers to POTWs -- are waste waters transferred through pipes or sewers to a publicly owned treatments works (POTW). Treatment and chemical removal depend on the chemical's nature and treatment methods used. Chemicals not treated or destroyed by the POTW are generally released to surface waters or land filled within the sludge.

Transfers to Recycling -- are sent off-site for the purposes of regenerating or recovering still valuable materials. Once these chemicals have been recycled, they may be returned to the originating facility or sold commercially.

Transfers to Energy Recovery -- are wastes combusted off-site in industrial furnaces for energy recovery. Treatment of a chemical by incineration is not considered to be energy recovery.

Transfers to Treatment -- are wastes moved off-site for either neutralization, incineration, biological destruction, or physical separation. In some cases, the chemicals are not destroyed but prepared for further waste management.

Transfers to Disposal -- are wastes taken to another facility for disposal generally as a release to land or as an injection underground.

IV.A. EPA Toxic Release Inventory for the Organic Chemicals Industry

According to the Toxics Release Inventory (TRI) data, 417 organic chemical facilities released (to the air, water or land) and transferred (shipped off-site or discharged to sewers) a total of 438 million pounds of toxic chemicals during calendar year 1993. That represents approximately 18 percent of the 2.5 billion pounds of releases and transfers from the chemical industry as a whole (SIC 28) and about six percent of the releases and transfers for all manufacturers reporting to TRI that year. By comparison, the inorganic chemical industry's releases and transfers in 1993 totaled 249.7 million pounds, or sixty percent of the releases and transfers of the industrial organic chemical sector.

The chemical industry's <u>releases</u> have been declining in recent years. Between 1988 and 1992 TRI emissions from chemical companies (all those categorized within SIC 28, not just organic chemical manufacturers) to air, land, and water were reduced 44 percent, which is average for all manufacturing sectors reporting to TRI.

Because the chemical industry (SIC 28) has historically released more TRI chemicals than any other industry, the EPA has worked to improve environmental performance within this sector. This has been done through a combination of enforcement actions, regulatory requirements, pollution prevention projects, and voluntary programs (e.g. EPA's 33/50 program). In addition, the chemical industry has focused on reducing pollutant releases. For example, the Chemical Manufacturer's Association's (CMA's) Responsible Care® initiative is intended to reduce or eliminate chemical manufacturers' wastes. All 185 members of the CMA, firms that account for the majority of U.S. chemical industry sales and earnings, are required to participate in the program as a condition of CMA membership. Participation involves demonstrating a commitment to the program's mandate of continuous improvement of the environment, health, and safety. In June of 1994, the CMA approved the use of a third-party verification of management plans to meet these objectives. State-level toxics use reduction requirements, public disclosure of release and transfer information contained in TRI, and voluntary programs such as EPA's 33/50 Program have also been given as reasons for release reductions.

Exhibit 16 presents the number and volumes of chemicals released by organic chemical facilities. The quantity of the basic feedstocks released reflects their volume of usage. The inorganic chemicals among the top ten released (ammonia, nitric acid, ammonium sulfate, and sulfuric acid) are also large volume reaction feedstocks. Inorganic chemicals contained in wastes injected underground on-site account for 58 percent of the industry's releases; ammonia makes up the vast majority of TRI chemicals disposed of via underground injection. Air releases account for 40 percent (61 million pounds), and the remaining approximately 1.5 percent (2.4 million pounds) is discharged directly to water or land disposed.

Exhibit 17 presents the number and volumes of chemicals transferred by organic chemical facilities. Off-site transfers account for the largest amount, 65 percent, of the organic chemical industry's total releases and transfers as reported in TRI. Three chemicals (sulfuric acid, methanol and *tert*-butyl alcohol) account for over one-half of the 287 million pounds transferred off-site. The 49 million pounds of POTW discharges (primarily methanol and ammonia) account for 17 percent of releases and transfers.

The frequency with which chemicals are reported by facilities within a sector is one indication of the diversity of operations and processes. Many chemicals are released or transferred by a small number of facilities, which indicates a wide diversity of production processes, particularly for specialty organic chemicals -- over one half of the 204 chemicals reported are released by fewer than 10 facilities. However, the organic chemical industry is also characterized by one of the largest numbers of chemicals reported by any manufacturing sector. Of the over 300 chemicals currently listed on TRI, 204 are reported as released or transferred by at least one organic chemical facility.

The TRI database contains a detailed compilation of self-reported, facility-specific chemical releases. The top reporting facilities for this sector are listed below (Exhibit 18). Facilities that have reported only the SIC codes covered under this notebook appear on the first list. Exhibit 19 contains additional facilities that have reported the SIC code covered within this report, and one or more SIC codes that are not within the scope of this notebook. Therefore, the second list includes facilities that conduct multiple operations -- some that are under the scope of this notebook, and some that are not. Currently, the facility-level data do not allow pollutant releases to be broken apart by industrial process.

Exhibit 18: Top 10 TRI Releasing Organic Chemical Manufacturing Facilities[b]

Rank	Facility	Total TRI Releases in Pounds
1	Du Pont Victoria Plant - Victoria, TX	22,471,672
2	BP Chemicals Inc. Green Lake - Port Lavaca, TX	20,650,979
3	Zeneca Specialties Mount Pleasant Plant - Mt. Pleasant, TN	13,429,259
4	Hoechst-Celanese Chemical Group Inc. Clear Lake Plant - Pasadena, TX	10,354,443
5	Du Pont Sabine River Works - Orange, TX	9,731,302
6	Merichem Co. - Houston, TX	3,832,980
7	Hoechst-Celanese Chemical Group Inc. - Bay City, TX	3,454,971
8	Union Carbide C & P CO. Institute WV Plant Ops. - Institute, WV	3,082,932
9	Aqualon - Hopewell, VA	3,007,010
10	Aristech Chemical Corp. - Haverhill, OH	2,858,009

Source: U.S. EPA, Toxics Release Inventory Database, 1993

[b] Being included on this list does not mean that the release is associated with non-compliance with environmental laws.

IV.B. Summary of Selected Chemicals Released

The brief descriptions provided below were taken from the *1993 Toxics Release Inventory Public Data Release* (EPA, 1994), the Hazardous Substances Data Bank (HSDB), and the Integrated Risk Information System (IRIS), both accessed via TOXNET.[d]

Ammonia[e] (CAS: 7664-41-7)

Toxicity. Anhydrous ammonia is irritating to the skin, eyes, nose, throat, and upper respiratory system.

Ecologically, ammonia is a source of nitrogen (an essential element for aquatic plant growth), and may therefore contribute to eutrophication of standing or slow-moving surface water, particularly in nitrogen-limited waters such as the Chesapeake Bay. In addition, aqueous ammonia is moderately toxic to aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Ammonia combines with sulfate ions in the atmosphere and is washed out by rainfall, resulting in rapid return of ammonia to the soil and surface waters.

Ammonia is a central compound in the environmental cycling of nitrogen. Ammonia in lakes, rivers, and streams is converted to nitrate.

Physical Properties. Ammonia is a corrosive and severely irritating gas with a pungent odor.

[d] TOXNET is a computer system run by the National Library of Medicine that includes a number of toxicological databases managed by EPA, National Cancer Institute, and the National Institute for Occupational Safety and Health. For more information on TOXNET, contact the TOXNET help line at 800-231-3766. Databases included in TOXNET are: CCRIS (Chemical Carcinogenesis Research Information System), DART (Developmental and Reproductive Toxicity Database), DBIR (Directory of Biotechnology Information Resources), EMICBACK (Environmental Mutagen Information Center Backfile), GENE-TOX (Genetic Toxicology), HSDB (Hazardous Substances Data Bank), IRIS (Integrated Risk Information System), RTECS (Registry of Toxic Effects of Chemical Substances), and TRI (Toxic Chemical Release Inventory). HSDB contains chemical-specific information on manufacturing and use, chemical and physical properties, safety and handling, toxicity and biomedical effects, pharmacology, environmental fate and exposure potential, exposure standards and regulations, monitoring and analysis methods, and additional references.

[e] The reporting standards for ammonia were changed in 1995. Ammonium sulfate is deleted from the list and threshold and release determinations for aqueous ammonia are limited to 10 percent of the total ammonia present in solution. This change will reduce the amount of ammonia reported to TRI. Complete details of the revisions can be found in 40 CFR Part 372.

Nitric Acid (CAS: 7697-37-2)

Toxicity. The toxicity of nitric acid is related to its potent corrosivity as an acid, with ulceration of all membranes and tissues with which it comes in contact. Concentrated nitric acid causes immediate opacification and blindness of the cornea when it comes in contact with the eye. Inhalation of concentrated nitric acid causes severe, sometimes fatal, corrosion of the respiratory tract. Ingestion of nitric acid leads to gastric hemorrhaging, nausea, and vomiting. Circulatory shock is often the immediate cause of death due to nitric acid exposure. Damage to the respiratory system may be delayed for months, and even years. Populations at increased risk from nitric acid exposure include people with pre-existing skin, eye, or cardiopulmonary disorders.

Ecologically, gaseous nitric acid is a component of acid rain. Acid rain causes serious and cumulative damage to surface waters and aquatic and terrestrial organisms by decreasing water and soil pH levels. Nitric acid in rainwater acts as a topical source of nitrogen, preventing "hardening off" of evergreen foliage and increasing frost damage to perennial plants in temperate regions. Nitric acid also acts as an available nitrogen source in surface water, stimulating plankton and aquatic weed growth.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Nitric acid is mainly transported in the atmosphere as nitric acid vapors and in water as dissociated nitrate and hydrogen ions. In soil, nitric acid reacts with minerals such as calcium and magnesium, becoming neutralized, and at the same time decreasing soil "buffering capacity" against changes in pH levels.

Nitric acid leaches readily to groundwater, where it decreases the pH of the affected groundwater. In the winter, gaseous nitric acid is incorporated into snow, causing surges of acid during spring snow melt. Forested areas are strong sinks for nitric acid, incorporating the nitrate ions into plant tissues.

Methanol (CAS: 67-56-1)

Toxicity. Methanol is readily absorbed from the gastrointestinal tract and the respiratory tract, and is toxic to humans in moderate to high doses. In the body, methanol is converted into formaldehyde and formic acid. Methanol is excreted as formic acid. Observed toxic effects at high dose levels generally include central nervous system damage and blindness. Long-term exposure to high levels of methanol via inhalation cause liver and blood damage in animals.

Ecologically, methanol is expected to have low toxicity to aquatic organisms. Concentrations lethal to half the organisms of a test population are expected to exceed one mg methanol per liter water. Methanol is not likely to persist in water or to bioaccumulate in aquatic organisms.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. Liquid methanol is likely to evaporate when left exposed. Methanol reacts in air to produce formaldehyde which contributes to the formation of air pollutants. In the atmosphere it can react with other atmospheric chemicals or be washed out by rain. Methanol is readily degraded by microörganisms in soils and surface waters.

Physical Properties. Methanol is highly flammable

Ethylene Glycol (CAS: 74-85-1)

Sources. Ethylene glycol is used as an antifreeze, heat transfer agent and solvent in industrial organic chemical facilities. The large quantity of ethylene glycol released is due to its ubiquitous use as an antifreeze and because in 1993 it had the 29th largest chemical production volume in the United States (*Chemical and Engineering News*). While the largest volume is released through underground injection, a substantial release also occurs from air point sources.

Toxicity. Long-term inhalation exposure to low levels of ethylene glycol may cause throat irritation, mild headache and backache. Exposure to higher concentrations may lead to unconsciousness. Liquid ethylene glycol is irritating to the eyes and skin.

Toxic effects from ingestion of ethylene glycol include damage to the central nervous system and kidneys, intoxication, conjunctivitis, nausea and vomiting, abdominal pain, weakness, low blood oxygen, tremors, convulsions, respiratory failure, and coma. Renal failure due to ethylene glycol poisoning can lead to death.

Environmental Fate. Ethylene glycol readily biodegrades in water. No data are available that report its fate in soils; however, biodegradation is probably the dominant removal mechanism. Should ethylene glycol leach into the groundwater, biodegradation may occur.

Ethylene glycol in water is not expected to bioconcentrate in aquatic organisms, adsorb to sediments or volatilize. Atmospheric ethylene glycol degrades rapidly in the presence of hydroxyl radicals.

Acetone (CAS: 67-64-1)

Toxicity. Acetone is irritating to the eyes, nose, and throat. Symptoms of exposure to large quantities of acetone may include headache, unsteadiness, confusion, lassitude, drowsiness, vomiting, and respiratory depression.

Reactions of acetone (see environmental fate) in the lower atmosphere contribute to the formation of ground-level ozone. Ozone (a major component of urban smog) can affect the respiratory system, especially in sensitive individuals such as asthmatics or allergy sufferers.

Carcinogenicity. There is currently no evidence to suggest that this chemical is carcinogenic.

Environmental Fate. If released into water, acetone will be degraded by microorganisms or will evaporate into the atmosphere. Degradation by microorganisms will be the primary removal mechanism.

Acetone is highly volatile, and once it reaches the troposphere (lower atmosphere), it will react with other gases, contributing to the formation of ground-level ozone and other air pollutants. EPA is reevaluating acetone's reactivity in the lower atmosphere to determine whether this contribution is significant.

Physical Properties. Acetone is a volatile and flammable organic chemical.

IV.C. Other Data Sources

The toxic chemical release data obtained from TRI captures the vast majority of facilities in the organic chemicals industry. It also allows for a comparison across years and industry sectors. Reported chemicals are limited however to the 316 reported chemicals. Most of the hydrocarbon emissions from organic chemical facilities are not captured by TRI.[1] The EPA Office of Air Quality Planning and Standards has compiled air pollutant emission factors for determining the total air emissions of priority pollutants (e.g., total hydrocarbons, SO_x, NO_x, CO, particulates, etc.) from many chemical manufacturing sources.[2]

The EPA Office of Air's Aerometric Information Retrieval System (AIRS) contains a wide range of information related to stationary sources of air pollution, including the emissions of a number of air pollutants which may be of concern within a particular industry. With the exception of volatile organic compounds (VOCs), there is little overlap with the TRI chemicals reported above. Exhibit 20 summarizes annual releases of carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter of 10 microns or less (PM10), total particulate (PT), sulfur dioxide (SO_2), and volatile organic compounds (VOCs).

Exhibit 20: Pollutant Releases (short tons/year)

Industry Sector	CO	NO_2	PM_{10}	PT	SO_2	VOC
Metal Mining	5,391	28,583	39,359	140,052	84,222	1,283

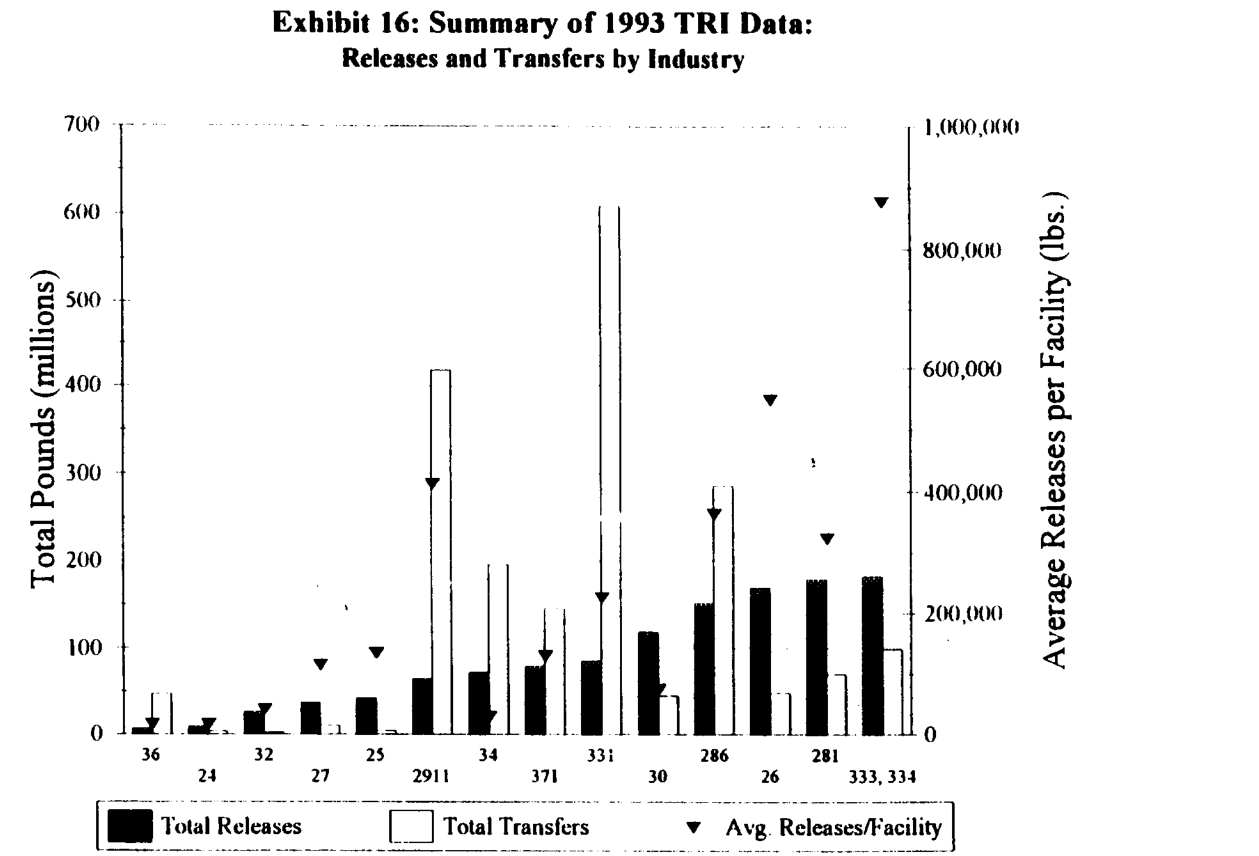
IV.D. Comparison of Toxic Release Inventory Between Selected Industries

The following information is presented as a comparison of pollutant release and transfer data across industrial categories. It is provided to give a general sense as to the relative scale of releases and transfers within each sector profiled under this project. Please note that the following figure and table do not contain releases and transfers for industrial categories that are not included in this project, and thus cannot be used to draw conclusions regarding the total release and transfer amounts that are reported to TRI. Similar information is available within the annual TRI Public Data Release Book.

Exhibit 21 is a graphical representation of a summary of the 1993 TRI data for the organic chemical industry and the other sectors profiled in separate notebooks. The bar graph presents the total TRI releases and total transfers on the left axis and the triangle points show the average releases per facility on the right axis. Industry sectors are presented in the order of increasing total TRI releases. The graph is based on the data shown in Exhibit 22 and is meant to facilitate comparisons between the relative amounts of releases, transfers, and releases per facility both within and between these sectors. The reader should note, however, that differences in the proportion of facilities captured by TRI exist between industry sectors. This can be a factor of poor SIC matching and relative differences in the number of facilities reporting to TRI from the various sectors. In the case of the organic chemical industry, the 1993 TRI data presented here covers 417 facilities. Only those facilities listing SIC Codes falling within SIC 286 were used.



SIC Range	Industry Sector	SIC Range	Industry Sector	SIC Range	Industry Sector
36	Electronic Equipment and Components	2911	Petroleum Refining	286	Organic Chemical Mfg.
24	Lumber and Wood Products	34	Fabricated Metals	26	Pulp and Paper

V. POLLUTION PREVENTION OPPORTUNITIES

The best way to reduce pollution is to prevent it in the first place. Some companies have creatively implemented pollution prevention techniques that improve efficiency and increase profits while at the same time minimizing environmental impacts. This can be done in many ways such as reducing material inputs, re-engineering processes to reuse by-products, improving management practices, and substituting benign chemicals for toxic ones. Some smaller facilities are able to actually get below regulatory thresholds just by reducing pollutant releases through aggressive pollution prevention policies.

In order to encourage these approaches, this section provides both general and company-specific descriptions of some pollution prevention advances that have been implemented within the organic chemical industry. While the list is not exhaustive, it does provide core information that can be used as the starting point for facilities interested in beginning their own pollution prevention projects. When possible, this section provides information from real activities that can, or are being implemented by this sector -- including a discussion of associated costs, time frames, and expected rates of return. This section provides summary information from activities that may be, or are being implemented by this sector. When possible, information is provided that gives the context in which the technique can be effectively used. Please note that the activities described in this section do not necessarily apply to all facilities that fall within this sector. Facility-specific conditions must be carefully considered when pollution prevention options are evaluated, and the full impacts of the change must examine how each option affects air, land and water pollutant releases.

The leaders in the organic chemical industry, similar to those in the chemical industry as a whole, have been promoting pollution prevention through various means. The most visible of these efforts is the Responsible Care® initiative of the Chemical Manufacturer's Association (CMA). Responsible Care is mandatory for CMA members who must commit to act as stewards for products through use and ultimate reuse or disposal. One of the guiding principles of this initiative is the inclusion of waste and release prevention objectives in research and in design of new or modified facilities, processes and products. The Synthetic Organic Chemical Manufactures Association (SOCMA) also requires its members to implement the Responsible Care® Guiding Principles as a condition of membership. SOCMA is instituting the Responsible Care® management practice codes on a phased-in basis to assist its approximately 110-non CMA members, which are primarily small and batch chemical manufacturers, in successfully implementing their programs.

Using pollution prevention techniques which prevent the release or generation of pollution in the first place have several advantages over end-of-pipe waste treatment technologies. The table below lists the direct and indirect benefits that could result.

Exhibit 23: Pollution Prevention Activities Can Reduce Costs

Direct Benefits

- Reduced waste treatment costs
  - Reduced capital and operating costs for waste treatment facilities
  - Reduced off-site treatment and disposal costs
- Reduced manufacturing costs due to improved yields
- Income or savings from sale or reuse of wastes
- Reduced environmental compliance costs (e.g., fines, shutdowns)
- Reduced or eliminated inventories or spills
- Reduced secondary emissions from waste treatment facilities
- Retained sales (production threatened by poor environmental performance or sales)

Indirect Benefits

- Reduced likelihood of future costs from:
  - Remediation
  - Legal liabilities
  - Complying with future regulations
- Use of emission offsets (internal and external)
- Improved community relations
- Increase environmental awareness by plant personnel and management
- Reduced societal costs
- Improved public health

Source: Chemical Manufacturer's Association *Designing Pollution Prevention into the Process*

These incentives may encourage organic chemical manufacturers to undertake pollution prevention activities voluntarily, but a number of barriers still exist in achieving widespread adoption of pollution prevention. The U.S. Office of Technology Assessment has identified and characterized a number of these barriers in its report titled *Industry, Technology, and the Environment*.

Pollution prevention can be carried out at any stage of the development of a process. In general, changes made at the research and development stage will have the greatest impact; however, changes in the process design and operating practices can also yield significant results.

In the research and development stage, all possible reaction pathways for producing the desired product can be examined. These can then be evaluated in light of yield, undesirable by-products, and their health and environmental impacts. The area of "green synthesis" is the focus of considerable research funded jointly by the Agency and by the National Science Foundation. Several alternative syntheses have already been developed that could reduce wastes. For example, Joseph M. Desimone of the University of North

Carolina, Chapel Hill, has used supercritical carbon dioxide as a medium for carrying out dispersion polymerizations. He uses a specially engineered free-radical initiator to start the reaction and a polymeric stabilizer to affect the polymerization of methyl methacrylate. Because the carbon dioxide can easily be separated from the reaction mixture, this reaction offers the possibility of reduced hazardous waste generation, particularly of aqueous streams contaminated with residual monomer and initiator.

Because of the large investment in current technology, and the lifetime of capital equipment, pollution prevention at the earliest stages is unlikely unless a company undertakes the design of a new production line or facility. There are, however, more numerous pollution prevention opportunities that can be realized by modifying current processes and equipment.

Exhibit 24: Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
By-products **Co-products**		
Quantity and Quality	▪ Process inefficiencies result in the generation of undesired by-products and co-products. Inefficiencies will require larger volumes of raw materials and result in additional secondary products. Inefficiencies can also increase fugitive emissions and wastes generated through material handling.	▪ Increase product yield to reduce by-product and co-product generation and raw material requirements.
Uses and Outlets	▪ By-products and co-products are not fully utilized, generating material or waste that must be managed.	▪ Identify uses and develop a sales outlet. Collect information necessary to firm up a purchase commitment such as minimum quality criteria, maximum impurity levels that can be tolerated, and performance criteria.
Catalysts		
Composition	▪ The presence of heavy metals in catalysts can result in contaminated process wastewater from catalyst handling and separation. These wastes may require special treatment and disposal procedures or facilities. Heavy metals can be inhibitory or toxic to biological wastewater treatment units. Sludge from wastewater treatment units may be classified as hazardous due to heavy metals content. Heavy metals generally exhibit low toxicity thresholds in aquatic environments and may bioaccumulate.	▪ Catalysts comprised of noble metals, because of their cost, are generally recycled by both onsite and offsite reclaimers.
Preparation and Handling	▪ Emissions or effluents are generated with catalyst activation or regeneration.	▪ Obtain catalyst in the active form. ▪ Provide insitu activation with appropriate processing/activation facilities.
	▪ Catalyst attrition and carryover into product requires de-ashing facilities which are a likely source of wastewater and solid waste.	▪ Develop a more robust catalyst or support.

R0076837

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
Catalysts (cont.)		
Preparation and Handling (cont.)	▪ Catalyst is spent and needs to be replaced.	▪ In situ regeneration eliminates unloading/loading emissions and effluents versus offsite regeneration or disposal.
	▪ Pyrophoric catalyst needs to be kept wet, resulting in liquid contaminated with metals.	▪ Use a nonpryrophoric catalyst. Minimize amount of water required to handle and store safely.
	▪ Short catalyst life.	▪ Study and identify catalyst deactivitation mechanisms. Avoid conditions which promote thermal or chemical deactivation. By extending catalyst life, emissions and effluents associated with catalyst handling and regeneration can be reduced.
Effectiveness	▪ Catalyzed reaction has by-product formation, incomplete conversion and less-than-perfect yield.	▪ Reduce catalyst consumption with a more active form. A higher concentration of active ingredient or increased surface area can reduce catalyst loadings.
		▪ Use a more selective catalyst which will reduce the yield of undesired by-products.
		▪ Improve reactor mixing/contacting to increase catalyst effectiveness.
	▪ Catalyzed reaction has by-product formation, incomplete conversion and less-than perfect yield.	▪ Develop a thorough understanding of reaction to allow optimization of reactor design. Include in the optimization, catalyst consumption and by-product yield.
Intermediate Products		
Quantity and Quality	▪ Intermediate reaction products or chemical species, including trace levels of toxic constituents, may contribute to process waste under both normal and upset conditions.	▪ Modify reaction sequence to reduce amount or change composition of intermediates.
	▪ Intermediates may contain toxic constituents or have characteristics that are harmful to the environment.	▪ Modify reaction sequence to change intermediate properties.
		▪ Use equipment design and process control to reduce releases.

R0076838

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
Process Conditions/ Configuration		
Temperature	▪ High heat exchange tube temperatures cause thermal cracking/decomposition of many chemicals. These lower molecular weight by-products are a source of "light ends" and fugitive emissions. High localized temperature gives rise to polymerization of reactive monomers, resulting in "heavies" or "tars." such materials can foul heat exchange equipment or plug fixed-bed reactors, thereby requiring costly equipment cleaning and production outage.	▪ Select operating temperatures at or near ambient temperature whenever possible. ▪ Use lower pressure steam to lower temperatures. ▪ Use intermediate exchangers to avoid contact with furnace tubes and walls. ▪ Use staged heating to minimize product degradation and unwanted side reactions. ▪ Use superheat of high-pressure steam in place of furnace. ▪ Monitor exchanger fouling to correlate process conditions which increase fouling, avoid conditions which rapidly foul exchangers. ▪ Use online tube cleaning technologies to keep tube surfaces clean to increase heat transfer. ▪ Use scraped wall exchangers in viscous service. ▪ Use falling film reboiler, pumped recirculation reboiler or high-flux tubes.
	▪ Higher operating temperatures imply "heat input" usually via combustion which generates emissions. ▪ Heat sources such as furnaces and boilers are a source of combustion emissions. ▪ Vapor pressure increases with increasing temperature. Loading/ unloading, tankage and fugitive emissions generally increase with increasing vapor pressure.	▪ Explore heat integration opportunities (e.g., use waste heat to preheat materials and reduce the amount of combustion required.) ▪ Use thermocompressor to upgrade low-pressure steam to avoid the need for additional boilers and furnaces. ▪ If possible, cool materials before sending to storage. ▪ Use hot process streams to reheat feeds.

R0076839

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities		
Area	**Potential Problem**	**Possible Approach**
Process Conditions/ Configuration (cont.)		
Temperature (cont.)		▪ Add vent condensers to recover vapors in storage tanks or process.
		▪ Add closed dome loading with vapor recovery condensers.
	▪ Water solubility of most chemicals increases with increasing temperature.	▪ Use lower temperature (vacuum processing).
Pressure	▪ Fugitive emissions from equipment.	▪ Equipment operating in vacuum service is not a source of fugitives; however, leaks into the process require control when system is degassed.
	▪ Seal leakage potential due to pressure differential.	▪ Minimize operating pressure.
	▪ Gas solubility increases with higher pressures.	▪ Determine whether gases can be recovered, compressed, and reused or require controls.
Corrosive Environment	▪ Material contamination occurs from corrosion products. Equipment failures result in spills, leaks and increased maintenance costs.	▪ Improve metallurgy or provide coating or lining.
		▪ Neutralize corrosivity of materials contacting equipment.
		▪ Use corrosion inhibitors.
	▪ Increased waste generation due to addition of corrosion inhibitors or neutralization.	▪ Improve metallurgy or provide coating or lining or operate in a less corrosive environment.
Batch vs. Continuous Operations	▪ Vent gas lost during batch fill.	▪Equalize reactor and storage tank vent lines.
		▪Recover vapors through condenser, adsorber, etc.
	▪ Waste generated by cleaning/purging of process equipment between production batches.	▪ Use materials with low viscosity. Minimize equipment roughness.

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities		
Area	**Potential Problem**	**Possible Approach**
Process Conditions/ Configuration (cont.) *Batch vs. Continuous Operations (cont.)*		▪ Optimize product manufacturing sequence to minimize washing operations and cross-contamination of subsequent batches.
	▪ Process inefficiencies lower yield and increase emissions.	▪ Sequence addition of reactants and reagents to optimize yields and lower emissions.
	▪ Continuous process fugitive emissions and waste increase over time due to equipment failure through a lack of maintenance between turnarounds.	▪Design facility to readily allow maintenance so as to avoid unexpected equipment failure and resultant release.
Process Operation/Design	▪ Numerous processing steps create wastes and opportunities for errors.	▪ Keep it simple. Make sure all operations are necessary. More operations and complexity only tend to increase potential emission and waste sources.
	▪ Nonreactant materials (solvents, absorbants, etc.) create wastes. Each chemical (including water) employed within the process introduces additional potential waste sources; the composition of generated wastes also tends to become more complex.	▪ Evaluate unit operation or technologies (e.g., separation) that do not require the addition of solvents or other nonreactant chemicals.
	▪ High conversion with low yield results in wastes.	▪ Recycle operations generally improve overall use of raw materials and chemicals, thereby both increasing the yield of desired products while at the same time reducing the generation of wastes. A case-in-point is to operate at a lower conversion per reaction cycle by reducing catalyst consumption, temperature, or residence time. Many times, this can result in a higher selectivity to desired products. The net effect upon recycle of unreacted reagents is an increase in product yield, while at the same time reducing the quantities of spent catalyst and less desirable by-products.

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities		
Area	**Potential Problem**	**Possible Approach**
Process Conditions/ Configuration (cont.)		
Process Operation/Design	■ Non-regenerative treatment systems result in increased waste versus regenerative systems.	■ Regenerative fixed bed treating or desiccant operation (e.g., aluminum oxide, silica, activated carbon, molecular sieves, etc.) will generate less quantities of solid or liquid waste than nonregenerative units (e.g., calcium chloride or activated clay). With regenerative units though, emissions during bed activation and regeneration can be significant. Further, side reactions during activation/regeneration can give rise to problematic pollutants.
Product		
Process Chemistry	■ Insufficient R&D into alternative reaction pathways may miss pollution opportunities such as waste reduction or eliminating a hazardous constituent.	■ R&D during process conception and laboratory studies should thoroughly investigate alternatives in process chemistry that affect pollution prevention.
Product Formulation	■ Product based on end-use performance may have undesirable environmental impacts or use raw materials or components that generate excessive or hazardous wastes.	■ Reformulate products by substituting different material or using a mixture of individual chemicals that meet end-use performance specifications.
Raw Materials		
Purity	■ Impurities may produce unwanted by-products and waste. Toxic impurities, even in trace amounts, can make a waste hazardous and therefore subject to strict and costly regulation.	■ Use higher purity materials. ■ Purify materials before use and reuse if practical. ■ Use inhibitors to prevent side reactions.
	■ Excessive impurities may require more processing and equipment to meet product specifications, increasing costs and potential for fugitive emissions, leaks, and spills.	■ Achieve balance between feed purity, processing steps, product quality and waste generation.
	■ Specifying a purity greater than needed by the process increases costs and can result in more waste generation by the supplier.	■ Specify a purity no greater than what the process needs.

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities		
Area	**Potential Problem**	**Possible Approach**
Raw Materials (cont.)		
Purity (cont.)	▪ Impurities in clean air can increase inert purges.	▪Use pure oxygen.
	▪ Impurities may poison catalyst prematurely resulting in increased wastes due to yield loss and more frequent catalyst replacement.	▪Install guard beds to protect catalysts.
Vapor Pressure	▪ Higher vapor pressures increase fugitive emissions in material handling and storage.	▪ Use material with lower vapor pressure.
	▪ High vapor pressure with low odor threshold materials can cause nuisance odors.	▪ Use materials with lower vapor pressure and higher odor threshold.
Water Solubility	▪ Toxic or nonbiodegradable materials that are water soluble may affect wastewater treatment operation, efficiency, and cost.	▪ Use less toxic or more biodegradable materials.
	▪ Higher solubility may increase potential for surface and groundwater contamination and may require more careful spill prevention, containment, and cleanup (SPCC) plans.	▪ Use less soluble materials.
	▪ Higher solubility may increase potential for storm water contamination in open areas.	▪ Use less soluble materials. ▪ Prevent direct contact with storm water by diking or covering areas.
	▪ Process wastewater associated with water washing or hydrocarbon/water phase separation will be impacted by containment solubility in water. Appropriate wastewater treatment will be impacted.	▪ Minimize water usage. ▪ Reuse wash water. ▪ Determine optimum process conditions for phase separation. ▪ Evaluate alternative separation technologies (coalescers, membranes, distillation, etc.)

R0076843

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
Raw Materials (cont.)		
Toxicity	▪ Community and worker safety and health concerns result from routine and nonroutine emissions. Emissions sources include vents, equipment leaks, wastewater emissions, emergency pressure relief, etc.	▪ Use less toxic materials. ▪ Reduce exposure through equipment design and process control. Use systems which are passive for emergency containment of toxic releases.
	▪ Surges or higher than normal continuous levels of toxic materials can shock or miss wastewater biological treatment systems resulting in possible fines and possible toxicity in the receiving water.	▪ Use less toxic material. ▪ Reduce spills, leaks, and upset conditions through equipment and process control. ▪ Consider effect of chemicals on biological treatment; provide unit pretreatment or diversion capacity to remove toxicity. ▪ Install surge capacity for flow and concentration equalization.
Regulatory	▪ Hazardous or toxic materials are stringently regulated. They may require enhanced control and monitoring; increased compliance issues and paperwork for permits and record keeping; stricter control for handling, shipping, and disposal; higher sampling and analytical costs; and increased health and safety costs.	▪ Use materials which are less toxic or hazardous. ▪ Use better equipment and process design to minimize or control releases; in some cases, meeting certain regulatory criteria will exempt a system from permitting or other regulatory requirements.
Form of Supply	▪ Small containers increase shipping frequency which increases chances of material releases and waste residues from shipping containers (including wash waters).	▪ Use bulk supply, ship by pipeline, or use "jumbo" drums or sacks. ▪ In some cases, product may be shipped out in the same containers the material supply was shipped in without washing.
	▪ Nonreturnable containers may increase waste.	▪ Use returnable shipping containers or drums.
Handling and Storage	▪ Physical state (solid, liquid, gaseous) may raise unique environmental, safety, and health issues with unloading operations and transfer to process equipment.	▪ Use equipment and controls appropriate to the type of materials to control releases.

Exhibit 24 (cont.): Process/Product Modifications Create Pollution Prevention Opportunities

Area	Potential Problem	Possible Approach
Raw Materials (cont.)		
Handling and Storage (cont.)	▪ Large inventories can lead to spills, inherent safety issues and material expiration.	▪ Minimize inventory by utilizing just-in-time delivery.
Waste Streams		
Quantity and Quality	▪ Characteristics and sources of waste streams are unknown.	▪ Document sources and quantities of waste streams prior to pollution prevention assessment.
	▪ Wastes are generated as part of the process.	▪ Determine what changes in process conditions would lower waste generation of toxicity.
		▪ Determine if wastes can be recycled back into the process.
Composition	▪ Hazardous or toxic constituents are found in waste streams. Examples are: sulfides, heavy metals, halogenated hydrocarbons, and polynuclear aromatics.	▪ Evaluate whether different process conditions, routes, or reagent chemicals (e.g., solvent catalysts) can be substituted or changed to reduce or eliminate hazardous or toxic compounds.
Properties	▪ Environmental fate and waste properties are not known or understood.	▪ Evaluate waste characteristics using the following type properties: corrosivity, ignitability, reactivity, BTU content (energy recovery), biodegradability, aquatic toxicity, and bioaccumulation potential of the waste and of its degradable products, and whether it is a solid, liquid, or gas.
Disposal	▪ Ability to treat and manage hazardous and toxic waste unknown or limited.	▪ Consider and evaluate all onsite and offsite recycle, reuse, treatment, and disposal options available. Determine availability of facilities to treat or manage wastes generated.

Source: Chemical Manufacturer's Association. *Designing Pollution Prevention into the Process, Research, Development and Engineering.*

Exhibit 25: Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Compressors, blowers, fans	▪ Shaft seal leaks, piston rod seal leaks, and vent streams	▪ Seal-less designs (diaphragmatic, hermetic or magnetic) ▪ Design for low emissions (internal balancing, double inlet, gland eductors) ▪ Shaft seal designs (carbon rings, double mechanical seals, buffered seals) ▪ Double seal with barrier fluid vented to control device	▪ Preventive maintenance program
Concrete pads, floors, sumps	▪ Leaks to groundwater	▪ Water stops ▪ Embedded metal plates ▪ Epoxy sealing ▪ Other impervious sealing	▪ Reduce unnecessary purges, transfers, and sampling ▪ Use drip pans where necessary
Controls	▪ Shutdowns and start-ups generate waste and releases	▪ Improve on-line controls ▪ On-line instrumentation ▪ Automatic start-up and shutdown ▪ On-line vibration analysis ▪ Use "consensus" systems (e.g., shutdown trip requires 2 out of 3 affirmative responses)	▪ Continuous versus batch ▪ Optimize on-line run time ▪ Optimize shutdown interlock inspection frequency ▪ Identify safety and environment critical instruments and equipment
Distillation	▪ Impurities remain in process streams	▪ Increase reflux ratio ▪ Add section to column ▪ Column intervals ▪ Change feed tray	▪ Change column operating conditions - reflux ratio - feed tray - temperature - pressure - etc.

Exhibit 25 (cont.): Modifications to Equipment Can Also Prevent Pollution			
		Possible Approach	
Equipment	Potential Environment Problem	Design Related	Operational Related
Distillation (cont.)	▪ Impurities remain in process streams (cont.)	▪ Insulate to prevent heat loss ▪ Preheat column feed ▪ Increase vapor line size to lower pressure drop	▪ Clean column to reduce fouling
	▪ Large amounts of contaminated water condensate from stream stripping	▪ Use reboilers or inert gas stripping agents	▪ Use higher temperature steam
General manufacturing equipment areas	▪ Contaminated rainwater	▪ Provide roof over process facilities ▪ Segregate process sewer from storm sewer (diking) ▪ Hard-pipe process streams to process sewer	▪ Return samples to process ▪ Monitor stormwater discharge
	▪ Contaminated sprinkler and fire water	▪ Seal floors ▪ Drain to sump ▪ Route to waste treatment	
	▪ Leaks and emissions during cleaning	▪ Design for cleaning ▪ Design for minimum rinsing ▪ Design for minimum sludge ▪ Provide vapor enclosure ▪ Drain to process	▪ Use drip pans for maintenance activities ▪ Rinse to sump ▪ Reuse cleaning solutions
Heat exchangers	▪ Increased waste due to high localized temperatures	▪ Use intermediate exchangers to avoid contact with furnace tubes and walls ▪ Use staged heating to minimize product degradation and unwanted side reactions. (waste heat >>low pressure steam >>high pressure steam)	▪ Select operating temperatures at or near ambient temperature when-ever possible. These are generally most desirable from a pollution prevention standpoint ▪ Use lower pressure steam to lower temperatures

Exhibit 25 (cont.): Modifications to Equipment Can Also Prevent Pollution			
		Possible Approach	
Equipment	**Potential Environment Problem**	**Design Related**	**Operational Related**
Heat exchangers (cont.)	▪ Increased waste due to high localized temperatures (cont.)	▪ Use scraped wall exchangers in viscous service ▪ Using falling film reboiler, piped recirculation reboiler or high-flux tubes ▪ Use lowest pressure steam possible	▪ Monitor exchanger fouling to correlate process conditions which increase fouling, avoid conditions which rapidly foul exchangers ▪ Use on-line tube cleaning techniques to keep tube surfaces clean
	▪ Contaminated materials due to tubes leaking at tube sheets	▪ Use welded tubes or double tube sheets with inert purge. Mount vertically	▪ Monitor for leaks
	▪ Furnace emissions	▪ Use superheat of high-pressure steam in place of a furnace	
Piping	▪ Leaks to groundwater; fugitive emissions	▪ Design equipment layout so as to minimize pipe run length ▪ Eliminate underground piping or design for cathodic protection if necessary to install piping underground ▪ Welded fittings ▪ Reduce number of flanges and valves ▪ All welded pipe ▪ Secondary containment ▪ Spiral-wound gaskets ▪ Use plugs and double valves for open end lines ▪ Change metallurgy ▪ Use lined pipe	▪ Monitor for corrosion and erosion ▪ Paint to prevent external corrosion

Exhibit 25 (cont.): Modifications to Equipment Can Also Prevent Pollution			
		Possible Approach	
Equipment	Potential Environment Problem	Design Related	Operational Related
Piping (cont.)	▪ Releases when cleaning or purging lines	▪ Use "pigs" for cleaning ▪ Slope to low point drain ▪ Use heat tracing and insulation to prevent freezing ▪ Install equalizer lines	▪ Flush to product storage tank
Pumps	▪ Fugitive emissions from shaft seal leaks	▪ Mechanical seal in lieu of packing ▪ Double mechanical seal with inert barrier fluid ▪ Double machined seal with barrier fluid vented to control device ▪ Seal-less pump (canned motor magnetic drive) ▪ Vertical pump	▪ Seal installation practices ▪ Monitor for leaks
	▪ Fugitive emissions from shaft seal leaks	▪ Use pressure transfer to eliminate pump	
	▪ Residual "heel" of liquid during pump maintenance	▪ Low point drain on pump casing	▪ Flush casing to process sewer for treatment ▪ Increase the mean time between pump failures by: - selecting proper seal material; - good alignment; - reduce pipe-induced stress - Maintaining seal lubrication
	▪ Injection of seal flush fluid into process stream	▪ Use double mechanical seal with inert barrier fluid where practical	
Reactors	▪ Poor conversion or performance due to inadequate mixing	▪ Static mixing ▪ Add baffles ▪ Change impellers	▪ Add ingredients with optimum sequence

R0076849

Exhibit 25 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach: Design Related	Possible Approach: Operational Related
Reactors (cont.)	■ Poor conversion (cont.)	■ Add horsepower ■ Add distributor	■ Allow proper head space in reactor to enhance vortex effect
	■ Waste by-product formation	■ Provide separate reactor for converting recycle streams to usable products	■ Optimize reaction conditions (temperature, pressure, etc.)
Relief Valve	■ Leaks	■ Provide upstream rupture disc	
	■ Fugitive emissions	■ Vent to control or recovery device	■ Monitor for leaks and for control efficiency
	■ Discharge to environment from over pressure	■ Pump discharges to suction of pump ■ Thermal relief to tanks ■ Avoid discharge to roof areas to prevent contamination of rainwater	■ Monitor for leaks
	■ Frequent relief	■ Use pilot operated relief valve ■ Increase margin between design and operating pressure	■ Reduce operating pressure ■ Review system performance
Sampling	■ Waste generation due to sampling (disposal, containers, leaks, fugitives, etc.)	■ In-line insitu analyzers ■ System for return to process ■ Closed loop ■ Drain to sump	■ Reduce number and size of samples required ■ Sample at the lowest possible temperature ■ Cool before sampling
Tanks	■ Tank breathing and working losses	■ Cool materials before storage ■ Insulate tanks ■ Vent to control device (flare, condenser, etc.) ■ Vapor balancing ■ Floating roof	■ Optimize storage conditions to reduce losses

Exhibit 25 (cont.): Modifications to Equipment Can Also Prevent Pollution

Equipment	Potential Environment Problem	Possible Approach	
		Design Related	Operational Related
Tanks (cont.)	■ Tank breathing and working losses (cont.)	■ Floating roof ■ Higher design pressure	
	■ Leak to groundwater	■ All aboveground (situated so bottom can routinely be checked for leaks) ■ Secondary containment ■ Improve corrosion resistance	■ Monitor for leaks and corrosion
	■ Large waste heel	■ Design for 100% de-inventory	■ Recycle to process if practical
Vacuum Systems	■ Waste discharge from jets	■ Substitute mechanical vacuum pump ■ Evaluate using process fluid for powering jet	■ Monitor for air leaks ■ Recycle condensate to process
Valves	■ Fugitive emissions from leaks	■ Bellow seals ■ Reduce number where practical ■ Special packing sets	■ Stringent adherence to packing procedures
Vents	■ Release to environment	■ Route to control or recovery device	■ Monitor performance

Source: Chemical Manufacturer's Association. *Designing Pollution Prevention into the Process, Research, Development and Engineering*.

It is critical to emphasize that pollution prevention in the chemical industry is process specific and oftentimes constrained by site-specific considerations. As such, it is difficult to generalize about the relative merits of different pollution prevention strategies. The age, size, and purpose of the plant will influence the choice of the most effective pollution prevention strategy. Commodity chemical manufacturers redesign their processes infrequently so that redesign of the reaction process or equipment is unlikely in the short term. Here operational changes are the most feasible response. Specialty chemical manufacturers are making a greater variety of chemicals and have more process and design flexibility. Incorporating changes at the earlier research and development phases may be possible for them.

Changes in operational practices may yield the most immediate gains with the least investment. For example, the majority of the waste generated by the chemical processing industry is contaminated water: Borden Chemical Company has collected and isolated its waste water in a trench coming from the phenol rail car unloading area and reused the water in resin batches. This eliminated the entire waste stream with a capital investment of $3,000 and annual savings of $1,500 a year in treatment costs. Rhone-Poulenc, in New Brunswick, New Jersey, is now sending all quality control and raw material samples back to be reused in the production process saving $20,000 per year and reducing waste volume by 3,000 pounds.

Another area that can yield significant benefits is improved process control so that less off-specification product is produced (that must be discarded) and the process is run more optimally (fewer by-products). Exxon Chemical Americas of Linden, New Jersey, used continuous process optimization to reduce the generation of acid coke, a process residue, thus saving $340,000 annually in treatment costs. New in-line process controls are under development (a fertile area of research being pursued by the Center for Process Analytic Chemistry at the University of Washington) that may allow better process optimization through tighter process control.

Chemical substitution, particularly of water for non-aqueous solvents, can also prevent pollution. For example, Du Pont at the Chamber Works in New Jersey is using a high-pressure water-jet system to clean polymer reaction vessels. This replaces organic solvent cleaning that annually produced 40,000 pounds of solvent waste. Installing the new cleaning system cost $125,000 but it will save $270,000 annually.

Improved separations design also offers a pollution prevention opportunity since separations account for about 20 percent of energy use in the chemical process industry. In one case, a solvent was replaced by an excess of a reaction component, thus eliminating the need to separate the solvent from the waste stream while reducing separation costs.

VI. SUMMARY OF APPLICABLE FEDERAL STATUTES AND REGULATIONS

This section discusses the Federal regulations that may apply to this sector. The purpose of this section is to highlight and briefly describe the applicable Federal requirements, and to provide citations for more detailed information. The three following sections are included:

- Section VI.A contains a general overview of major statutes
- Section VI.B contains a list of regulations specific to this industry
- Section VI.C contains a list of pending and proposed regulations

The descriptions within Section VI are intended solely for general information. Depending upon the nature or scope of the activities at a particular facility, these summaries may or may not necessarily describe all applicable environmental requirements. Moreover, they do not constitute formal interpretations or clarifications of the statutes and regulations. For further information readers should consult the Code of Federal Regulations and other state or local regulatory agencies. EPA Hotline contacts are also provided for each major statute.

VI.A. General Description of Major Statutes

Resource Conservation And Recovery Act (RCRA)

RCRA of 1976, which amended the Solid Waste Disposal Act, addresses solid (Subtitle D) and hazardous (Subtitle C) waste management activities. The Hazardous and Solid Waste Amendments (HSWA) of 1984 strengthened RCRA's waste management provisions and added Subtitle I, which governs underground storage tanks (USTs).

Regulations promulgated pursuant to Subtitle C of RCRA (40 CFR Parts 260-299) establish a "cradle-to-grave" system governing hazardous waste from the point of generation to disposal. RCRA hazardous wastes include the specific materials listed in the regulations (commercial chemical products, designated with the code "P" or "U"; hazardous wastes from specific industries/sources, designated with the code "K"; or hazardous wastes from non-specific sources, designated with the code "F") or materials which exhibit a hazardous waste characteristic (ignitibility, corrosivity, reactivity, or toxicity and designated with the code "D").

Regulated entities that generate hazardous waste are subject to waste accumulation, manifesting, and record keeping standards. Facilities that treat, store, or dispose of hazardous waste must obtain a permit, either from EPA or from a State agency which EPA has authorized to implement the permitting program. Subtitle C permits contain general facility standards such as contingency plans, emergency procedures, record keeping and reporting requirements, financial assurance mechanisms, and unit-specific standards. RCRA also contains provisions (40 CFR Part 264 Subpart S and §264.10) for

R0076853

conducting corrective actions which govern the cleanup of releases of hazardous waste or constituents from solid waste management units at RCRA-regulated facilities.

Although RCRA is a Federal statute, many States implement the RCRA program. Currently, EPA has delegated its authority to implement various provisions of RCRA to 46 of the 50 States.

Most RCRA requirements are not industry specific but apply to any company that transports, treats, stores, or disposes of hazardous waste. Here are some important RCRA regulatory requirements:

- **Identification of Solid and Hazardous Wastes** (40 CFR Part 261) lays out the procedure every generator should follow to determine whether the material created is considered a hazardous waste, solid waste, or is exempted from regulation.

- **Standards for Generators of Hazardous Waste** (40 CFR Part 262) establishes the responsibilities of hazardous waste generators including obtaining an ID number, preparing a manifest, ensuring proper packaging and labeling, meeting standards for waste accumulation units, and record keeping and reporting requirements. Generators can accumulate hazardous waste for up to 90 days (or 180 days depending on the amount of waste generated) without obtaining a permit.

- **Land Disposal Restrictions** (LDRs) are regulations prohibiting the disposal of hazardous waste on land without prior treatment. Under the LDRs (40 CFR 268), materials must meet land disposal restriction (LDR) treatment standards prior to placement in a RCRA land disposal unit (landfill, land treatment unit, waste pile, or surface impoundment). Wastes subject to the LDRs include solvents, electroplating wastes, heavy metals, and acids. Generators of waste subject to the LDRs must provide notification of such to the designated TSD facility to ensure proper treatment prior to disposal.

- **Used Oil** storage and disposal regulations (40 CFR Part 279) do not define **Used Oil Management Standards** impose management requirements affecting the storage, transportation, burning, processing, and re-refining of the used oil. For parties that merely generate used oil, regulations establish storage standards. For a party considered a used oil marketer (one who generates and sells off-specification used oil directly to a used oil burner), additional tracking and paperwork requirements must be satisfied.

- **Tanks and Containers** used to store hazardous waste with a high volatile organic concentration must meet emission standards under RCRA. Regulations (40 CFR Part 264-265, Subpart CC) require generators to test the waste to determine the concentration of the waste, to satisfy tank and container emissions standards, and to inspect and monitor regulated units. These regulations apply to all facilities who store such waste, including generators operating under the 90-day accumulation rule.

- **Underground Storage Tanks** (USTs) containing petroleum and hazardous substance are regulated under Subtitle I of RCRA. Subtitle I regulations (40 CFR Part 280) contain tank design and release detection requirements, as well as financial responsibility and corrective action standards for USTs. The UST program also establishes increasingly stringent standards, including upgrade requirements for existing tanks, that must be met by 1998.

- **Boilers and Industrial Furnaces** (BIFs) that use or burn fuel containing hazardous waste must comply with strict design and operating standards. BIF regulations (40 CFR Part 266, Subpart H) address unit design, provide performance standards, require emissions monitoring, and restrict the type of waste that may be burned.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, responds to questions and distributes guidance regarding all RCRA regulations. The RCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Comprehensive Environmental Response, Compensation, And Liability Act (CERCLA)

CERCLA, a 1980 law commonly known as Superfund, authorizes EPA to respond to releases, or threatened releases, of hazardous substances that may endanger public health, welfare, or the environment. CERCLA also enables EPA to force parties responsible for environmental contamination to clean it up or to reimburse the Superfund for response costs incurred by EPA. The Superfund Amendments and Reauthorization Act (SARA) of 1986 revised various sections of CERCLA, extended the taxing authority for Superfund, and created a free-standing law, SARA Title III, also known as the Emergency Planning and Community Right-to-Know Act (EPCRA).

The CERCLA **hazardous substance release reporting regulations** (40 CFR Part 302) direct the person in charge of a facility to report to the National Response Center (NRC) any environmental release of a hazardous substance which exceeds a reportable quantity. Reportable quantities are defined and listed in 40 CFR §302.4. A release report may trigger a response by EPA, or by one or more Federal or State emergency response authorities.

EPA implements **hazardous substance responses** according to procedures outlined in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 CFR Part 300). The NCP includes provisions for permanent cleanups, known as remedial actions, and other cleanups referred to as "removals." EPA generally takes remedial actions only at sites on the

National Priorities List (NPL), which currently includes approximately 1300 sites. Both EPA and states can act at other sites; however, EPA provides responsible parties the opportunity to conduct removal and remedial actions and encourages community involvement throughout the Superfund response process.

EPA's RCRA/Superfund/UST Hotline, at (800) 424-9346, answers questions and references guidance pertaining to the Superfund program. The CERCLA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Emergency Planning And Community Right-To-Know Act (EPCRA)

The Superfund Amendments and Reauthorization Act (SARA) of 1986 created EPCRA, also known as SARA Title III, a statute designed to improve community access to information about chemical hazards and to facilitate the development of chemical emergency response plans by State and local governments. EPCRA required the establishment of State emergency response commissions (SERCs), responsible for coordinating certain emergency response activities and for appointing local emergency planning committees (LEPCs).

EPCRA and the EPCRA regulations (40 CFR Parts 350-372) establish four types of reporting obligations for facilities which store or manage specified chemicals:

- **EPCRA §302** requires facilities to notify the SERC and LEPC of the presence of any "extremely hazardous substance" (the list of such substances is in 40 CFR Part 355, Appendices A and B) if it has such substance in excess of the substance's threshold planning quantity, and directs the facility to appoint an emergency response coordinator.

- **EPCRA §304** requires the facility to notify the SERC and the LEPC in the event of a release exceeding the reportable quantity of a CERCLA hazardous substance or an EPCRA extremely hazardous substance.

- **EPCRA §311 and §312** require a facility at which a hazardous chemical, as defined by the Occupational Safety and Health Act, is present in an amount exceeding a specified threshold to submit to the SERC, LEPC and local fire department material safety data sheets (MSDSs) or lists of MSDS's and hazardous chemical inventory forms (also known as Tier I and II forms). This information helps the local government respond in the event of a spill or release of the chemical.

- **EPCRA §313** requires manufacturing facilities included in SIC codes 20 through 39, which have ten or more employees, and which manufacture, process, or use specified chemicals in amounts greater than threshold quantities, to submit an annual toxic chemical release report. This report, commonly known as the Form R, covers releases and transfers of toxic chemicals to various facilities and environmental media, and allows EPA to compile the national Toxic Release Inventory (TRI) database.

All information submitted pursuant to EPCRA regulations is publicly accessible, unless protected by a trade secret claim.

EPA's EPCRA Hotline, at (800) 535-0202, answers questions and distributes guidance regarding the emergency planning and community right-to-know regulations. The EPCRA Hotline operates weekdays from 8:30 a.m. to 7:30 p.m., ET, excluding Federal holidays.

Clean Water Act (CWA)

The primary objective of the Federal Water Pollution Control Act, commonly referred to as the CWA, is to restore and maintain the chemical, physical, and biological integrity of the nation's surface waters. Pollutants regulated under the CWA include "priority" pollutants and various toxic pollutants: "conventional" pollutants, such as biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH; and "non-conventional" pollutants which are pollutants not identified as either conventional or priority.

The CWA regulates both direct and indirect discharges. The **National Pollutant Discharge Elimination System (NPDES)** program (CWA §402) controls direct discharges into navigable waters. Direct discharges or "point source" discharges are from sources such as pipes and sewers. NPDES permits, issued by either EPA or an authorized State (EPA has authorized approximately forty States to administer the NPDES program), contain industry-specific, technology-based and/or water quality-based limits, and establish pollutant monitoring requirements. A facility that intends to discharge into the nation's waters must obtain a permit prior to initiating its discharge. A permit applicant must provide quantitative analytical data identifying the types of pollutants present in the facility's effluent. The permit will then set forth the conditions and effluent limitations under which a facility may make a discharge.

A NPDES permit may also include discharge limits based on Federal or State water quality criteria or standards that were designed to protect designated uses of surface waters, such as supporting aquatic life or recreation. These standards, unlike the technological standards, generally do not take into account technological feasibility or costs. Water quality criteria and standards vary from state to state, and site to site, depending on the use classification of the receiving body of water. Most states follow EPA guidelines, which propose aquatic life and human health criteria for many of the 126 priority pollutants.

Storm Water Discharges

In 1987 the CWA was amended to require EPA to establish a program to address **storm water discharges**. In response, EPA promulgated the NPDES storm water permit application regulations. Storm water discharge associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw material storage areas at an industrial plant (40 CFR 122.26 (b)(14)). These regulations require that facilities with the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

The term "storm water discharge associated with industrial activity" means a storm water discharge from one of 11 categories of industrial activity defined at 40 CFR 122.26. Six of the categories are defined by SIC codes while the other five are identified through narrative descriptions of the regulated industrial activity. If the primary SIC code of the facility is one of those identified in the regulations, the facility is subject to the storm water permit application requirements. If any activity at a facility is covered by one of the five narrative categories, storm water discharges from those areas where the activities occur are subject to storm water discharge permit application requirements.

Those facilities/activities that are subject to storm water discharge permit application requirements are identified below. To determine whether a particular facility falls within one of these categories, the regulation should be consulted.

Category i: Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

Category ii: Facilities classified as SIC 24-lumber and wood products (except wood kitchen cabinets); SIC 26-paper and allied products (except paperboard containers and products); SIC 28-chemicals and allied products (except drugs and paints); SIC 291-petroleum refining; and SIC 311-leather tanning and finishing.

Category iii: Facilities classified as SIC 10-metal mining; SIC 12-coal mining; SIC 13-oil and gas extraction; and SIC 14-nonmetallic mineral mining.

Category iv: Hazardous waste treatment, storage, or disposal facilities.

Category v: Landfills, land application sites, and open dumps that receive or have received industrial wastes.

Category vi: Facilities classified as SIC 5015-used motor vehicle parts; and SIC 5093-automotive scrap and waste material recycling facilities.

Category vii: Steam electric power generating facilities.

Category viii: Facilities classified as SIC 40-railroad transportation; SIC 41-local passenger transportation; SIC 42-trucking and warehousing (except public warehousing and storage); SIC 43-U.S. Postal Service; SIC 44-water transportation; SIC 45-transportation by air; and SIC 5171-petroleum bulk storage stations and terminals.

Category ix: Sewage treatment works.

Category x: Construction activities except operations that result in the disturbance of less than five acres of total land area.

Category xi: Facilities classified as SIC 20-food and kindred products; SIC 21-tobacco products; SIC 22-textile mill products; SIC 23-apparel related products; SIC 2434-wood kitchen cabinets manufacturing; SIC 25-furniture and fixtures; SIC 265-paperboard containers and boxes; SIC 267-converted paper and paperboard products; SIC 27-printing, publishing, and allied industries; SIC 283-drugs; SIC 285-paints, varnishes, lacquer, enamels, and allied products; SIC 30-rubber and plastics; SIC 31-leather and leather products (except leather and tanning and finishing); SIC 323-glass products; SIC 34-fabricated metal products (except fabricated structural metal); SIC 35-industrial and commercial machinery and computer equipment; SIC 36-electronic and other electrical equipment and components; SIC 37-transportation equipment (except ship and boat building and repairing); SIC 38-measuring, analyzing, and controlling instruments; SIC 39-miscellaneous manufacturing industries; and SIC 4221-4225-public warehousing and storage.

Pretreatment Program

Another type of discharge that is regulated by the CWA is one that goes to a publicly-owned treatment works (POTWs). The national **pretreatment program** (CWA §307(b)) controls the indirect discharge of pollutants to POTWs by "industrial users." Facilities regulated under §307(b) must meet certain pretreatment standards. The goal of the pretreatment program is to protect municipal wastewater treatment plants from damage that may occur when hazardous, toxic, or other wastes are discharged into a sewer system and to protect the quality of sludge generated by these plants. Discharges to a POTW are regulated primarily by the POTW itself, rather than the State or EPA.

EPA has developed technology-based standards for industrial users of POTWs. Different standards apply to existing and new sources within each category. "Categorical" pretreatment standards applicable to an industry on a nationwide basis are developed by EPA. In addition, another kind of pretreatment standard, "local limits," are developed by the POTW in order to assist the POTW in achieving the effluent limitations in its NPDES permit.

Regardless of whether a State is authorized to implement either the NPDES or the pretreatment program, if it develops its own program, it may enforce requirements more stringent than Federal standards.

EPA's Office of Water, at (202) 260-5700, will direct callers with questions about the CWA to the appropriate EPA office. EPA also maintains a bibliographic database of Office of Water publications which can be accessed through the Ground Water and Drinking Water resource center, at (202) 260-7786.

Safe Drinking Water Act (SDWA)

The SDWA mandates that EPA establish regulations to protect human health from contaminants in drinking water. The law authorizes EPA to develop national drinking water standards and to create a joint Federal-State system to ensure compliance with these standards. The SDWA also directs EPA to protect underground sources of drinking water through the control of underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its SDWA authority. EPA and authorized states enforce the primary drinking water standards, which are, contaminant-specific concentration limits that apply to certain public drinking water supplies. Primary drinking water standards consist of maximum contaminant level goals (MCLGs), which are non-enforceable health-based goals, and maximum contaminant levels (MCLs), which are enforceable limits set as close to MCLGs as possible, considering cost and feasibility of attainment.

The SDWA **Underground Injection Control** (UIC) program (40 CFR Parts 144-148) is a permit program which protects underground sources of drinking water by regulating five classes of injection wells. UIC permits include design, operating, inspection, and monitoring requirements. Wells used to inject hazardous wastes must also comply with RCRA corrective action standards in order to be granted a RCRA permit, and must meet applicable RCRA land disposal restrictions standards. The UIC permit program is primarily state-enforced, since EPA has authorized all but a few states to administer the program.

The SDWA also provides for a Federally-implemented Sole Source Aquifer program, which prohibits Federal funds from being expended on projects that may contaminate the sole or principal source of drinking water for a given area, and for a State-implemented Wellhead Protection program, designed to protect drinking water wells and drinking water recharge areas.

EPA's Safe Drinking Water Hotline, at (800) 426-4791, answers questions and distributes guidance pertaining to SDWA standards. The Hotline operates from 9:00 a.m. through 5:30 p.m., ET, excluding Federal holidays.

Toxic Substances Control Act (TSCA)

TSCA granted EPA authority to create a regulatory framework to collect data on chemicals in order to evaluate, assess, mitigate, and control risks which may be posed by their manufacture, processing, and use. TSCA provides a variety of control methods to prevent chemicals from posing unreasonable risk.

TSCA standards may apply at any point during a chemical's life cycle. Under TSCA §5, EPA has established an inventory of chemical substances. If a chemical is not already on the inventory, and has not been excluded by TSCA, a premanufacture notice (PMN) must be submitted to EPA prior to manufacture or import. The PMN must identify the chemical and provide available information on health and environmental effects. If available data are not sufficient to evaluate the chemicals effects, EPA can impose restrictions pending the development of information on its health and environmental effects. EPA can also restrict significant new uses of chemicals based upon factors such as the projected volume and use of the chemical.

Under TSCA §6, EPA can ban the manufacture or distribution in commerce, limit the use, require labeling, or place other restrictions on chemicals that pose unreasonable risks. Among the chemicals EPA regulates under §6 authority are asbestos, chlorofluorocarbons (CFCs), and polychlorinated biphenyls (PCBs).

EPA's TSCA Assistance Information Service, at (202) 554-1404, answers questions and distributes guidance pertaining to Toxic Substances Control Act standards. The Service operates from 8:30 a.m. through 4:30 p.m., ET, excluding Federal holidays.

Clean Air Act (CAA)

The CAA and its amendments, including the Clean Air Act Amendments (CAAA) of 1990, are designed to "protect and enhance the nation's air resources so as to promote the public health and welfare and the productive capacity of the population." The CAA consists of six sections, known as Titles, which direct EPA to establish national standards for ambient air quality and for EPA and the States to implement, maintain, and enforce these standards through a variety of mechanisms. Under the CAAA, many facilities will be required to obtain permits for the first time. State and local governments oversee, manage, and enforce many of the requirements of the CAAA. CAA regulations appear at 40 CFR Parts 50-99.

Pursuant to Title I of the CAA, EPA has established national ambient air quality standards (NAAQSs) to limit levels of "criteria pollutants," including carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur dioxide. Geographic areas that meet NAAQSs for a given pollutant are classified as attainment areas; those that do not meet NAAQSs are classified as non-attainment areas. Under §110 of the CAA, each State must develop a State Implementation Plan (SIP) to identify sources of air pollution and to determine what reductions are required to meet Federal air quality standards.

Title I also authorizes EPA to establish New Source Performance Standards (NSPSs), which are nationally uniform emission standards for new stationary sources falling within particular industrial categories. NSPSs are based on the pollution control technology available to that category of industrial source but allow the affected industries the flexibility to devise a cost-effective means of reducing emissions.

Under Title I, EPA establishes and enforces National Emission Standards for Hazardous Air Pollutants (NESHAPs), nationally uniform standards oriented towards controlling particular hazardous air pollutants (HAPs). Title III of the CAAA further directed EPA to develop a list of sources that emit any of 189 HAPs, and to develop regulations for these categories of sources. To date, EPA has listed 174 categories and developed a schedule for the establishment of emission standards. The emission standards will be developed for both new and existing sources based on "maximum achievable control technology (MACT)." The MACT is defined as the control technology achieving the maximum degree of reduction in the emission of the HAPs, taking into account cost and other factors.

Title II of the CAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few of the mechanisms EPA uses to regulate mobile air emission sources.

Title IV establishes a sulfur dioxide emissions program designed to reduce the formation of acid rain. Reduction of sulfur dioxide releases will be obtained by granting to certain sources limited emissions allowances, which, beginning in 1995, will be set below previous levels of sulfur dioxide releases.

Title V of the CAAA of 1990 created a permit program for all "major sources" (and certain other sources) regulated under the CAA. One purpose of the operating permit is to include in a single document all air emissions requirements that apply to a given facility. States are developing the permit programs in accordance with guidance and regulations from EPA. Once a State program is approved by EPA, permits will be issued and monitored by that State.

Title VI is intended to protect stratospheric ozone by phasing out the manufacture of ozone-depleting chemicals and restrict their use and distribution. Production of Class I substances, including 15 kinds of chlorofluorocarbons (CFCs), will be phased out entirely by the year 2000, while certain hydrochlorofluorocarbons (HCFCs) will be phased out by 2030.

EPA's Control Technology Center, at (919) 541-0800, provides general assistance and information on CAA standards. The Stratospheric Ozone Information Hotline, at (800) 296-1996, provides general information about regulations promulgated under Title VI of the CAA, and EPA's EPCRA Hotline, at (800) 535-0202, answers questions about accidental release prevention under CAA §112(r). In addition, the Technology Transfer Network Bulletin Board System (modem access (919) 541-5742)) includes recent CAA rules, EPA guidance documents, and updates of EPA activities.

VI.B. Industry Specific Requirements

The organic chemical industry is affected by nearly all federal environmental statutes. In addition, the industry is subject to numerous laws and regulations from state and local governments designed to protect and improve the nation's health, safety, and environment. A summary of the major federal regulations affecting the chemical industry follows. The Synthetic Organic Chemical Manufacturer's Association is undertaking a year-long study to identify the environmental regulations that apply to their members. The study should be available in early 1996.

Federal Statutes

Toxic Substances Control Act (TSCA)

TSCA gives the Environmental Protection Agency comprehensive authority to regulate any chemical substance whose manufacture, processing, distribution in commerce, use or disposal may present an unreasonable risk of injury to health or the environment. Three sections are of primary importance to the organic chemical industry. TSCA §5 mandates that chemical companies submit pre-manufacture notices that provide information on health and environmental effects for each new product and test existing products for these effects (40 CFR Part 720). TSCA §4 authorizes the EPA to require testing of certain substances (40 CFR Part 790). TSCA §6 gives the EPA authority to prohibit, limit or ban the manufacture, process and use of chemicals (40 CFR Part 750). To date over 20,000 premanufacturing notices have been filed.

Clean Air Act

The original CAA authorized EPA to set limits on chemical plant emissions. Many of these new source performance standards (NSPS) apply to organic chemical manufacturers including those for flares (40 CFR Part 60 Subpart A), storage vessels (40 CFR Part 60 Subpart K), synthetic organic chemical manufacturers equipment leaks (40 CFR Part 60 Subpart VV), synthetic organic chemicals manufacturers using air oxidation processes (40 CFR Part 60 Subpart III), distillation operations (40 CFR Part 60 Subpart NNN), reactor processes (40 CFR Part 60 Subpart RRR), and wastewater (40 CFR Part 60 Subpart YYY).

The Clean Air Act Amendments of 1990 set control standards by industrial sources for 41 pollutants to be met by 1995 and for 148 other pollutants to be reached by 2003. Several provisions affect the organic chemical industry. Under the air toxics provisions of the CAAA, more sources are covered including small businesses. In April 1994, the EPA proposed regulations to reduce air toxics emissions at chemical plants. The Hazardous Organic National Emissions Standard for Hazardous Air Pollutants, also known as HON, covers hundreds of chemical plants and thousands of chemical process units (40 CFR Part 63 Subparts F, G, H, I, J, K). The HON also includes innovative provisions such as emissions trading, that offer industry flexibility in complying with the rule's emissions goals. Subsets of the industry are regulated under other National Emission Standards for Hazardous Air Pollutants (NESHAP). These include vinyl chloride manufacturers (40 CFR Part 61 Subpart F), benzene emission from ethylbenzene/styrene manufacturers (40 CFR Part 61 Subpart I), benzene equipment leaks (40 CFR Part 61 Subpart J), emissions from storage tanks (40 CFR Part 61 Subpart K), benzene emissions from benzene transfer operations (40 CFR Part 61 Subpart BB), and benzene waste operations (40 CFR Part 61 Subpart FF). Another NESHAP that may affect organic chemical manufacturers is that for treatment, storage, and disposal facilities (TSDF) (40 Part CFR 63 Subpart AA). CAAA provisions on oxygenated additives for reformulated gasoline have also affected the chemical industry by encouraging production of the oxygenates methyl *tert*-butyl ether and ethyl *tert*-butyl ether.

Title V of the CAA introduces a new permit system that will require all major sources to obtain operating permits to cover all applicable control requirements. States were required to develop and implement the program in 1993 and the first permits were to be issued in 1995.

Clean Water Act

The Clean Water Act, first passed in 1972 and amended in 1977 and 1987, gives EPA the authority to regulate effluents from sewage treatment works, chemical plants, and other industrial sources into waters. The act sets "best available" technology standards for treatment of wastes for both direct and indirect (to a Publicly Owned Treatment Works) discharges. In 1987, EPA proposed final effluent guidelines for the organic, polymer and synthetic fiber industry. The majority of this rule was upheld by the federal courts. A final proposal for the remaining portions of the rule was issued in August 1993. The implementation of the guidelines is left to the states who issue National Pollutant Discharge Elimination System (NPDES) permits for each facility.

The Storm Water Rule (40 CFR §122.26(b)(14) Subparts (i, ii)) requires the capture and treatment of stormwater at facilities producing chemicals and allied products, including industrial organic chemical manufacture. Required treatment will remove from stormwater flows a large fraction of both conventional pollutants, such as suspended solids and biological oxygen demand (BOD), as well as toxic pollutants, such as certain metals and organic compounds.

Superfund

The Comprehensive Environmental Response Compensation and Liability Act of 1980 (CERCLA) and the Superfund Amendments and Reauthorization Act of 1986 (SARA) provide the basic legal framework for the federal "Superfund" program to clean up abandoned hazardous waste sites (40 CFR Part 305). The 1986 SARA legislation extended those taxes for five years and adopted a new broad-based corporate environmental tax. In 1990, Congress passed a simple reauthorization that did not substantially change the law but extended the program authority until 1994 and the taxing authority until 1995. The chemical industry (all SIC codes) pays about $300 million a year in Superfund chemical feedstock taxes. A comprehensive reauthorization was considered in 1994. The industry believes several serious concerns need to be addressed including the liability standard which threatens Potentially Responsible Parties (PRPs) with the entire cost of clean-up at sites even though they may be responsible for only a tiny fraction of the waste; clean-up requirements, which are often unaffordable, unattainable, and unjustified by the risks presented by the sites; and the punitive, adversarial nature of the enforcement program.

Title III of the 1986 SARA amendments (also known as Emergency Response and Community Right-to-Know Act, EPCRA) requires all manufacturing facilities, including chemical facilities, to report annual information to the public about stored toxic substances as well as release of these substances into the environment (42 U.S.C. 9601). This is known as the Toxic Release Inventory (TRI). Between 1988 and 1993 TRI emissions by chemical companies to air, land, and water were reduced 44 percent. EPCRA also establishes requirements for federal, state, and local governments regarding emergency planning. In 1994, over 300 more chemicals were added to the list of chemicals for which reporting is required.

VI.C. Pending and Proposed Regulatory Requirements

Chemical Inventory Update Rule

Every four years chemical manufacturers must report to EPA on their manufacture, importation, and, in 1994, use of chemicals on the Toxic Substances Control Act inventory.

VII. COMPLIANCE AND ENFORCEMENT PROFILE

Background

To date, EPA has focused much of its attention on measuring compliance with specific environmental statutes. This approach allows the Agency to track compliance with the Clean Air Act, the Resource Conservation and Recovery Act, the Clean Water Act, and other environmental statutes. Within the last several years, the Agency has begun to supplement single-media compliance indicators with facility-specific, multimedia indicators of compliance. In doing so, EPA is in a better position to track compliance with all statutes at the facility level, and within specific industrial sectors.

A major step in building the capacity to compile multimedia data for industrial sectors was the creation of EPA's Integrated Data for Enforcement Analysis (IDEA) system. IDEA has the capacity to "read into" the Agency's single-media databases, extract compliance records, and match the records to individual facilities. The IDEA system can match Air, Water, Waste, Toxics/Pesticides/EPCRA, TRI, and Enforcement Docket records for a given facility, and generate a list of historical permit, inspection, and enforcement activity. IDEA also has the capability to analyze data by geographic area and corporate holder. As the capacity to generate multimedia compliance data improves, EPA will make available more in-depth compliance and enforcement information. Additionally, sector-specific measures of success for compliance assistance efforts are under development.

Compliance and Enforcement Profile Description

Using inspection, violation, and enforcement data from the IDEA system, this section provides information regarding the historical compliance and enforcement activity of this sector. In order to mirror the facility universe reported in the Toxic Chemical Profile, the data reported within this section consists of records only from the TRI reporting universe. With this decision, the selection criteria are consistent across sectors with certain exceptions. For the sectors that do not normally report to the TRI program, data have been provided from EPA's Facility Indexing System (FINDS) which tracks facilities in all media databases. Please note, in this section, EPA does not attempt to define the actual number of facilities that fall within each sector. Instead, the section portrays the records of a subset of facilities within the sector that are well defined within EPA databases.

As a check on the relative size of the full sector universe, most notebooks contain an estimated number of facilities within the sector according to the Bureau of Census (See Section II). With sectors dominated by small businesses, such as metal finishers and printers, the reporting universe within the EPA databases may be small in comparison to Census data. However, the group selected for inclusion in this data analysis section should be consistent with this sector's general makeup.

Following this introduction is a list defining each data column presented within this section. These values represent a retrospective summary of inspections and enforcement actions, and solely reflect EPA, State, and local compliance assurance activities that have been entered into EPA databases. To identify any changes in trends, the EPA ran two data queries, one for the five calendar years August 10, 1990 to August 9, 1995, and the other for the most recent twelve-month period, August 10, 1994 to August 9, 1995. The five-year analysis gives an average level of activity for that period for comparison to the more recent activity.

Because most inspections focus on single-media requirements, the data queries presented in this section are taken from single media databases. These databases do not provide data on whether inspections are state/local or EPA-led. However, the table breaking down the universe of violations does give the reader a crude measurement of the EPA's and states' efforts within each media program. The presented data illustrate the variations across regions for certain sectors.[f] This variation may be attributable to state/local data entry variations, specific geographic concentrations, proximity to population centers, sensitive ecosystems, highly toxic chemicals used in production, or historical noncompliance. Hence, the exhibited data do not rank regional performance or necessarily reflect which regions may have the most compliance problems.

Compliance and Enforcement Data Definitions

General Definitions

Facility Indexing System (FINDS) -- this system assigns a common facility number to EPA single-media permit records. The FINDS identification number allows EPA to compile and review all permit, compliance, enforcement, and pollutant release data for any given regulated facility.

Integrated Data for Enforcement Analysis (IDEA) -- is a data integration system that can retrieve information from the major EPA program office databases. IDEA uses the FINDS identification number to "glue together" separate data records from EPA's databases. This is done to create a "master list" of data records for any given facility. Some of the data systems accessible through IDEA are: AIRS (Air Facility Indexing and Retrieval System, Office of Air and Radiation), PCS (Permit Compliance System, Office of Water), RCRIS (Resource Conservation and Recovery Information System, Office of Solid Waste), NCDB (National Compliance Data Base, Office of Prevention, Pesticides, and Toxic Substances), CERCLIS (Comprehensive Environmental and Liability Information System, Superfund),

[f] EPA Regions include the following states: I (CT, MA, ME, RI, NH, VT); II (NJ, NY, PR, VI); III (DC, DE, MD, PA, VA, WV); IV (AL, FL, GA, KY, MS, NC, SC, TN); V (IL, IN, MI, MN, OH, WI); VI (AR, LA, NM, OK, TX); VII (IA, KS, MO, NE); VIII (CO, MT, ND, SD, UT, WY); IX (AZ, CA, HI, NV, Pacific Trust Territories); X (AK, ID, OR, WA).

and TRIS (Toxic Release Inventory System). IDEA also contains information from outside sources such as Dun and Bradstreet and the Occupational Safety and Health Administration (OSHA). Most data queries displayed in notebook sections IV and VII were conducted using IDEA.

Data Table Column Heading Definitions

Facilities in Search -- are based on the universe of TRI reporters within the listed SIC code range. For industries not covered under TRI reporting requirements, the notebook uses the FINDS universe for executing data queries. The SIC code range selected for each search is defined by each notebook's selected SIC code coverage described in Section II.

Facilities Inspected -- indicates the level of EPA and state agency facility inspections for the facilities in this data search. These values show what percentage of the facility universe is inspected in a 12 or 60 month period. This column does not count non-inspectional compliance activities such as the review of facility-reported discharge reports.

Number of Inspections -- measures the total number of inspections conducted in this sector. An inspection event is counted each time it is entered into a single media database.

Average Time Between Inspections -- provides an average length of time. expressed in months, that a compliance inspection occurs at a facility within the defined universe.

Facilities with One or More Enforcement Actions -- expresses the number of facilities that were party to at least one enforcement action within the defined time period. This category is broken down further into federal and state actions. Data are obtained for administrative, civil/judicial, and criminal enforcement actions. Administrative actions include Notices of Violation (NOVs). A facility with multiple enforcement actions is only counted once in this column (a facility with three enforcement actions counts as one). All percentages that appear are referenced to the number of facilities inspected.

Total Enforcement Actions -- describes the total number of enforcement actions identified for an industrial sector across all environmental statutes. A facility with multiple enforcement actions is counted multiple times (a facility with three enforcement actions counts as three).

State Lead Actions -- shows what percentage of the total enforcement actions are taken by state and local environmental agencies. Varying levels of use of EPA data systems by states may limit the volume of actions accorded state enforcement activity. Some states extensively report enforcement activities into EPA data systems, while other states may use their own data systems.

Federal Lead Actions -- shows what percentage of the total enforcement actions are taken by the United States Environmental Protection Agency. This value includes referrals from state agencies. Many of these actions result from coordinated or joint state/federal efforts.

Enforcement to Inspection Rate -- expresses how often enforcement actions result from inspections. This value is a ratio of enforcement actions to inspections, and is presented for comparative purposes only. This measure is a rough indicator of the relationship between inspections and enforcement. This measure simply indicates historically how many enforcement actions can be attributed to inspection activity. Reported inspections and enforcement actions under the Clean Water Act (CWA), the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA) are included in this ratio. Inspections and actions from the TSCA/FIFRA/EPCRA database are not factored into this ratio because most of the actions taken under these programs are not the result of facility inspections. This ratio does not account for enforcement actions arising from non-inspection compliance monitoring activities (e.g., self-reported water discharges) that can result in enforcement action within the CAA, CWA, and RCRA.

Facilities with One or More Violations Identified -- indicates the number and percentage of inspected facilities having a violation identified in one of the following data categories: In Violation or Significant Violation Status (CAA); Reportable Noncompliance, Current Year Noncompliance, Significant Noncompliance (CWA); Noncompliance and Significant Noncompliance (FIFRA, TSCA, and EPCRA); Unresolved Violation and Unresolved High Priority Violation (RCRA). The values presented for this column reflect the extent of noncompliance within the measured time frame, but do not distinguish between the severity of the noncompliance. Percentages within this column can exceed 100 percent because facilities can be in violation status without being inspected. Violation status may be a precursor to an enforcement action, but does not necessarily indicate that an enforcement action will occur.

Media Breakdown of Enforcement Actions and Inspections -- four columns identify the proportion of total inspections and enforcement actions within EPA Air, Water, Waste, and TSCA/FIFRA/EPCRA databases. Each column is a percentage of either the "Total Inspections," or the "Total Actions" column.

VII.A. Organic Chemicals Compliance History

Exhibit 26 provides an overview of the reported compliance and enforcement data for the organic chemical industry over the past five years (August 1990 to August 1995). These data are also broken out by EPA Region thereby permitting geographical comparisons. A few points evident from the data are listed below.

- About 77 percent of the organic chemical producing facilities identified in the IDEA search were inspected in the past five years. These facilities were inspected on average every six months.
- Those facilities with one or more enforcement actions had, on average, over the five year period, almost five enforcement actions brought against them.
- The complexity of reactions and diversity among and within facilities makes it difficult to generalize about the types of compliance problems facilities will face.

Exhibit 26: Five-Year Enforcement and Compliance Summary for Organic Chemicals

A	B	C	D	E	F	G	H	I	J

VII.B. Comparison of Enforcement Activity Between Selected Industries

Exhibits 27 and 28 allow the compliance history of the organic chemical industry to be compared with the other industries covered by the industry sector notebooks. Comparisons between Exhibits 27 and 28 permit the identification of trends in compliance and enforcement records of the industry by comparing data covering the last five years to that of the past year. Some points evident from the data are listed below.

- The organic chemical industry has a relatively high frequency of inspections compared to the other sectors shown. On average, organic chemical facilities were inspected every six months.

- Over the last five years, the organic chemical industry has had a relatively high ratio of enforcement actions to inspections. This relatively high ratio has continued in the past year.

- Of the sectors shown, the organic chemical industry has one of the highest percentage of EPA led enforcement actions versus state led actions.

Exhibits 29 and 30 provide a more in-depth comparison between the organic chemical industry and other sectors by breaking out the compliance and enforcement data by environmental statute. As in Exhibits 29 and 30, the data cover the last five years (Exhibit 27) and the previous year (Exhibit 28) to facilitate the identification of recent trends. A few points evident from the data are listed below.

- Over the past five years, RCRA has accounted for the largest share of inspections and enforcement actions at organic chemical facilities. This trend has increased over the past year.

- The share of enforcement actions and inspections has decreased in the past year for the Clean Water Act and FIFRA/TSCA/EPCRA/Other and has increased for the Clean Air Act and RCRA in comparison to the previous five years.

VII.C. Review of Major Legal Actions

This section provides summary information about major cases that have affected this sector, and a list of Supplementary Environmental Projects (SEPs). SEPs are compliance agreements that reduce a facility's stipulated penalty in return for an environmental project that exceeds the value of the reduction. Often, these projects fund pollution prevention activities that can significantly reduce the future pollutant loadings of a facility.

VII.C.1. Review of major cases

Historically, OECA's Office of Enforcement Capacity and Outreach does not regularly compile information related to major cases and pending litigation within an industry sector. The staff are willing to pass along such information to Agency staff as requests are made. In addition, summaries of completed enforcement actions are published each fiscal year in the Enforcement Accomplishments Report. To date, these summaries are not organized by industry sector. (Contact: Office of Enforcement Capacity and Outreach, 202-260-4140)

VII.C.2. Supplementary Environmental Projects (SEPs)

Supplemental environmental projects (SEPs) are negotiated environmental projects such that a fraction of the costs may be applied to their fine. Regional summaries of SEPs actions undertaken in the 1993 and 1994 federal fiscal year were reviewed. Seventeen projects were undertaken that involved organic chemical manufacturing facilities, as shown in the following table. CERCLA violations engendered approximately half of all projects. Other actions were associated with EPCRA, CAA, RCRA and TSCA violations; the specifics of the original violations are not known.

The majority of SEPs were done in Region VI. Taken alone, Texas accounted for approximately one-third of all projects (6 of 17). The fact that only one fifth of all organic chemical manufactures are located in Region VI; may suggest that negotiating SEPs is a regional priority.

One project was conducted at a facility that manufactured both inorganic and organic chemicals. This project has been included in both industry sector project summaries. Unlike other sectors, none of the organic chemical manufacturing SEPs undertaken in FY-1993 and FY-1994 involved specific manufacturing process changes. The SEPs fall into two categories:

- Non-process related projects: Eleven of the seventeen SEPs involved projects not directly related to the organic chemical manufacturing process or its outputs. Ten of these projects involved a contribution to the Local Emergency Planning Committee (LEPC). Contributions ranged from donation of equipment (e.g., computer systems and emergency materials) to training programs for LEPC members. One project involved the replacement of QA/QC lab equipment with less solvent-requiring alternatives. The other project involved removing and properly disposing of 26 PCB capacitors. Cost to company ranged from $3,000 to $257,000 for these projects.

- Control and recovery technology improvement/installation: In four of the projects, control or recovery technologies were installed or upgraded to reduce toxic chemical production from manufacturing processes. Cost for project implementation ranged from $125,000 to $200,000.

94	---	Allied Signal, Inc.	IN	TSCA	$7,000	$2,500	---	$7,000	---	---	Removed and properly disposed of 26 PCB capacitors

[*] Facilities identified as combined inorganic and organic chemical manufacturers

Violation Information Terms
Initial penalty: Initial proposed cash penalty for violation
Final penalty: Total penalty after SEP negotiation
SEP credit: Cash credit given for SEP so that, Final penalty - SEP credit = Final cash penalty
SEP cost to company: Actual cost to company of SEP implementation

NOTE: Due to differences in terminology and level of detail between regional SEP information, in some cases the figure listed as Final penalty may be the Final cash penalty after deduction for SEP credit

R0076880

VIII. COMPLIANCE ACTIVITIES AND INITIATIVES

This section highlights the activities undertaken by this industry sector and public agencies to voluntarily improve the sector's environmental performance. These activities include those independently initiated by industrial trade associations. In this section, the notebook also contains a listing and description of national and regional trade associations.

VIII.A. Sector-related Environmental Programs and Activities

Chemical Manufacturer's Association and EPA are discussing developing plant level compliance guides, auditing protocols, and training materials for new regulations.

VIII.B. EPA Voluntary Programs

33/50 Program

The "33/50 Program" is EPA's voluntary program to reduce toxic chemical releases and transfers of seventeen chemicals from manufacturing facilities. Participating companies pledge to reduce their toxic chemical releases and transfers by 33 percent as of 1992 and by 50 percent as of 1995 from the 1988 baseline year. Certificates of Appreciation have been given out to participants meeting their 1992 goals. The list of chemicals includes seventeen high-use chemicals reported in the Toxics Release Inventory. Exhibit 32 lists those companies participating in the 33/50 program that reported the SIC code 286 to TRI. Many of the companies shown listed multiple SIC codes and, therefore, are likely to carry out operations in addition to organic chemical manufacturing. The SIC codes reported by each company are listed in no particular order. In addition, the number of facilities within each company that are participating in the 33/50 program and that report SIC 286 to TRI is shown. Finally, each company's total 1993 releases and transfers of 33/50 chemicals and the percent reduction in these chemicals since 1988 are presented.

The organic chemicals industry as a whole used, generated or processed all seventeen target TRI chemicals. Of the target chemicals, benzene, toluene, xylenes and methyl isobutyl ketone are released most frequently and in similar quantities. Significant amounts of methyl ethyl ketone are also released, although it is only the seventh most frequently reported 33/50 chemical. These five toxic chemicals account for about eight percent of TRI releases and transfers from organic chemicals facilities. From Exhibit 32, 115 companies representing 335 facilities listed under SIC 286 are currently participating in the 33/50 program. They account for 34 percent of the 986 facilities carrying out organic chemicals manufacturing operations (as identified by the 1992 Census of Manufacturers), which is significantly higher than the average for all industries of 14 percent participation. (Contact: Mike Burns, 202-260-6394 or the 33/50 Program 202-260-6907)

Environmental Leadership Program

The Environmental Leadership Program (ELP) is a national initiative piloted by EPA and state agencies in which facilities have volunteered to demonstrate innovative approaches to environmental management and compliance. EPA has selected 12 pilot projects at industrial facilities and federal installations which will demonstrate the principles of the ELP program. These principles include: environmental management systems, multimedia compliance assurance, third-party verification of compliance, public measures of accountability, community involvement, and mentor programs. In return for participating, pilot participants receive public recognition and are given a period of time to correct any violations discovered during these experimental projects.

Forty proposals were received from companies, trade associations, and federal facilities representing many manufacturing and service sectors. One chemical company's proposal was accepted (Ciba Geigy of St. Gabriel, LA). Another chemical firm (Akzo Chemicals of Edison, NJ), one pharmaceutical manufacturer (Schering Plough of Kenilworth, NJ) and one manufacturer of agricultural chemicals (Gowan Milling of Yuma, AZ) have submitted proposals. (Contact: Tia-Ming Chang, ELP Director 202-564-5081 or Robert Fentress 202-564-7023)

Project XL

Project XL was initiated in March 1995 as a part of President Clinton's *Reinventing Environmental Regulation* initiative. The projects seek to achieve cost effective environmental benefits by allowing participants to replace or modify existing regulatory requirements on the condition that they produce greater environmental benefits. EPA and program participants will negotiate and sign a Final Project Agreement, detailing specifc objectives that the regulated entity shall satisfy. In exchange, EPA will allow the participant a certain degree of regulatory flexibility and may seek changes in underlying regulations or statutes. Participants are encouraged to seek stakeholder support from local governments, businesses, and environmental groups. EPA hopes to implement fifty pilot projects in four categories including facilities, sectors, communities, and government agencies regulated by EPA. Applications will be accepted on a rolling basis and projects will move to implementation within six months of their selection. For additional information regarding XL Projects, including application procedures and criteria, see the May 23, 1995 Federal Register Notice. (Contact: Jon Kessler at EPA's Office of Policy Analysis 202 260-4034)

Green Lights Program

EPA's Green Lights program was initiated in 1991 and has the goal of preventing pollution by encouraging U.S. institutions to use energy-efficient lighting technologies. The program has over 1,500 participants which include major corporations; small and medium sized businesses; federal, state, and local governments; non-profit groups; schools; universities; and health care facilities. Each participant is required to survey their facilities and upgrade lighting wherever it is profitable. EPA provides technical assistance to the participants through a decision support software package, workshops and manuals, and a financing registry. EPA's Office of Air and Radiation is responsible for operating the Green Lights Program. (Contact: Maria Tikoff at 202-233-9178 or the Green Light/Energy Star Hotline at 202-775-6650)

WasteWi$e Program

The WasteWi$e Program was started in 1994 by EPA's Office of Solid Waste and Emergency Response. The program is aimed at reducing municipal solid wastes by promoting waste minimization, recycling collection, and the manufacturing and purchase of recycled products. As of 1994, the program had about 300 companies as members, including a number of major corporations. Members agree to identify and implement actions to reduce their solid wastes and must provide EPA with their waste reduction goals along with yearly progress reports. EPA, in turn, provides technical assistance to member companies and allows the use of the WasteWi$e logo for promotional purposes. (Contact: Lynda Wynn 202-260-0700 or the WasteWi$e Hotline at 800-372-9473)

Climate Wise Recognition Program

The Climate Change Action Plan was initiated in response to the U.S. commitment to reduce greenhouse gas emissions in accordance with the Climate Change Convention of the 1990 Earth Summit. As part of the Climate Change Action Plan, the Climate Wise Recognition Program is a partnership initiative run jointly by EPA and the Department of Energy. The program is designed to reduce greenhouse gas emissions by encouraging reductions across all sectors of the economy, encouraging participation in the full range of Climate Change Action Plan initiatives, and fostering innovation. Participants in the program are required to identify and commit to actions that reduce greenhouse gas emissions. The program, in turn, gives organizations early recognition for their reduction commitments; provides technical assistance through consulting services, workshops, and guides; and provides access to the program's centralized information system. At EPA, the program is operated by the Air and Energy Policy Division within the Office of Policy Planning and Evaluation. (Contact: Pamela Herman 202-260-4407)

NICE^3

The U.S. Department of Energy and EPA's Office of Pollution Prevention are jointly administering a grant program called The National Industrial Competitiveness through Energy, Environment, and Economics (NICE^3). By providing grants of up to 50 percent of the total project cost, the program encourages industry to reduce industrial waste at its source and become more energy-efficient and cost-competitive through waste minimization efforts. Grants are used by industry to design, test, demonstrate, and assess the feasibility of new processes and/or equipment with the potential to reduce pollution and increase energy efficiency. The program is open to all industries; however, priority is given to proposals from participants in the pulp and paper, chemicals, primary metals, and petroleum and coal products sectors. (Contact: DOE's Golden Field Office 303-275-4729)

VIII.C. Trade Association/Industry Sponsored Activity

VIII.C.1. Environmental Programs

The Global Environmental Management Initiative (GEMI) is made up of group of leading companies dedicated to fostering environmental excellence by business. GEMI promotes a worldwide business ethic for environmental management and sustainable development, to improve the environmental performance of business through example and leadership. In 1994, GEMI's membership consisted of about 30 major corporations including Union Carbide Corporation and Dow Chemical.

Center for Waste Reduction Technologies under the aegis of the American Institute of Chemical Engineers sponsored research on innovative technologies to reduce waste in the chemical processing industries. The primary mechanism is through funding of academic research.

The National Science Foundation and the Environmental Protection Agency's Office of Pollution Prevention and Toxics signed an agreement in January of 1994 to coordinate the two agencies' programs of **basic research related to pollution prevention**. The collaboration will stress research in the use of less toxic chemical and synthetic feedstocks, use of photochemical processes instead of traditional ones that employ toxic reagents, use of recyclable catalysts to reduce metal contamination, and use of natural feedstocks when synthesizing chemicals in large quantities.

The **Chemical Manufacturer's Association** funds research on issues of interest to their members particularly in support of their positions on proposed or possible legislation. They recently funded a study to characterize the environmental fate of organochlorine compounds.

ISO 9000 is a series of international total quality management guidelines. After a successful independent audit of their management plans, firms are qualified to be ISO 9000 registered. In June of 1993, the International Standards Organization created a technical committee to work on new standards for environmental management systems.

The **Responsible Care® Initiative** of the Chemical Manufacturer's Association requires all members and partners to continuously improve their health, safety, and environmental performance in a manner that is responsive to the public. Launched in 1988, the Responsible Care® concepts are now being applied in 36 countries around the world. Responsible Care® is a comprehensive, performance-oriented initiative composed of ten progressive Guiding Principles and six board Codes of Management Practices. These Management Practices cover all aspects of the chemical industry's operations, from research to manufacturing, distribution, transportation, sales and marketing, and to downstream users of chemical products. Through Responsible Care®, CMA members and partners gain insight from the public through, among other means, a national Public Advisory Panel and over 250 local Community Advisory Panels. This, coupled with the fact that participation in Responsible Care® is an obligation of membership with the Chemical Manufacturer's Association, make this performance improvement initiative unique. The Synthetic Organic Chemical Manufacturer's Association whose membership consists of smaller batch and custom chemical manufacturers with typically fewer than 50 employees and less than $50 million in annual sales, encourages its members to achieve continuous performance improvement in their health, safety, and environmental programs through implementation of the chemical industry's Responsible Care® initiative. SOCMA is a partner in Responsible Care®.

VIII.C.2. Summary of Trade Associations

American Chemical Society
1155 16th Street, NW
Washington, D.C. 20036
Phone: (202) 872-8724
Fax: (202) 872-6206

Budget: $192,000,000
Staff: 1700
Members: 145,000

The American Chemical Society (ACS) has an educational and research focus. The ACS produces approximately thirty different industry periodicals and research journals, including *Environmental Science and Technology* and *Chemical Research in Toxicology*. In addition to publishing, the ACS presently conducts studies and surveys; legislation monitoring, analysis, and reporting; and operates a variety of educational programs. The ACS library and on-line information services are extensive. Some available on-line services are *Chemical Journals Online*, containing the full text of 18 ACS journals, 10 Royal Society of Chemistry journals, five polymer journals and the Chemical Abstracts Service, *CAS*, which provides a variety of information on chemical compounds. Founded in 1876, the ACS is presently comprised of 184 local groups and 843 student groups nationwide.

Chemical Manufacturer's Association
2501 M St., NW
Washington, D.C. 20037
Phone: (202) 887-1100
Fax: (202) 887-1237

Members: 185
Staff: 246
Budget: $36,000,000

A principal focus of the Chemical Manufacturer's Association (CMA) is on regulatory issues facing chemical manufacturers at the local, state, and federal levels. At its inception in 1872, the focus of CMA was on serving chemical manufacturers through research. Research is still ongoing at CMA. Member committees, task groups, and work groups routinely sponsor research and technical data collection that is then provided to the public in support of CMA's advocacy. Much additional research takes place through the CHEMSTAR® program. CHEMSTAR® consists of a variety of self-funded panels working on single-chemical research agendas. This research fits within the overall regulatory focus of CMA; CHEMSTAR® study results are provided to both CMA membership and regulatory agencies. Other initiatives include the Responsible Care® program, which includes six codes of management practices designed to go beyond simple regulatory compliance. CAM is currently developing measurement and appropriate verification systems for these codes. CMA also conducts workshops and technical symposia, promotes in-plant safety, operates a chemical emergency center (CHEMTREC®) which offers guidance in chemical emergency situations, and operates the Chemical Referral Center which provides chemical health and safety information to the public. Publications include the annual *U.S. Chemical Industry Statistical Handbook*, containing detailed data on the industry; *Responsible Care in Action*, the 1993-94 progress report on implementing Responsible Care®; and *Preventing Pollution: A Chemical Industry Progress Report (1988-1992)*, summarizing waste generation and reduction data for the years 1988-92. CMA holds an annual meeting for its membership in White Sulphur Springs, WV.

Ethylene Oxide Industry Council
2501 M St. NW, Ste. 330
Washington, DC 20037
Phone: (202) 887-1198

The Ethylene Oxide Industry Council (EOIC), founded in 1981, is an example of a panel group within the CHEMSTAR® program of the Chemical Manufacturer's Association (CMA). The EOIC consists of ethylene oxide producers and users. Ethylene oxide is used in the manufacture of antifreeze and polyester fibers, and is widely used as a sterilizing agent. The EOIC develops scientific, technological, and economic data on the safe use and manufacture of ethylene oxide. Other duties include informing scientific and governmental organizations of the industry's views and interests.

Synthetic Organic Chemicals
Manufacturer's Association
1100 New York Avenue, NW
Washington, D.C. 20005
Phone: (202) 414-4100 Members: 250
Fax: (202) 289-8584 Staff: 50

Synthetic Organic Chemicals Manufacturer's Association (SOCMA) is the national trade association representing the legislative, regulatory, and commercial interests of some 250 companies that manufacture, distribute, or market organic chemicals. Most of SOCMA's members are batch and custom chemical manufacturers who are the highly innovative, entrepreneurial and customer-driven sector of the U.S. chemical industry. The majority of SOCMA's members are small businesses with annual sales of less than $50 million and fewer than 50 employees. SOCMA assists its members in improving their environmental, safety, and health performance through various programs focusing on continuous improvement. A bi-monthly newsletter provides information on legislative and regulatory developments, as well as on education and training opportunities. SOCMA holds an annual meeting in May and also sponsors INFORMEX, the largest custom chemical trade show in the U.S. In addition, SOCMA's Association Management Center includes two dozen self-funded groups that focus on single chemical issues.

Chemical Specialties Manufacturer's Association
1913 I St. NW
Washington, D.C. 20006
Phone: (202) 872-8110
Fax: (202) 872-8114

Members: 425
Staff: 31

This organization represents the manufacturers of such specialty chemical products as pesticides, cleaners, disinfectants, sanitizers, and polishes. The Chemical Specialties Manufacturer's Association (CSMA) was founded in 1914. Today, the CSMA works with federal and state agencies and public representatives, to provide their membership with information on governmental activities and scientific developments. Some committees include: Government Affairs Advisory and Scientific Affairs. Publications include the quarterly *Chemical Times & Trends*, the biweekly *Legislative Reporter*, and compilations of laws and regulations. CSMA holds an annual December meeting in Washington, D.C.

Halogenated Solvents Industry Alliance
1225 19th St. NW, Ste. 300
Washington, D.C. 20036
Phone: (202) 223-5890

Members: 200
Budget: $1,400,000

The goal of the Halogenated Solvents Industry Alliance (HSIA) is to develop programs to address problems involving halogenated solvents. The group is actively involved in legislative and regulatory issues affecting the industry, providing industry comments and information to agencies, and representing the industry at administrative hearings. The HSIA also sponsors working groups on issues specific to the solvent industry. Publications include the bimonthly newsletter *Halogenated Solvents Industry Alliance*, which includes a listing of publications available from the group and the monthly newsletter *Solvents Update*, which covers regulatory development and HSIA actions.

Methyl Chloride Industry Association
c/o Robert Sussman
Latham and Watkins
1001 Pennsylvania Ave. NW, Ste.1300
Washington, D.C. 20004
Phone: (202) 637-2200

The Methyl Chloride Industry Association (MCIA) was founded in 1981 to meet the needs of the methyl chloride manufacturing industry on the issue of government regulation. The group participates in EPA rulemakings as an industry representative. The MCIA has no publications or annual meetings.

American Institute of Chemical Engineers
1707 L Street, NW, Ste. 333
Washington, D.C. 20036
Phone: (202) 962-8690 Members: 54,000
Fax: (202) 833-3014 Staff: 103

The American Institute of Chemical Engineers (AICHE) is a professional society of chemical engineers. AICHE develops chemical engineering curricula and sponsors a variety of chemical study forums. AICHE is split into twelve divisions including the Environmental, Forest Products, Fuels and Petrochemical, and Safety and Health divisions. Approximately fourteen publications are produced by AICHE, such as the quarterly *Environmental Progress*, a periodic directory of members, and a variety of pamphlets. AICHE holds three conferences per year in various locations.

Color Pigments Manufacturer's Association, Inc.
300 N. Washington St., Ste. 102
Alexandria, VA 22314
Phone: (703) 684-4044 Members: 50
Fax: (703) 684-1795 Staff: 5

The Color Pigments Manufacturer's Association (CPMA) represents North American manufacturers of pigments and pigment ingredients (i.e., dyes). The CPMA also represents the affiliates of manufacturers of those products who happen to manufacture the product overseas. The CPMA represents its membership before government agencies. No further information is available at this time.

Fire Retardant Chemical Association
851 New Holland Ave., Box 3535
Lancaster, PA 17604
Phone: (717) 291-5616 Members: 42
Fax: (717) 295-4538 Staff: 5

Chemical distributors/manufacturers active in promoting fire safety through chemical technology comprise the Fire Retardant Chemical Association (FRCA), founded in 1973. The FRCA serves as a forum for information dissemination on new developments, new applications, and current testing procedures for fire retardants and chemical fire safety products. Publications include the periodic *Fire Retardant Chemicals Association - Membership Directory* and the *Fire Retardant Chemical Association Proceedings*. Educational conferences are held semiannually.

National Paint and Coatings Association
1500 Rhode Island Avenue, NW
Washington, DC 20005
Phone: (202) 462-6272 Members: 700
Fax: (202) 462-8549 Staff: 40

Founded in 1933, the National Paint and Coatings Association (NPCA) represents manufacturers of paints and chemical coatings as well as suppliers of paint manufacturing equipment and raw materials. NPCA is involved in government relations programs, statistical surveys, and industry research. Committees include Labeling, Scientific, and Government Supply. The NPCA publishes an annual report, a periodic newsletter and trade directory, and a variety of guides. The NPCA holds an annual meeting.

Drug, Chemical, and Allied Trades Association
2 Roosevelt Ave., Suite 301
Syosset, NY 11791 Members: 500 Members: 500
Phone: 516-496-3317 Staff: 3 Staff: 3
Fax: 516-496-2231 Budget: $500,000

Drug, Chemical, and Allied Trades Association (DCAT) is comprised of drug, chemical, and related product (e.g., packaging, cosmetics, essential oils) manufacturers, advertisers, brokers, and importers. The association publishes *DCAT*, a monthly with coverage of federal regulations.

National Association of Chemical Recyclers
1875 Connecticut Ave., NW
Suite 1200
Washington, DC 20009
Phone: 202-986-8150 Members: 70
Fax: 202-986-2021 Staff: 3

National Association of Chemical Recyclers (NACR) founded in 1980, consists of recyclers of used industrial solvents. The organization promotes "responsible and intelligent" regulation and the beneficial reuse of waste. NACR monitors and reports on regulatory and legislative action affecting the practice of solvent recycling. NACR also compiles industry statistics. NACR publishes *Flashpoint* and a semiannual membership list. NACR holds a semiannual conference, usually in April or October.

IX. CONTACTS/ACKNOWLEDGMENTS/RESOURCE MATERIALS/BIBLIOGRAPHY

For further information on selected topics within the organic chemical industry a list of publications and contacts are provided below:

Contacts[8]

Name	Organization	Telephone	Subject
Walter DeRieux	EPA/OECA	(202) 564-7067	Regulatory requirements and compliance assistance
Jim Gould	EPA Region VI	(713) 983-2153	Industrial processes and regulatory requirements (CAA, CWA)
David Langston	EPA Region IV	(404) 347-7603	Industrial resources and regulatory requirements (RCRA)
Jim Seidel	EPA/NEIC	(303) 236-5132	Industrial processes and regulatory requirements
Mary J. Legatski	Synthetic Organic Chemical Manufacturers Association	(202) 414-4100	Federal environmental requirements

CAA: Clean Air Act
CWA: Clean Water Act
OECA: Office of Enforcement and Compliance Assurance
NEIC: National Enforcement Investigations Center
RCRA: Resource Conservation and Recovery Act

Waste Minimization and Recycling Report, Government Institutes, Inc., (301) 921-2300.

Software/Databases

AQUIRE, Aquatic Toxicity Information Retrieval Database, NTIS, (703) 487-4650.

ATTIC, Alternative Treatment Technology Information Center Database, (301) 816-9153.

CESARS, Chemical Evaluation Search & Retrieval System, Chemical Information Systems Inc., (301) 321-8440.

IRIS, Integrated Risk Information System Database (summary information related to human health risk assessment), EPA, NTIS No. PB90-591330/CCE.

NIOSHTIC, database on bibliographic occupational safety and health, DIALOG Information Services.

STARA, Studies on Toxicity Applicable to Risk Assessment, EPA (919) 541-3629.

SWAMI, Strategic Waste Minimization Initiative, Version 2.0, EPA, contact Doug Williams at (513) 569-7361.

TERRE-TOX, Terrestrial Toxicity Database (aid in evaluating pre-manufacturing notices and research), NTIS.

TOXNET, Toxicology Data Network, National Library of Medicine.

WHWTD, Waste & Hazardous Waste Treatability Database, EPA.

ENDNOTES

1. Amoco - U.S. EPA Pollution Prevention Project, Yorktown, Virginia, Project Summary, January 1992.

2. *Compilation of Air Pollutant Emission Factors, Volume I: Stationary Point and Area Sources, Chapter 9, Petroleum Industry*. U.S. EPA, Office of Air and Radiation, Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina, U.S. Government Printing Office, Washington, D.C., September 1985.

APPENDIX A
INSTRUCTIONS FOR DOWNLOADING THIS NOTEBOOK

Electronic Access to this Notebook via the World Wide Web (WWW)

This Notebook is available on the Internet through the World Wide Web. The Enviroene Communications Network is a free, public, interagency-supported system operated by EPA's Office of Enforcement and Compliance Assurance and the Office of Research and Development. The Network allows regulators, the regulated community, technical experts, and the general public to share information regarding: pollution prevention and innovative technologies; environmental enforcement and compliance assistance; laws, executive orders, regulations, and policies; points of contact for services and equipment; and other related topics. The Network welcomes receipt of environmental messages, information, and data from any public or private person or organization.

ACCESS THROUGH THE ENVIROENE WORLD WIDE WEB

To access this Notebook through the Enviroene World Wide Web, set your World Wide Web Browser to the following address:

http://es.inel.gov/oeca - then select "EPA Sector Notebooks"

or after 1997, (when EPA plans to have completed a restructuring of its web site) set your web browser to the following address:

www.epa.gov/oeca - then select the button labeled Gov't and Business Sectors and select the appropriate sector from the menu. The Notebook will be listed.
