## **EXECUTIVE SUMMARY**

Geosyntec Consultants, Inc. (Geosyntec), on behalf of Crystal Geyser Roxane (CGR) has completed this *Revised Phase 3 Site Groundwater Investigation Report* (Revised Phase 3 Report) for the CGR Spring Water Bottling Facility (Site) located at 1210 South U.S. Highway 395, near Olancha, California. The Phase 3 Site investigation was conducted in general accordance with the Lahontan Regional Water Quality Control Board's (RWQCB's) Amended Investigative Order R6V-2014-0063A1. This Revised Phase 3 Report was provided to respond to comments 1, 3, 4, and 14 of the RWQCB's letter dated December 30, 2016.

The Phase 3 Site investigation was conducted to further evaluate the soil and groundwater conditions in the areas around the former Arsenic Pond, the East Pond, and the Fire Pond. Additionally, the investigation was completed to evaluate groundwater gradient and flow patterns in the upper-most shallow groundwater aquifer. During the Phase 3 Site investigation, soil sampling was conducted near the Fire Pond, groundwater grab samples were collected near the former Arsenic Pond, six additional groundwater monitoring wells were installed, and the third quarter 2016 monitoring event was conducted.

Results of soil samples collected near the Fire Pond indicate concentrations of arsenic and molybdenum are representative of naturally occurring regional background levels that are higher than the median California background levels. The distribution and concentrations of the detected metals in soil and groundwater indicate that there have been no significant impacts due to waste water discharges near the Fire Pond.

The RWQCB required soil samples near the Fire Pond due to an unsubstantiated third-party report that CGR allegedly disposed of arsenic filter media in the area. Surface soil samples were collected in an area northeast of the southern bottling facility as a split sample with the RWQCB to determine whether uncontrolled releases of arsenic containing materials historically occurred in this area. There was no evidence of a release found based on the soil sampling.

Soil vapor sampling was conducted near the valve distribution box. Low detections of several volatile organic compounds (VOCs) were detected; however, all soil vapor sample results were consistently lower than the most conservative screening levels for residential vapor intrusion concerns. Based on the soil vapor sample results and the soil and groundwater sample results, there has not been a significant release of VOCs.

The groundwater gradient in the area of the former Arsenic Pond and East Pond was calculated to be towards the northeast at a magnitude of approximately 0.009 feet/ft. A significant upward groundwater gradient is observed in the vicinity of the former Arsenic Pond. The groundwater gradient in the area of the Fire Pond is towards the northeast at a magnitude of approximately 0.005 feet/ft.

The groundwater grab results from the Phase 3 investigation indicate that elevated dissolved arsenic concentrations are present at the Site. The results suggest that naturally occurring arsenic concentrations associated with the fine-grained lacustrine (lake bed) deposits are highly elevated. Elevated concentrations of arsenic are also detected near the former Arsenic pond. Based on the naturally occurring arsenic concentrations in the Site vicinity (Cabin Bar Ranch and nearby Owens Dry Lake areas), any potential impacts from the former Arsenic Pond to shallow site groundwater appear to be within natural background concentrations. The basis for natural background concentrations of arsenic are presented in Geosyntec's *Technical Memorandum – Arsenic Distribution and Background Analysis at the CGR Facility in Olancha, CA*, (Geosyntec, 2016b). Gradient data and groundwater modeling indicate that groundwater near the former Arsenic Pond will migrate any high concentrations of arsenic to an area beneath the Owens Dry Lake where concentrations of arsenic are one to two orders of magnitude higher than concentrations found on Site. Groundwater originating at and near the former Arsenic Pond will not impact any water supply wells in the area and, based on current information, no known material harm to the environment or reasonably foreseeable beneficial uses for waters of the State have occurred.

## **1.0 INTRODUCTION, OBJECTIVES, AND REPORT ORGANIZATION**

Geosyntec Consultants, Inc. (Geosyntec), on behalf of Crystal Geyser Roxane (CGR), is pleased to present the following *Revised Phase 3 Site Groundwater Investigation Report* (Revised Phase 3 Report) for the CGR Spring Water Bottling Facility (Site) located at 1210 South U.S. Highway 395, near Olancha, California.

The Phase 3 groundwater investigation was performed to address the requirements of the Lahontan Regional Water Quality Control Board (RWQCB) Investigative Order Number R6V-2014-0063 (Order) dated July 24, 2014 and an e-mail from Ms. Lisa Scoralle of the RWQCB dated October 26, 2015. The October 2015 e-mail presented comments on Geosyntec's Phase 2 Site Investigation (Geosyntec, 2015b) and requested additional investigation related to soil, soil vapor, and groundwater at and near the Facility.

The scope of work for the Phase 3 investigation was presented in the *Revised Additional Site Investigation Work Plan* (workplan) dated December 29, 2015 and revised July 13, 2016 (Geosyntec, 2016). The workplan was approved by the RWQCB in correspondence dated July 11, 2016. The original Phase 3 Site Groundwater Investigation Report was submitted on October 20, 2016. The RWQCB subsequently provided comments in a letter dated December 30, 2016. This Revised Phase 3 Report specifically addresses comments 1, 3, 4 and 14 of the December 30 letter. CGR will provide a separate letter responding to comments 2, 6, 8, 12, 15, 16, and 17. The remaining comments 5, 7, 9, 10, 11, and 13 do not require a formal response.

The scope and objectives of the work implemented were in general accordance with the approved workplan and included:

- Sample soil adjacent to the Fire Pond (B-01) to evaluate elevated concentrations detected during the Phase 2 Investigation;
- Collection of groundwater grab samples and installation of an upgradient monitoring well (MW-15) screened in the deeper portion of the shallow aquifer to evaluate vertical distribution of arsenic in groundwater in the vicinity of the former Arsenic Pond (AP);
- Install five additional groundwater monitoring wells (MW-10 through MW-14) to further characterize the shallow groundwater quality around the Fire Pond (FP), former Arsenic Pond, and East Pond (EP); and
- Continue routine groundwater monitoring including collection of groundwater samples from fifteen groundwater monitoring wells and soil vapor from one soil vapor probe.

In addition to the approved written scope of work, additional groundwater grab samples were collected from new monitoring well locations based on RWQCB correspondence in areas upgradient, cross-gradient, and downgradient to the former AP.

The Phase 3 Report has been organized as follows:

- Section 1. – *Introduction, Objectives, and Report Organization.*
- Section 2.0. –*General Site Information.* This section includes a general description of the site location, site topography and site features such as surface water, structures, and wells.
- Section 3.0 – *Previous Site Hydrogeologic Studies.* A summary of the previous investigations is presented.
- Section 4.0. – *Site Geology and Hydrogeology.* This section includes a brief description of the regional and Site geology and hydrogeology including regional watershed information.
- Section 5.0. – *Field Methodology.* Procedural information on drilling and well installation in addition to soil, soil vapor, and water sampling is presented.
- Section 6.0. – *Investigation Results.* This section presents the results of the drilling, groundwater monitoring well installation, groundwater level gauging, and soil, soil vapor, and groundwater sample analyses.
- Section 7.0. – *Data Evaluation and Conclusions.* A discussion of the Site hydrogeology, soil conditions, soil vapor conditions, and groundwater quality conditions is presented, including comparison of sample results to established screening levels and maximum contaminant levels (MCLs). This section also provides conclusions regarding potential impacts based on the investigative data generated to date.
- Section 8.0. –*Recommendations.* This section provides recommendations for additional Site monitoring work.
- Section 9.0. – *References*

## **2.0 GENERAL SITE INFORMATION**

The Site is an irregularly-shaped property that consists of approximately 170 acres adjacent to Highway 395 approximately 3 miles north of Olancha, California (**Figure 1**). CGR operates a spring water bottling facility using groundwater production wells for bottled spring water supply and for domestic and industrial purposes. The facility consists of two large bottling-production and warehouse buildings, CGR North and CGR South, containing a total of six main bottling production lines. A full description of the bottling facility waste discharge systems and processes was submitted in the *Facility Waste Generation and Discharge Systems Report* (CGR, 2014). The facility pumps groundwater from production wells located on the property for spring water bottling and domestic/industrial uses.

Regionally, the Site is located in the southern portion of the Owens Valley. Owens Lake (dry lake bed) is located east of the Site, and the base of the Sierra Nevada Mountains is located 1 mile west of the Site. Highway 395, which runs north-south, crosses the western portion of the Site (**Figure 1**). The Los Angeles Aqueduct is located approximately ½-mile west of the Site.

In 2010, CGR purchased the Cabin Bar Ranch property located directly to the north of the Site. The town of Cartago is located to the north of the Cabin Bar Ranch. The Cartago Mutual Water Company (CMW) owns two wells, CMW-1 and CMW-2, located approximately 3,500 feet north of the northern Site boundary in the town of Cartago. CMW-1 was installed to a depth of approximately 250 or 325 feet. CMW reports that CMW-2 is currently used to supply water to approximately 43 residences in the town of Cartago.

There are numerous other private domestic wells located in the town of Cartago. Based on a survey conducted by CGR in which available County files were reviewed (by permission of the individual residences) and a private residence survey was completed, it is estimated that there are currently 14 active private wells in Cartago. The pumping in the CMW wells and the 14 active private wells are the only known significant groundwater withdrawals in the area surrounding the Site. These wells are all located a minimum of approximately 3,500 feet north of the Site. A summary of CGR production wells and observation wells for the Site and municipal/private wells in the surrounding area were presented in Geosyntec's *Phase 2 Site Groundwater Investigation Report*, dated August 14, 2015 (Geosyntec, 2015b).

### **3.0 PREVIOUS SITE HYDROGEOLOGIC STUDIES**

There have been numerous previous hydrogeologic Site studies relating to the CGR spring water bottling operations. These hydrogeologic studies and associated reports were listed in the Phase 2 Report (Geosyntec, 2015b). More recently, several workplans and investigation reports were prepared in response to orders by the RWQCB. These work plans and reports were listed in the Phase 3 workplan (Geosyntec, 2016).

To date, there have been three phases of site investigation in response to RWQCB requirements. The Phase 1 field investigation as documented in the *Phase 1 Site Groundwater Investigation Report*, dated February 16, 2015 (Geosyntec, 2015a), was completed as a screening evaluation to preliminarily evaluate the groundwater conditions in the areas around the former AP, the EP, and the FP, as well as near the cooling tower on the north side of the northern site bottling facility. A total of ten grab groundwater samples were collected to gather screening level data in order to better evaluate groundwater quality conditions and identify appropriate locations for groundwater monitoring wells. Additionally, production waste water samples were collected from both the northern and southern bottling plants and at water discharge locations of the former AP, the EP, and the FP for characterization and comparison to groundwater quality. The results of the Phase 1 investigation indicated that the primary constituents of concern in groundwater in the investigation areas are metals. Of the metals detected, the primary metal of concern exceeding its corresponding Maximum Contaminant Level (MCLs) was arsenic. Additionally, elevated concentrations of sulfate and total dissolved solids (TDS) were also detected at concentrations exceeding their secondary MCLs in borings adjacent to the former AP. Based on the data collected during the Phase 1 investigation, installation of groundwater monitoring wells was recommended for the areas surrounding the former AP, the EP, and the FP to verify the Phase 1 screening data.

The Phase 2 field investigation was conducted in June and July 2015 to further evaluate the soil, soil vapor, and groundwater conditions in the areas around the former AP, the EP, and the FP. The monitoring wells and soil vapor probe sampling locations were selected based on data obtained from the Phase 1 investigation. Additionally, quarterly groundwater monitoring was begun in 2015. During the Phase 2 investigation, a total of nine groundwater monitoring wells and one temporary soil vapor probe were installed and soil, soil vapor, and groundwater samples were collected and analyzed. Findings from the Phase 2 investigation include the following:

- The groundwater gradient in the area of the EP and former AP was calculated to be 0.006 to 0.007 ft/foot towards the northeast.

- Of the metals detected in soil, only detections of arsenic and molybdenum exceeded the California median background for soil concentrations (UCR/DTSC, 1996). Arsenic exceeded the median background concentration in soil samples collected across the site; however, the potential for higher naturally occurring arsenic in site soil are discussed in Section 4. Molybdenum exceeded the medium background concentration in one sample collected from boring MW-01. Geosyntec concluded that the distribution and concentrations of the detected metals did not indicate a significant release to soil due to waste water discharges at the Site. However, the RWQCB, in their e-mail dated October 26, 2015, opined that anomalously high metal concentrations were detected in a soil sample collected near the Fire Pond relative to other soil samples collected at the site.
- Soil vapor sample results from probe SV-01 located adjacent to the former AP were lower than conservative residential screening levels used to assess vapor intrusion potential.
- The groundwater sample analytical results did not contain detections of VOCs or SVOCs indicating there are no significant VOC or SVOC impacts to groundwater due to waste water discharges at the site.
- Concentrations of metals in groundwater, in particular, antimony and arsenic were detected at concentrations exceeding their MCLs of 6 and 10 micrograms per liter ( $\mu\text{g/L}$ ), respectively. The elevated occurrences of antimony and arsenic, as documented in quarterly groundwater sampling events, were primarily located in wells located adjacent and downgradient of the former AP (wells MW-04, MW-05, and MW-09) and in an area of lower quality groundwater toward Owens Dry Lake.
- Elevated concentrations of sulfate and TDS were also detected at concentrations exceeding their upper secondary MCLs in monitoring wells located adjacent to the former AP (MW-04, MW-05, and MW-09). Chloride was also detected above the secondary MCL in MW-06.

Groundwater monitoring has occurred on a quarterly basis since the third quarter of 2015. The documented groundwater gradient is consistently towards the northeast (Owens Dry Lake) and groundwater elevations fluctuate seasonally, with decreases observed during the second and third annual quarters and increases observed during the first and fourth annual quarters. In general, arsenic concentrations in the Site monitoring wells are stable or decreasing and other detected compounds are generally similar between monitoring events.

## **4.0 SITE GEOLOGY AND HYDROGEOLOGY**

### **4.1 Regional Geology**

The Site is located in the southern portion of the Owens Valley which has a length of 150 miles and width of generally less than 8 miles. The Owens Valley is the westernmost valley of the Basin Range Province and is formed by the Sierra Nevada Mountains to the west and the White/Inyo Mountains to the east. The Sierra Nevada Mountains are generally composed of Mesozoic age igneous rocks of granodiorite-granite composition whereas the White/Inyo Mountains, to the east, consist of Pre-Cambrian to Triassic sedimentary rock locally intruded with Mesozoic granitic rocks.

Structurally, the Owens Valley is a graben bounded by the Sierra Nevada Frontal fault and the Inyo Mountain Frontal fault. These faults are considered active and the offset on these faults is the cause of the dramatic relief in the Owens Valley area. The Site is located on the valley floor at an elevation of approximately 3,640 feet, while Olancha peak, to the west of the Site in the Sierra Nevada Mountains, stands at an elevation of over 12,000 feet. The Inyo Mountains east of the Site have an elevation greater than 8,000 feet.

The California Department of Water Resources (DWR, 2003) shows the Site to be located in the southern portion of the Owens Valley Groundwater Basin. The groundwater basin has a surface area of 1,030 square miles and includes valleys in both Mono and Inyo County. The basin, as defined by the Department of Water Resources, is bounded to the south by the Coso Range, the Sierra Nevada to the west, the White/Inyo Mountains to the east, and the Benton Range to the north. Groundwater occurs in the sediments that fill the valley.

### **4.2 Site Hydrogeology**

Based on the previous investigations, (see Section 3.0), the following description provides the basis of understanding for the Site hydrogeology. Further discussion of the Site hydrogeology based on the results of the Phase 3 investigation is presented in Section 6.2.3.

The most important water bearing formation in the vicinity of the Site is alluvium consisting of sands and gravels derived from erosion of Sierra Nevada Mountains to the west. The upper zone of the alluvial aquifer, in which the westernmost Site production wells are installed, is unconfined. Deeper zones of water bearing alluvium beneath the Site are under semi-confined conditions. The sandy and gravelly alluvium is locally interbedded or interfingering with fine-grained lacustrine (lake) deposits. Fine-grained lacustrine deposits increase in occurrence and thickness to the east towards Owens Dry Lake (GSI, 1983). The thickness of the alluvial and lacustrine sequence is thought to be

several thousand feet thick and up to 6,000 feet or more in the middle of the Owens Dry Lake (Pakiser et. al., 1964).

The primary source of groundwater recharge in the Owens Valley Groundwater basin is from percolation of stream flow from the Sierra Nevada range. In the case of the Site and the Cartago area, the main aquifer is thought to recharge primarily by flow in Olancha Creek, Cartago Creek, and Walker Creek that have watersheds to the west of the Site in the Sierra Nevada Mountains. Stream flow in these creeks is derived from precipitation in the mountains and infiltrates through relatively permeable alluvium closer to the valley floor. There is also thought to be some recharge of the alluvium from underflow of groundwater in fractures in the mountain bedrock, although the volume of such recharge is not known. Recharge of direct precipitation into the alluvium may also contribute a relatively small component of recharge into the groundwater basin.

Groundwater in the shallow unconfined aquifer is the source for numerous springs and seeps that collectively form along a north-south trending fault (a part of the Sierra Nevada Frontal fault system). The north-south trending fault is known locally as the “Spring-line fault” (**Figure 2**). The former AP and EP are located east of the fault, whereas the FP is located west the fault. The fault is inferred to cause a “damming” effect and the subsequent rise of groundwater to the surface creates the large linear spring areas or spring seeps (Dames and Moore, 1991). Production wells that have been installed by CGR draw water from the shallow unconfined aquifer in hydraulic connection with the spring water. Wells used for spring water production are all located west of the Spring-line fault.

Monitoring wells, OW-8U, OW-8US, OW-8D and OW-9U were installed east of the Spring-line fault. These wells are screened at depths of 55 – 75 feet below ground surface (ft bgs) for wells OW-8US and OW-9U, to 190 – 230 ft bgs for well OW-8U, and 582 – 642 ft bgs for well OW-8D. Groundwater in these wells has a significant upward gradient (potentiometric surface higher than ground level) and the well screens were not installed in the upper-most portion of the aquifer; therefore, the groundwater from these wells is not representative of the conditions of the upper-most aquifer.

Based on an extensive hydrogeological investigation conducted at the Site in 1991 by Dames and Moore, the groundwater gradient west of the Spring-line fault in the Site vicinity was calculated to be to the northeast towards Owens Dry Lake at a gradient of approximately 0.007 (see Figures 3 and 4 in Dames and Moore, 1991). More recently the groundwater gradient in the central portion of the Cabin Bar Ranch located north of the Site was calculated to be 0.015 to the east also toward Owens Dry Lake (Geosyntec, 2011). Additional discussion of the shallow groundwater gradient from data collected during the Phase 3 investigation areas is discussed further in Section 6.2.3.

As presented in Geosyntec's *Phase 3 – Additional Site Investigation Work Plan Addendum*, dated March 30, 2016 (Geosyntec, 2016), the Site groundwater model was updated to determine the following:

- 1) Maximum potential groundwater extraction in CGR production wells does not impact the groundwater flow direction east of the Spring-line fault,
- 2) Groundwater pumping at the Site and projected maximum groundwater production at the Cabin Bar Ranch does not produce a capture zone that draws water from east of the Spring-line fault, and
- 3) The particle track estimation for non-retarded groundwater flow shows that the path of groundwater from the area around the former AP, the EP, and the FP migrates northeast towards Owens Dry Lake, and is not influenced by pumping at the Site or at Cabin Bar Ranch.

The site groundwater model was further updated following the Phase 3 investigation as described in Section 5.1 and Appendix A of this report.

## 5.0 HYDROGEOLOGICAL SITE CONCEPTUAL MODEL

A hydrogeological site conceptual model (SCM), based on the information collected during the Phase 1 - 3 investigations and past hydrogeological investigations, is presented in this section.

The Site is located in the southern portion of the Owens Valley Groundwater Basin (DWR, 2003). The basin occupies a structural valley that, in the vicinity of the Site, is bounded on the west by the granitic bedrock of the Sierra Nevada Mountains and on the east by the sedimentary bedrock of the Inyo Mountains. To the east of the Site and in the middle portion of the valley is the Owens Dry Lake. The Owens Dry Lake is a desert playa where salts are generated at the surface via evaporation processes.

A hydrogeological conceptual model illustration of the Site is provided on **Figure 3<sup>1</sup>**. The major groundwater bearing unit in the basin is a thick sequence of alluvium that has been derived from erosion of bedrock in the bordering mountain areas. The alluvium beneath the site is principally derived from the Sierra Nevada Mountains to the west and generally consists of sands and gravels. These alluvial sands and gravels are interbedded or interfingered with finer-grained lacustrine deposits (i.e., lake deposits from the ancient Owens Lake). The sequence of alluvium and lacustrine deposits beneath the site is at least 750 feet thick (Montgomery, 1993).

The alluvial sand and gravels, and lacustrine clays and silts were encountered during drilling investigations at the site. The observed sequence of lacustrine and alluvial sediments beneath the site is the result of deposition associated with ancient fluctuations of water levels at the southwestern shoreline in Owens Lake. Alluvial materials derived from the Sierra Nevada Mountains were deposited along the shoreline while fine-grained lacustrine materials were deposited in the shallow lake waters. As the elevation of the lake varied, the shoreline moved laterally, causing interfingering of the coarse alluvial materials and the fine-grained lake deposits. The lacustrine deposits generally consist of silts, clays and very fine sands and have a relatively high organic content. Based on regional models and site drilling logs, the percentage of fine-grained material (lacustrine deposits) generally increases to the east. That is, the occurrence or presence of fine-grained silts and clays in the subsurface increases as one moves from the Sierra Nevada Mountain range towards Owens Dry Lake. It should also be noted that a shoreline deposit, generally consisting of light brown to white fine to coarse sands with some gravel, is located at the ground surface to a depth of approximately 12 to 15 ft bgs on the

---

<sup>1</sup> Note that this illustration is not to scale and site features are not included. It is intended for general visualization purposes only.

Site. The shoreline deposit is shown on **Figure 2** as the large non-vegetated area east of the bottling plant. The former AP and the EP are located on the shoreline deposit.

Groundwater beneath the site is mostly derived from precipitation (rainfall) and snowmelt in the Sierra Nevada Mountains to the west. Surface water runs off the Sierra Nevada mountain front and infiltrates the alluvium near the mountain base. Surface water or runoff quickly percolates into the sandy and gravelly alluvium and moves downward to the groundwater table. Some groundwater recharge also may occur from underflow through bedrock fractures and from direct precipitation on the valley floor.

Groundwater in the alluvium flows eastward, away from the Sierra Nevada Mountains and towards the central portion of the basin or towards Owens Dry Lake. The Owens Dry Lake is a groundwater discharge area where up-flowing groundwater is evaporated and, consequently, evaporite salts are produced.

Shallow groundwater beneath the site occurs under unconfined conditions; although where fine-grained layers are present, local semi-confined conditions may occur. The upper aquifer material beneath the site is referred to as the Shallow Zone. The Shallow Zone is defined herein as the saturated sand and gravel aquifer that overlies the fine grained lacustrine layer that occurs at a depth of approximately 80 feet. All monitoring wells, with exception to MW-15, installed during the investigation phases are completed in the upper-most portion of the Shallow Zone.

The depth to the shallow groundwater table beneath the site gradually decreases towards the east. A small and subtle escarpment extends from the area north of the Site (Cabin Bar Ranch) along an approximate north-south trend to the southern portion of the site. A series of springs in a linear trend occurs along this subtle escarpment. The easterly groundwater flow is impeded and subsequently produces a rise of the groundwater table resulting in observed springs/seeps along a linear trend in the central and eastern portions of the site. This escarpment is interpreted to be associated with the presence of an underlying fault referred to as the Spring-line fault. The interpreted Spring-line fault location is shown on **Figure 2**. The former AP and EP are located east of the fault, whereas the FP is located west the fault. The fault is generally interpreted to act as a leaky groundwater barrier and the aligned springs and seeps are caused by a small rise of shallow groundwater and the subsequent intersection of groundwater with ground surface along the fault. An alternate interpretation is that the rise of groundwater is associated with the increase of fine-grained lacustrine deposits towards the east causing a permeability barrier. However, the linear nature of the spring locations suggests the fault interpretation is more likely. The rise of groundwater in the area as a result of this

interpreted fault, together with the high regional evaporation rate, has resulted in soils with high salt content.

Located on the Cabin Bar Ranch property directly adjacent and to the north of the Site, there are production wells, domestic water supply wells, observation monitoring wells, and piezometers. Additionally, there are active domestic water supply wells and one municipal production well in the town of Cartago. The production wells and domestic wells at the Site and at Cabin Bar Ranch are completed in the deeper portions of the Shallow Zone. Some observation wells at the Site and at Cabin Bar Ranch are completed in the Deep Zone. Based on previous studies completed by Geosyntec and others, there is some leakage between the Deep and Shallow Zones, however, there is a site-wide upward groundwater gradient based on comparison of water levels in co-located observation wells completed in the Deep and Shallow zones. That is, wells completed in the Deep Zone have static water level at a higher elevation than those completed in the Shallow Zone. This condition can be seen at observation wells OW-7U and OW-7M, and at OW-10U and OW-10M for example (Appendix A-3). The majority of the site wells, except for monitoring wells associated with the investigation, have been installed west of the Spring-line fault. Groundwater quality and water levels are monitored at the Cabin Bar Ranch on a quarterly basis in accordance with the Groundwater Monitoring, Mitigation, and Reporting Plan (GMMRP) dated June 18, 2014 (GMMRP, Geosyntec Consultants, 2014). The GMMRP monitoring program was developed to evaluate potential water level and water quality impacts due to proposed pumping at the Cabin Bar Ranch facility. The GMMRP quarterly groundwater monitoring program was initiated in March 2016, and pertinent data will be provided to update this SCM and investigation results as they are available.

Groundwater quality is an important component of the groundwater investigation at the Site. Generally, concentrations of TDS, sodium, carbonate, and metals, including arsenic in the Shallow Zone substantially increase to the east toward Owens Dry Lake where up-flow of groundwater and evaporation processes have created salt pans. As noted in previous reports (Geosyntec, 2015a and 2015b) and based on previous investigations at the site, arsenic is well known to be a naturally occurring element in the soil, alluvium, and groundwater in the region of the Site. Generally, elevated arsenic concentrations (> the MCL) are characteristic of groundwater derived from the Eastern Sierra Nevada watershed. Site production wells located west of the Spring-line fault, which produce from deeper portions of the Shallow Zone, have arsenic in the approximate range of 16 to 28  $\mu\text{g/L}$ <sup>2</sup>. It is reasonably concluded that naturally occurring arsenic concentrations in groundwater increases eastward of the Spring-line fault as a result of the increasing

---

<sup>2</sup> Range of arsenic concentrations based on annual sample results in 2012 and 2013 from CGR production wells CGR-1, CGR-3, CGR-5, CGR-6, and CGR-7.

presence of the lacustrine sediments toward Owens Dry Lake. Shallow groundwater sampling (<~10 feet) by others beneath the eastern portion of Owens Dry Lake documented arsenic concentrations in the range of 1,400 – 163,000 µg/L (Levy et. al., 1999). Levy et. al. (1999) also report very high salinity [up to 300,000 milligrams per liter (mg/L)] in the shallow Owens Dry Lake groundwater. Further, arsenic concentrations in shallow groundwater in the southern Owens Dry Lake area, i.e. the Dirty Socks-Cartago Creek Area near the Site, average 32,055 µg/L at 4 ft bgs and 5,596 µg/L at 10 ft bgs (Great Basin Unified APCD, 2009). Again, it is very likely that these elevated concentrations are associated with the fine-grained lacustrine deposits and salt deposits. Thus, as the presence of these layers increases, it is expected that naturally occurring arsenic concentrations as well as TDS will likewise increase substantially. However, this expected eastward increase in arsenic and salinity is a general trend that is locally dependent on the volume of fine-grained lacustrine sediment and its impact of groundwater encountered in each area. Recent shallow groundwater samples collected at a location north of the former AP and east of the Spring-line fault on Cabin Bar Ranch provide a reasonable environmental analog to the former AP location. Naturally occurring arsenic concentrations of up to 521 µg/l have been detected at this analog location indicating that high arsenic background concentrations occur locally east of the Spring-line fault (Geosyntec, 2016b).

As noted in the previous paragraphs, the former AP and EP are located east of the Spring-line fault. The groundwater gradient in this area is towards the northeast. Therefore, migration of groundwater containing elevated arsenic and other compounds is towards Owens Dry Lake where groundwater is extremely saline with elevated natural concentrations of arsenic in the shallow groundwater. Although the shallow groundwater in the Owens Valley Groundwater Basin is designated for beneficial use, the groundwater beneath the Owens Dry Lake proximal to the Site is not currently nor can foreseeably be used as a drinking water or agricultural resource in the future.

## **5.1 MODFLOW Groundwater Model Update**

A hydrogeological groundwater model originally developed for the Cabin Bar Ranch in 2014 was updated and applied to evaluate groundwater flow conditions in the vicinity of the former Arsenic Pond (**Appendix A**). The model prepared using MODFLOW™ software was calibrated based on data collected from hydrogeologic investigations conducted on the Cabin Bar Ranch property as well as at the Site. The original model for the Cabin Bar Ranch property was used to estimate the impacts to groundwater levels, spring flow, and other water supply wells in the area based on future pumping scenarios. This model was updated to include water levels based on data collected at the Site and vicinity in September 2016. The updated model is provided as **Appendix A** and includes:

1. A description of the numerical modeling approach used in the simulations;
2. An assessment of the groundwater flow and potential mounding at the former AP and EP under historical wastewater discharge conditions;
3. Capture zones of all significant production wells based on current and projected pumping rates; and
4. Groundwater particle tracks for all site waste discharge ponds under projected pumping conditions.

Updates to the model include groundwater levels from site wells based on groundwater level monitoring conducted in September 2016, inclusion of all the monitoring wells associated with the investigation (MW-01 through MW-15), as well as monitoring wells and piezometers installed as part of the Cabin Bar Ranch project and the GMMRP program. Additionally, the model includes a sensitivity analysis using a range of hydraulic conductivity<sup>3</sup> values in the areas east of the Spring-line fault to represent the inter-fingered, fine-grained lacustrine deposits found in these areas. This analysis was conducted to determine the potential for groundwater mounding to have occurred in the area of the former AP and the EP.

The updated model results are provided in **Appendix A**. The results of the updated model indicate that groundwater flows to the east from the Sierra Nevada Mountains and into the alluvial deposits west of the Spring-line fault, then rises to the ground surface along a line of springs identified near the Spring-line fault. East of the Spring-line fault, groundwater flows to the northeast and ultimately discharges at Owens Dry Lake. The model results indicate that under historical typical and maximum discharge flow rates, the impacts to water levels in the vicinity of the Former Arsenic Pond and East Pond is minimal with no groundwater mounding evident. Therefore, it is unlikely that any potential leak from the Former AP migrated significantly up-gradient towards the area of monitoring wells MW-03 and MW-15 and impacted groundwater quality.

Additionally, the capture zone and particle track analysis indicates that proposed future pumping at the Site or at Cabin Bar Ranch will not draw water from east of the Spring-line fault towards the west. The particle track analysis also indicates that groundwater in the area of all waste discharge ponds will migrate to the northeast and discharge at Owens Dry Lake (an area of very high TDS and arsenic in groundwater). The model clearly

---

<sup>3</sup> The hydraulic conductivity east of the spring line fault was estimated at approximately 250 ft/day to account for the interbedded sands and fine-grained silts and clay lacustrine deposits found east of the Spring-line fault.

indicates that groundwater originating at and near the former AP will not impact any pumping wells (current or foreseeably planned) including those of the Cartago Mutual Water District.

## **6.0 FIELD METHODOLOGY**

The following sections describe the general procedures for the Phase 3 field work. The Phase 3 borings and well locations are shown on **Figure 2**.

### **6.1 Health & Safety Plan**

A site-specific Health & Safety Plan (HASP) was prepared for Geosyntec personnel. Sub-contractors working on the project provided their own personnel with HASPs. All site personnel had 40-hour health and safety training (CFR 1919.120).

### **6.2 Well Permitting**

Prior to mobilizing to the Site, Geosyntec applied for and obtained monitoring well permits from the County of Inyo Environmental Health Department. Copies of the well permits are provided in **Appendix B**.

### **6.3 Drilling, Soil Logging, and Soil and Groundwater Grab Sampling**

Two soil borings and six monitoring well borings were continuously cored using a direct push rig operated by Gregg Drilling and Testing, Inc. between August 22 and August 30, 2016. Drilling, sampling, and decontamination procedures were conducted in accordance with the standard operating procedure (SOP) provided in Appendix C of the Phase 1 Workplan (Geosyntec, 2014). All re-useable equipment was decontaminated.

During drilling, the field geologist prepared a boring log describing soil lithology and well construction logs documenting the monitoring well construction details. Soil lithology was logged in general accordance with the Unified Soil Classification System under the supervision of a licensed Professional Geologist. Lithologic boring logs are included in **Appendix C**.

Soil samples were collected from boring B-01 by cutting approximately a 6-inch undisturbed section of the continuously cored acetate liners. The ends of the soil cores were covered with Teflon tape, capped, and placed in a cooler for transport to the analytical laboratory. Additionally, two soil samples, SS-01 and SS-02, were collected in an area of exposed soil northeast of the southern bottling facility per a direct onsite request from the RWQCB (**Figure 2**). These samples were collected in 8-ounce jars with one sample collected at ground surface and the other collected at approximately 10-inches bgs. All samples were placed in a cooler with wet ice for transport to the analytical laboratory.

Groundwater grab samples were collected from borings B-02, MW-12, MW-13, MW-14 and MW-15. The grab groundwater samples were collected using a Hydropunch® sampling system pushed into undisturbed soil via direct push drilling rods. Once the

Hydropunch® sampling equipment was pushed to the desired depth, the rods were pulled up to expose the Hydropunch® screen across the target saturated zone, allowing formation water to enter the drill/sample rods. The formation water within the sampling system was “developed” by carefully removing approximately 1-2 gallons via a bailer prior to sampling for metals. Groundwater samples were first collected in a one-liter unpreserved container to serve as an aliquot. This aliquot was then shaken to homogenize the suspended sediment and half of the aliquot was poured into a preserved bottle for total metals analysis. The second half of the aliquot was field filtered and poured into a preserved bottle for dissolved metals analysis.

#### **6.4 Monitoring Well Installation, Development, and Sampling**

Monitoring well installation, development, sampling, and decontamination procedures were performed in accordance with the SOP provided in Appendix C of the Phase 1 Workplan (Geosyntec, 2014). Following the direct push drilling, logging, and groundwater grab sampling, a total of six, 2-inch diameter Schedule 40 PVC groundwater monitoring wells were installed by Gregg Drilling and Testing, Inc. between August 22 and August 30, 2016. Monitoring well installation was conducted using an 8-inch diameter hollow-stem auger (HSA) drill rig in locations approximately ten feet away from the initial direct push borings. Following direct push lithologic logging, the monitoring well construction designs and screen lengths were designed to appropriately target the uppermost shallow groundwater zone while taking precautions to avoid installing the screen across significant silt or clay layers. The annulus between the screen interval and the borehole wall was filled with #2/12 sand that extended from the bottom of the borehole to approximately one foot above the top of the screen. The well was sealed using a minimum of 1-foot thick hydrated bentonite chips above the sand filter pack and a bentonite grout mix was placed via tremie pipe to the ground surface. The monitoring wells were completed with three-foot tall, above ground monuments set in 4-foot by 4-foot concrete pads at the ground surface as required by the County of Inyo Environmental Health Department permit requirements. Monitoring well completion logs are included in **Appendix C**.

Between August 30 and September 01, 2016, the wells were developed a minimum of 48-hours following installation. The wells were developed using a surge block, bailer, and submersible pump. Well development was finished by pumping the wells using a 2-inch diameter electric submersible pump. Development continued until the turbidity reduced to approximately 50 NTUs and water quality parameters had stabilized. An exception to this was monitoring wells MW-14, which did not yield water after construction, and MW-11 which was pumped dry numerous times and was completed with a turbidity of 148 NTU. Well development logs are included in **Appendix D**.

Following well development, groundwater samples were collected from the monitoring wells using the low-flow purge and sampling technique. During monitoring well

groundwater sampling for dissolved and total metals analysis, water samples were first collected in a one-liter unpreserved container to serve as an aliquot. This aliquot was then shaken to homogenize the suspended sediment and half of the aliquot was poured into a preserved bottle for total metals analysis. The second half of the aliquot was field filtered and poured into a preserved bottle for dissolved metals analysis. Water quality parameters of temperature, electrical conductivity, pH, oxidation reduction potential (ORP), dissolved oxygen (DO), and turbidity were collected using a field water quality meter calibrated in accordance with the manufacturer's specifications. Additionally, total and residual chlorine were analyzed in the field using a colorimeter. Monitoring well field sampling logs are included in **Appendix E**.

A survey of the latitude, longitude, and top of well casing elevations of the groundwater monitoring wells was conducted following installation by Triad/Holmes Associates, Inc., a licensed professional surveyor (**Appendix F**).

## **6.5 Soil Vapor Probe Sampling**

The soil vapor probe (SVP) was purged and sampled on August 30, 2016, in general accordance with State of California Department of Toxic Substances Control (DTSC)/Los Angeles Regional Water Quality Control Board *Advisory on Active Soil Gas Investigations* (DTSC/Regional Board, 2015).

The general soil vapor sampling procedures were as follows:

- Static pressure or vacuum in the SVP was measured and recorded.
- Leak checks involving “shut-in” and helium tracer testing were performed to verify that all couplings and fittings in the sampling train are free of leaks.
- Soil vapor was purged prior to sample collection in order to ensure the sample was representative of soil vapor contained within the geologic materials outside the SVP and filter sand surrounding the SVP screen.
- During purging, soil vapor was collected in a Tedlar® bag and screened for VOCs using a photoionization detector (PID) calibrated to isobutylene.
- Helium was used as a leak check tracer compound during purging and monitoring. Helium was introduced into a shroud which encompassed the SVP surface connections during the purge prior to sample collection.
- After purging and stabilization of field monitoring parameters, soil vapor samples for laboratory analysis were collected in 1-L Summa canisters; one primary and one duplicate sample. The canisters used for sampling were batch certified by the analytical laboratory.

- Sample identification and sample times were recorded on standard chain-of-custody documentation and transferred to the analytical laboratory.

Soil vapor sampling logs are included in **Appendix E**.

## **6.6      Laboratory Analytical Schedule**

All soil, groundwater, and soil vapor samples were analyzed by Eurofins-Calscience Environmental Laboratory. The soil samples were analyzed for the following parameters:

- Boring B-01 soil samples were analyzed for Title 22 metals using EPA Method 6010B and 7471A; and
- Surface soil samples (SS-01 and SS-02) were analyzed for Title 22 metals using EPA Method 6010B and 7471A, semi-volatile organic compounds (SVOCs) using EPA Method 8270C, and VOCs using EPA Method 8260B<sup>4</sup>.

Groundwater grab samples were analyzed for:

- CAM 17 metals, (total and dissolved) using EPA Method 6010B and 7470A;

Groundwater monitoring well samples were analyzed for:

- CAM 17 metals, (total and dissolved) using EPA Method 6010B and 7470A;
- VOCs using EPA Method 8260B;
- Semi-Volatile Organic Compounds (SVOCs) using EPA Method 8270C;
- Methylene Blue Active Substances (MBAS) using SM Method 5540C;
- General Minerals (sodium, calcium, magnesium, chloride, bicarbonate, and sulfate) using EPA Method 200.7, 300.0 and Standard Method (SM) 2320B;
- Total Dissolved Solids (TDS) using SM 2540C;
- Total phosphate and phosphorus using SM 4500;
- Total nitrogen, nitrate as nitrogen, ammonia, and Total Kjeldahl nitrogen using SM 4500; and

---

<sup>4</sup> VOCs and SVOCs were added to the analytical suite six days after collection due to information from the RWQCB of their intent to run split samples for these analyses.

- Total and fecal coliform using SM 8221B (analyzed by BC Laboratories due to short hold time).

Soil vapor samples were analyzed for:

- VOCs using EPA Method TO-15.

## **6.7 Investigative Derived Waste**

Soil cuttings were transferred to a lined roll-off bin while well development and purge/decontamination water was transferred to a holding tank. All soil and water IDW was stored onsite pending laboratory analysis and profile acceptance. A composite sample of both the soil cuttings and the purge/decontamination water were collected and analyzed for VOCs using EPA Method 8260B and Title 22 Metals using EPA Methods 6020/7470A (aqueous) or 6010B/7471A (solid); soil was also analyzed for total petroleum hydrocarbons using EPA Method 8015M. Based on the results of the waste profile samples, a non-hazardous waste profile was accepted at a licensed waste disposal facility. The soil bin was transported to Soil Safe of California in Adelanto, California on September 9, 2016 and the water was transported to Crosby and Overton, in Long Beach California on September 20, 2016. The transportation waste manifests for the soil and water transported off the Site is included as **Appendix G**.

## 7.0 INVESTIGATION RESULTS

The following sections present the results of the Phase 3 investigation. A summary of the soil sample analytical results are presented in **Table 1**. A summary of the groundwater well construction details and historical groundwater elevations are presented in **Table 2**. The field groundwater quality parameters collected during sampling are presented in **Table 3**. Groundwater analytical results are presented in **Tables 4 through 6** and soil vapor sample results are presented in **Table 7**. A site plan with Phase 3 investigation locations and all groundwater monitoring well locations are presented on **Figure 2**. The groundwater elevations and groundwater gradient from measurements collected during the third quarter of 2016 are shown on **Figure 4**. Dissolved arsenic isoconcentration contours are shown on **Figure 5**. **Figure 6** shows the lines of geologic cross sections presented in **Figure 6A** through **6E**. Stiff plot comparisons of inorganic data collected during the third quarter 2016 are presented on **Figure 7**. The laboratory analytical reports for soil, soil vapor, and groundwater samples are presented in **Appendix H**.

### 7.1 Soil Results

#### 7.1.1 Soil Classification and Field Data

The soil types encountered in borings B-01 and MW-10, located in the vicinity of the FP, generally consist of well graded sand interbedded with silt and silty sand from ground surface to total depth. The soils classified in these borings are interpreted to be alluvial fan sediments derived from erosion of the Sierra Nevada Mountains to the west of the Site. Both B-01 and MW-10 are installed in locations west of the Spring-line fault and significant lacustrine deposits were generally not encountered.

In borings B-02 and MW-15, completed in locations around the former AP, the soil types generally consist of well graded sand with trace gravel, from ground surface to depths ranging from approximately 11 to 14 ft bgs. Underlying the well graded sands are alternating layers of silts/clays and sands to total depth. In borings for monitoring wells MW-11 and MW-12, located downgradient from the former AP and within the historical lake bed footprint, fine-grained silt was encountered at ground surface with alternating layers of silts/clays and sands to total depth. The soil sequence observed in these borings is interpreted to be recent alluvial deposits at the former lake shore of the Owens Dry Lake shoreline underlain by interfingered fine-grained lacustrine sediments. These borings were all completed east of the Spring-line fault.

In boring MW-13 completed cross-gradient of the former AP and the EP, the soil types consisted of well graded sand and gravel interbedded with silty sand from ground surface to approximately 12 ft bgs. Underlying the well graded sands were alternating layers of silts/clays and sands to total depth. In boring MW-14 located upgradient of the EP, well graded sand was encountered from ground surface to 16 ft bgs underlain by silt to total

depth. The soil encountered in these borings are similar to the soils encountered near the former AP and interpreted to be alluvial deposits at the former shoreline of Owens Dry Lake underlain by interfingered fine-grained lacustrine sediments. These borings were also completed east of the Spring-line fault.

No indications of contamination such as staining, discoloration, or odors were encountered during soil logging. PID readings collected in the field ranged from 0.0 to 0.6 parts per million volume (ppmv), with the highest PID reading recorded in MW-15 at approximately 25 ft bgs. The borehole logs are presented in **Appendix C**.

### **7.1.2     Soil Sample Analytical Results**

A total of 4 soil samples were collected at different depths in boring B-01 located adjacent to MW-01 and the FP and analyzed for Title 22 metals. Two surface soil samples, SS-01 and SS-02, were collected at ground surface to the northeast of the southern bottling facility and were analyzed for Title 22 metals and VOCs. **Table 1** presents a summary of the detected metals for soil boring samples from B-01 and surface soil samples. Only detections above the laboratory minimum reporting limits (MRLs) are presented in the table; all other results were not detected above laboratory MRLs. **Table 1** also includes two regulatory screening levels including 1) the United States Environmental Protection Agency (EPA) Regional Screening Levels (RSLs) (USEPA, 2016) based on an industrial site setting and 2) the maximum contaminant level (MCL)-based protection of groundwater value.

In boring B-01, arsenic, barium, beryllium, chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc were detected above the laboratory MRL in one or more samples collected. The maximum concentration of arsenic [23.1 milligrams per kilogram (mg/kg)] was detected at 15 feet bgs. Additionally, the maximum concentration of all detected metals in boring B-01 were detected at 15 or 18 feet bgs.

In soil samples SS-01 and SS-02, VOCs and SVOCs were non-detect<sup>5</sup>. Antimony, arsenic, barium, beryllium, chromium, cobalt, copper, lead, molybdenum, nickel, vanadium, and zinc were detected above the laboratory MRL in one or both soil samples. Soil sample analytical reports are included in **Appendix H**.

## **7.2     Groundwater Results**

### **7.2.1    Groundwater Grab Analytical Results**

Groundwater grab samples were collected as described in Section 5.3 at five locations: B-02, MW-12, MW-13, MW-14, and MW-15. Concentrations of antimony, arsenic, barium, beryllium, cadmium, chromium, copper, lead, mercury, and nickel were detected

---

<sup>5</sup> Note data validation qualification for soil sample VOC analysis. See Section 6.4.

above their respective MCLs as indicated by shaded cells in **Table 4**. Dissolved arsenic and total arsenic concentrations are included in the cross-sections on **Figures 5A** through **5E**. Dissolved arsenic concentrations in groundwater grab samples from boring MW-15, located upgradient to the former AP, ranged from 62.9 to 201 µg/L. Concentrations of dissolved arsenic in groundwater grab samples from boring B-02, located downgradient to the former AP, ranged from 13.3 to 363 µg/L. Concentrations of dissolved arsenic in other groundwater grab samples collected from borings both down- and cross-gradient to the former AP ranged from 27.4 to 111 µg/L.

In general, concentrations of other metals were detected within the range of concentrations detected in groundwater grab samples collected in either boring MW-14 or MW-15, located cross- and upgradient to the former AP, respectively (**Figure 2**).

### **7.2.2 Monitoring Well Groundwater Analytical Results**

Fifteen groundwater monitoring well samples and two duplicate samples were collected as part of this investigation to coincide with the third quarter 2016 monitoring event. The stabilized field groundwater quality monitoring parameters collected prior to groundwater sample collection are presented in **Table 3**. The analytical results for the groundwater samples are summarized in **Tables 4** through **6**.

The primary constituent of concern in groundwater at the Site continues to be arsenic which was detected above the MCL in 12 of the Site monitoring wells. In general, concentrations of dissolved arsenic and other metals detected in the third quarter 2016 monitoring event were similar to the previous monitoring event (**Table 4**).

Concentrations of general minerals were similar to results from previous monitoring events (**Table 5**). Stiff plots for each of the monitoring wells are presented on **Figure 7** for comparison. Based on the stiff plot comparison, concentrations of anions and cations generally increase towards the east of the Site in the direction of the Owens Dry Lake. The secondary MCLs for the following constituents were exceeded during the third quarter 2016:

- The TDS secondary MCL of 500 mg/L was exceeded in wells MW-04, MW-05, MW-06, MW-09, MW-11, and MW-12;
- The sulfate secondary MCL of 250 mg/L was exceeded in wells MW-04, MW-05, MW-09, and MW-11;
- The chloride secondary MCL of 250 mg/L was exceeded in well MW-06; and

Fecal and/or total coliform were detected slightly above the laboratory MRL in monitoring wells MW-07, MW-09, MW-13, and MW-15. Note that MW-15 is a deep screened well located upgradient of the former AP suggesting that potential cross-

contamination (i.e. field or laboratory contamination) could be responsible for the detection.

VOCs and SVOCs were not detected during the third quarter 2016 sampling event. Further discussion of the groundwater sample analytical results is presented in Section 7.3.

### **7.2.3 Groundwater Elevation Data**

Groundwater level measurements were collected from the Site monitoring wells during the third quarter 2016 monitoring event. The well construction specifications and historical groundwater level monitoring data are presented in **Table 2**. Decreases in groundwater elevations since the previous monitoring event were observed across the Site with the greatest decrease noted in monitoring well MW-09 (1.55 feet). Groundwater elevations for the shallow zone monitoring wells ranged from 3,589.82 feet above sea level (ft asl) in well MW-12 to 3,620.32 ft asl measured in MW-01. Monitoring wells MW-15, OW-8US, and OW-8U are screened deeper than the shallow zone monitoring wells at 43-48 ft bgs, 55-75 ft bgs, and 190-230 ft bgs respectively. The groundwater elevation measured in MW-15 is 15.84 feet higher than the groundwater elevation measured in the adjacent shallow zone well MW-03, indicating a significant upward groundwater gradient. Additionally, OW-8US has approximately 2 psi of artesian pressure at the well head, corresponding to a projected groundwater elevation of 3604.88 ft asl, whereas OW-8U has approximately 12 psi of artesian pressure at the well head corresponding to a projected groundwater elevation of 3627.69 ft asl.

Groundwater elevation contours for the third quarter 2016 are presented on **Figure 4**. The groundwater flow direction is towards the northeast in the area beneath the former AP and the EP. The groundwater gradient, calculated using the 3-point method, is approximately 0.009 feet/ft in the area of the former AP and EP, consistent with previous measurements. The groundwater gradient calculated in this and previous investigations indicates that the flow direction and magnitude is similar on both sides of the Spring-line fault.

## **7.3 Soil Vapor Sample Results**

Site SVP SV-01 was sampled during the third quarter 2016 monitoring event with one primary and one duplicate sample collected. Acetone, 2-butanone, trichloroethene (TCE) and vinyl acetate were detected at very low levels above laboratory reporting limits in either the primary or duplicate sample (**Table 7**). Since the concentrations were not reproducible in both the primary and duplicate samples at similar concentrations, the detections were qualified as estimated. These concentrations were well below the screening levels for residential vapor intrusion concerns. All other VOCs were not detected above the laboratory MRLs.

## 7.4 Data Validation

The data were validated at a United States Environmental Protection Agency (EPA) Stage 2A data validation level. Based on this Stage 2A data validation covering the quality control (QC) parameters listed in the data validation summaries, the data as qualified are usable for meeting project objectives, with the exceptions of rejected data. Further summary of the data validation results is presented in **Appendix I**. Qualified data should be used within the limitations of the qualification. The following rejection qualifications for soil samples were identified based on the Stage 2A data validation:

- The non-detect results of VOCs in samples SS-01-160823 and SS-02-160823 are R qualified as rejected, based on professional and technical judgment and gross exceedance (more than two times) of the VOC extraction holding time of 48 hours<sup>6</sup>.
- Due to matrix spike/matrix spike duplicate (MS/MSD) recoveries less than 20%, the non-detect result of vinyl acetate in sample SS-02-160823 was R qualified as rejected.

---

<sup>6</sup> VOC analysis was requested by the RWQCB six days following sample collection.

## **8.0 DATA EVALUATION AND CONCLUSIONS**

### **8.1 Soil Conditions**

The soil types encountered in the vicinity of the FP, west of the Spring-line fault, are interpreted to be alluvial fan sediments derived from erosion of the Sierra Nevada Mountains to the west of the Site. The soil types encountered surrounding the former AP and the EP, east of the Spring-line fault, indicate that the surficial soils are coarse-grained sands representative of the former shoreline of the now dry Owens Lake. Soil types encountered below the coarse-grained sands were fine-grained lacustrine deposits interbedded with alluvial sands. This sequence of soil types is consistent with borings that have been completed east of the Spring-line fault.

Soil sample analytical results for metals were compared to two regulatory screening levels including 1) the EPA RSLs based on an industrial site setting and 2) the MCL-based protection of groundwater value. In addition, soil concentrations were compared to the California median background soil values (UCR/DTSC, 1996). Of the metals detected in the soil samples, antimony and arsenic were detected at concentrations exceeding one or more of these screening levels. Additionally, concentrations of arsenic and molybdenum detected in boring B-01 at depths of 15 and 18 ft bgs, respectively, exceeded the California median background for soil concentrations (UCR/DTSC, 1996 and Chernoff, et.al., DTSC, 2008). Concentrations of arsenic in the upper portion of boring B-01 at 5 and 10 ft bgs were 1.34 and 1.61 mg/kg, respectively. Boring B-01 is located approximately 350 feet upgradient of the original FP outfall, and over 200 feet cross-gradient from the current outfall. Based on the B-01 soil sample depths and the location which is up/cross-gradient from discharge outfalls, it appears that the concentrations of arsenic and molybdenum are representative of naturally occurring regional levels that are higher than the median California background levels.

Samples SS-01 and SS-02 were collected as a split sample with the RWQCB. The objective of collection of these samples, according to the RWQCB, was to evaluate if uncontrolled releases of spent arsenic filter media had occurred in the past at the sample location. The RWQCB selected the sample location, based on the color and texture of the surface soils, and the color and texture of the soil underlying the surficial soil. The results of both the surficial soil sample and the sample collected in the soil horizon directly below did not contain concentrations of arsenic indicative of a release of spent arsenic filtration media.

### **8.2 Soil Vapor**

Concentrations of VOCs were detected at low concentrations in the sample collected. While vapor intrusion is very unlikely at this Site, all sample results were much lower than the most conservative screening levels for residential vapor intrusion concerns. In

addition, VOCs in groundwater from surrounding locations did not have detections of VOCs. Based on the results of current and historical soil vapor sample results and the current and historical groundwater sample results, there has not been a significant release of VOCs in the area around the valve distribution box.

### **8.3        Groundwater**

Based on groundwater samples collected during the Phase 3 Site Investigation, groundwater quality has been characterized in both the lateral and vertical directions for the constituents of concern. In particular, arsenic has been delineated with lateral control from wells MW-08 and MW-11 located to the north of the former AP, and wells MW-06 and MW-09 located to the south of the former AP and EP. Monitoring wells MW-07 and MW-12, located to the east of the former AP and EP, provide downgradient control points for arsenic concentrations. In addition, monitoring well MW-10 provides downgradient control in the area of the Fire Pond (**Figure 4**). While groundwater samples could not be collected in well MW-14 as it was dry at the time of sampling, this well will also provide additional future control to the south of the former AP as water levels are expected to increase in this well due to seasonal groundwater fluctuation.

Supplemental to the lateral groundwater delineation efforts, groundwater modeling under historical wastewater discharge conditions indicated the impact to water levels in the vicinity of the former AP is minimal with no groundwater mounding evident (i.e. upgradient towards MW-03 and MW-15). Therefore, it is highly unlikely that any leaks from the former AP could be expected to have migrated upgradient towards the area of monitoring wells MW-03 or MW-15 and cause groundwater quality impacts. This further supports the conclusion that groundwater in wells MW-03 and MW-15 are representative of background groundwater quality concentrations at the site.

Groundwater was characterized vertically in relation to the former AP based on the numerous groundwater grab samples collected in upgradient boring MW-15, downgradient boring B-02, and down- and cross-gradient borings MW-12, MW-13, and MW-14. In groundwater grab samples collected from boring MW-15, located approximately 70 feet upgradient of the former AP, dissolved arsenic concentrations ranged from 62.9 to 201 µg/L. The highest concentration of dissolved arsenic in boring MW-15 was detected in the sample collected from 14 ft bgs in a sandy layer identified just below a fine-grained silt layer. Note that in monitoring well MW-03, located approximately 30 feet upgradient of MW-15, dissolved arsenic was detected an order of magnitude lower at 11.9 µg/L with the pump inlet depth at a comparable depth to the high detection in MW-15.

In downgradient boring B-02, groundwater grab samples from 12.25, 15.5, and 23 ft bgs were collected in every water-bearing coarse-grained (sand) unit. Note that low permeability, fine-grained silt and clay units were present between the coarse-grained

units where groundwater grab samples were collected (**Figure 6A**). The concentrations of dissolved arsenic decreased between the 12.25 ft bgs and the 15.5 ft bgs sample from 363 to 45.5  $\mu\text{g/L}$  and decreased again between the 15.5 ft bgs and 23 ft bgs sample from 45.5 to 13.3  $\mu\text{g/L}$ . An elevated dissolved arsenic concentration of 119  $\mu\text{g/L}$  was observed in the deepest sample collected from downgradient boring B-02 at a depth of 25.5 ft bgs within the same sand unit as the 23 ft bgs sample, and directly above a fine-grained unit. The distribution of dissolved arsenic concentrations in the deeper samples (i.e. higher in the deepest sample than shallower samples) is not consistent with a leak from the former AP and may indicate elevated background levels at depth.

These findings suggest that arsenic concentrations in groundwater near the former AP (and the overall area east of the Spring-line fault) is very heterogeneous, varying between tens or hundreds of  $\mu\text{g/L}$  within short distances (i.e., within feet) both laterally and vertically. Elevated arsenic concentrations are often associated with the fine-grained deposits due to adsorption of arsenic onto iron-bearing clay minerals and organic matter, both of which are also commonly concentrated in clay and silt deposits. Thus, as the presence of the lacustrine layers increases, it is expected that naturally occurring arsenic concentrations will likewise increase substantially, but this general trend will not be laterally continuous due to the heterogeneous distribution of the fine-grained deposits. Arsenic concentrations would also be expected to increase near and within these fine-grained deposits on a localized basis, thus, possibly explaining the observed dramatic variations observed in groundwater grab samples collected at the Site (Geosyntec, 2016b).

In groundwater monitoring well samples collected as part of the third quarter 2016 monitoring event, concentrations of dissolved arsenic and other metals were generally similar to previous monitoring events. The dissolved arsenic concentrations detected in groundwater monitoring well samples, may be the result of monitoring well screens spanning across multiple fine-grained units. Additionally, naturally occurring arsenic concentrations in groundwater increase east of the Spring-line fault reaching very high concentrations beneath the Owens Dry Lake. Further, increases in concentrations of anions and cations in Site monitoring wells generally increase towards the east of the Site in the direction of the Owens Dry Lake.

In conclusion, impacts from any potential prior releases of arsenic from the former AP are minimal compared to the naturally high background arsenic concentrations in the area, including extremely elevated arsenic concentrations known to occur hydraulically downgradient of the former AP in the Owens Dry Lake area. Any potential impacts of dissolved arsenic releases from the former AP are within the Site natural background levels and considerably below concentrations found within groundwater beneath the southern portion of the Owens Dry Lake. In addition, current analyses clearly show that groundwater originating at and near the former AP will not impact any water supply wells in the area and, based on current information, no known material harm to the environment

or reasonably foreseeable beneficial uses for waters of the State have occurred (Geosyntec, 2016b).

## **9.0 RECOMMENDATIONS**

The Phase 3 Site investigation was conducted to further evaluate the soil, soil vapor, and groundwater conditions in the areas around the former AP, the EP and the FP. Additionally, the investigation was completed to evaluate groundwater gradient and flow patterns in the upper-most shallow groundwater aquifer. Based on results obtained from the Phase 3 investigation and the third quarter 2016 monitoring event, Geosyntec provides the following recommendations:

1. Based on very low to non-detected and inconsistent results over the last year of quarterly monitoring, and in consideration that all sewage waste water is fully contained in a tank system and not discharged to the groundwater, Geosyntec again recommends that the analytical requirements for total and fecal coliform be removed.
2. Considering that VOCs have not been detected in quarterly groundwater monitoring samples (with the exception of acetone detected during the second quarter 2016), Geosyntec again recommends that VOCs be removed from the groundwater analytical schedule.
3. SVOCs have not been detected in groundwater since monitoring was initiated and therefore Geosyntec again recommends removing SVOCs from the analytical schedule.
4. Based on very low to non-detected and inconsistent detections of VOCs in soil vapor samples collected for the past five quarters (below conservative screening levels for residential vapor intrusion concerns) and in consideration that VOCs have not been detected in groundwater samples, Geosyntec again recommends that soil vapor sampling is removed from the sampling schedule and the soil vapor probe be destroyed.
5. Based on consistent results obtained from five consecutive groundwater monitoring events, Geosyntec recommends that a reduction in groundwater sampling frequency to a semi-annual schedule is requested for the Site (spring and fall).

Notes:

Soil samples were analyzed for CAM 17 Metals by Eurofins Calscience Environmental Laboratories, in Garden Grove, California.

Samples were analyzed using EPA Methods 6010B and 7471A. Only detected metals shown in this table. Other metals were not detected above the laboratory Minimum Reporting Limit.

Shaded cells represent an exceedance of one or more of the listed screening levels.

California median background soil derived from "Background Concentrations of Trace and Major Elements in California Soils", Kearny Foundation of Soil Science, March 1996

Arsenic median background soil value is the upper-bound background arsenic concentration from Chernoff, G., Bosan, W., Oudiz, D., 2008 "Determination of a Southern California Regional Background Arsenic Concentration in Soil", DTSC

ND <x.xx: Indicates sample result was less than laboratory minimum reporting limit.

ft bgs: Feet below ground surface

mg/kg: milligrams per kilogram

RSL: United States Environmental Protection Agency Regional Screening Level.

nl: not listed

J: Estimated concentration.

SSL: Soil screening level

ND<: Not detected above the listed laboratory minimum reporting limit.

## Concentration is above screening level

California Maximum Contaminant Level					0.63	nl	nl	100	100	50	50	nl	nl	nl	nl	nl	nl	

Notes:

Groundwater samples were analyzed for CAM 17 Metals by Eurofins Calscience Environmental Laboratories, in Garden Grove, California.

Samples were analyzed using EPA Methods 6010B and 7470A. Only detected metals shown in this table. Other metals were not detected above the laboratory Minimum Reporting Limit.

Shaded cells represent an exceedance of the listed maximum contaminant level.

<x.xx: Indicates sample result was less than laboratory minimum reporting limit.

ft bgs: Feet below ground surface

µg/l: micrograms per liter

nl: not listed

J: Estimated concentration.

J: Estimated concentration biased high based on data validation

## Concentration is above MCL

<b>Secondary Maximum Contaminant Level</b>			nl	nl	nl	nl	250	nl	0.5	10	nl	nl	nl	nl	nl	250	500

Notes:

Groundwater samples were analyzed by Eurofins Calscience Environmental Laboratories, in Garden Grove, California. Only detected compounds shown.

<x.xx: Indicates sample result was less than laboratory minimum reporting limit.

mg/l: milligrams per liter

RSL: United States Environmental Protection Agency Regional Screening Level.

MBAS: Methylene Blue Activated Substances

NA: Not Analyzed

nl: not listed

J: Estimated concentration

J+: Estimated concentration biased high based on data validation

J-: Estimated concentration biased low based on data validation

## Concentration is above secondary MCL

**APPENDIX A**

**GROUNDWATER MODFLOW MODELING**

## APPENDIX A

### Groundwater MODFLOW Modeling

Date: February 28, 2017  
Subject: Groundwater MODFLOW Modeling  
Crystal Geyser Roxane, Spring Water Bottling Facility,  
Olancha, California

---

#### **1. INTRODUCTION**

Geosyntec Consultants, Inc., (Geosyntec) has prepared this memorandum describing the results of groundwater flow modeling for Crystal Geyser Roxane, Spring Water Bottling Facility, Olancha, California (site).

Numerical modeling was used to estimate the groundwater flow and particle tracking under current and future groundwater pumping conditions at site discharge ponds and to estimate historical mounding along with groundwater flow at the Former Arsenic Pond (AP) and the East Pond (EP). The numerical model used to perform this assessment was updated from an existing model developed by Geosyntec (Geosyntec, 2014 and 2016) in connection with the Cabin Bar Ranch bottling facility project. The updated model is described in this appendix.

##### **1.1 Purpose**

The purposes of this memorandum are to: 1) describe the numerical modeling approach used to assess the groundwater flow and potential mounding, and 2) present the model simulation results including particle tracking from the site discharge ponds under historical and future conditions.

#### **2. MODEL CONSTRUCTION AND CALIBRATION**

##### **2.1 Conceptual Model and Overview**

Groundwater beneath the site is mostly derived from precipitation (rainfall) and snowmelt that runs off the Sierra Nevada Mountains to the west and infiltrates into the alluvial fan near the mountain base or enters the alluvial aquifer through fractures in the bedrock. Groundwater in the

alluvium flows eastward, away from the Sierra Nevada Mountains and towards the central portion of the Owens Valley basin. In the site vicinity, the alluvium layer is divided into two permeable layers, separated by a fine-grained lacustrine layer that occurs at a depth of approximately 80 feet below ground surface (bgs). The upper aquifer material is referred to as the Shallow Zone, and consists predominately of sand and gravel interspersed with fine-grained layers. The 80-foot deep fine-grained layer is an aquitard that separates the Shallow Zone from deeper sandy and gravelly alluvium. This fine-grained layer pinches out towards the west. The Deep Zone in the site vicinity is found at depths of greater than 80-feet bgs, and generally consists of coarse sands and gravel layers. In the site vicinity, the Shallow Zone is an unconfined aquifer and the Deep Zone is a confined aquifer. A site-wide upward groundwater gradient exists based on comparison of water levels in co-located observation wells completed in the Deep and Shallow Zones. Groundwater flow direction in the upper shallow zone is generally in the northeast direction towards the Owens Dry Lake with a gradient of approximately 0.01 feet/foot.

The depth to the shallow groundwater table beneath the site gradually decreases towards the east. In the south-central portion of the site, shallow groundwater intersects the ground surface along an approximate line where springs and seeps are observed. These springs and seeps occur along a fault called the Spring-line fault. This fault appears to act as a barrier to groundwater flow in the Shallow Zone, resulting in a rise of the groundwater table, and the observed springs and meadowlands in the central and eastern portions of the site.

## **2.2 Numerical Model Domain, Grid, and Layers**

The three-dimensional model for groundwater flow was developed using MODFLOW, an industry standard finite-difference code. Groundwater flow in the model is assumed to be steady-state.

The model domain is illustrated on Figure A-1. The model domain extends from the foothills of the Sierra Nevada Mountains on the west to the Owens Dry Lake bed on the east. In the north-south direction, the model extends to include the town of Cartago in the north and the Crystal Geyser-Roxanne facility in the south. The trapezoidal model domain is 11,900 feet (ft) wide in the north-south direction, 7,200 ft wide in the east-west direction at the north boundary, and 11,800 ft wide in the east-west direction at the south boundary.

The model domain simulates groundwater flow in the Shallow and Deep zones and includes simulation of pumping in active groundwater supply wells at the site, to the south of the Cabin Bar Ranch, and in the town of Cartago, to the north of the Cabin Bar Ranch. The three geological layers at the site, Shallow zone, clay/silt layer and deeper sandy and gravelly alluvium, were simulated with three model layers. The top of the model domain was interpolated from a Digital Elevation

Model obtained from the USGS National Map Viewer (USGS, 2012)<sup>1</sup>. The top of the middle layer was defined based on well logs and previous hydrogeological investigations (Geosyntec, 2011) and was calculated as the minimum of either 3,550 ft mean sea level (ft msl) or the top of the domain minus 75 ft. The thickness of the middle layer was 10 ft across the model domain. The bottom of the model domain was fixed at 3,300 ft msl. This corresponds to a total average model thickness of 325 ft in the vicinity of the site. The sequence of alluvium and lacustrine deposits beneath the site is at least 750 feet thick (Geosyntec, 2011). The model domain focuses on the upper portion of the deposits, as it was developed to assess the impacts of pumping in the shallow zone and in the upper deep zone. A cross-section of the model domain is shown on Figure A-2.

## **2.3 Groundwater Flow Model**

### **2.3.1 Observation data – Head**

Groundwater head measurements from the September 2016 quarterly groundwater monitoring event were used for model calibration. The well locations and observed water levels are shown on Figure A-3 and in Table A-1, respectively.

The interpolated water level contour map in the vicinity of the AP, based on September 2016 monitoring event data, was also used qualitatively for calibration.

### **2.3.2 Observation data – Spring Flows**

Flow rates at selected spring flows were measured in 2010 as part of the hydrogeological investigations (Geosyntec, 2011). Spring discharge generally flows eastward into the main collection ditch and the total flow at the ditch was estimated at roughly 350 gallons per minute (gpm) (Geosyntec, 2011). This total spring flow rate was used to calibrate the model.

### **2.3.3 Model Boundaries and Stresses**

Groundwater flow in the model domain is from west to east, consistent with measured northeasterly flow in the AP area. A no-flow boundary was applied at the northern and southern sides of the model. A constant head boundary is applied to the east and west sides of the model. Constant head boundaries were based on the extrapolation of a surface created from water levels measured in various wells and piezometers in September 2016. The constant head boundaries resulted in a horizontal regional gradient of approximately 0.01 ft/ft.

---

<sup>1</sup> The upper model layer is simulated as an unconfined aquifer such that the layer is not fully saturated.

The model simulated a maximum evapotranspiration (ET) rate of 0.01 feet per day from the surface which equates to 3.65 feet per year (ft/yr). This ET rate is consistent with an ET rate of 3.2 ft/year estimated by Duell (1988) for meadows in the Owens Valley and is within the range of previously published ET rates for the Owens Valley as presented in JMM (1993) for the site. The ET rates reported by JMM range from 2.6 ft/year (empirical method where groundwater is less than 8 ft bgs) published by Williams (1969) to 4.4 ft/year (open water or mudflats) published by Danskin (1988) (as cited by JMM., 1993). The ET extinction depth was setup to 10 ft bgs.

The springs along the Spring-line fault were simulated with the drain package and the bottom elevation of the drains was defined 2 feet below ground elevation. Springs were defined at locations ES-1A, ES-3, ES-3A, and CBS-1 to CBS-9. The spring locations are shown on Figure A-4.

The Spring-line fault was simulated as a horizontal flow barrier, in both the shallow and deep sand zones. The modeled and observed spring flow was used to calibrate the hydraulic characteristics of the barrier (hydraulic conductivity divided by fault thickness). Further discussion of groundwater flow calibration results is presented in Section 2.4.

There are several private active pumping wells in the model domain, located in the Cartago area. Average pumping rates of 650 gallons per day (gpd) were used in the model, unless reported otherwise by the owner. There is also one municipal water supply well in Cartago (CMW-2), which provides water to 43 residences. The average pumping rate at this well was estimated based on an estimate rate of 650 gpd per residence (27,950 gpd at the well). The production wells from the CGR Olancha facility and proposed production wells at the Cabin Bar Ranch property are also included in the model. The location of all pumping wells in the model are shown on Figure A-4. The model inputs of each pumping well (pumping rates, pumping zone) are summarized in Table A-2.

The EP and Fire Pond (FP) (see Figure A-4) are simulated with discharge rates of 40 and 2 gpm, respectively (CGR, 2014).

### 2.3.4 Material Properties

The deep zone was modeled with uniform hydraulic parameters (i.e., horizontal and vertical hydraulic conductivity). The Shallow Zone was modeled with three zones for hydraulic conductivities, shown on Figure A-4. Pumping tests performed in 2010 in wells CGR-8, CGR-9 and CGR-10 resulted in estimates of average hydraulic conductivity of the Shallow Zone between 230 to 550 ft/day (Geosyntec, 2011). These values were used to calibrate groundwater flow simulation. Further discussion of groundwater flow calibration results is presented in Section 2.4. Parameters used in the model are summarized in Table A-3.

The aquitard-like properties of the clay/silt layer are represented in the model to extend from the eastern domain boundary westward to the western edge of the valley floor/HWY-395 area. The remainder of the middle layer to the west was assigned the same properties as the deep sand layer, simulating a westward pinching out of the aquitard. The aquitard extent is based on well logs, which shows that the clay/silt layer is present at wells PAL-1 and CMW-2 but not at wells PAT-1 and HAR-1.

## **2.4 Model Calibration**

The flow model was calibrated to fit the observed head at the monitoring wells (Figure A-3), and the total spring flow rate (see Section 2.3.2).

The model parameters are summarized in Table A-3. These parameters are further discussed below.

### **2.4.1 Groundwater Flow Model Parameters**

Significant groundwater flow model parameters are as follows:

- The calibrated hydraulic conductivity values for the Shallow Zone are 315 ft/day west of the fault, 400 ft/day northeast of the fault and 250 ft/day southeast of the fault (Figure A-4), which are consistent with the range estimated from pumping tests (230 to 550 ft/day, Geosyntec, 2011). Hydraulic conductivity values southeast of the fault are estimated based on coarse-grained units encountered during drilling activities. Hydraulic conductivity values northeast of the fault is based on calibration.
- A sensitivity analysis was performed to assess the impact of lower hydraulic conductivity values east of the fault on particle tracking and mounding in the vicinity of the AP and EP (see Section 3.1).
- The calibrated evaporation rate is 3.65 feet per year.
- Figure A-5 presents a plot of observed versus simulated heads, illustrating a good model fit to the observed heads. The root mean squared residual is 3.4 feet, approximately 9.9% of the observed head difference at the site (34.1 feet).
- The simulated total spring flow (which is assumed to include water flowing to the main collector ditch) is 310 gpm. This value is consistent with observed discharge (roughly 350 gpm) from the main collection ditch (see section 2.3.2).

- The calibrated head contours are illustrated on Figure A-6.

### 3. GROUNDWATER FLOW AND PARTICLE TRACKING SIMULATIONS

The calibrated model was used to assess groundwater flow at the discharge ponds at the site under historical and future proposed pumping conditions. The historical scenario simulation includes the pumping of wells CGR-2, CGR-3, CGR-4, and CGR-7 only. The future scenario simulation includes additional pumping at the Cabin Bar Ranch facility (CGR-8, CGR-9, and CGR-10).

#### 3.1 Historical Groundwater Flow Simulation at Discharge Ponds

The calibrated model was used to assess groundwater flow and potential groundwater mounding from the AP and the EP under historical wastewater discharge conditions<sup>2</sup>. This assessment assumes that the discharge ponds are un-lined and discharged waste water infiltrated directly to groundwater.

Two scenarios were simulated for infiltration at the AP and EP based on historical information:

1. Typical wastewater discharge flow rates of 1,700 and 56,000 gpd to the AP and EP, respectively; and
2. Maximum flow rates of 4,000 and 60,000 gpd at AP and EP, respectively<sup>3</sup>.

Figure A-7 shows the simulated water level in the vicinity of the EP and AP and forward particle tracking illustrating the groundwater flow from the ponds for the two scenarios (typical and maximum flow rates).

The model results illustrate that in both scenarios simulated, the groundwater infiltrating at the AP and EP flow towards the northeast and that the impacts on the water levels in the vicinity of the ponds is minimal (i.e. no mounding is evident).

In order to assess the impact of lower hydraulic conductivity values east of the fault, a sensitivity analysis run was performed, using 100 ft/day as the horizontal hydraulic conductivity east (both northeast and southeast) of the fault. The vertical hydraulic conductivity value east of the fault was also reduced to 1 ft/day. Figure A-8 shows the simulated water level in the vicinity of the EP and AP and forward particle tracking illustrating the groundwater flow from the ponds for this

---

<sup>2</sup> Hydraulic conductivity values used in this scenario assumed no vertical migration below the upper-most encountered fine-grained layer in the soil beneath the AP and the EP.

<sup>3</sup> Historical typical and maximum flow rates were obtained via Crystal Geyser communication based on internal documentation.

sensitivity scenario, using the maximum flow rates. Similar to the results shown on Figure A-7, the groundwater infiltrating at the AP and EP flow towards the northeast and the impacts on the water levels in the vicinity of the ponds is minimal (i.e. no mounding is evident). This sensitivity analysis run represents a worst-case scenario in that it assumes that there was no liner in the AP such that all waste water discharged to the AP was infiltrated directly to groundwater. Additionally, the lower hydraulic conductivity values do not appear to be representative of the aquifer, as the calibration (comparison of simulated and observed water levels and comparison of simulated and observed spring flow) decreases with decreasing hydraulic conductivity.

### **3.2 Future Groundwater Flow Simulation at Discharge Ponds**

Four additional pumping wells, CGR-8, CGR-9, CGR-10, and CBR-1 (see Figure A-4), were added to the model to simulate groundwater flow under future conditions. CGR-8, CGR-9, and CGR-10 were set at a constant rate of 67 gpm and CBR-1, used as a domestic well, was set to 0.3 gpm. The scenario includes pumping in site production wells CGR-2, CGR-3, CGR-4, and CGR-7, and active domestic wells in the town of Cartago including the Cartago Mutual Water Well (Table A-2). Pumping rates in these off-site wells were based on either reported rates by the owner or estimated rates based on typical average residential use (650 gallons per day).

In addition to the AP and EP, the future scenario simulation includes particle tracking from the Fire Pond (FP) and a proposed wastewater infiltration pond at the Cabin Bar Ranch property north of the site (Figure A-4). The wastewater infiltration pond was modeled with an anticipated flow rate of 23,000 gpd. Under future conditions the EP and FP are simulated as infiltration ponds, however, no discharge and therefore no infiltration is assumed at the AP.

Figure A-8 shows the simulated capture zones at the pumping wells and forward particle tracking illustrating the groundwater flow path from the discharge ponds.

The model results illustrate that the groundwater at the ponds flow towards the northeast ultimately discharging in Owens Dry Lake and that this groundwater is not captured by any of the pumping wells.

## **4. CONCLUSIONS**

In conclusion, results of the groundwater modeling indicate the following:

1. Under historical typical and maximum discharge flow rates, impacts to water levels in the vicinity of the AP and EP is minimal with no groundwater mounding evident;
2. Using maximum historical discharge flow rates and lower range hydraulic conductivity values, groundwater mounding at the AP and EP is not evident;

3. Groundwater at the site ponds is shown to flow towards the northeast toward Owens Dry Lake under both historical and future conditions; and
4. Under future pumping conditions, water discharged from the site ponds will not be captured by any of the site pumping wells.

## REMARKS

## WELL CONSTRUCTION DATA (ft)

WELL CASING:  $TD = 10.94'$ TOP OF CASING HEIGHT/DEPTH (TOC),  
 $= 3.00$ 

INSIDE DIAM

 $d_{w, ID} = 0.19'$ 

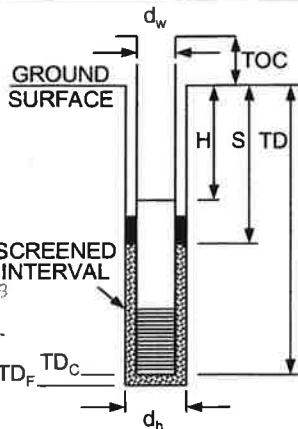

OUTSIDE DIAM

 $d_{w, OD} = 0.20'$ 

HOLE DIAMETER

 $d_h = 0.67'$ 

DEPTH TO:

 $8 - 10.5$ 

SCREENED INTERVAL

5 TO 7.5 ft

WATER LEVEL

 $H = 9.35$  ft TOC

BASE OF SEAL

 $S = 7.00$  ft TOC

BASE OF CASING

 $TD_c = 10.50$ 

BASE OF FILTER PACK

 $TD_f = 10.50$ ESTIMATED FILTER PACK POROSITY  $P = 0.25$ 

## WELL VOLUME CALCULATION

CASING VOLUME =

$$V_c = \pi \left( \frac{d_w ID}{2} \right)^2 (TD_c - H) = 3.14 \left( \frac{0.19}{2} \right)^2 (10.50 - 9.35) = 0.03 \text{ ft}^3$$

FILTER PACK PORE VOLUME =

$$V_f = \pi \left[ \left( \frac{d_h}{2} \right)^2 - \left( \frac{d_w OD}{2} \right)^2 \right] (TD_f - (S \text{ or } H)) (P) \\ = 3.14 \left[ \left( \frac{0.67}{2} \right)^2 - \left( \frac{0.19}{2} \right)^2 \right] (10.50 - 9.35) (0.25) = 0.192 \text{ ft}^3$$

(if  $S > H$ , use  $S$ . If  $S < H$ , use  $H$ )

TOTAL WELL VOLUME =

$$V_T = V_c + V_f = 0.03 + 0.192 = 0.12 \text{ ft}^3 \times 7.48 = 0.90 \text{ GAL}$$

Eurofins Calscience, Inc. (Calscience) certifies that the test results provided in this report meet all NELAC requirements for parameters for which accreditation is required or available. Any exceptions to NELAC requirements are noted in the case narrative. The original report of subcontracted analyses, if any, is attached to this report. The results in this report are limited to the sample(s) tested and any reproduction thereof must be made in its entirety. The client or recipient of this report is specifically prohibited from making material changes to said report and, to the extent that such changes are made, Calscience is not responsible, legally or otherwise. The client or recipient agrees to indemnify Calscience for any defense to any litigation which may arise.

## Work Order Narrative

---

Work Order: 16-08-1807

Page 1 of 1

---

### **Condition Upon Receipt:**

Samples were received under Chain-of-Custody (COC) on 08/25/16. They were assigned to Work Order 16-08-1807.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

### **Holding Times:**

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

### **Quality Control:**

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

### **Subcontractor Information:**

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

### **Additional Comments:**

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

Page 1 of 1

<b>Qualifiers</b>	<b>Definition</b>
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.
	Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.
	Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.
	A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

## SAMPLE ANOMALY REPORT

**SAMPLES, CONTAINERS, AND LABELS:**

- Sample(s) NOT RECEIVED but listed on COC
  - Sample(s) received but NOT LISTED on COC
  - Holding time expired (list client or ECI sample ID and analysis)
  - Insufficient sample amount for requested analysis (list analysis)
  - Improper container(s) used (list analysis)
  - Improper preservative used (list analysis)
  - No preservative noted on COC or label (list analysis and notify lab)
  - Sample container(s) not labeled
  - Client sample label(s) illegible (list container type and analysis)
  - Client sample label(s) do not match COC (comment)
    - Project information
    - Client sample ID
    - Sampling date and/or time
    - Number of container(s)
    - Requested analysis
  - Sample container(s) compromised (comment)
    - Broken
    - Water present in sample container
  - Air sample container(s) compromised (comment)
    - Flat
    - Very low in volume
    - Leaking (not transferred; duplicate bag submitted)
    - Leaking (transferred into ECI Tedlar™ bags\*)
    - Leaking (transferred into client's Tedlar™ bags\*)
- \* Transferred at client's request.

**Subject:** RE: CG Roxane / SB0794 - 16-08-1807 - Sample Receipt Confirmation & COC Document

Tina,  
Please hold the samples. We won't run the samples for STLC until we see the final metals results.

Thanks.

Kevin Coffman  
Geosyntec

**Subject:** RE: CG Roxane / SB0794 - 16-08-1807 - Sample Receipt Confirmation & COC Document

For the soluble metals, it does not look like any of the metals were above the limit for STLC, did you still want us to run the soluble metals? If so, please let me know which elements.

Best Regards,

Hoaibao (Tina) Nguyen

Assistant Project Manager

**Subject:** RE: CG Roxane / SB0794 - 16-08-1807 - Sample Receipt Confirmation & COC Document

Tina,

In addition to the VOCs on the 2 soil samples, please analyze them for SVOCs and soluble metals.

Standard TAT.

Thanks,

Kevin Coffman

Tina,

As a follow up, please run soil samples SS-01-160823 and SS-02-160823 for VOCs.

Thanks.

Hi Kevin,

Could you please confirm that you wanted all water samples listed on COC ran on a 3day TAT.

## Work Order Narrative

---

Work Order: 16-08-1807

Page 1 of 1

---

### **Condition Upon Receipt:**

Samples were received under Chain-of-Custody (COC) on 08/25/16. They were assigned to Work Order 16-08-1807.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

### **Holding Times:**

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

### **Quality Control:**

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

### **Subcontractor Information:**

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

### **Additional Comments:**

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

## Detections Summary

Client: Geosyntec Consultants  
 924 Anacapa Street, Suite 4A  
 Santa Barbara, CA 93101-2177

Work Order: 16-08-1807  
 Project Name: CG Roxane / SB0794  
 Received: 08/25/16

Attn: Kevin Coffman

Page 5 of 5

**Client SampleID**

<b>Analyte</b>	<b>Result</b>	<b>Qualifiers</b>	<b>RL</b>	<b>Units</b>	<b>Method</b>	<b>Extraction</b>

Page 1 of 1

<b>Qualifiers</b>	<b>Definition</b>
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.
	Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.
	Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.
	A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

For the soluble metals, it does not look like any of the metals were above the limit for STLC, did you still want us to run the soluble metals? If so, please let me know which elements.

Best Regards,

Hoaibao (Tina) Nguyen

## Work Order Narrative

---

Work Order: 16-09-0004

Page 1 of 1

---

### **Condition Upon Receipt:**

Samples were received under Chain-of-Custody (COC) on 09/01/16. They were assigned to Work Order 16-09-0004.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

### **Holding Times:**

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

### **Quality Control:**

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

### **Subcontractor Information:**

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

### **Additional Comments:**

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

Page 1 of 1

<b>Qualifiers</b>	<b>Definition</b>
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.
	Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.
	Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.
	A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.
