Memorandum**Date :**

April 20, 1995

To :

Tom Howard, Chief
Bay-Delta Unit
State Water Resources Control Board
901 "P" Street
Sacramento, California 95814

From : Department of Water Resources**Subject:** DWRDSM Study: Draft Water Quality Control Plan

In response to your March 23, 1995 request, attached are results of a DWRDSM study conducted to simulate Delta water quality conditions resulting from the December 1994 draft Water Quality Control Plan. If you have any questions, please call me.

**Estimating Water Quality Conditions in the Delta Under the
December 1994 Draft Water Quality Control Plan**

Division of Planning
DWR
April 20, 1995

Summary

The State Water Resources Control Board requested the DWR to conduct hydrodynamics and water quality simulations comparing a draft Water Quality Control Plan hydrology representative of the December 15, 1994 Delta accord (DWRSIM study 1995c6b-SWRCB-409), to a "base" study hydrology, representative of nominal D1485 operations (DWRSIM study 1995c6b-MONTERY-412). The DWR Delta Simulation Model was used to estimate monthly average flow, stage, and salinity for the period from water year 1987 through water year 1992. (memo from Tom Howard, March 23, 1995; Attachment I).

The request was made in response to comments received by the Board on the draft Plan. The comments regard 1) the potential impacts on water quality in the central Delta due to new Delta Cross-Channel (DCC) operation rules increased flow on the San Joaquin River, and 2) the water quality needs for irrigation and leaching in months not covered by the agricultural standards in the Plan.

Findings:

Monthly or semi-monthly average time-series salinity at ten locations for water years 1987 through 1992 are shown in Figures 1 through 10. Several observations can be made on the basis of these results:

Under the draft Plan hydrology, salinity at central delta stations (Jersey Point, San Andreas, and Prisoners Point) increase significantly during the November through January period when the DCC is closed the first half of each month. The increase persists into February when the DCC is closed continuously. The Terminous station shows similar increases but tends to lag by one month. The magnitude of delta outflow in the plan study is only slightly greater than the base in the November through January period (Figure 11A).

Under the draft Plan, the DCC is continuously closed between February and June, and delta outflow is 15 to 66% greater over the same period compared to the base (Figure 11B). The result is generally lower spring and summer salinity at Jersey Point, San Andreas, Prisoners Point, and Terminous in the Plan (Figures 2, 3, 4, 5). The increase in delta outflow is attributable mainly to reductions in project export to meet X2 requirements and export/inflow ratios.

Draft Plan agricultural water quality standards are satisfied within the bounds of model accuracy for the central and north delta stations requested for analysis by the Board. Standards in the south delta are often exceeded however because DWRSIM was run using a 70 TAF cap on flows released to the San Joaquin River for water quality purposes. As a result, standard exceedences occur in dry and critical years during the April through August period when the standard is 0.7 mmhos/cm.

South delta water quality is only marginally affected by DCC operation. Most salinity differences between the draft Plan and the base hydrology are due to temporal differences in inflow and export magnitudes.

The body of this report presents the study request, modeling assumptions, results and discussion.

Background

The State Water Resources Control Board (Board) requested the DWR to conduct hydrodynamics and water quality simulations to determine the effect of the 1994 draft Water Quality Control Plan (draft Plan) standards on water quality in the delta (memo from Tom Howard, March 23, 1995; Attachment I). Board hearings to solicit comments on the draft Plan identified concerns about the impact of the DCC operation on water quality in the north and central delta. Specifically, concerns were raised about the effect of increased San Joaquin River flow and DCC closure during the irrigation and leaching months not covered by agricultural standards in the draft Plan.

The Board requested that the simulations be conducted using hydrology generated by statewide reservoir operations studies (DWRSIM). A "base" study hydrology, representative of nominal D1485 operations (DWRSIM study 1995c6b-MONTERY-412), and a "draft Plan" study hydrology, representative of the December 15 1995 Delta accord (DWRSIM study 1995c6b-SWRBC-409), were identified. Using these studies as input hydrology, the DWR Delta Simulation Model was used to estimate monthly average flow, stage and salinity for the period from water year 1987 through water year 1992.

The Board requested model output results for ten delta locations including hydrodynamics as instantaneous maximum, minimum, and average monthly flows, and water quality as average monthly electrical conductivity. The ten output locations are shown in Figure 13.

Modeling Approach and Assumptions

The following assumptions were used for modeling delta hydrodynamics and water quality under monthly changing hydrologic conditions generated by DWRSIM studies 1995-Monterey-412 (base) and 1995-SWRBC-409 (plan). Assumptions are required with regard to delta temporary barrier operation, DCC operation, Montezuma Slough operation, Clifton Court Forebay operation priority, and San Joaquin River boundary input salinity. The assumptions used are listed below.

- 1) Simulation Model: Hydrodynamics and water quality modeling was conducted using the DWR Delta Simulation Model (DWRDSM). A description of the model with verification results is given in WRINT DWR-134A (Attachment II). The computational grid is shown in Figure 13.
- 2) Montezuma Slough Control Structure Operation. In recent years, the Montezuma Control Structure has been operated as a tidal pump between October and May in all year-types except wet years (40-30-30 year-type classification). Since only critical and below-normal years were modeled (water-years 1987 through 1992), the gates were operated in the model each year between October and May. When the control structure was not operating, all radial gates and flash boards were removed.
- 3) Temporary Delta Barriers. Since 1987, three temporary rock barriers have been deployed in the delta at the Old River head, Old River near DMC, and Middle River near Victoria Island. For planning purposes, a nominal installation and removal schedule representative of the historical pattern was devised. This installation and removal schedule was used identically in the base and plan studies as follows:

	<u>Installed</u>	<u>Removed</u>
Middle River barrier:	May 1	September 30
Old River head barrier	September 1	November 30
Old River near DMC	and May 1 May 1	May 30 October 1

- 4) Delta Cross-Channel: The draft standard requires that the DCC be closed 45 days between November 1 and January 31, closed continuously between February 1 and May 20, and closed four consecutive days each week excluding weekends between May 21 and June 15. The DWRSIM operation studies model the 45 day November through January requirement by averaging 15 days open and 15 days closed in the delta cross-transfer calculation. Similarly, the May requirement is simulated for 20 days closed and 11 days open. The DWRSIM assumes that the gate is continuously open between May 21 and June 15.

Given the somewhat flexible nature of DCC operation under the draft Plan between November 1st and January 30th, for modeling purposes the DCC was closed between November 1 and November 15, December 1 and December 15, and January 1 and January 15. The DCC was re-opened in the second half of each

month. This nominal operation is somewhat conservative (i.e. it may over-emphasize the water quality impact of the DCC) because the draft Plan requires the DCC to be closed "up to" 45 days. Presumably, the Operations Group will make these decisions on the basis of current water quality conditions and the presence of fish in the Sacramento north of Walnut Grove.

The May 20 through June 15 draft Plan requirement that the DCC can be closed up to four days in a row not including weekends is modeled simply by leaving the DCC closed through May, and opening it thereafter.

5) Clifton Court Forebay operation priority: Clifton Court Forebay is currently operated on a seasonal basis to protect water levels in the south Delta. The priorities used by DWR are summarized in Figure 12. The following priority schedule was used:

Month:	J	F	M	A	M	J	J	A	S	O	N	D
Priority:	4	4	4	3	2	2	3	3	3	3	4	4

6) San Joaquin River Input Salinity: Vernalis is the upstream San Joaquin River boundary condition of the model. As such, the boundary salinity must be provided at that location. Salinity is assumed to be an exponential function of flow by the following equation:

$$\ln ec = 10.0800014 - 0.48230 * \ln (\text{SJR flow in cfs})$$

7) TDS to EC conversion: Output salinity was requested in electrical conductivity units to be consistent with agricultural standards in the draft Plan. The model computes salinity as TDS which therefore must be converted to EC. Location specific conversion equations from DWR [1986] were used for this purpose.

8) Salinity Output: Hydrodynamic inflows are constant within each month. Therefore, salinity approaches a steady-state condition as it is simulated within each month. For output purposes, the average monthly salinity is assumed to be the salinity on the last tidal day of the month.

9) Other Assumptions:

- Use 19-year mean tide at Benicia
- No duck club operation was simulated in Suisun Marsh
- Tom Paine Slough has culvert flow and siphons operating
- Benicia boundary salinity calculated using "Saldif4" program
- Maximum Clifton Court Forebay gate flow is 15,000 cfs
- East-side stream boundary salinity was constant 85 ppm TDS
- Sacramento River salinity at the Sacramento boundary was constant 100 ppm TDS

Results and Discussion

Time-series monthly average salinity for ten standard locations for water years 1987 through 1992 are shown in Figures 1 through 10 (the same output in tabular form is provided in Table 7 for the base and Table 8 for the draft Plan). Salinity output is shown in step form to emphasize that these are monthly average values resulting from steady, monthly average flow inputs. Half-month steps are shown in November, December, and January when the DCC is closed the first half and open the second half of the month. Each plot also indicates the months, or portion of months that the DCC is closed at the bottom of each plot. DCC closure in the base study only occurs for flood control when Sacramento River flow at Freeport is greater than 25,000 cfs.

Minimum, maximum, and average monthly flows for the same ten stations are presented in Tables 1, 2, and 3 for the base study, and Tables 4, 5, and 6 for the plan study. Sign conventions are relative to flow directions shown on the DWRDSM grid map shown in Figure 13. Again, the plan study shows half-month results for November, December, and January to show the effect DCC operation.

On the basis of the results shown in the plots and tables, several observations can be made:

Under the draft Plan hydrology, salinity at central delta stations Jersey Point, San Andreas, and Prisoners Point increases significantly in the November through January period when the DCC is closed the first half of the month. The increase persists into February when the DCC is closed continuously. The Terminous station shows similar increases but tends to lag by one month. The magnitude of delta outflow in the plan study is only slightly greater than the base in the November through January period (Figure 11A).

Outflow is 15 to 66% greater in the draft Plan over the February through June period (Figure 11B) resulting in generally lower spring and summer salinity at Jersey Point, San Andreas, and Prisoners Point. The increase in delta outflow is attributable mainly to reductions in project export. This lower salinity occurs despite continuous DCC closure between March and June under the draft Plan. Salinity at Terminous remains generally higher in the spring despite higher Plan flows suggesting that the DCC has relatively greater effect there.

Draft Plan agricultural water quality standards are satisfied within the bounds of model accuracy for central and north delta stations requested for analysis by the Board. Standards in the south delta are often exceeded however because DWRSIM was run using a 70 TAF cap on flows released from New Melones Reservoir to the San Joaquin River for water quality purposes. As a result, standard exceedences occur in dry and critical years during the April through August period when the standard is 0.7 mmhos/cm.

Emmaton responds to DCC closure opposite to Jersey Point during the October through December period. When the DCC closes, the water surface elevation at Emmaton increases marginally, the average flow increases 35 to 40% (Table 4), and salinity decreases between 10 and 15% (Figure 1). Jersey Point responds in the opposite direction (Figure 2). In contrast, higher winter and spring inflows cause Emmaton and Jersey Point salinity to respond in concert despite continuous closure of the DCC through June (Figures 1 and 2).

The highest annual salinity peaks at Emmaton under the draft Plan hydrology occur in October when delta outflow is reduced— mainly by reduced Sacramento River inflow— about 15% (Figure 1).

The salinity patterns at San Andreas landing and Prisoners Point tend to follow Jersey Point closely. However, there are greater incremental salinity increases in response to DCC closure (Figures 3 and 4).

Salinity changes in the south delta due to DCC closure are small— generally less than 5% at Buckley Cove (Figure 6), 3% at Brandt Bridge (Figure 9), 2% at Old River Near Tracy (Figure 7), and 2% at Old River at Middle River (Figure 8).

Since salinity is an inverse function of flow at Vernalis, the base versus draft Plan differences in salinity shown in Figure 10 directly reflect differences in flow. For example, November, December, and January flows are 0 to 14% less in the draft Plan resulting in 0 to 7% greater salinity. In general, the draft Plan generates higher flows and lower salinities in October, and April, May and June, while the base generates higher flow and lower salinity in November December and January (Figure 10).

Salinity at Brandt Bridge tends to follow the Vernalis pattern when the flow there is positive and/or when the Old River head barrier is in place in May (Figure 9). Buckley Cove generally has higher salinity in April despite higher San Joaquin River flow (Figure 6). This could reflect the influence of DCC closure. In May, when the Old River head barrier is installed, larger San Joaquin River flows and reduced pumping improve salinity at Brandt Bridge and Buckley Cove under the draft Plan.

Draft Plan salinity at the Old River near Tracy station is generally higher between August and January, and lower between March and July (Figure 7).

Memorandum

To : Francis Chung, Chief
Delta Modeling Section
Department of Water Resources
1416 Ninth Street
Sacramento, California 95814

Date: MAR 23 1995

Thomas Howard
Thomas Howard, Chief
Bay-Delta Unit
From : STATE WATER RESOURCES CONTROL BOARD
901 P Street Sacramento, CA 95814
Mail Code G-8
Subject: REQUEST FOR DWRDSM STUDIES

The purpose of this memorandum is to request the Department of Water Resources' (DWR) assistance in estimating water quality conditions in the Delta under the standards of the December 1994 draft Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (draft Plan).

On February 23, 1995, the State Water Resources Control Board conducted a hearing to solicit comments on the draft Plan and accompanying environmental report. Among the comments received from hearing participants are concerns regarding: (1) the potential impacts on water quality in the central Delta due to the Delta Cross Channel gate closure and increased San Joaquin River flow standards in the draft Plan; and (2) the water quality needs for irrigation and leaching in months not covered by the agricultural standards in the draft Plan.

Consequently, we are requesting that studies be conducted using the DWR Delta Simulation Model (DWRDSM) to estimate year-round water quality conditions in the Delta. A base case study and a draft Plan study should be conducted using outputs from DWRSIM studies 1995c6b-MONTERY-412 and 1995c6b-SWRCB-409m, respectively. These DWRSIM studies were conducted earlier by the DWR to estimate water supply impacts of the draft Plan. As necessary, assumptions used to model the base case and draft Plan DWRSIM operations should be used for the DWRDSM studies. Please include a discussion of these and other DWRDSM major assumptions and operational criteria, along with a brief model description, when transmitting the results of the studies.

For the base case and draft Plan DWRDSM studies, we are specifically interested in obtaining average monthly salinity (as electrical conductivity in millimhos per centimeter) and maximum, minimum, and average monthly flow (in cubic feet per second) for water years 1987 through 1992 at the following locations:

- (1) Sacramento River at Emmaton;
- (2) San Joaquin River at Jersey Point;
- (3) San Joaquin River at San Andreas Landing;
- (4) South Fork of the Mokelumne River at Terminus;

- (5) San Joaquin River at Prisoners Point;
- (6) San Joaquin River at Buckley Cove.
- (7) San Joaquin River at Brandt Bridge site;
- (8) Old River near Middle River;
- (9) Old River near Tracy Road Bridge; and
- (10) San Joaquin River at Vernalis;

Please provide the flow outputs in tabular forms, and the salinity outputs in both tabular and graphical forms. Tabular outputs should be in ASCII or other Lotus 1-2-3 compatible formats. We would appreciate receiving the requested information as soon as possible. Your staff has indicated that this would be no later than April 28, 1995.

Thank you for your consideration of this request. Please contact me at (916) 657-1873 if you have any questions.

WRINT DWR-134A

The Delta Simulation Model DWRDSM

Calibration and Verification

WRINT DWR-134B

Description of the DWR MDO Program

The Delta Simulation Model DWRDSM

Introduction

The objective of this exhibit is two-fold:

1. Present the latest version of the DWR Delta Simulation Model (DWRDSM). DWRDSM is a variant of the Fischer Delta Model version 7E (FDM) which incorporates significant enhancements to create an improved tool for analysis of structural and operational impacts on Delta hydrodynamics and water quality. A brief discussion of the major enhancements is included.
2. Present results of DWRDSM calibration and verification against Delta stage, flow and salinity data. These results are described in Appendix I, II and III as part of this exhibit.

Since the 1987 Water Rights Hearings when DWR presented the FDM as a modeling tool for analysis of impacts, DWR has engaged in an extensive effort to enhance the flexibility of the FDM so that analysis of complex and specific operational and structural modifications of the Delta could be appropriately modeled. Enhancements include improvements to simulation of agricultural drainage quality, improved description of Delta geometry, accurate simulation of gate structures, and mass tracking. The basic mathematical formulation of the FDM is unchanged. Calibration and verification of the DWRDSM have been incrementally improved as new data has become available and automatic calibration techniques have been developed.

1.

DWRDSM Enhancements

Agricultural Diversion and Drainage Modeling Enhancements

A significant enhancement to the FDM incorporated in the DWRDSM is the capability to dynamically simulate agricultural drainage quality. Field experience shows that agricultural drainage concentrations and time of peak concentration change significantly from one year to the next. Given the magnitude of Delta island drainage flows, an approach which captured the overall physics of salt exchange between irrigated land and Delta channels was required.

The mathematical approach to dynamic island drainage quality simulation considers actual irrigation water quantity and quality, soil moisture content, salt concentration, soil leaching efficiency, surface runoff, and soil type. A conceptual model of the dynamic salt balance process is shown in Figure 1. This enhancement is an improvement over the predetermined agricultural diversion and drainage used in the FDM. Details of the computational approach may be found in the Twelfth Annual Report to the State Water Resources Control Board, "Methodology for flow and Salinity Estimates in the Sacramento-San Joaquin Delta and San Francisco Bay," April 1991.

The agricultural drainage model was calibrated and verified against drainage quality field data for Grand Island using a leaching efficiency factor and a drainage activity factor. Data for water years 1985 and 1986 was used for calibration purposes, while data for water years 1987 and 1988 was used for model verification. The result of both calibration and verification are shown in Figure 2.

Expanded Description of Delta Diversion and Drainage Locations

A related enhancement which is critical to accurate agricultural drainage quality modeling was refinement of the mathematical description of Delta diversion and drainage locations. There are over 1,600 agricultural diversion points in the Delta. The FDM simulates these diversion points with only twelve aggregated model diversion points (Figure 3). This capability has been enhanced in DWRDSM by expanding to 253 diversion locations (Figure 4a). Similarly, 370 actual Delta island drainage locations are simulated by 23 locations in the FDM and is enhanced to 197 locations in the DWRDSM model (Figure 4b). The importance of this effort was to more realistically distribute the effects of local salt loads and flow due to agricultural drainage.

Enhancements To The Mathematical Description of Delta Geometry

Accurate simulation of Delta hydrodynamics and water quality require adequate mathematical descriptions of channel cross-section geometry. The DWRDSM model is applied principally for the purpose of comparing alternative design, location, or operation of proposed Delta improvements. Errors in the basic description of Delta geometry render inferences about the impact of proposed Delta facilities suspect. For example, investigations into the hydrodynamic and water quality impact of channel enlargements for improved conveyance rely on accurate base channel geometry descriptions. If base conditions are grossly inadequate or erroneous, there is little basis on which to provide meaningful impact assessments of proposed alternatives.

The limited resolution of the FDM geometry proved inadequate for the scale of impact analysis of interest to DWR planners. The geometric description of 1000 miles of Delta channels was therefore improved from 134 channels of uniform geometry in the FDM (Figure 3) to 496 channels in the DWRDSM (Figure 4c).

Enhancements For Simulation Of Gate Structures

The DWRDSM includes several enhancements that allow accurate modeling of existing and planned hydraulic structures in the Delta.

1. Suisun Marsh Salinity Control Gates

A gate was implemented in the DWRDSM to simulate the action of the Suisun Marsh Salinity Control Gates. Gate operation can be implemented according to hydraulic head gradient and velocity criteria, or it can be operated according to a set time schedule. The model also simulates the twenty minute opening and closing sequence of the prototype gate.

2. Clifton Court Forebay Gates

The FDM did not provide for simulation of a forebay gate at Clifton Court which in the prototype is opened generally on the ebb tide and closed on the flood. Accurate simulation of south Delta area water levels depend on forebay gate simulation. Additionally, the capability of simulating more than one Clifton Court Forebay (CCFB) gate in alternative locations has been added for future planning studies.

3. Automatic Adjustment of SWP Pumping Based On Minimum Water Levels in Clifton Court Forebay

Export rates from Banks Pumping Plant are constrained by minimum water levels in CCFB. This constraint will be approached when the SWP expands pumping capacity to 10,300 cfs. A routine was added to determine the total monthly volume of pumping with varying tides (spring and neap) or hydrology. As critical water levels are approached in CCFB, the DWRDSM begins an automatic iterative pumping reduction routine to maintain forebay water levels above the minimum.

4. Combined Weir-Pipe Hydraulic Structures

Existing and planned channel gate structures often have combination weir and culvert flow capability. The DWRDSM was enhanced to allow water to flow through both weirs and pipes. When water levels at the upstream of the combined structure drop below the crest of the weir, water flows solely through the pipes. Provisions were made to simulate open channel flow or submerged flow in all cases.

5. Weirs With Double Size Openings

Some Delta channel gates are designed to create a pool of water behind the gate for irrigation purposes when the flow reverses direction. Such a gate is proposed for Grant Line Canal where landward flow will pass through a 268 foot wide weir which reduces to 80 feet when the flow reverses to the seaward direction. The DWRDSM has been enhanced to read two different weir widths, one for each flow direction.

Tracer Modeling

A new system has been developed to track and account for all conservative constituent mass entering and leaving the Delta. Typically, transported materials are reported in concentration units which are appropriate when sources of solute are continuously available at the boundaries of the model (e.g. ocean or land derived salt). However, if the transport and fate of finite quantities of material which arrive in the Delta only infrequently and only for short durations are of interest, then it is useful to track the material in mass units. This is the case in modeling transport of fish eggs and larvae. It is now possible to inject a known number of particles (tracer) into any Delta location, and track the time fate of particles as they disperse in the Delta and move through one of several Delta sinks. At any time after the simulation begins, we track the percentage of the initial tracer release entrained in project pumping plants, Delta islands, out of the Delta into Suisun Bay, and remaining in Delta channels. This capability has been successfully applied to analysis of south Delta barrier impacts on Striped Bass egg and larvae transport. Figure 5 shows a typical time series result for a tracer injection on the Sacramento River at I street. Additional work is underway to develop a particle tracking capability which will account for variable settling, transverse shear, and mortality of biological constituents.

2.

CALIBRATION AND VERIFICATION OF DWRDSM

1990 Automatic Calibration of DWRDSM

A parameter estimation program based on a Newton gradient algorithm has been used for automatic calibration of DWRDSM. Model coefficients, Manning's n and dispersion coefficients, are systematically adjusted to minimize the sum of the squared differences between DWRDSM stage, and salinity, and actual stage and salinity. The procedure is extremely computer intensive since the model must be run once for each degree of freedom in the coefficient matrix.

DWRDSM was calibrated using field hydrodynamic and water quality data for selected months in 1988. Several verifications were made on months in 1988 and 1989. All calibration and verification periods are shown in Table 1. A complete record of this effort is reported in the Twelfth Annual Progress Report to the SWRCB, "Methodology for Flow and Salinity Estimates in the Sacramento-San Joaquin delta and Suisun Marsh," June, 1991.

1992 Calibration and Verification

A new calibration and verification is made when there are source code changes, if new data becomes available for comparison, or if improvement is needed for specific Delta locations. New flow data became available in late 1991. This provided an opportunity not only to incorporate this data, but to improve model predictions at important Delta locations.

Calibration Procedure

An iterative, stepwise calibration procedure was followed:

1. Steady-state runs were made using a dry year July hydrology and the previously calibrated and verified geometry. This provided the base condition for comparison with improved calibrations.
2. Changes were made to the base condition Manning's n or dispersion coefficients and a steady state simulation was performed using the same dry year July hydrology. Fifteen minute flow values were compared between the base and the modified version at various locations. This process may continue for several iterations until a satisfactory result is generated.
3. Daily average flow values for the intermediate calibration were compared at Middle River, Old River, Georgiana Slough, and the Cross Channel. Flow-splits were compared with field data for adequacy. If flow-splits were not adequate, then procedure 2 was repeated.
4. If flow-splits compared well to field data, a three year historical simulation was made. Table 2 lists the sources of all input data and assumptions. Three year historical simulations have been made using monthly average flow data for 1976-1978 and 1983-1985. Salinity output is plotted against observed USBR data (converted EC to TDS). Flow-split plots were

made using the regression equations developed in DAYFLOW. If the results were not considered adequate, the calibration coefficients are changed and the process was repeated.

Verification Process and Results

1. A one month verification run using the actual tide for May 1988 and actual Cross Channel and Clifton Court Forebay gate operation was also made. Prototype flow data is from USGS ADCP flow measurements made in 1988 and 1989. Results of this effort are organized as follows:

Appendix I: May 1988 Water Surface Stage Verification
Appendix II: May 1988 Flow Verification

Each Appendix begins with a location map which indicates the location of the referenced stations that follow.

2. When the results of the three year run are deemed satisfactory, a 24 year historical simulation is performed. Table 2 provides a complete listing of input data and assumptions used for the 24 year verification. Flow-split and salinity plots were made and compared with observed data. Appendix III exhibits the results of the 24-year salinity verification. Appendix III begins with a location map which indicates the referenced stations that follow.

DWRDSM Verification Via Flow-Split Analysis

Data for Delta channel flows is difficult and expensive to collect. As a result, there is little flow data available. Of the data that exists, some is of very high quality, while some must be considered anecdotal. An efficient way to take advantage of limited flow data is to focus on the distribution of Delta flows. The distribution concept is useful because it provides understanding of the complex nature of delta flows and the resulting distribution of salinity.

The approach was to focus on three important flow-split locations in the Delta:

1. Delta Cross-Transfer Flow - determined in several field studies to be as follows:

Cross Transfer Q (both gates open)	$Q = 0.293 * \text{Sac } Q + 2090 \text{ cfs}$
Cross-Channel Q (both gates open)	$Q = 0.190 * \text{Sac } Q + 1205 \text{ cfs}$
Georgiana Slough (both gates open)	$Q = 0.103 * \text{Sac } Q + 885 \text{ cfs}$
Georgiana Slough (both gates closed)	$Q = 0.133 * \text{Sac } Q + 829 \text{ cfs}$

2. North Fork vs South Fork Mokelumne River - determined by field studies reported in DWR Bulletin 76. Based on these studies, the target net flow relation is 80% North Fork, 20% South Fork.

3. Old River vs Middle River - measured at USGS AVM sites at Bacon Island. Based on this data, the target net flow relation is 50% Old River, 50% Middle River adjacent to Bacon Island.

The locations of Delta flow split analysis sites is shown in Figure 6. Six steady-state DWRDSM and FDM model runs were made using a wide range of Delta

inflows, channel depletions and export amounts. Results of the analysis follow:

1. Delta Cross-Transfer Flow

Figure 7 shows the monthly average flow from DAYFLOW data verification of DWRDSM. The model tracks all four empirical relations well.

2. North Fork vs South Fork Mokelumne River

Figure 8 shows the Bulletin 76 80%-20% flow split. The DWRDSM result indicates that there is a fairly robust relationship over a range of hydrologies.

3. Old River vs Middle River

New data at the USGS AVM sites adjacent to Bacon Island have recently become available. On four occasions in 1988 and 1989 the USGS employed their hull-mounted acoustic doppler current profiler (ADCP) capability to obtain data with which to calibrate their permanent AVM's. This data represents an effectively simultaneous measurement of flows at the Old and Middle River AVM sites. The DWR used the DAYFLOW hydrology for each of the four occasions to run the DWRDSM model for verification against these data. The hydrologies are show in Table 3 and the results of the verification are shown in Figure 9. Net flow results for the 50% Old River, 50% Middle River flow-split are shown in Figure 10.

Table 1
Calibration and Verification Periods
Hydrodynamics

Period	Description
May 1988	Delta and Suisun Marsh stage calibration Delta stage, flow, and velocity verification
December 1988	Delta and Suisun Marsh stage verification Suisun Marsh Salinity Control Gate stage, flow, and velocity verification Montezuma-Nurse Slough flow verification
February 1989	Delta and Suisun Marsh stage verification SMSCG stage, flow, and velocity verification Montezuma-Cutoff Slough flow verification
April 1989	Delta and Suisun Marsh stage verification SMSCG stage, flow, and velocity verification Montezuma-Hunters Cut flow verification
December 1989	Delta and Suisun Marsh stage verification SMSCG calibration

Quality

Period	Description
January-April 1988	Delta and Suisun Marsh warmup
May-August 1988	Delta and Suisun Marsh calibration
September-October 1988	Delta and Suisun Marsh verification, SMSCG not operating
November-December 1988	Delta and Suisun Marsh verification, SMSCG operating

Table 2 - Input For Long Term Historical Verification

Salinities (TDS):

	DWRDSM Input Data
Seaward Boundary	Saldif generated or Observed Data (EC to TDS converted)
Sacramento	100 ppm TDS or observed data (EC to TDS converted)
Yolo	100 ppm TDS
Eastside	85 ppm TDS
SJR (Irrigation Season)	$\ln(\text{ec})=10.080014-0.48230*\log(Q)$, $\text{tds}(\text{ppm})=0.583793*\text{ec}-2.67$
(Non Irrigation Season)	or observed data (EC to TDS converted) same equations as above or observed data
Agricultural Returns	Return Quality is a function of diversion and soil salinity.

Hydrodynamics:

	DWRDSM Input Data
Seaward Boundary	19 year mean tide
Rimflows	Use daily flows from Dayflow and convert them to monthly average flows for DWRSAL input and "tidal" monthly average flows for DWRFLO input. Separate flows of Eastside streams on a percentage basis.
Exports	CCFB gate is always open. "Tidal" monthly average pumping is used
Consumptive Use	Values calculated using variable evapotranspiration and critical and non critical land use for 142 areas.

Geometry:

	DWRDSM Input Data
Delta Cross Channel	Close gates when DOI is > 12000 cfs. Close gates when Sacramento flow > 27,000 cfs. (Handled in DWRFLO input file.)
Barriers	Currently incorporates 20 different barrier configurations
Floods	Simulates the 1972 and 1983 summer flooding.

Description of the DWR MDO Program

The Minimum Delta Outflow (MDO) computer program computes minimum Delta outflow requirements due to various water quality and flow standards in the Delta, and is run as a separate, adjunct program to the DWRSIM program.

MDO may be discussed in terms of two independent parts. The first part consists of those standards where salinity concentrations are generally a function of net Delta outflow (NDO) only, and not a function of export, for instance, a water quality standard at Emmaton. The second part of MDO are those standards which are considered to vary with net export as well as NDO; only Jersey Point, Rock Slough, and Clifton Court Forebay fall into this category. Contra Costa Water District Pumping #1 and Rock Slough are assumed to be the same by the MDO routine, even though in reality local drainage effects the Pumping Plant #1 quality. This second part of MDO is often referred to as the "Carriage Water" routine.

MDO produces two main tables, corresponding to the two different routines, for input to DWRSIM. The first table contains estimates of minimum required NDO by month and year over the desired study period (usually from 1922 to 1991). Water quality standards in the Delta are converted to NDO values by means of empirical relationships, while standards already in terms of NDO are used directly.

The second table consists of NDO estimates for the five different water year types, as a function of month and net export level. The net export is project pumping by Contra Costa, the SWP, and the Central Valley Project, minus San Joaquin and Eastside stream inflows.

Most of the second part of MDO was described by the DWR in Phase I testimony by Mike Ford, July 21, 1987, Volume VI, pp. 63-71, and in exhibits DWR-260 through DWR-264. That testimony described the method used to calculate the NDO required because of water quality standards at Rock Slough. In addition to that standard, there are standards at Clifton Court Forebay and at Jersey Point that are also considered to be a function of exports.

For Clifton Court Forebay, the standard is converted to a Rock Slough standard by a linear equation: 100 ppm Cl at Contra Costa Canal equals 70 ppm Cl at Clifton Court, and 250 ppm Cl at CCC equals 140 ppm Cl at Clifton Court. The Jersey Point standard is converted to a net Delta outflow requirement by means of a bilinear interpolation between both net export and water quality.

For each table, the NDO is computed for every standard in that table; whichever is highest controls for that day. The daily NDO requirements are averaged for each month, and that number output in the table. A minimum daily outflow of 2500 cfs is output if all the other standards produce a required outflow of less than that.

Output from both portions of the MDO program are read by DWRSIM as input tables. In any given month and year, DWRSIM uses data from the first table "as-is", since it is already listed by month and year. DWRSIM uses information from the second table (the "carriage water" table) by first determining the proper year type, then interpolating between net export levels to find the minimum required net Delta outflow. The minimum required net Delta outflow for the month is taken as the higher of either the first or second table. At that point, DWRSIM may modify its releases and/or exports so as to satisfy minimum outflow requirements and its internal rule curves. If exports are modified, then some iteration is required to arrive at a final Delta balance, because carriage water requirements are a function of export.
