The Lower Klamath Project License Surrender Final Environmental Impact Report is being made available to the public in accordance with the California Environmental Quality Act.

Visit Lower Klamath Project License Surrender Project Web Site (**https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/lower_klamath_ferc14803.shtml**) where you can view and download an electronic copy of the Final EIR.

To receive future email notifications regarding the Lower Klamath Project, please subscribe to the "Lower Klamath Project License Surrender" email subscription list under "Water Rights".

Instructions on how to sign up for the State Water Board's Email Subscription List are outlined below:

- Visit the State Water Board's email subscription website: **http://www.waterboards.ca.gov/resources/email_subscriptions/swrcb_subscribe.shtml#rights**
- Provide your name and email in the required fields.
- In the categories below the email and name fields, select "Water Rights," then "Lower Klamath Project License Surrender."
- Click on the "Subscribe" button.
- An email will be sent to you. You must respond to the email message(s) to confirm your membership on the selected list(s).

1 INTRODUCTION

The Klamath River Renewal Corporation (KRRC) has applied to the Federal Energy Regulatory Commission (FERC) to decommission and remove the four Lower Klamath Project dams and associated facilities to create a free-flowing Klamath River and provide for volitional fish passage in the Klamath River.

The State Water Resources Control Board (State Water Board) is the Lead Agency responsible for complying with the California Environmental Quality Act (CEQA)[1] for the Lower Klamath Project License Surrender (Proposed Project). This final Lower Klamath Project Environmental Impact Report (Final EIR) has been prepared in conformance with CEQA. This Final EIR encompasses three numbered volumes and recirculated portions of the Draft EIR. Volume I and Volume II of the EIR were issued on December 27, 2018 as the Draft EIR and include the following sections:

Volume I

- Section 1 − Introduction
- Section 2 − Project Description
- Section 3 − Environmental Setting, Potential Impacts, and Mitigation Measures
- Section 4 − Alternatives
- Section 5 − Other CEQA Considerations

Volume II

- Technical Appendices Appendix A through Appendix X

Recirculated portions of the Draft EIR were issued on December 21, 2019, and replace the air quality, greenhouse gas emissions, and energy portions of Draft EIR Volume I and Volume II.

Volume III of the EIR includes public comments on Draft EIR Volume I and Volume II and the recirculated portions of the Draft EIR; responses to public comments; and revisions to the Draft EIR and recirculated portions to address public comments. Revisions to Draft EIR Volume I and Volume II are presented in Volume III Attachment 1, consistent with CEQA Guidelines section 15088 (d). Revisions to recirculated portions of the Draft EIR are presented in Volume III Attachment 2, consistent with CEQA Guidelines section 15088 (d).

[1] Public Resources Code, sections 21000 et seq.

All three numbered volumes of the EIR and the recirculated portions of the Draft EIR can be found on the Lower Klamath Project License Surrender Project Web Site (https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/low er_klamath_ferc14803.shtml).

2 PUBLIC COMMENTS AND RESPONSES

2.1 Summary of Written and Oral Comments

The Lower Klamath Project Draft EIR, Volumes I and II, was released on December 27, 2018, for public review and comment. All forms of written comments were accepted, including emails and letters. In addition, the State Water Board conducted four public meetings in Northern California in February 2019, which allowed the public the opportunity to provide oral comments on the Draft EIR, Volumes I and II. All comments on Draft EIR, Volumes I and II that were received by February 26, 2019 are summarized and responded to in Section 2.3 and Section 2.4. All comments on the Draft EIR were given full consideration.

The air quality, greenhouse gas emissions, and energy portions of the Draft EIR, Volumes I and II were recirculated on December 21, 2019. All comments on the recirculated portions of the Draft EIR were received by February 6, 2020 and all comments were given full consideration. All forms of written comments were accepted during the comment period on the recirculated portions of the Draft EIR, including emails and letters. Comments that address the recirculated portions of the Draft EIR are responded to in Section 2.5.

A total of 441 comment letters and oral comments from approximately 108 commenters were received on the Draft EIR, Volumes I and II and recirculated portions of the Draft EIR from state and local agencies as well as Native American Tribes, organizations, and individuals.

Table 2-1. Summary of Written Comments on the Lower Klamath Project Draft EIR, Volumes I and II Organized by Commenter Affiliation.

[1] Comments were coded in the order that they were received and thus the commenter identification codes may skip numbers in this table. Please refer to Table 2-4 for additional commenter identification codes associated with written comments on recirculated portions of the Draft EIR.

2.2 Master Responses

Certain topics associated with the Lower Klamath Project EIR received numerous public comments, or received multiple comments that depend on shared background information or analysis. For these topics, the State Water Board has developed a set of master responses to reduce the amount of repetition necessary in Volume III, to provide useful context to common comments, and to ensure that responses to public comments are consistent across a large number of comments. As appropriate, the responses to comments on the Draft EIR and the recirculated portions of the Draft EIR include a reference to the master responses using a short code. The master responses short codes and titles are presented below, by topic area.

2.2.1 General Master Responses

GEN-1 Dam Removal Support and Opposition

The State Water Board acknowledges that there are many people who support dam removal and there are many people who support the dams remaining in place. Although statements expressing a project or policy preference are noted, a response is not required under CEQA in the absence of a comment on a significant environmental issue (e.g., the identification and analysis of potential significant impacts of the Lower Klamath Project on the environment, the identification of alternatives to the Lower Klamath Project, or the manner in which significant impacts can be mitigated or avoided) (CEQA Guidelines sections 15088(a), 21002.1 (a)). The EIR acknowledges in Volume I Table ES-2 on page ES-23 and in Volume I Section 2 *Proposed Project* (page 2-21) that during the Siskiyou County Advisory Election Vote on November 2, 2010 (Measure G), approximately 79 percent of voters expressed their opinion and voted “No” to dam removal, while 22 percent voted “Yes”. It further discusses that a range of parties have entered into an agreement predicated on dam removal.

GEN-2 Comment Included as Part of the Record

Many comments received by the State Water Board expressed personal opinions, histories, or experiences with the Klamath River Basin and/or Lower Klamath Project dams and associated facilities, including the reservoirs. A response to these comments is not required under CEQA because these comments do not raise a significant environmental issue (CEQA Guidelines, section 15088). Regardless, these comments are included as part of the record and will be considered by the State Water Board before certifying the EIR (CEQA Guidelines section 15090).

Further, the Lower Klamath Project EIR presents a range of reasonable alternatives to the Proposed Project. Volume I Section 4.1 *Alternatives Selection/Overview* (pages 4-1 to 4-15) discusses 17 potential alternatives in relation to the Proposed Project’s underlying purpose and objectives, six of which are examined in detail. Of these six alternatives, two involve removal of all four

Lower Klamath Project dams, and four involve two or three dams remaining in place. Potential impacts and beneficial effects are identified for each of these alternatives in the EIR and each will be fully considered by the State Water Board before certifying the EIR (CEQA Guidelines section 15090).

2.2.2 CEQA Requirements Master Responses

CEQ-1 Coordination Between CEQA and NEPA Lead Agencies

Some comments assert that the EIR is not in compliance with California Environmental Quality Act (CEQA) Guidelines section 15222 or is otherwise deficient in its coordination with federal environmental review by the Federal Energy Regulatory Commission (FERC), under the National Environmental Policy Act (NEPA). These comments do not raise a significant environmental issue requiring response under CEQA Guidelines section 15088. However, the State Water Resources Control Board (State Water Board) is providing additional information on the relationship between NEPA and CEQA in a FERC hydroelectric relicensing context.

CEQA Guidelines, Article 14, sections 15220, et seq., address ways to avoid unnecessarily duplicating efforts for projects that require review under both NEPA and CEQA. In this case, the Klamath River Renewal Corporation (KRRC) filed a water quality certification application with the State Water Board prior to the decision by FERC to start review under the National Environmental Policy Act. When, as in this case, CEQA review occurs before NEPA review ends, Article 14 recommends preparing a joint NEPA/CEQA document and combining environmental review procedures – but Article 14 also acknowledges that this may not be possible. (See Cal. Code Regs., tit. 14, §§ 15222, 15226, 15228.) FERC's rules include a broad "ex parte communication" ban that prevents FERC staff from talking about the substance of a license application except with notice on a formal record. FERC interprets these rules to preclude communications required for preparation of joint documents if the agency they are communicating with is a party to the licensing proceeding. See Statement of Administrative Policy on Separation of Functions (2002) 101 FERC 61, 340; FERC Order 607-A (2000), FERC Order 607 (1999). The State Water Board is a party to FERC licensing proceedings in order to be able to protect the state's interest in water quality. The State Water Board has developed a Memorandum of Understanding with FERC to reduce redundancy and delays in environmental review of hydroelectric licensing projects prior to application submittal and FERC's implementation of an ex parte communication bar. However, in light of the communications bar currently in place, the coordination required for a joint document is not possible.

The State Water Board provided FERC notice of its intent to prepare a CEQA document and the notice of preparation (NOP). Additionally, the State Water Board has provided updates on the CEQA process at semi-annual meetings with FERC. FERC has elected not to provide comments on the document. However, the State Water Board anticipates that the information developed in the EIR will be helpful in the NEPA process for the Proposed Project in light of the similarity between the two environmental review statutes, and because the EIR was informed by two previous NEPA documents (the 2007 FERC EIS for relicensing of the Klamath Hydroelectric Project and the 2012 Klamath Hydropower Settlement Agreement Environmental Impact Statement/Environmental Impact Report (KHSA EIS/EIR) for Klamath facilities removal).

CEQ-2 Federal Power Act Preemption of State and Local Authority

A number of comments raise concerns or questions about how the EIR addresses the preemption of state and local authority under the Federal Power Act.

Some comments suggest that the State Water Board should treat certain state or local agencies as responsible agencies and that it is premature or otherwise inappropriate to consider other state or local agencies' authority preempted. Several comments raise concern with the EIR's discussion of Recommended Measures and the feasibility of mitigation measures that are outside of the State Water Board's water quality certification authority. Some claim that the EIR's Recommended Measures (which the EIR analyzes but does not describe as feasible mitigation measures due to Federal Power Act preemption) are actually feasible despite preemption. For example, some comments state that the EIR must consider Recommended Measures feasible due to state or local authority or because it is reasonable to expect the Federal Energy Regulatory Commission (FERC) or another federal agency to enforce them. Similarly, some commenters have suggested that some Recommended Measures are feasible because they may be required in federal permits, particularly under the Endangered Species Act (ESA).

Other comments state that some Mitigation Measures described in the EIR are not actually feasible because they are outside of State Water Board authority. This Master Response first discusses the scope of Federal Power Act preemption. It then discusses the how the EIR applied that principle to responsible agencies and to Recommended Measures and Mitigation Measures.

Federal Power Act "Field Preemption"

As explained in Volume I Section 2.8 *Intended Uses of the EIR* (pages 2-110 and 2-111), the Federal Power Act gives FERC broad authority to regulate power production facilities in a manner that FERC "occupies the field" of power regulation. This means that there is no authority for state- or local-level regulation except where there is an exception to the general rule of preemption (see for example Volume I Section 2.8, page 2-110). Both the United States Supreme Court and the Ninth Circuit Court of Appeals have clarified the broad preemptive reach of the Federal Power Act vis-à-vis state authority in hydropower licensing decisions, emphasizing that elimination of state authority is part of implementing Congress' comprehensive plan for power development.

California v. FERC (1990) 495 U.S. 490; *First Iowa Coop. v Power Comm'n* (1946) 328 U.S. 152; *Sales-Hydro v. Maughn* (9th Cir. 1993) 985 F.2d 451. Similarly, the California Court of Appeals for the Third District has acknowledged the broad preemptive reach of the Federal Power Act. *Karuk Tribe of Northern California v. California Regional Water Quality Control Board, North Coast Region* (2010) 183 Cal.App.4th 330.

The Federal Power Act's "field preemption" applies to hydropower licensing decisions – such as the KRRC's decommissioning application – unless there is an exception to the preemption. One exception from the Federal Power Act's "field preemption" is state water quality certification under Clean Water Act Section 401. *PUD No. 1 of Jefferson Co. v. Washington Department of Ecology* (1994) 511 U.S. 700. While the state's water quality authority is broad, it does not extend beyond water quality-related matters. *Id.* The State Water Board is not aware of any other exceptions to preemption that would apply here, as the facilities are privately-owned, single-use hydropower facilities.

Effect of Federal Power Act preemption on responsible agencies

Under CEQA, a lead agency is the public agency with the "principal responsibility for carrying out or approving" a project. Pub. Resc. Code, § 21067. A responsible agency under CEQA is a state or local agency, other than the lead agency under CEQA, that has "responsibility for carrying out or approving a project." Pub. Resc. Code, § 21069. Thus, a responsible agency must have responsibility for or authority over the project. As discussed above, the Federal Power Act preempts the field of hydropower regulation, leaving no room for state or local agencies to exert authority. As noted, the applicable exception to this broad preemption of state authority over the Proposed Project is water quality certification under Clean Water Act Section 401. The State Water Board is the California agency charged with implementing Section 401 of the Clean Water Act for FERC-licensed hydroelectric facilities. Since the exception to FERC preemption under Clean Water Act Section 401 is only for water quality certification, the authority of other agencies remains preempted, and other agencies cannot have the responsibility over the project that would make them "responsible agencies" under CEQA.

Regardless of preemption, the State Water Board has noticed the State Clearinghouse for distribution and notified state and local agencies in the same manner as if state authority were not preempted. (See CEQA Guidelines, §§ 15082, 15085, 15086.) The State Water Board has sought agency input through an expansive scoping, comment and engagement process that provides the same opportunities for state and local input to the analysis as if agencies were able to exert authority over the project. This consultation with state and local agencies allows the document to be informed by the wealth of expertise in state and local agencies that exists regardless of Federal Power Act preemption, and fulfills the purpose of responsible agency consultation, even though it is not foreseeable that other agencies will need to rely on the document for their own

discretionary actions. State and local agencies had the opportunity to participate – and have engaged –in the CEQA process in the same manner as responsible agencies, including comments and input on the scope of review, materials for consideration, potential impacts, potential mitigation measures, and significance of potential environmental impacts. The State Water Board expects that this information will be valuable not only to the State Water Board, but also to the KRRC in implementation and to FERC in its license surrender process.
As noted by commenters, FERC has a policy encouraging licensees to adopt "good neighbor" agreements regarding power facilities that can provide an ability for licensees to engage with local authorities and comply with local standards and regulations. However, such "good neighbor" agreements do not contract the scope of preemption or provide state agencies with permitting authority and its accompanying requirement to comply with CEQA as either a lead or a responsible agency.

Additionally, commenters have raised two examples of dam removal proceedings in which FERC has required licensees to obtain limited local permits. In both instances, those permits were required as part of water quality certification. *Arizona Public Service Co*., 109 FERC 61036, 61149 (2004); *Wisconsin Electric Power Co.* 94 FERC 61038; see also *Wisconsin Electric Power Co*. 96 FERC 61009, pp. 5-6 [clarifying that the requirement to obtain a permit from the Land and Water Management Division of the Michigan Department of Environmental Quality and a county soil erosion and sedimentation control permit were 401 water quality certification requirements]. Siskiyou County presented these examples of "FERC requiring compliance with all local permitting in other dam removal contexts." However, these examples do not require compliance with all local permitting – rather, the decisions incorporate the terms of water quality certification. The cases cited do not indicate that FERC has either the authority or the intention to allow state or local agencies to exert control over their license outside of the exception to preemption in Clean Water Act Section 401.

Effect of Federal Power Act preemption on mitigation measures
CEQA requires that mitigation measures be "fully enforceable through permit conditions, agreements, or other legally-binding instruments." CEQA Guidelines Section 15126.4(a)(2). As discussed above, because of preemption under the Federal Power Act, the only state or local permit that will be issued is for state water quality certification.

Broad state substantive requirements for water-quality-related impacts may be incorporated into the water quality certification. *PUD No. 1 of Jefferson Co. v. Washington Department of Ecology* (1994) 511 U.S. 700. Therefore, the CEQA document can evaluate measures to mitigate water-quality-related impacts as enforceable mitigation measures. For example, the state requirements to consult with trustee agencies of, and mitigate impacts to, the aquatic ecosystem can be incorporated into the water quality certification. However, for the EIR to evaluate a mitigation measure outside of the State Water Board's water quality

certification authority, it must be otherwise enforceable, i.e., the subject of a federal permit, an agreement or other legally-binding instrument.
Commenters refer to several state environmental and health protection laws as potential sources of authority for mitigation measures, and request that the EIR disclose these measures and these authorities, or reconsider recommended measures as enforceable mitigation measures in light of these authorities. However, application of state laws unrelated to water quality and outside the parameters of water quality certification is preempted.

Recommended Measures
The State Water Board understands that KRRC is currently in discussions with various state and local agencies to develop agreements regarding other resource protection measures (see, e.g. KRRC Comment Letter ORG47-2). However, because these measures are not yet final, it would be premature to consider these to be enforceable mitigation measures. Doing so would mislead readers as to the finality and enforceability of potential steps to protect the environment. Instead, the EIR discloses and evaluates Recommended Measures in order to provide decisionmakers and the public with information on measures that – while not currently enforceable – have potential to be implemented. By describing Recommended Measures, the EIR discloses both the availability of measures to protect the environment and the lack of an enforcement mechanism for such measures. This provides information regarding available steps to protect the environment that could be developed (e.g., through enforceable good neighbor agreements), even though it is currently not possible to rely on those measures in assessing the impacts of the Proposed Project. Generally, the Recommended Measures stem from some mixture of recommendations from agencies with specific expertise, from submittals by the applicant, or from common industry practice. In addition to providing information for "good neighbor" agreement efforts, disclosure and analysis of these measures can serve as a recommendation for adoption by FERC or the KRRC outside of a formal agreement with a state or local agency.

Federal Authorities: Federal Power Act, Endangered Species Act, and Bald and Golden Eagle Protection Act
Some comments recommend analyzing all Recommended Measures as enforceable under FERC authority. Some comments also recommend analyzing new measures that could similarly be enforceable under the FERC license. As noted above, under the Federal Power Act, FERC is granted broad authority over all aspects of the Proposed Project and has the authority to require mitigation measures. FERC has not, however, indicated which mitigation measures it intends to require, and is not bound to mitigate effects to a level of less than significant by state standards. Instead, FERC applies a "public interest" standard to license proceedings requesting surrender, providing for safety, disposition of facilities, and a level of environmental protection it considers appropriate. While FERC does allow third parties to comment on its license surrender proceedings, there is no reason to believe that an ability to comment provides a reasonable

basis on which to find that a recommended term will be adopted and thereby become enforceable. Therefore, the existence of FERC authority alone is insufficient certainty for enforcement of a mitigation measure, or for presenting a recommended measure as an enforceable mitigation measure.

In addition to FERC's broad authority, the United States Fish and Wildlife Service (USFWS) conducts Endangered Species Act permitting for hydropower projects.[2] This Endangered Species Act permitting authority includes permitting for terrestrial species not covered under the State Water Board's water quality certification authority. Measures that the USFWS includes in permitting are, therefore, enforceable even without a nexus to water quality. There are indications that USFWS Endangered Species Act permits would impose many of the measures described in Volume I of the EIR as Recommended Terrestrial Measures 1 through 12, because, as noted in the EIR, most of these measures were developed in consultation with KRRC, CDFW, USFWS, and other species experts, and also because the measures largely reflect generally-accepted best practices. Therefore, for species listed under the federal Endangered Species Act, the EIR has been revised to add new Mitigation Measures TER-6 and TER-7 requiring the KRRC to consult with the USFWS and/or CDFW, regarding impacts to listed species, and to obtain necessary permits to protect these species. However, the USFWS Endangered Species Act review and permitting is only for federally protected species, while the recommended terrestrial measures address potential impacts to a broader range sensitive species including species listed at under the California Endangered Species Act and other federal and state programs to identify species requiring special protections. Thus, even with the additional protection of federal permit conditions, the types of actions in the recommended measures are not enforceable for all sensitive species. Therefore, the EIR continues to disclose and evaluate recommended measures. Additionally, USFWS issues any necessary permits under the Bald and Golden Eagle Protection Act for FERC orders on hydropower projects. As Recommended Terrestrial Measure 11 (addressing specific measures for the protection of Bald and Golden Eagles) is within USFWS's permitting authority and was developed in consultation with the USFWS, there is sufficient certainty

[2] As noted by commenters discussing preemption, the National Marine Fisheries Service (NMFS) also conducts federal Endangered Species Act permitting. However, as NMFS' permitting is specific to aquatic species, and impacts to aquatic species are already considered to be enforceable (via the water quality certification) and as NMFS is a federal agency (and therefore not a CEQA responsible agency), NMFS authority does not require further discussion in this comment response. Similarly, some comments discussing preemption have specifically noted the Army Corps of Engineers' authority over projects affecting navigable waterways. As the EIR already considers protection of waterways to be enforceable (via the water quality certification) and as the Army Corps of Engineers is a federal agency (and therefore not a CEQA responsible agency), these comments are not further addressed here.

that the USFWS will require the measure or equally protective conditions. It is also worth noting that a substantial portion of bald eagles' diet consist of fish (Knight et al. 1990). California's wildlife beneficial use[3] includes protecting water quality impacts to bald eagles, and such protections can be included in a water quality certification. This provides an additional layer of certainty for mitigation of potential impacts to bald eagles. Recommended Measure 11 has been revised to be a Mitigation Measure and is updated in Volume III Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities – Recommended Terrestrial Measure 11 – Bald and Golden Eagle*. As disclosed in Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* (pages 3-546 and 3-547), implementation of the actions described in Recommended Terrestrial Measure 11, now Mitigation Measure TER-7, would reduce the potential impact to bald and golden eagles to no significant impact with mitigation. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities– Recommended Terrestrial Measure 11 – Bald and Golden Eagle* for revisions to Mitigation Measure TER-7.

The grey wolf, a federally endangered species, is protected under the USFWS Endangered Species Act. Because Recommended Terrestrial Measure 8 addresses specific measures for the protection of gray wolves, USFWS was consulted and confirmed that these measures are generally as accepted best practices (Heather Beeler, USFWS, pers. comm, September 2019). Recommended Terrestrial Measure 8 has been revised to be a Mitigation Measure and is updated in Volume III Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities*. The measure, at the request of the USFWS (Heather Beeler, USFWS, pers. comm, September 2019), includes coordination with CDFW biologists and accessing the CDFW gray wolf activity map to inform potential overlap between the wolf and the LKP to evaluate further measures to prevent impacts. Implementation of the actions described in Recommended Terrestrial Measure 8, now Mitigation Measure TER-6, would reduce the potential impact to gray wolf to no significant impact with mitigation. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for revisions to Mitigation Measure TER-6.

[3] As discussed in Volume I, Section 3.2.3 *Water Quality – Significance Criteria*, and in Table 3.2-2, California water quality standards include the designation of the beneficial uses of the state's waters. Use of the waters by wildlife is one such beneficial use.

Other Recommended or Mitigation Measures

PacifiCorp has suggested that Tribal Cultural Resource Mitigation Measures are not enforceable because they are outside the scope of the State Water Board's water quality certification authority. The KRRC participated in tribal consultation on development of Tribal Cultural Resource Mitigation Measures and has agreed to implement the measures. Additionally, the KRRC has proposed these measures as part of the FERC licensing proceeding. Thus, these measures are enforceable under the requirements of CEQA Guidelines Section 15126.4 (a)(2), because the KRRC has agreed to them.

PacifiCorp has further suggested that the aspects of Mitigation Measure GEO-1 that specify measures to avoid or minimize the impacts of slope instability on structures, and roads are outside of water quality certification authority, even though aspects of the mitigation measure related to slope stabilization to avoid and minimize sediment discharges to water are within such authority. Please note that Mitigation Measure GEO-1 has undergone minor modifications. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 for the final Mitigation Measure GEO-1. Mitigation Measure GEO-1 addresses the potential for mass wasting (e.g., shallow and deep-seated landsliding), and it requires monitoring for slope instability and measures to address slope instability, including a specific requirement to address slope instability that affects structures and roads. The specific requirements to address instability associated with structures and roads are appropriate to include in a water quality certification because, should mass wasting at the reservoir rim occur during drawdown, it would be important to undertake the actions included Mitigation Measure GEO-1 to avoid and reduce future sediment discharges, and because efforts to protect, repair, or replace the associated structures and/or roads can result in construction-related water quality impacts. Additionally, the KRRC has agreed to implement the mitigation measure. Therefore, the measure is appropriate as a mitigation measure both because it is enforceable in the water quality certification and because KRRC has agreed to implement the measure (please refer to Volume III Section 2.3.4 comment ORG47-51 and L. Zagar, Perkins Coie as KRRC representative, pers. comm., March 2020).

Some commenters asserted that Recommended Measure TR-1, which involved preparation of a Traffic Management Plan (TMP) to address potentially significant traffic impacts from construction activities related to dam removal, should be made an enforceable condition of the water quality certification. The Draft Environmental Impact Report (Draft EIR) included TR-1 among its Recommended Measures because at the time the Draft EIR was being prepared KRRC had not yet committed to preparing a TMP that met clearly discernable standards. On December 3, 2019, KRRC submitted a revised water quality certification application in which it committed to preparing a TMP that adhered to specific state and federal requirements, including the Caltrans California Manual on Uniform Traffic Control Devices (MUTCD), Caltrans Traffic Management Plan

Guidelines, Oregon Department of Transportation (ODOT) Supplement to the MUTCD, ODOT Traffic Control Plans Design Manual, ODOT TMP Project Level Guidance Manual, Caltrans and ODOT's respective Highway Design Manuals, among others. These recent commitments by KRRC in its revised water quality certification application would render TR-1 an enforceable term of the water quality certification. It is therefore appropriate to reclassify TR-1 as a mitigation measure.

The text of the Final EIR has therefore been revised to reflect that Recommended Measure TR-1 is now Mitigation Measure TR-1.
Note that this change results in corresponding revisions to multiple findings regarding the significance of potential traffic impacts. The Draft EIR found that implementation of Recommended Measure TR-1 would reduce Potential Impacts 3.22-1 through 3.22-5 to a less than significant level, but nonetheless concluded that these impacts would be significant and unavoidable based on the fact that Recommended Measure TR-1 was not within the State Water Board's enforcement authority. Because preparation of a TMP in accordance with Mitigation Measure TR-1 now would be an enforceable term in the water quality certification, Potential Impact 3.17-1, Potential Impact 3.21-7, and Potential Impacts 3.22-1 through 3.22-5 have been revised to reflect that implementation of Mitigation Measure TR-1 would reduce these impacts to a less than significant level.

CEQ-3 Definition of 'Substantial' As Used in EIR Significance Criteria

Some comments assert that the EIR should uniformly define the term 'substantial' as used in the significance criteria identified for each environmental resource area analyzed in the EIR. EIRs identify and focus on the significant environmental effects of the proposed project (CEQA Guidelines section 15126.2). A "significant effect on the environment" means a "substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project, including land, air, water, minerals, flora, fauna, ambient noise, and objects of historic or aesthetic significance" (CEQA Guidelines section 15382). CEQA does not require an EIR to deviate from the common English language usage of the word 'substantial' to mean of considerable importance, size, number, and/or amount (Dictionary.com 2019, Lexico 2019); considerable in quantity, significantly great; being largely but not wholly that which is specified (Merriam-Webster 2019). For the analysis of potential impacts in the Lower Klamath Project EIR, significance criteria are identified for each environmental resource area, as described in Volume I Section 3.1 *Introduction* (pages 3-1 and 3-2) and presented in each of the 22 environmental resource areas analyzed in the EIR and the cumulative effects analysis. To the extent that identified significance criteria can be expressed quantitatively, either the 'significance criteria' subsection for each resource area and the analysis of cumulative effects does so explicitly, or the details are provided in the 'impact analysis approach' subsection that appears immediately following the identification of significance criteria. If it is not possible to identify defensible quantitative significance criteria, or if such criteria would otherwise be inappropriate for a particular analysis, then qualitative thresholds of significance are presented and discussed instead. Together, the stated significance criteria and impact analysis approach subsections for each environmental resource area and the cumulative effects analysis provide the necessary clarity and disclosure regarding any particular use of the word ‘substantial’ in determining significance for the environmental effects analyzed in the Lower Klamath Project EIR.

Lastly, lacking any specific identification of a problem with an impact analysis in the EIR due to use of the term ‘substantial’, the repeated assertion that term ‘substantial’ must be redefined or uniformly defined at each usage in the EIR does not constitute substantial evidence regarding the potential physical impacts of the Proposed Project on the environment (CEQA Guidelines section 15384).

CEQ-4 Klamath River Basin Compact

Multiple commenters have raised concerns regarding the relationship between the Federal Energy Regulatory Commission (FERC) decommissioning process and the California Environmental Quality Act (CEQA) process on the one hand, and the Klamath River Basin Compact (Compact) and the Klamath River Compact Commission (Commission) on the other. These comments do not raise concerns regarding the potential effects of the Proposed Project on the environment or on the measures available to mitigate them. However, the EIR provides the below additional information in light of confusion regarding the perceived role of the Compact and the Commission created by it.

The Klamath River Basin Compact is an agreement entered into by the states of California and Oregon, and ratified by the United States Congress in 1957. Like other interstate river compacts, the Compact is intended to address the equitable distribution of interstate waters. It also sets forth several other terms, including terms addressing pollution and terms referencing hydropower. These three topics included in the Compact are discussed in more detail below.

- **Equitable Distribution of Interstate Waters:** The Compact affirms the validity of existing water appropriations, and clarifies that it does not affect the rights of tribes. The Compact sets forth guidelines and use priorities for the future appropriation of waters in the Klamath River Basin – here, ‘future’ means appropriations initiated after the 1957 effective date of the Compact. Up to certain irrigation acreage limits, such future appropriations for domestic and agricultural purposes in the Upper Klamath Basin take priority over future appropriations for other purposes in the Klamath Basin in California, or for any use outside of the Klamath River Basin. Future diversions in the Upper Klamath Basin are also subject to export and return-flow restrictions and additional terms. The Compact further establishes the framework for a Klamath River Compact Commission to administer the Compact. The Compact does not, as some comments assert, allocate water for the Shasta Valley, Butte Valley, or Iron Gate Hatchery. Rather, it sets up a framework for future water allocations between the states and in alignment with prioritizing municipal and irrigation use – especially in the Upper Klamath Basin – over other future uses. The water allocation terms of the Compact are self-executing and do not require Commission action. Further, the Compact does not require the continued exercise of any water rights.

- **Pollution Abatement and Control:** The Compact acknowledges that interstate pollution may affect the beneficial uses of the Klamath River, and it affirms the states' intentions to address such pollution. Each state is charged with the primary responsibility for the control and abatement of interstate pollution. In the event of conflicts regarding interstate pollution, each state's water pollution control agency may file a complaint to the Klamath River Compact Commission. The Commission can then investigate, confer, and recommend actions to abate such pollution. If appropriate action does not occur in a reasonable time, the Commission may then hold hearings that can result in enforceable abatement orders. Additionally, the Commission may coordinate with states and agencies on standard-setting and rulemaking.
- **Hydroelectric Power:** The Compact has miscellaneous other provisions, including a declaration that each state's planning for distribution and use of water in the Klamath River Basin will have an objective of efficient and economic use of available power head to lower the cost of irrigation water deliveries and drainage pumping. This declaration of objectives is relevant to state planning for water distribution and use, and to implementation of such plans. It does not mandate particular actions regarding the Lower Klamath Project facilities or in water quality certifications. The Compact also specifically affirms state authority over regulation of discharges from hydroelectric facilities.

The Compact explicitly affirms the primacy of state action in addressing pollution, hydroelectric-related discharges, and water diversion and use. The Commission is granted specific authorities relating to Compact implementation and resolving conflicts that arise under the Compact, but nothing in the Compact requires the Commission – of its own accord – to take any specific action regarding allocation of water, pollution abatement, or the operation or removal of hydroelectric facilities. Nor does it suggest that the Commission is intended to supplant the role of states. Neither the Compact nor the Commission limit the authority of the states to issue water quality certifications under Section 401 of the Clean Water Act.

The Commission is not acting here with respect to the Proposed Project, and so it cannot be a proper lead agency under CEQA. The State Water Board is the agency charged with issuing water quality certifications in California, and it is the only state agency with a discretionary approval in light of federal preemption. As the state agency with a discretionary action before it, the State Water Board is the appropriate lead agency to prepare the CEQA analysis.

2.2.3 Klamath River Flow Related Master Responses

HYD-1 Consideration of Klamath River Flows under the 2019 BiOp Operations Criteria for the Klamath Irrigation Project

The Lower Klamath Project Draft EIR considered the potential effects of dam removal using the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS) Joint Biological Opinion operations criteria for the Klamath Irrigation Project (2013 BiOp Flows) to represent existing hydrology. This was appropriate because the 2013 BiOp Flows were the standard to which the USBR Klamath Irrigation Project operated at the time of the Notice of Preparation for the Lower Klamath Project EIR (i.e., December 22, 2016). After the issuance of the Lower Klamath Project Draft EIR on December 27, 2018, the applicable biological opinion and the operational flow requirements for the Klamath River changed in March 2019, when the new biological opinions were issued by NMFS (2019) and USFWS (2019a). The 2019 Biological Opinion flows (2019 BiOp Flows) are now the current operational flow requirement for the Klamath River.

The Final EIR analyzes both sets of biological opinion flows, with the 2019 BiOp Flows serving as a second CEQA baseline and representing flows under newly defined existing conditions. Inclusion of two baselines (existing condition and 2019 BiOp Flows hydrology regimes) in the Lower Klamath Project EIR is consistent with CEQA Guidelines section 15125 (a). It also simplifies the process of addressing a previously un-analyzed hydrology regime in a large and complex document by first rigorously comparing the new set of flows (2019 BiOp Flows) to the originally modeled flows for dam removal scenarios (KBRA Flows), as well as to the originally modeled flows for scenarios where the dams remain in place (2010 BiOp Flows). Then, based on the outcome of those comparisons (see below), the EIR adds consideration of the 2019 BiOp Flows to the consideration of the 2013 BiOp Flows in the resource-specific impact analyses (previously circulated in the Draft EIR).

The comparison of the 2019 BiOp Flows to the KBRA Flows, which is relevant to the Proposed Project and alternatives where dams are removed, is presented in Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*. This comparison indicates that modeled 2019 BiOp Flows are within the range of modeled KBRA Flows 99.0 percent of the time at Keno Dam and 99.9 percent of the time at Iron Gate Dam. The comparison of the 2019 BiOp Flows to the 2010 BiOp Flows, which is relevant to alternatives where the dams remain in place, is presented in Volume III Attachment 1 Section 4.2.1.1 *No Project Alternative – Introduction – Alternative Description*. This comparison indicates that modeled 2019 BiOp Flows are within the range of modeled 2010 BiOp Flows 99.9 percent of the time at Keno and Iron Gate dams.

Therefore, the Draft EIR has been revised to add consideration of the 2019 BiOp Flows alongside consideration of the 2013 BiOp Flows in the below sections. Given the similarity of the 2019 BiOp Flows to the other flow regimes analyzed in the Draft EIR, these revisions do not constitute significant new information (CEQA Guidelines section 15088.5 (a)).

The 2019 BiOp-related revisions for the aforementioned sections are presented in Volume III Attachment 1.

2.2.4 Water Quality Master Responses

WQ-1 Role of Lower Klamath Project Dams/Reservoirs with Respect to Overall Water Quality

Multiple comments assert that the Lower Klamath Project dams improve water quality, making the water cleaner as it is travels through the reservoirs and into the Klamath River downstream of Iron Gate Dam. Several comments reference visual observations as evidence that the dams improve water quality, suggesting that the commenter is concerned about turbidity. Some comments refer specifically to the settling of suspended material (like algae and sediment) in the relatively calm reservoir environment. Some comments refer to historical accounts of low flows and poor water quality (e.g., taste, odor, and visual quality) as evidence of the asserted beneficial water quality impact of the hydroelectric dams. These include accounts based on personal memory and on pre-dam period writings.

Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* for a general summary of the effects that Lower Klamath Project hydroelectric facilities and operations have on Klamath River water quality, including changes in water temperature, dissolved oxygen, phytoplankton (suspended algae), nutrients, suspended sediment (turbidity), and periphyton (attached algae). Figure 3.2-2 illustrates the general seasonal influence of reservoirs formed by large dams, such as Copco No. 1 and Iron Gate reservoirs, on water quality parameters. The specific influence of the Lower Klamath Project dams and reservoirs on water quality parameters in the Klamath River are summarized in Volume III Attachment 1 Section 3.2.2 *Water Quality – Environmental Setting* and further detailed in Volume III Attachment 1 Appendix C *Water Quality Supporting Technical Information*.

As described in Volume III Attachment 1 Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments*, Potential Impacts 3.2-5 and 3.2-6, and Volume III Attachment 1 Appendix C, Section C.2 *Suspended Sediments*, and shown in Figure C-13, suspended material from upstream sources (including Upper Klamath Lake) settles out within the Keno Impoundment/Lake Ewauna in Oregon upstream of the Lower Klamath Project reservoirs, with approximately 50 percent of organic suspended material (measured as total suspended sediments [TSS]) settling out between the mouth of Link River (RM 253.1) and Keno Dam (RM 233.4) based on May to October TSS measurements from 2000 to 2005. Volume III Attachment 1 Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* (and Volume III Attachment 1 Appendix C, Section C.2

Suspended Sediments) also describe how additional settling of suspended sediment occurs in the Lower Klamath Project reservoirs on an annual basis, even as algal blooms in the Lower Klamath Project reservoirs during the phytoplankton growth season (May to October) can seasonally increase organic suspended material in the reservoirs and the Klamath River downstream of Iron Gate Dam to Seiad Valley (Figure C-14). Further, Volume I Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Phytoplankton* (pages 3-405 to 3-413) provides data supporting the assertion that Upper Klamath Lake is not the main source of the toxin-producing blue-green algae (cyanobacteria) *Microcystis aeruginosa* to the Klamath River downstream of Iron Gate Dam; instead, the most likely sources are Copco No. 1 and Iron Gate reservoirs.

Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* and Volume III Attachment 1 Appendix C, Section C.3 *Nutrients* describe the net annual decrease in nutrients in the Klamath River due to settling of suspended materials and associated nutrients in the reservoirs as well as the seasonal nutrient fluctuations downstream of Iron Gate Dam due to seasonal releases of nutrients from reservoir sediments when anoxic conditions associated with thermal stratification occur in reservoir bottom waters.

Seasonal changes in water quality due to thermal stratification within Copco No. 1 and Iron Gate reservoirs are summarized in Volume III Attachment 1 Section 3.2.2 *Water Quality –Environmental Setting* and further detailed in Volume III Attachment 1 Appendix C *Water Quality Supporting Technical Information* under the individual water quality parameter sub-sections. Figure C-1 highlights the seasonal variations in water temperature within Copco No. 1 and Iron Gate reservoirs, including the formation and breakdown of thermal stratification, while the seasonal variations in dissolved oxygen in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs during the period the reservoirs are thermally stratified are shown in Figure 3.2-4 and Figures C-29, C-30, C-31, and C-32. Seasonal variations in pH within Copco No. 1 and Iron Gate reservoirs during thermal stratification are shown in Figure 3.2-4 and in the Klamath River from upstream of Copco No. 1 Reservoir to downstream of Iron Gate Dam are shown in Figures C-38 and C-39. Seasonal and longitudinal trends in nutrients at Klamath River sites upstream and downstream of the Lower Klamath Project reservoirs are shown in Figures C-24 and C-25 and highlight how nutrients vary during and after thermal stratification in the reservoirs. Seasonal and longitudinal trends in chlorophyll-*a* and algal toxins in the Klamath River and the Lower Klamath Project reservoirs are discussed in Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins*, with chlorophyll-*a* longitudinal trends shown in Figure 3.2-5.

Please refer to Volume I Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* (pages 3-392 to 3-422) for information on the seasonal trends in phytoplankton and periphyton in the Klamath River from upstream of

J.C. Boyle Reservoir to downstream of Iron Gate Dam. Overall, Volume III Attachment 1 Sections 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* through 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Volume III Attachment 1 Appendix C *Water Quality Supporting Technical Information* provide data on the Lower Klamath Project's adverse impacts to water quality by: 1) increasing the water residence time (days to weeks) in Copco No. 1 and Iron Gate reservoirs and warming summer and fall water temperatures downstream of Iron Gate Dam; 2) exhausting dissolved oxygen in reservoir bottom waters and waters released to the downstream river; and 3) seasonally releasing nutrients stored in reservoir bottom sediments such that nutrients become more available during late summer and fall to support large blooms of toxin-producing blue-green algae (cyanobacteria) that are transported into the downstream river, as well as river periphyton (attached algae) that harbor parasites and potentially cause high levels of fish disease.

As described in Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, the amount of flow in the Klamath River is determined by the operation of the Klamath Irrigation Project and the applicable biological opinion(s) to meet the needs of listed species and maintain full irrigation deliveries in accordance with existing contracts, contingent upon available water supplies. The Proposed Project does not include any changes to the amount of flow released by the Klamath Irrigation Project and the applicable biological opinion(s), so historical observations of low flows and associated poor water quality are not anticipated to reoccur due to removal of the Lower Klamath Project Dams.

Overall, the comments' references to cloudy, 'dirty' water from upstream, and clear, 'clean' water samples from downstream of the Lower Klamath Project dams, and to historical observations of low flows and poor water quality prior to installation of the dams, as proof of water quality improvements due to the dams are unpersuasive. The assertions do not recognize changes in flow regulation since historic accounts or, the more comprehensive set of water quality parameters affected by the Lower Klamath Project dams and operations, as supported by the data and analyses presented in the EIR and summarized above.

WQ-2 Potential for Lower Klamath Project Dams/Reservoirs to Cool River Water During Summer and Fall

Several comments assert that the Lower Klamath Project dams beneficially cool or have the potential to cool Klamath River water downstream of Iron Gate Dam during summer and fall, which would benefit fish. Comments note examples of other dams that provide cool water for fisheries, including Shasta Dam on the Sacramento River in California and Lost Creek Dam on the Rogue River in Oregon. Existing water temperature data and numeric models described in Volume III Attachment 1 Section 3.2.2.2 *Water Quality – Environmental Setting –*

Water Temperature, including Figure 3.2-3, demonstrate that the Lower Klamath Project dams cool the Klamath River water downstream of Iron Gate Dam in the spring by approximately 1.8°F to 4.5°F (approximately 1°C to 2.5°C), and warm the Klamath River water downstream of Iron Gate dam in the late summer and early fall by 4°F to 18°F (approximately 2°C to 10°C). Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* for a discussion of why reservoirs and hydroelectric project operations affect water temperature, including Figure 3.2-2 that depicts how seasonal thermal stratification occurs in these waterbodies.

Unlike Shasta Dam on the Sacramento River (California), Lost Creek Dam on the Rogue River (Oregon), or other deep reservoirs that support coldwater fisheries just downstream of the dam by releasing cold water from low level outlets, the location of dam outlets in Copco No. 1 and Iron Gate dams cannot be adjusted to access large volumes of cool water in the bottom of the reservoirs on a reliable basis spanning the several month-long reservoir stratification period. This is because summertime bottom waters in Copco No. 1 and Iron Gate reservoirs are of limited volume and poor water quality (e.g., low dissolved oxygen concentrations), and J.C. Boyle and Copco No. 2 reservoirs do not strongly stratify and thus do not provide a pool of cool water in the summer.

Please refer to Volume I *Alternatives – Continued Operations with Fish Passage – Water Quality – Water Temperature* Potential Impact 4.2.2-1 (pages 4-103 to 4-108) for a discussion of why there is currently no reasonable proposal to operate the Lower Klamath Project to reliably cool summer and fall water released from Copco No. 1 and Iron Gate dams, or to achieve the water temperature allocations in the Klamath total maximum daily loads (TMDLs), with the Lower Klamath Project dams remaining in place.

Please refer to Volume III Attachment 1 Section 3.2 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-2 for a discussion of why dam removal under the Proposed Project would cause water temperatures in the Klamath River downstream of Iron Gate Dam to align better with historical anadromous migration and spawning periods, warming earlier in the spring, and cooling earlier in the fall compared to existing conditions, and how this action would rapidly and substantially contribute to Klamath River TMDL compliance.

WQ-3 Adequacy of Modeling for Sediment Deposits and Suspended Sediments During Reservoir Drawdown

Some commenters assert that the suspended sediment modeling conducted by the United States Bureau of Reclamation (USBR) for the 2012 KHSA EIS/EIR does not adequately represent conditions under the Proposed Project. Some of the specific concerns raised include that the estimated mass and/or volume of the reservoir sediment deposits based on reservoir sediment samples collected in 2006 and 2009 is uncertain and will change in the future when the dams would be removed, that the current Proposed Project involves a faster reservoir drawdown rate than was originally modeled, that the process of sediment jetting was not included in the 2012 project description, and that the models may not represent the hydrology that will occur during dam removal. These commenters express concern that if the suspended sediment modeling approach is not applicable to the Proposed Project, that related impact analyses (e.g., inorganic and organic contaminants) also are not adequately characterized in the EIR.

Please refer to Volume I Section 2.7.3 *Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown*, specifically page 2-65, for a discussion of the volume and weight of sediment for each reservoir as estimated in 2009, the estimated volume as of 2020 taking into account ongoing annual sediment deposition, and a discussion of why the uncertainty in the sediment volume estimates does not affect the analysis of sediment erosion potential for the reservoirs. Table 2.7-11 (page 2-68) presents the estimated amount of sediment in the Lower Klamath Project reservoirs in 2020 and explains in a footnote that between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir. The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so the range of model results using the 2020 sediment volumes would still be applicable to the Proposed Project.

Please refer to Volume I Section 2.7.3 *Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown*, specifically page 2-66, for a discussion of why the rate of reservoir drawdown and the Klamath River Renewal Corporation's proposal for sediment jetting would not substantially affect existing projections of reservoir sediment deposit mobility in the Lower Klamath Project reservoirs during drawdown. This section also explains how in a dry hydrologic year, reservoir pool levels can be drawn down steadily and relatively quickly, resulting in a shorter period of interaction between the flow and sediment deposits, and thus less overall sediment erosion. In a wet hydrologic year, the reservoir pool may experience cycles of drawdown followed by periods of refilling during high flow events, resulting in longer period of interaction between the flow and the sediment deposits, and thus more overall sediment erosion. Please note that the sediment transport model developed by USBR (2012a) for analyzing dam removal scenarios for the Lower Klamath Project was run for 49 water years in the available hydrology record (1961 through 2009), a timespan which includes very dry, dry, normal, wet, and very wet year types, including multiple extreme drought years (i.e., 1977, 1981, 1991, 1992, 1994, 2001, 2005) of similar magnitude to that which occurred more recently (i.e., 2013−2015), and occurrences of back-to-back drought years (i.e., 1990−1992, 2001−2005) (Figure WQ-3-1 and Figure WQ-3-2).

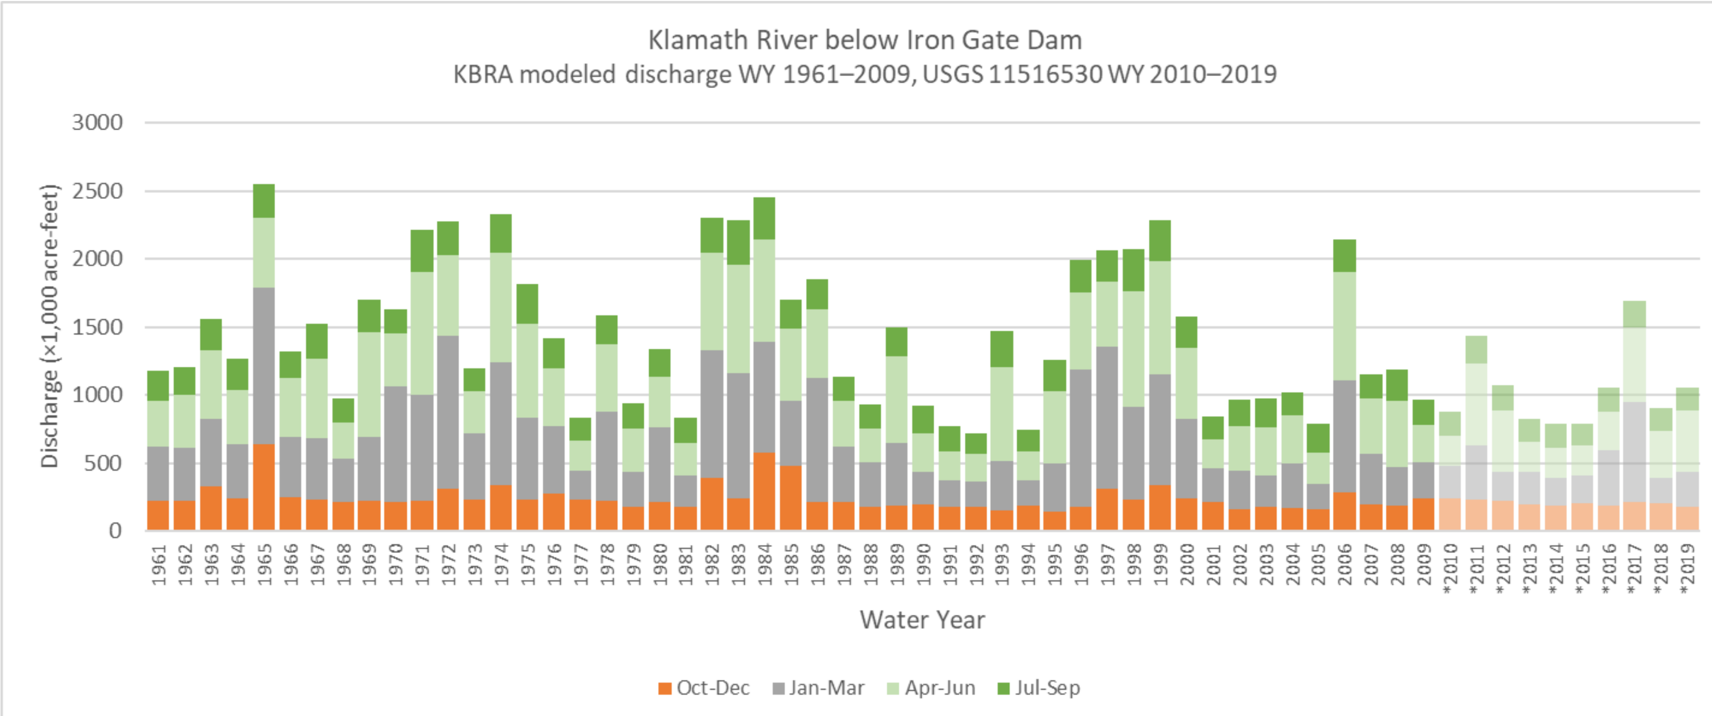

Figure WQ-3-1. Klamath River below Iron Gate Dam KBRA modeled discharge for water years (WY) 1961−2009 used in the USBR (2012a) sediment transport modeling for dam removal analyses and actual flows for WY 2010−2019 (USGS Gage No. 11516530). Water years outside of the hydrology record used in the USBR (2012a) sediment transport modeling are shown with an asterisk and in lighter shading for comparison.

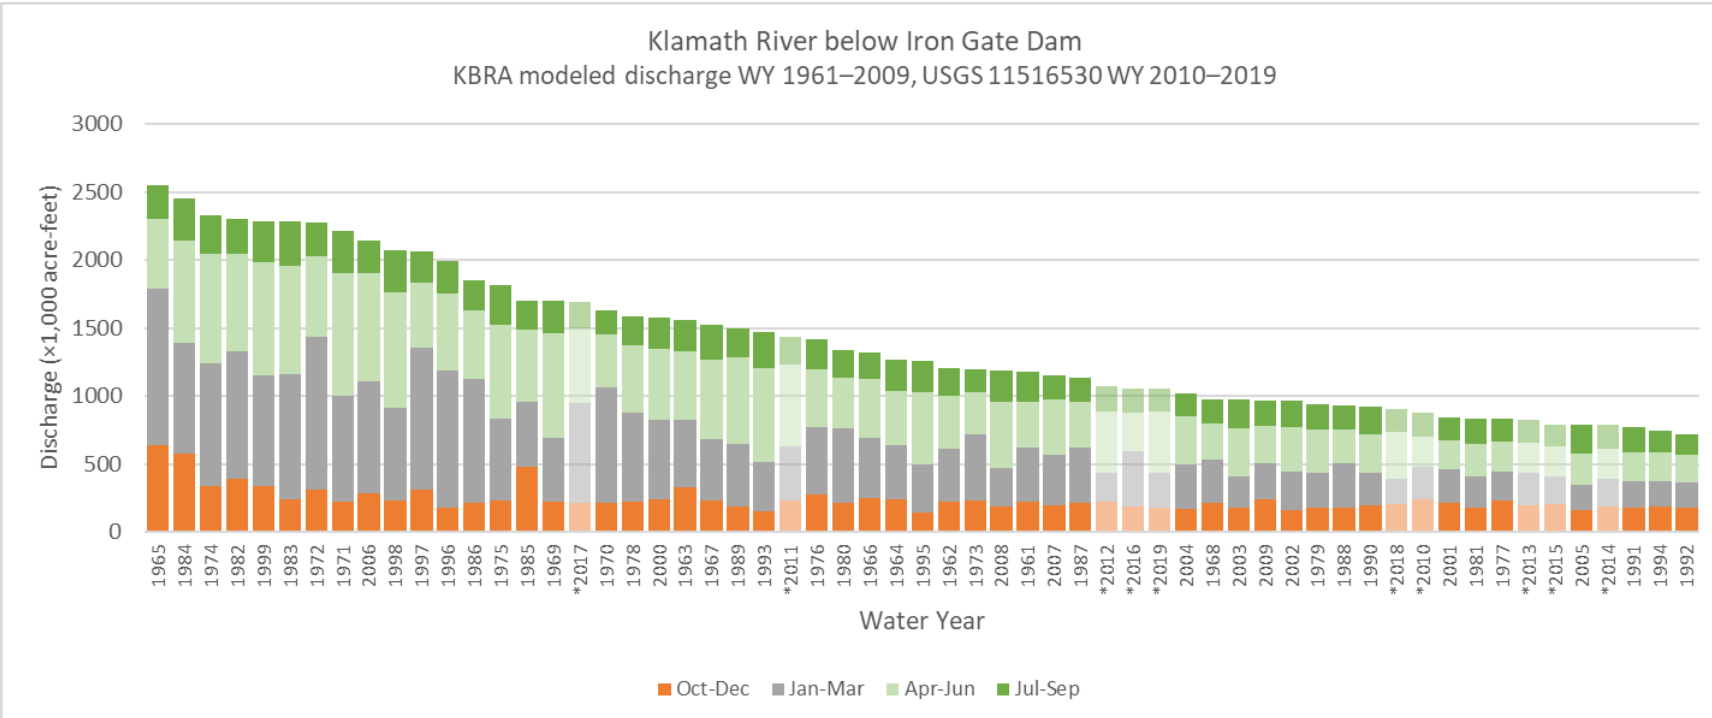

Figure WQ-3-2. Klamath River below Iron Gate Dam KBRA modeled discharge for water years (WY) 1961−2009 used in the USBR (2012a) sediment transport modeling for dam removal analyses and actual flows for WY 2010−2019 (USGS Gage No. 11516530). Water years outside of the hydrology record used in the USBR (2012a) sediment transport modeling are shown with an asterisk and in lighter shading for comparison.

Please refer to Volume III Attachment 1 Section 3.2.4.2 *Water Quality –Impact Analysis Approach – Suspended Sediments* for a discussion of why an adequate analysis of the Proposed Project does not require new suspended sediment modeling despite differences in the reservoir drawdown rates compared with conditions previously modeled by USBR.

Please refer to Volume III Attachment 1 Potential Impact 3.2-3, for an analysis of potential for increases in suspended sediments due to release of sediments currently trapped behind the Lower Klamath Project dams, including detailed consideration of the higher rate of reservoir drawdown and the process of sediment jetting.

WQ-4 Time Period of Water Quality Data

Several commenters assert that the data relied upon for the water quality analysis are too old to adequately assess existing conditions of the project area, specifying that total phosphorus, total nitrogen, dissolved oxygen, pH, inorganic and organic matter, sediment contaminants, and aquatic biota contaminants data are all over ten years old and do not represent the current environment.

Please refer to Volume III Attachment 1 Section 3.2.2 *Water Quality – Environmental Setting* and Volume III Attachment 1 Appendix C *Water Quality Supporting Technical Information* for a general summary of the water quality data collected from 2000 through 2017. Water quality data from 2012 through 2017 are discussed along with water quality data from 2011 or earlier in numerous places throughout Volume III Attachment 1 Section 3.2.2 *Water Quality – Environmental Setting* and Volume III Attachment 1 Appendix C *Water Quality Supporting Technical Information*, and associated citations are provided to the numerous reports that have been published compiling and/or analyzing these water quality data. Interim Measure 15 (IM 15) baseline and public health water quality data collected at multiple locations in the Klamath River from the Link River Dam to the Klamath River Estuary along with locations in the Lower Klamath Project reservoirs is documented in Watercourse Engineering, Inc. (2011a, 2011b, 2012, 2013, 2014, 2015, 2016), and these data are frequently utilized in the EIR. The list of reports published after 2012 considered in the EIR containing water quality data from 2012 to 2017, analysis of water quality data from 2012 to 2017, or analysis of historical water quality data (potentially including data from 2012 to 2017) that provide more recent insight into water quality conditions in the Klamath River include the following:

YTEP. 2015. July 28 & 29 BGA Results. Yurok Tribe Environmental Program (YTEP) Memorandum. Prepared by Yurok Tribe Environmental Program, Klamath, California.

While many of the studies and models developed for the 2012 KHSA EIS/EIR (and included in this Lower Klamath Project EIR) use data from 2000 through 2011, data from 2012 through 2017 were also reviewed and included in the overview of existing water quality conditions and considered in this Lower Klamath Project EIR analyses of potential water quality impacts. Further, comparisons of more recent and historical water quality data indicate that adding more recent available water quality data to existing model and/or analysis results would not materially change anticipated water quality parameter responses to dam removal. For example, in Volume III Attachment 1 Appendix C, Section C.1.2.1 *Iron Gate to Salmon River* (page C-5) the Klamath River water temperature trends at monitoring sites between Iron Gate Dam and the confluence with the Salmon River between 2001 and 2012 are specifically compared with the water temperature trends between 2013 and 2015 and, as described in the appendix, water temperature trends are consistent from 2001 through 2015. As such, Potential Impact 3.2-1 uses an analysis of existing water temperature data along with previous water temperature modeling results based upon historical data (i.e., pre-2013) to evaluate the potential for short-term and long-term alterations in water temperatures due to conversion of the reservoir areas to a free-flowing river. Assessments of available suspended sediment, nutrient, dissolved oxygen, pH, chlorophyll-*a*, and algal toxin data from 2013 through 2017 are used along with historical data (i.e., 2012 or earlier) in EIR discussions of the range of variation in water quality parameters over time, especially for chlorophyll-*a* and algal toxins (see Volume III Attachment 1 Appendix C in their respective sections and Klamath River reaches).

As further clarification, Figure WQ-4-1 and Figure WQ-4-2 (below) present graphical comparisons of the available IM15 water temperature, dissolved oxygen, pH, total phosphorous, and total nitrogen from 2000 through 2017 at the Klamath River monitoring site downstream of Iron Gate Dam (approximately RM 192.75), demonstrating that the range of historical (i.e., 2012 or earlier) and more recent (i.e., 2013 to 2017) total nitrogen and total phosphorus concentrations are similar. Please note that the IM15 data through 2015 was generally considered in Appendix C. Figure WQ-4-1 shows the IM15 water temperature, dissolved oxygen, pH, total phosphorous, and total nitrogen data for the period before and after 2012, with the mean values shown as a black line and the 95 percent confidence bands around the mean shown in cyan. The 95 percent confidence bands indicate that there is a 95 percent probability that the mean value would occur within the band. While there are differences between the means before and after 2012 downstream of Iron Gate Dam, those differences are small relative to the range of values for the water quality parameters. Additionally, the 95 percent confidence bands for the means before and after 2012 partially overlap for all water quality parameters, indicating that the mean values for each individual water quality parameter before and after 2012 are likely to be statistically the same and the difference in the mean values before and after 2012 is only due to the water quality being sampled periodically.

Figure WQ-4-2 also presents the IM15 data, but this figure displays an estimate of seasonal water quality variation downstream of Iron Gate Dam from 2000 to 2017, by using a non-parametric smoothing regression line with a time-step of three months (each season is approximately three months long). The associated 95 percent confidence bands are shown in cyan and they are calculated for the pre-2012 and the post-2012 IM 15 data to characterize how water quality varied seasonally during these two periods. No IM 15 data were reported during 2006, so the seasonal water quality trends in the three months before and the three-months after 2006 are based on limited data and do not likely represent the longer-term trends. As highlighted by Figure WQ-4-2, the seasonal variations in water temperature, dissolved oxygen, pH, total phosphorus, and total nitrogen are generally similar between pre-2012 and post-2012 periods, with most post-2012 variations in water quality parameters also within the range of pre-2012 variations. Seasonal pH trends during 2013 and 2014 downstream of Iron Gate Dam tended to peak higher than those pre-2012, but the seasonal pH trends in subsequent years (i.e., 2015 to 2017) were generally similar to those pre-2012.

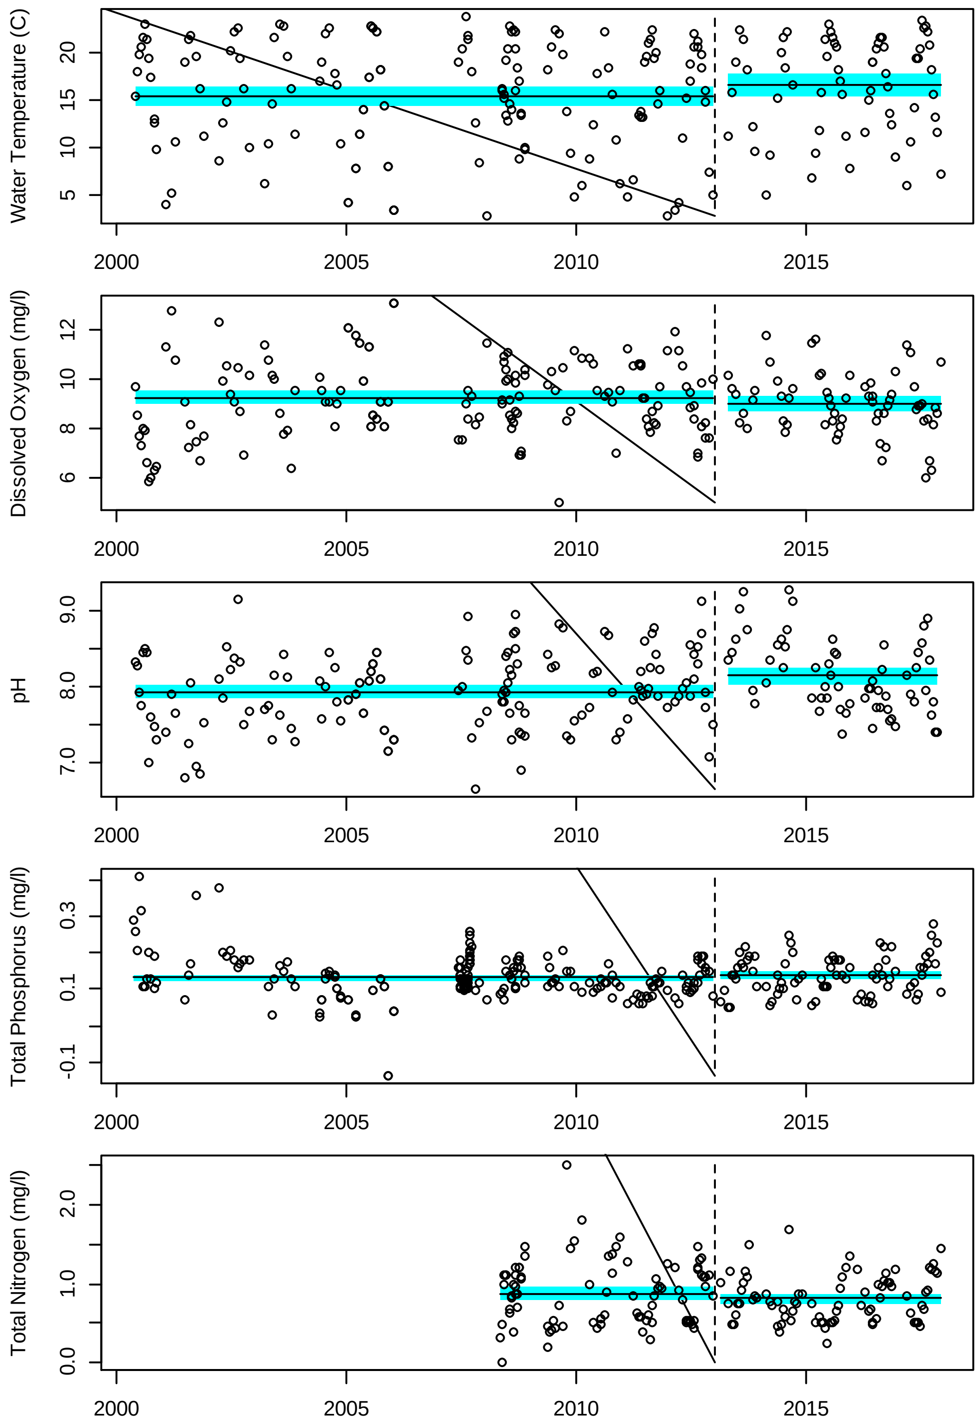

Figure WQ-4-1. Interim Measure 15 Data at the Klamath River Monitoring Site Downstream of Iron Gate Dam (Approximately RM 192.75) from 2000 to 2017 Along with the Mean Values and 95 Percent Confidence Bands (in cyan). Source: PacifiCorp 2003a, 2004b, 2005b, 2007, 2008b, 2009, 2010, 2011, 2012, 2013, 2014c, 2015b, 2016b, 2017b.

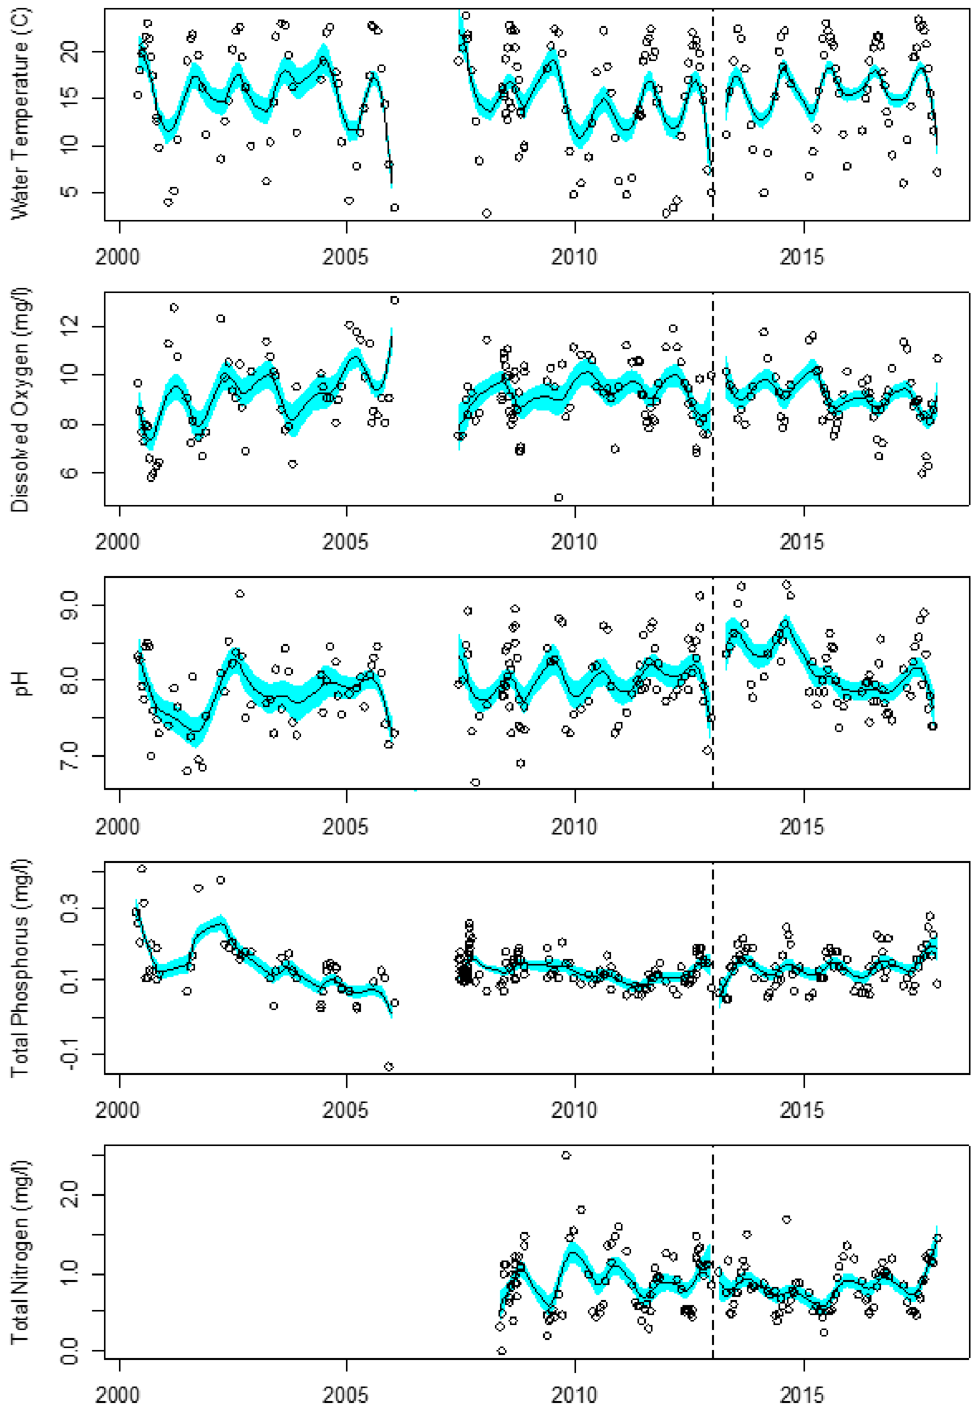

Figure WQ-4-2. Interim Measure 15 Data at the Klamath River Monitoring Site Downstream of Iron Gate Dam (Approximately RM 192.75) from 2000 to 2017 Along with a Non-parametric 3-month Smoothing Regression Curve Representing the Seasonal Water Quality Trends and the Associated 95 Percent Confidence Bands (in cyan). Source: PacifiCorp 2003a, 2004b, 2005b, 2007, 2008b, 2009, 2010, 2011, 2012, 2013, 2014c, 2015b, 2016b, 2017b.

Insofar as the data are available and applicable to the reaches being evaluated, the potential impacts to water quality under the Proposed Project are analyzed using the synthesis of the historical (i.e., 2012 or earlier) and more recent (i.e., 2013 to 2017) water quality data, modeling using historical data (e.g., Klamath River TMDL [total maximum daily loads] model of pH), modeling using historical data supplemented with additional analysis based on current conditions (e.g., variations in modeled suspended sediment concentrations [SSCs] during drawdown due to modifications in drawdown rates), and/or new modeling (e.g., short-term dissolved oxygen decreases in the Klamath River during reservoir drawdown assuming an initial dissolved oxygen saturation at Iron Gate Dam of zero).

In the EIR water quality data summary and analysis (Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants*, Volume III Attachment 1 Appendix C, Section C.7 *Inorganic and Organic Contaminants*, and Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants*), existing inorganic and organic contaminant data in the Lower Klamath Project reservoirs and Klamath River monitoring sites were compared with more recent available screening levels; there are no readily available inorganic or organic sediment contaminant data from the reservoirs after 2010 or for Klamath River monitoring sites after 2013. However, concentrations of inorganic and organic contaminants in the reservoirs or the Klamath River are not expected to vary significantly after 2010 or 2013 respectively. The State Water Board is unaware of any new sources of inorganic or organic contaminants due to climate or local land-use alterations that would alter the concentration of contaminants accumulated in Lower Klamath Project reservoir sediments since 2010. Additionally, the sediment that will have accumulated in the reservoirs between 2010 and the projected year of dam removal (2021) ranges from approximately 11 to 21 percent of the total sediment volume, so potential deposition of contaminants between 2010 and dam removal would have a limited influence on the overall contaminant concentration that would occur during and after dam removal. Concentrations of contaminants in aquatic biota are related to concentrations of contaminants in the water column and sediment, so no substantial change in the water column or sediment contaminant concentrations would be expected to result in a substantial change in aquatic biota contaminant concentrations. Lastly, the comments expressing concern regarding the time period for the sediment contaminant data reported in the EIR do not provide substantial evidence regarding the potential for any new data of this type. Overall, the inorganic and organic contaminant data summarized in Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* and Volume III Attachment 1 Appendix C, Section C.7 *Inorganic and Organic Contaminants* are representative of existing conditions and the analysis of this data in Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* sufficiently characterizes the potential impacts under the Proposed Project and the alternatives.

WQ-5 Inclusion of Klamath River TMDL Model in the EIR Analysis

Commenters express several concerns related to the use of the Klamath River TMDL models in the EIR analysis. Some commenters assert that the model assumption that all waters entering the state of California are fully compliant with applicable Total Maximum Daily Loads (TMDLs) results in an overestimate of the effects of dam removal on TMDL target constituents since it is not likely that TMDLs would be met at the Oregon-California state line when the dams would be removed. Several commenters also assert that the Oregon and California TMDL modeling results are flawed; the EIR does not adequately summarize the disagreement about the TMDL modeling approach; the EIR does not provide substantial evidence supporting the use of the TMDL model results in the EIR analysis; and the Oregon TMDL was withdrawn.

The EIR addresses how and why certain models, including the applicable California and Oregon TMDL models, are considered in the analysis of the Proposed Project and the alternatives. Volume III Attachment 1 Section 3.2.4 *Water Quality – Impact Analysis Approach* explains that the EIR water quality impact analysis relies on multiple numeric models, including the California Klamath River TMDL model, because no single existing numeric model captures all of the water quality conditions anticipated for and encompassed by the Proposed Project (see also Volume II Appendix D, Section D.1).

Volume III Attachment 1 Section 3.2.4 *Water Quality – Impact Analysis Approach* states that the California Klamath River TMDL model stemmed from a significant five-year effort by the North Coast Regional Water Quality Control Board (North Coast Regional Board) in collaboration with PacifiCorp and working jointly with the U.S. Environmental Protection Agency (USEPA) Regions 9 and 10 and the Oregon Department of Environmental Quality. That work was subject to extensive peer review and public comment before adoption by the North Coast Regional Board. It was further reviewed and subject to additional public comment before being approved unanimously by the State Water Board. It was then subsequently reviewed and approved by USEPA in December 2010. This information is fully consistent with the definition of “substantial evidence” under CEQA Guidelines Section 15384.

The Oregon Klamath River TMDL model was developed by the Oregon Department of Environmental Quality in cooperation with the North Coast Regional Board, PacifiCorp, and USEPA Regions 9 and 10, and also underwent peer review and public comment prior to its adoption. Results from this model are not analyzed directly in the Lower Klamath Project EIR because the Klamath River reaches to which this TMDL applies are in Oregon. However, key concerns with respect to the Oregon TMDL model are included in the summary below because the output from this model sets the upstream boundary condition for the California Klamath River TMDL model at the Oregon-California state line. Consistent with CEQA Guidelines Section 15151, the following minor modification has been made to Section 3.2.4 *Water Quality – Impact Analysis Approach* to summarize the main points of disagreement among the experts regarding the Klamath TMDL models:

"Key concerns with respect to the California and Oregon TMDL models, which were raised during the respective public comment processes, include concerns regarding how the natural condition was determined, how model uncertainty was considered in the analysis, and need for additional years of data for calibration of the model. As discussed in North Coast Regional Board (2010) Appendix 10 *Public Comments & Responses*, the North Coast Regional Board found the uncertainty associated with the Klamath TMDL models to be minimal relative to the magnitude of the source load reductions needed to meet water quality standards in both Oregon and California and that any additional analysis would bring diminishing returns for determining implementation actions for the basin. The North Coast Regional Board indicated that if updates to the California model demonstrate that TMDL allocations and targets should be adjusted, the Regional Water Board staff would propose changes to the TMDL. To date, no such changes have been proposed. The North Coast Regional Board also provided extensive documentation describing the development of the modeled natural condition and indicated that the year chosen for developing the model and establishing the TMDL was selected because it included periods of critical low flow and poor water quality conditions, consistent with the margin of safety requirement and the goal of developing environmentally conservative allocations. While the Oregon portion of the model was calibrated using two model years, there were not sufficient data to evaluate the California portion of the model for the second year. The North Coast Board indicated that adding more model years to the model development process would not significantly change the model parameters, given the within-year variability in the Klamath River system (North Coast Regional Board 2010)."

The Oregon Klamath River water temperature and nutrient TMDLs were reissued in 2019. Oregon Department of Environmental Quality made minor modifications to the tributary inflow water temperatures for the natural conditions baseline model scenario, as well as minor modifications to point source water temperatures for the allocation scenario. Because the Oregon water temperature TMDL (ODEQ 2010) and the Oregon water temperature TMDL (ODEQ 2019) present modeling results using different averaging functions of water temperature, the exact range of differences between water temperature model outputs cannot be compared between the two versions of the model. However, general seasonal trends in water temperature with distance downstream in the Upper Klamath River are consistent with those analyzed in the EIR, and the EIR's conclusion that conditions under the Proposed Project would better align with the California Thermal Plan's prohibitions and move waters within the hydroelectric reach towards TMDL compliance (see discussion under Volume III Attachment 1 Potential Impact 3.2-1) would not be altered by revisions to the water temperature portion of the Oregon TMDL (ODEQ 2019). Oregon Department of Environmental Quality also reissued the Klamath River nutrient TMDL (ODEQ 2019), which updated the ammonia analysis, modified the requirements of water treatment facilities operated in the Upper Klamath Basin from an annual to a seasonal wasteload allocation, and specified allowable reductions in dissolved oxygen from the natural conditions baseline. These changes would have no effect on the analysis of potential impacts of the Proposed Project or alternatives on total nitrogen in the EIR. While these changes would increase total phosphorus concentrations in the spring at the Oregon-California state line, which could increase the potential for seasonal periphyton growth in the Hydroelectric Reach under the Proposed Project, as well as associated increases in daily maximum pH, this would not alter the EIR's conclusion that the potential for establishment and growth of periphyton or specifically nuisance periphyton within the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam would be significant and unavoidable in the long term (see discussion under Volume I Potential Impact 3.4-4).

Volume III Attachment 1 Section 3.2.4 *Water Quality – Impact Analysis Approach* also acknowledges limitations of the TMDL models in analyzing the impact of the Proposed Project, because of its assumption of full TMDL implementation for both the dams-in and dams-out scenarios. The EIR recognizes that the mechanisms for implementation and the timing required to achieve future TMDL compliance are speculative. Despite this assumption, the Klamath River TMDL model results are still a useful source of information with respect to the EIR analyses, particularly in light of the TMDL models' inclusion of a "natural condition". The EIR appropriately includes the TMDL models in the EIR analysis, along with a suite of other available facts and credible information.

Please refer to Volume III Attachment 1 Section 3.2.4 *Water Quality – Impact Analysis Approach* for a general discussion of how TMDL model results are considered in the analysis of potential water temperature impacts, potential nutrient impacts, potential dissolved oxygen impacts, and pH impacts due to implementation of the Proposed Project. The section also discloses that the TMDL output was not used for analysis of chlorophyll-*a*. The TMDL model does not provide output for, and is thus not utilized in the EIR analysis of, suspended sediments, algal toxins, or inorganic and organic contaminants.

In analyzing the potential impacts to various parameters, the EIR further contextualizes the use of the Klamath TMDL models in light of the assumption of full compliance and the other information available. For example, for water temperature, Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-1 describes how the Klamath TMDL models are useful for determining the dominance of Lower Klamath Project removal in achieving a water temperature response, in light of the comparatively negligible impact of other upstream temperature point sources. This is helpful context, despite the disclosure that the models' assumption of compliance does not reflect the existing condition. Similarly, for dissolved oxygen, Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-10, explains that the dissolved oxygen mechanism modeled for the Klamath River TMDLs would be the same even if model inputs for dissolved oxygen were changed from the TMDL compliance values to concentrations less than existing conditions (i.e., worse dissolved oxygen baseline); thus, the general trends indicated by the Klamath TMDL models output are still informative for conditions where full TMDL compliance has not occurred. The EIR provides similar context for nutrients and pH, and in all cases where the TMDL model output is used, the results are considered with respect to general trends only and they are used along with the results of other available numerical model output.

WQ-6 Potential Contaminants in Sediments

Several commenters have expressed general concern regarding the impact of contaminants in reservoir sediments, including concern that the release of reservoir sediments could cause contamination of the Klamath River. Some comments assert that sediment sampling to date has been inadequate because it has not extended deep enough into the sediments to be accurate. Comments express concern that release of sediments with certain contaminants, including poly-chlorinated biphenyls (PCBs), lead, mercury, and dichlorodiphenyltrichloroethane (DDT), would not comply with California laws. Other comments express concern that the human health risk assessment is not adequate.

Please refer to Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* for a general summary of the inorganic and organic contaminants measured in the Klamath River waters, the reservoir sediments, and aquatic biota. Please also refer to Volume III Attachment 1 Appendix C, Section C.7 *Inorganic and Organic Contaminants* for further details about the inorganic and organic contaminants measured in the Klamath River waters, the reservoir sediments, and aquatic biota. Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* includes the chemicals of potential concern detected in reservoir samples, sediment toxicity test results for benchmark benthic indicator species, and comparisons of detected chemical concentrations with USEPA and California Environmental Protection Agency (CalEPA) human health screening levels to assess human health risk as well as with National Oceanic and Atmospheric Administration (NOAA), U.S. Fish and Wildlife Service (USFWS), and Oregon Department of Environmental Quality (ODEQ) ecological screening levels to assess ecological health risk. As explained in Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants, Sediment Contaminants*, on-site geologists verified that sediment cores collected during

2009 and 2010 reached the reservoir-deposited/pre-reservoir sediment boundary to characterize the inorganic and organic contaminants throughout the entire depth of the existing reservoir sediments. Thus, the depth of the samples was sufficient.

Please refer to Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-13 for the evaluation of the potential impacts of human exposure to inorganic and organic contaminants in reservoir sediments due to the release of these sediments during dam removal and exposure to these sediments during and following dam removal. Human exposure is assessed for both direct contact with reservoir sediments and subsistence eating of fish or shellfish exposed to inorganic and organic contaminants in reservoir sediments using USEPA and CalEPA screening levels that are conservatively protective of human health and available screening level values to assess whether contaminants would bioaccumulate to unhealthy levels for humans who eat them.

Please refer to Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-14 for the evaluation of the potential impacts of freshwater and marine aquatic exposure to inorganic and organic contaminants in reservoir sediments due to the release of these sediments during dam removal and exposure to these sediments during and following dam removal.

WQ-7 Algal Toxicity

Several comments assert that algae in the Iron Gate and Copco No. 1 reservoirs and the Klamath River do not cause health problems. The comments base this statement on the commenters' personal experience swimming in the lake and river during the summer without resulting health problems or their understanding that people, dogs, cattle, and wildlife interact with water in the river and lakes during summer months without any associated deaths. Some comments express mistrust of state water quality postings explaining the potential harmful, deadly effects of algal toxins on human and animal health. Others note that blue-green algae is a natural health supplement.

While is it true that some types of blue-green algae (e.g., "spirulina" which includes the species *Arthrospira platensis* and *Arthrospira maxima*) are used as a dietary food supplement, it is also true that some blue-green algae species (including spirulina) produce algal toxins (also referred to as cyanotoxins). As stated in Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins*, while exposure to cyanotoxins can in extreme cases cause death to exposed organisms including humans, chronic exposure symptoms include a number of forms of physical irritation and sickness (e.g., visual disturbance, nausea, vomiting, muscle weakness) such that a lack of reported deaths associated with exposure to seasonal cyanotoxins in the

Klamath River and/or the Lower Klamath Project reservoirs does not represent substantial evidence demonstrating that there is no potential risk to public health due to the presence of cyanotoxins. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Volume III Attachment 1 Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a* for a summary of the potential health impacts of exposure to cyanotoxins citing credible studies by national, federal, and state agencies including the World Health Organization (WHO), the United States Environmental Protection Agency (USEPA), and the California Office of Environmental Health Hazard Assessment (OEHAA). These sections also present algal toxin concentrations measured in the Lower Klamath Project reservoirs and the Klamath River from 2005 to 2016. As noted in these sections, cyanotoxins (e.g., microcystin) are produced only periodically and by only specific species of blue-green algae [cyanobacteria] (e.g., *Microcystis aeruginosa*) found in the Lower Klamath Project reservoirs and the Klamath River. Other species of algae and blue-green algae present in the Lower Klamath Project reservoirs and the Klamath River may not produce cyanotoxins or may not produce them at high enough levels to cause health impacts for humans, dogs, cattle, and/or wildlife.

Please also refer to Volume I Section 3.4 *Phytoplankton and Periphyton* (pages 3-389 to 3-440) for a discussion of the phytoplankton and periphyton communities in the Klamath River, including diatoms, green algae, and blue-green algae [cyanobacteria]. As described in Volume I Section 3.4.2.1 *Phytoplankton and Periphyton – Environmental Setting – Phytoplankton* (page 3-392 to 3-403), algae like diatoms and green algae are generally considered to be beneficial to the ecosystem, but algal blooms primarily composed of the blue-green algae species *Aphanizomenon flos-aquae, Anabaena flos-aquae*, and *Microcystis aeruginosa* in the Lower Klamath Project reservoirs and the Klamath River are the cause of water quality or human health concerns since these blue-green algae species are associated with the release of cyanotoxins on a seasonal basis.

2.2.5 Aquatic Resources Master Responses

AQF-1 Removal of Lower Klamath Project Reservoirs and Lost River and Shortnose Sucker Populations

Several comments assert that removal of the Lower Klamath Project reservoirs will eliminate Lost River and shortnose sucker populations in those reservoirs, resulting in take of a fully protected species under California Fish and Game Code.

Please refer to Volume III Attachment 1 Section 3.3 *Aquatic Resources*, Potential Impact 3.3-13 for a summary of the anticipated effects of removing the Lower Klamath Project reservoirs on Lost River and shortnose sucker populations. The EIR notes that the reservoir habitat for these species would be removed and evaluates the effect of this loss on the populations. As described in Potential

Impact 3.3-13, the Lost River and shortnose suckers in Copco No. 1 and Iron Gate reservoirs are considered by the USFWS (2012) as “sink populations”, citing Moyle (2002) and NRC (2004). These sucker groups are not likely to be self-sustaining due to a lack of access to spawning habitat, which results in low recruitment (i.e., success of juveniles living to adulthood). Buettner et al. (2006) conclude that since little or no reproduction occurs downstream from Keno Dam, and there is no potential for interaction with upstream populations, these sucker groups are not considered to substantially contribute to the achievement of conservation goals or recovery for these two species. This finding is also consistent with the findings of Hamilton et al. (2011) and NRC (2004). In addition, and as described in Potential Impact 3.3-13, Assembly Bill Number 2640 (Wood 2018) added Section 2081.11 to the Fish and Game Code to allow the take of both sucker species resulting from impacts attributable to the decommissioning and removal of the Lower Klamath Project and associated facilities, consistent with CDFW take provisions. Finally, Potential Impact 3.3-13 describes that the Proposed Project includes measures to conduct genetic testing of the sucker populations prior to dam removal, and to relocate individual suckers.

AQF-2 Fate of Hatchery Operations

Several comments express the concern that under the Proposed Project, and alternatives that involve removal of Iron Gate Dam, the term of hatchery operations should extend until successful recolonization of both Chinook and coho has occurred and not be limited to eight years of operations. Additionally, comments asserted hatchery production goals as listed in the Proposed Project should be increased. Conversely, other comments express the opinion that hatchery production should be eliminated, or that the No Hatchery Alternative be selected as the preferred alternative.

As discussed in Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries*, Iron Gate Hatchery was built to mitigate for the loss of spawning and rearing habitat resulting from the construction of Iron Gate Dam. Under the Proposed Project and alternatives that would remove Iron Gate Dam (i.e., Partial Removal, Two Dam Removal, Three Dam Removal, and No Hatchery alternatives), the Iron Gate Hatchery facilities located at the base of Iron Gate Dam, including the adult fish ladder and holding tanks at the toe of the dam, would be removed. Similarly, removal of Iron Gate Reservoir would eliminate the cold-water supply and aerator for the hatchery. With the exception of the No Hatchery Alternative, under alternatives that remove Iron Gate Dam, portions of Iron Gate Hatchery located downstream near the confluence of Klamath River and Bogus Creek would remain in place or would be altered, including conversion of two of the existing raceways to adult holding tanks, and construction of a new spawning facility, so that more limited operations could continue at the facility for eight years following dam removal (please also refer to

Volume I Section 2.7.6.1 *Proposed Project – Hatchery Operations – Iron Gate Hatchery* [pages 2-77 to 2-80]).

The EIR does not evaluate an alternative or mitigation measure of extended (beyond eight years) hatchery operations for two primary reasons. First, such an alternative or mitigation measure would not reduce an identified significant impact to fisheries associated with implementation of the Proposed Project. The EIR's analysis indicates that the Proposed Project is likely to result in long-term benefits to fish populations. (See Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*). Secondly, there is currently no feasible plan for extended operations, as contemplated under CEQA Guidelines, sections 15126.4 and 15126.6. No funding source for the considerable cost of hatchery operations after eight years has been identified. The hatchery operator and owners have not proposed to continue operations themselves or to pass on operations to a different entity with the capacity to operate the hatcheries. Additionally, long-term operation of the hatchery or hatcheries outside of the larger restoration project of dam removal would potentially require additional water treatment actions and facilities modifications for which there is no identified plan or funding source. In light of the lack of identified funding or plan for continuation of facilities operation after eight years, the EIR assumes a cessation of operations: however, it is worth noting that neither the EIR nor the water quality certification requires elimination of hatchery operations. Should the population improvements anticipated in the EIR prove to be incorrect, or should hatchery operation be called for as an appropriate response to address circumstances unrelated to the Proposed Project, CDFW or another entity or group of entities could seek to overcome the above-described technical and financial barriers to continue hatchery operations beyond the eight years proposed by the Project. Such a decision would not be barred by either the current EIR or the water quality certification but would be subject to additional environmental review.

Similar to comment recommendations to evaluate hatcheries' operations beyond eight years, the recommendation to increase production goals beyond those identified in Volume I Section 2 *Proposed Project* Table 2.7-13 (page 2-80) would not reduce an identified significant impact of the Proposed Project. Additionally, water supply analysis suggests that there would be water supply limitations at Iron Gate Hatchery that would prohibit increased production over the goals proposed. KRRC (2017) conducted an analysis of water supply needs and associated production at the Iron Gate Hatchery during and following dam decommissioning under the Proposed Project and identified and evaluated four potential options to supply water to the hatchery in its current location. KRRC concluded that a direct Klamath River water diversion was not feasible due to suspended sediment concentrations and summer water temperatures. Further, KRRC found that groundwater sources are limited to a supply of approximately five or ten cfs to the hatchery, and that even such amounts would require additional evaluation. Additionally, the investigation did not indicate that supplies from Fall Creek and Bogus Creek would be sufficient to meet higher production goals. For additional discussion of the limits of water supply from Bogus Creek, please also see Vol. III, *Potential Impact 3.3-23 Effects on anadromous salmonid populations due to short-term and long-term Bogus Creek flow diversions for the Iron Gate Hatchery*. Please note that the diversion from Fall Creek analyzed in KRRC 2017 for use at Iron Gate Hatchery is now proposed for hatchery use at Fall Creek Hatchery (FCH).

With regard to increased production, nothing in the EIR or Section 401 water quality certification prohibits a reevaluation of production numbers at a later date in the future, should additional water sources or new information become available. Such a change would be subject to additional environmental review.

In response to comments expressing the view that hatchery production should be eliminated, or that the No Hatchery Alternative should be selected as the preferred alternative, please note that Volume I Section 4.7 *No Hatchery Alternative* (pages 4-301 to 4-323) analyzes the No Hatchery Alternative, and finds no significant impacts on aquatic resources due to the elimination of hatchery production.

This alternative would also eliminate potentially significant short-term water quality impacts related to hatchery operation on Fall Creek (Potential Impact 3.2-17). As described in Potential Impact 3.2-17, the temporary exceedances of the water quality standards for temperature at Fall Creek Hatchery are expected to be small (-0.5 – 2.2° F) and to occur intermittently, rather than constantly. Any temporary exceedances of the dissolved oxygen standards resulting from Fall Creek Hatchery are expected to be infrequent under the Proposed Project.

Though the EIR finds no significant impact to aquatic resources due to the elimination of hatchery production, the elimination of hatchery produced fall-run Chinook salmon and coho salmon under this alternative would likely result in a reduction in adult returns in post-dam removal years for an indeterminate period of potentially one to five years (i.e., short-term), before the benefits of dam removal are realized. The potential for the reduction in fish available for tribal harvest results in a potentially significant short-term impact on the Klamath Riverscape as a tribal cultural resource (Potential Impact 3.12-9). The lack of access to fish has profound effects for many tribal people in the Klamath Basin (see e.g., Sowerwine et al. 2019, Mozingo 2017).

In contrast, under the Proposed Project, returns to the newly accessible habitat and hatchery returns would occur in the short-term. Please note that the EIR differentiates between an increase in abundance of naturally produced fall-run Chinook salmon, and an increase in total adult returns (which could include adults produced from either hatchery or natural production). The elimination of hatchery produced fall-run Chinook salmon and coho salmon under the No Hatchery Alternative is predicted to result in a faster increase in *naturally* produced salmon, mostly because there would be no competition or other impacts from hatchery produced fish. However, under the Proposed Project, both hatchery returns and natural returns from newly accessible habitat would occur in the short-term. Thus, the *total* adult returns from naturally produced and hatchery released production are anticipated to be greater in the short-term than natural production alone. The combined production under the Proposed Project is anticipated to increase the rate of reintroduction of fall-run Chinook salmon and coho salmon into newly accessible habitat, with the hatchery-origin strays into the new habitat becoming part of the new natural fish population. This increase in population as well as the hatchery production itself are anticipated to provide increased resiliency to unforeseen environmental disturbance or other threats to the populations (NMFS 2017b), and more rapid realization of the other benefits of increased habitat access to these populations. Further, it is worth noting that the coho salmon hatchery is managed under a Hatchery Genetic Management Plan HGMP to address any potential negative genetic impacts of hatchery operations and has been deemed necessary to protect the remaining genetic resources of the Upper Klamath River Population unit (PacifiCorp and CDFW 2014). NMFS (2016) reported that, "The implementation of the HGMP is a positive step toward meeting viability targets for the Upper Klamath population unit, the diversity stratum, and the ESU." Both naturally produced and naturalized hatchery strays will increase the natural population available to recolonize newly accessible habitat following dam removal.

One of the environmental objectives of the proposed Project is to *timely* "advance the long-term restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation."

Thus, on balance, the Proposed Project is the environmentally superior alternative.

Please note that the EIR's evaluation of the proposed production goals and operations as well as a No Hatchery Alternative brackets a range of production goals and operations that can be relied upon in developing an initial Hatchery Operations Plan, or as part of future adaptive management decisions in light of the expected repopulation of new habitat or other factors influencing salmon in the Klamath Basin.

AQF-3 Chinook Salmon Abundance for Harvest

Several comments express concern that a reduction in hatchery operations for fall-run Chinook salmon under the Proposed Project could reduce harvest for salmonids, including for commercial, recreational, and tribal harvests. Some comments question the EIR's analysis of the combined long-term effect of reintroduction and reduced hatchery production, and its potential effects on harvest, while others express support for the analysis.

Please refer to Volume III Attachment 1 Section 3.3 *Aquatic Resources – Potential Impacts and Mitigation* Potential Impact 3.3-7 for analysis of predicted escapement of fall-run Chinook salmon following reduced hatchery production under the Proposed Project, and Potential Impact 3.12-9 for additional discussion of the effect of anticipated changes in fall-run Chinook salmon abundance (including reduced hatchery production) on tribal fisheries. These sections include revised averages of the predicted impact on fall-run Chinook returns that take the differences in smolt and yearling production goals into account. The revised analysis indicates that the average reduction in adult returns will be 3,552, rather than 7,120 as estimated in the draft EIR. The revised analysis does not change significance determinations. Volume I Section 5.4.1.1 *Consideration of Economic Information for Resources Potentially Affected by Dam Removal – Commercial Fishing* (pages 5-5 to 5-7) and Volume I Section 5.4.1.2 *Consideration of Economic Information for Resources Potentially Affected by Dam Removal – Ocean Sport Fishing* (page 5-7) provides a discussion of the potential economic effects of the Proposed Project for commercial and ocean sport fishing.

As described in Volume 1 Section 2.1 *Proposed Project – Project Objectives* (page 2-1), one of the primary objectives of the Proposed Project is to advance the long-term restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation. Overall, the EIR finds that implementing the Proposed Project would further that objective. Dam removal would improve and expand spawning and rearing habitat for salmon on the Klamath River, improve water quality, reduce the incidence of disease, and restore more natural variation in the flow regime in the areas currently affected by Lower Klamath Project, all of which would benefit salmon populations over the long term.

As described in Volume III Attachment 1 Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* and Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, the EIR acknowledges that fewer hatchery adults are likely to return starting in post-dam-removal-year three, and that there is uncertainty as to the rate at which these stocks would be replaced through increases in wild-spawned salmonids and expected improved survival of both hatchery and wild fish in light of the Proposed Project. The EIR ultimately finds that dam removal would benefit the fish population in the long term, and would not significantly reduce fish populations – including fish available for harvest – in the short term (Potential Impact 3.3-7, Potential Impact 3.12-9).

Overall, multiple lines of evidence discussed in the EIR (both quantitative and qualitative), including consideration for the uncertainty in predicting adult abundance following the Proposed Project (which is discussed in Master Response AQF-8), support a prediction of increased fall-run Chinook salmon abundance available for commercial, recreational, and traditional cultural uses of salmon.

The multiple lines of evidence evaluated in the EIR include the following:

- limited duration of expected suspended sediment effects from dam removal;
- expected improved survival for both wild and hatchery-spawned juvenile salmonids after dam removal, based on improved water quality conditions and reduced disease;
- continued hatchery operations for eight years post-dam-removal;
- quantitative fish population modeling output from multiple studies;
- multiple overview studies, including Expert Panel consideration, indicating that dam removal is likely to result in increased anadromous fish abundance;
- availability of additional high-quality spawning and rearing habitat; and
- available observations in other watersheds of rates of recolonization after dam removal projects and other major habitat accessibility events.

Please note that potential effects from implementing a project that are solely social or economic in nature – such as reduced income from fisheries harvests – are not environmental impacts that must be analyzed under CEQA (please also refer to Volume I Section 5.4 *Social and Economic Factors Under CEQA* [pages 5-3 to 5-12]). Economic and related social effects form the core of some commenters concerns. Because these issues are a profound concern for affected communities, this response summarizes the results of an analysis conducted by the United States Bureau of Reclamation (USBR) for development of the 2012 KHSA EIS/EIR. In summary, USBR found that commercial fishing landings would increase in the long-term following dam removal because salmon would have access to more habitat upstream of Iron Gate Dam, which would increase salmon abundance that would also be likely to increase fishing revenues. Increased salmon populations would also attract more ocean recreational fishing, which would be likely to increase spending in the regional economy (USBR 2012c). Dam removal would increase fish harvest for subsistence, cultural practices, and commercial uses, and it would be likely to provide economically beneficial opportunities for Native American Tribes residing on the Klamath River, as described in Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources* Potential Impact 3.12-9. These conditions are also likely to result in increased opportunities and revenue for recreational fishing guides.

AQF-4 Historical Abundance of Salmonids

Several comments assert that historical salmonid abundance was low in the Klamath River, or that historical abundance of salmonids upstream of Iron Gate Dam was low, or that no anadromous fish occurred upstream of the current location of Iron Gate Dam. Some comments make assertions about particular species of salmonids. Other comments assert that strong salmon runs were found upstream of the current Hydroelectric Reach. These comments do not address the EIR's analysis of the Proposed Project's and project alternatives' respective potential impacts on salmonid abundance as compared to baseline conditions.

The EIR was developed to analyze environmental impacts from the KRRC's Proposed Project as well as alternatives to the KRRC's Proposed Project and does not include a comprehensive history detailing the physical extent of each anadromous fish species in the Klamath Watershed. Available data on historical abundance of salmon in the Klamath River watershed prior to Lower Klamath Project construction is summarized in the Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Anadromous Fish Species*, specifically Table 3.3-2.

AQF-5 Disease Risk Upstream of Iron Gate Dam

Several comments assert that disease risk will increase upstream of Iron Gate Dam under the Proposed Project, and that the EIR does not provide an accurate prediction of disease risk or use best available information for the analysis.

Factors that Influence Development of a Nidus

As described in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, the current infectious nidus (reach with high infectivity) for *C. shasta* and *P. minibicornis* is located in the Klamath River downstream of Iron Gate Dam, where returning adult spawners congregate. As summarized in this section, the current infectious zone and high parasite loads below Iron Gate Dam are the result of a synergistic effect of numerous factors that occur downstream of Iron Gate Dam, and result in a observed high incidence of disease in the Klamath River from the confluence with the Shasta River downstream to Seiad Valley (FERC 2007, Hamilton et al. 2011, Bartholomew and Foott 2010). These factors include: (1) close proximity of myxospore-shedding carcasses (high concentration of carcasses); (2) abundant polychaete populations that are found in atypically stable habitats; (3) disease-suitable water temperatures (greater than 59°F) during periods when juvenile salmonids are present; and (4) low flow variability (Bartholomew and Foott 2010). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources.*

Bartholomew and Foott (2010) report that it is uncertain what threshold density of salmon carcasses is required to maintain infection in polychaetes, and suggest that when returning adult salmon migrate past Iron Gate Dam into upriver tributaries to spawn there may be a reduction in myxospore availability in the current nidus downstream of Iron Gate Dam. PacifiCorp cites Foott et al. (2016) to claim that the concentration of carcasses does not influence the formation of a nidus, pointing to the Foott et al. (2016) finding that relatively few, very highly infected, adult Chinook carcasses are capable of fully seeding polychaete populations in the river reaches. However, Foott et al (2016) experimentally tested the effect of removing carcasses from the river after spawning on future disease transmission – their work did not examine the effect of reduced congregations of spawners on the formation of a nidus. Foott et al. (2016) recommended that mitigation measures should focus on the reduction of polychaetes or increased flows rather than the labor-intensive effort of removing carcasses. The study did not conclude that spawning congregations do not contribute to the formation of a nidus.

Consistent with Foott el al (2016) recommendations, removal of the Lower Klamath Project dams under the Proposed Project would disrupt polychaete microhabitat conditions. Dam removal is expected to reduce polychaete populations (Stocking and Bartholomew 2007, Bartholomew and Foott 2010) and presumably reduce infection rates within polychaete populations both in the short and long term (Hetrick et al. 2009).

Additionally, implementation of the 2019 BiOp flows (see Master Response HYD-1), coupled with implementation of the Proposed Project, would increase flushing flows above the 2016 existing conditions baseline, which relied on the 2013 biological opinion flows that did not include a flushing flow requirement. These flushing flows would be managed with the intent of mobilizing bedload sediments to disrupt the periphyton intermediate host of the polychaete.

PacifiCorp also cites the summaries of Som and Hetrick (2016) and the results from 2016 monitoring reported by Bartholomew et al. (2017) to note that highest prevalence of mortality from disease has shifted over the years from Beaver Creek (RM 163.4) downstream to Seiad Valley (RM 132.7). PacifiCorp contends that this suggests that congregations of spawners do not contribute to the formation of a nidus. However, in contrast to PacifiCorp’s contention, Bartholomew and Foott (2010) state that the spatial overlap of both carcasses resulting from large spawning congregations and polychaetes is a key factor in predicting where parasite abundance would increase. Furthermore, the formation of a nidus between the Shasta River and Indian Creek could be explained by a high concentration of spawning adult salmon within the same river reach, since a high concentration of spawning adult salmon creates carcasses that provides myxospores the ability to infect the dense polychaete populations in the reach downstream of Iron Gate Dam.

In addition, Som and Hetrick (2016), summarized results examining a range of potential variables for myxospore concentration. Som and Hetrick (2016) cited “a decade of monitoring” and the work of Foott et al. (2016), to conclude that Iron Gate Hatchery and Iron Gate Dam influence the current concentration of adult carcasses upstream of the Shasta River confluence. Som and Hetrick (2016) explain that the high concentration of adult salmon that return to the Iron Gate Hatchery area congregate below the dam due to homing and the elimination of upstream migration due to Iron Gate Dam. Congregation of adult salmon below

Iron Gate Dam contributes the bulk of myxospores due to adult spawners' close proximity to each other, a concentration of fish carcasses, and the stable river substrate that provides polychaete habitat allowing myxospores to continue the parasites life cycle within the nidus.

Bartholomew et al. (2017) reported lower infection at all monitoring sites in 2016, particularly from Beaver Creek and other upstream locations, which they attribute to the effectiveness of high flows that occurred in March 2016 and resulted in decreased polychaete densities at the upstream sites. Bartholomew et al. (2017) suggest that polychaetes displaced from reaches downstream of Iron Gate Dam during the high magnitude, short duration flood in March 2016, settled out further downstream resulting in the relatively high polychaete densities detected at the Orleans site. Bartholomew el al. did not conclude that congregations of adult Chinook salmon are not contributors to the formation of a nidus, as suggested by PacifiCorp.

In summary, none of the sources cited in the comments indicate that the EIR erred in identifying and analyzing multiple factors relating to the formation of reaches of high disease transmission, including crowding and its relation to migration barriers.

Risk of Nidus Forming Upstream of Iron Gate Dam

As discussed in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, it is unlikely that a new infectious nidus would be created upstream following implementation of the Proposed Project. The likelihood of the synergistic factors described above in *Factors that Influence Development of a Nidus* (AQF-5) developing upstream of Iron Gate Dam would be reduced (Hamilton et al. 2011). Close proximity of myxospore-shedding carcasses would be reduced because salmonid carcasses would be more likely to be dispersed over a greater area in the watershed upstream of Iron Gate Dam as well as downstream of Iron Gate Dam, than currently occurring under existing conditions (Foott et al. 2012, Som and Hetrick (2016), suitable water temperatures (greater than 59°F) would be reduced, and flow variability would be increased.

The Federal Energy Regulatory Commission (FERC) has determined that restoring access to reaches upstream of Iron Gate Dam for anadromous fish would allow adult fall-run Chinook salmon to distribute over a greater length of the river, reducing crowding and the concentration of disease pathogens that currently occur in the reach between Iron Gate Dam and the Shasta River (FERC 2007). Under the Proposed Project, the hatchery would reduce production numbers, and then ultimately cease operations, reducing the number of adult spawners returning to the site of the current nidus by post-dam removal year 3, and then further by post-dam removal year 11 (Volume III Attachment 1 Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries*).

At this time, Iron Gate Dam is both the limit of anadromy, and the site of the fish hatchery.

Nidus Risk Downstream of Keno Impoundment/Lake Ewuana

As discussed in Volume III Attachment 1 Section 3.3.5.3 *Aquatic Resources – Potential Impacts and Mitigation – Water Quality*, the Keno Impoundment/Lake Ewuana has the potential to be a habitat barrier during most years for fall-run Chinook during July through October due to poor water quality. In light of this, NMFS and USFWS had prescribed fish passage measures for the Keno Impoundment/Lake Ewuana to be implemented during periods of poor water quality as part of the previous relicensing efforts for the then PacifiCorp owned Klamath Hydroelectric Project (DOI 2007). Currently, fish passage around the Keno Impoundment/Lake Ewana at times of poor water quality is not proposed under the Proposed Project. Comments have suggested that if fish passage were not provided around the Keno reach, fall-run Chinook salmon could congregate downstream of Keno Impoundment/Lake Ewuana thereby creating the crowding conditions related to increased fish disease transmission. However, as discussed in the Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, if fish passage were not provided at Keno Impoundment/Lake Ewuana, likely fewer fall-run Chinook salmon would migrate past this location, and therefore fewer smolts would return from reaches above Keno. This means that fewer returning adults would have a natal cue to migrate past this location, and so congregations of adult fall-run Chinook salmon would be less likely to gather downstream of Keno Dam. In contrast, downstream of Iron Gate Dam, thousands of adults return to the hatchery, and congregations annually occur during the fall.

Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* has been revised to provide additional information regarding the potential for a fish disease nidus to form upstream of Iron Gate Dam (including at Keno Impoundment/Lake Ewuana) under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* for the revisions.

Nidus Risk Within the Sprague River

Regarding the potential for a disease nidus upstream of Keno Dam, it appears that historically, spawning concentrations of Chinook salmon in the Upper Klamath Basin were located primarily in the Sprague River (Lane and Lane Associates 1981). However, there is no information indicating that high densities of polychaetes historically occurred in the Sprague River (Foott et al. 2012), there are not fish passage obstacles or other factors leading to large congregations of adults, and water temperatures are low (< 59ºF). Thus, the synergistic factors that currently contribute to an infectious nidus for emigrants below Iron Gate Dam and near the Iron Gate Hatchery are unlikely to occur just downstream of Keno Impoundment/Lake Ewuana under the Proposed Project or farther upstream.

Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* has been revised to provide additional information regarding the potential for a fish disease nidus to form in the Sprague River under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* for the revisions.

Periphyton Growth and Polychaete Habitat

Comments also assert that under the Proposed Project increased periphyton[4] growth downstream of Keno Dam in the Hydroelectric Reach would increase habitat for the polychaete intermediate host of *C. shasta* and *P. minibicornis* and citing Bartholomew et al. (2017) as evidence of high polychaete density in that reach. Other comments note that the J.C. Boyle Bypass Reach also has a high density of periphyton. Some comments assert that the Draft EIR does not consider increased habitat for polychaetes as a potential for increased disease risk upstream of Iron Gate Dam.

Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* considers factors under the Proposed Project anticipated to result in a potential for increased periphyton growth, as well as factors anticipated to result in a reduction in periphyton growth. The EIR acknowledges that some of the Proposed Project's anticipated effects (such as the elimination of lotic reservoir habitat) would tend to support increased periphyton growth in the Hydroelectric reach. Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* also discloses that other anticipated effects of the Proposed Project would reduce periphyton growth from existing conditions by removing adverse environmental effects of continued operations of the Lower Klamath Project and restoring more natural conditions such as bedload transport processes and natural temperature regimes. Overall, the EIR finds that under the Proposed Project additional periphytic growth including *Cladophora* is anticipated within the Hydroelectric Reach, which would continue to provide habitat for the intermediate host of *C. shasta* and *P. minibicornis*. This anticipated increase in the intermediate host in the Hydroelectric Reach is one of the considerations the EIR evaluates in discussing the risk of formation of a new nidus upstream of Iron Gate Dam. As noted above, this is one factor in a multi-factor causation that can contribute to nidus formation and as implementation of the Proposed Project removes several other factors needed for formation of a nidus, it is not anticipated that an increase in periphyton in the Hydroelectric Reach would result in the formation of a nidus upstream of Iron Gate Dam.

[4] Periphyton is a complex mixture of algae, cyanobacteria, heterotrophic microbes, and detritus that is attached to submerged surfaces in most aquatic ecosystems.

Flushing Flows

As described in Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required downstream of Iron Gate Dam between February 2017 and March 2019, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments to disrupt the polychaete intermediate host that lives within periphyton mats. As described in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, under the Proposed Project, if a nidus were to form within newly accessible upstream habitat (as discussed above), flushing and emergency dilution flow releases as required by the 2017 court order may be required from a new upstream location to achieve the same ecological benefits (i.e., disruption of nidus).

After the issuance of the Lower Klamath Project Draft EIR on December 27, 2018, the applicable biological opinion and the operational flow requirements for the Klamath River changed again in March 2019, when the new biological opinions were issued by NMFS (2019) and USFWS (2019a), which continue the requirements for surface flushing flows. The 2019 BiOp Flows are now the current operational flow requirement for the Klamath River.

Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* has been revised to clarify how the 2019 BiOp Flows would likely affect the potential for a new infectious nidus to form downstream of Keno Dam. The addition of 2019 BiOp flows do not change the significance determinations of the EIR. Please refer to Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* for revisions regarding BiOp flow requirements.

Migration Distance and Actinospore Exposure Duration

Comments also assert that juvenile salmon spawned and reared upstream of Iron Gate Dam would be exposed to actinospores for a longer period of time than salmon spawned and reared downstream, since the migration distance to the Klamath River Estuary is greater. Actinospores are a life history stage of the parasite released by the polychaete host – these actinospores can then infect salmonids. Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* discusses the available scientific data on actinospore exposure of juvenile salmonids and resulting disease risk.

Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* has been revised to discuss actinospore exposure upstream of Iron Gate Dam. Please refer to Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* for the revisions.

While migration distance and time for salmonids accessing historical habitat upstream of Iron Gate Dam would be greater than under the current conditions, environmental conditions resulting in disease infection are a result of several variables in addition to migration distance, as discussed in more detail in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites,* and in *Factors that Influence Development of a Nidus* (AQF-5) above.

AQF-6 Disease Risk Downstream of Iron Gate Dam

Several comments assert that disease risk will not improve downstream of Iron Gate Dam under the Proposed Project, while other comments express support for the EIR's conclusion that the Proposed Project is likely to reduce disease risk, and that the Proposed Project is urgently needed to improve survival of salmonids produced in the Klamath River Basin. Some comments point to declines in disease rates in 2017 and 2018, and/or to recent information on the number of infected carcasses necessary to seed a stream reach, to suggest that the Proposed Project will not reduce disease risk downstream of Iron Gate Dam.

As discussed in detail in Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Diseases and Parasites* and Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, fish diseases that may affect fish in the Klamath Basin include the external protozoan parasite *Ichthyophthirius multifis* ("Ich") and the bacterial pathogen *Flavobacterium columnare* ("columnaris disease"). There is increasing evidence to suggest that disease levels are adversely affecting freshwater production of Chinook and coho salmon in the Lower Klamath River, particularly during periods of high ocean productivity. Additional fish diseases periodically result in substantial mortality for Klamath River salmonids – including most prominently diseases resulting from infection by two parasites from a class of parasites called "myxozoa" *Ceratomyxa shasta (C. shasta)* and *Parvicapsula minibicornis (P. minibicornis)*. These parasites require two hosts – one salmonid, and the other a type of worm called a polycheate that lives in stable river sediments, and particularly prefers habitats created by attached algae that forms matts, like *Cladophora*. High infection rates have been documented in emigrating juvenile Chinook and coho salmon, primarily by one or both of these myxozoan parasites. Steelhead can become infected as well, though steelhead are generally resistant to *C. shasta*. Fish health studies have consistently documented high infection incidence in the Klamath River during the spring and summer. Infection by *C. shasta* has been identified as the most significant disease for juvenile salmon in the lower Klamath River and salmon that become are not likely to survive to adulthood. FERC (2007) concluded that dam removal would enhance water quality and reduce the cumulative water quality and habitat effects that contribute to disease-induced fish kills in the Klamath River downstream of Iron Gate Dam. In general, improvements to water quality, increased bedload mobility (i.e., scour of stable substrate), diversity of flows, water temperature regimes unaltered by reservoir storage, and reduced planktonic drift from reservoirs with dam removal would alleviate many of the conditions conducive to salmon disease downstream of Iron Gate Dam.

This master response summarizes the key factors that affect disease risk downstream of Iron Gate Dam, which are detailed in the EIR, including the location of the infectious nidus, trends in the prevalence of infection, polychaete population resilience to flow-mediated disturbance, and water temperature and disease risk downstream of Iron Gate Dam.

Location of Infectious Nidus

As described in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites, and AQF Master Response 5* the current infectious nidus (portion of the Klamath River with high infectivity) for *C. shasta* and *P. minibicornis* can vary among years, but is primarily located in the Klamath River downstream of Iron Gate Dam, often in the reach from the confluence of the Shasta River to Seiad, where returning adults spawners congregate. The current infectious nidus and high parasite loads downstream of Iron Gate Dam are the result of a synergistic effect of numerous factors, some of which result from the presence of Iron Gate Dam and operations of the Lower Klamath Project, including close proximity of myxospore-shedding carcasses (concentration of carcasses), abundant polychaete populations that are found in atypically stable habitats, suitable water temperatures (greater than 59°F) during periods when juvenile salmonids are present, and low flow variability (Bartholomew and Foott 2010).

Please also see further discussion in Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites*, which provides further explanation of the connection between the atypical stability of the river channel downstream from Iron Gate Dam since dam construction, and the corresponding favorable habitat for the polychaete worm host, which, in turn, likely increases the parasite load to which the fish are exposed.

Removing the Lower Klamath Project dams would improve flow variability, increase substrate mobility, reduce seasonally warm water temperatures in key juvenile outmigration periods, and reduce planktonic food sources for polychaetes, disrupting these factors that favor polychaetes and *C. shasta* and *P. minibicornis* infection (Hetrick et al. 2009). Dam removal would also remove a major barrier to fish migration and reduce the concentration of spawners and carcasses that presently occurs downstream from the dam and contributes to disease. Greater dispersal of salmon spawners (and thus their carcasses) would reduce their proximity to dense populations of polychaetes.

As described in Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites,* FERC's analysis

(FERC 2007) concluded that restoring access to reaches above Iron Gate Dam for anadromous fish would allow adult fall-run Chinook salmon to distribute over a greater length of the river, reducing crowding and the concentration of disease pathogens that currently occur in the reach between Iron Gate Dam and the Shasta River. The effect of carcass density on infection risk is discussed in additional detail in Master Response AQF-5. Additionally, FERC (2007) concluded that restoring natural sediment transport processes would likely contribute to the scour of periphyton downstream from the current location of Iron Gate Dam, and deposited gravel and sand would provide a less favorable substrate for periphyton because of its greater mobility during high flow events than the existing armored substrate. The reduction in periphyton would provide less habitat for the polychaete intermediate host of *C. shasta* and *P. minibicornis*, which is predicted to reduce the infection rate of juvenile salmonids downstream from Iron Gate Dam (FERC 2007).

Trends in Prevalence of Infection (POI)

Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* discusses available data on infection rates for fish disease and parasites in the Klamath River. The section has been revised to incorporate fish infection information from True et al. (2017) and Voss et al. (2018) as cited by commenters. Please see Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* for the revisions.

However, contrary to some comments' assertions, existing data is insufficient to identify a declining trend in fish disease. Voss et. al. (2018), and True et. al. (2017) do not conclude that there has been a significant decline in infection rates or suggest that disease is no longer a substantial limitation to salmonid production in the Klamath River. The lower disease numbers after years of much higher disease rates are within the variability of the past decade, and do not warrant a shift in the EIR's approach to analyzing disease dynamics. Following surface flushing flows in 2019, POI in juvenile Chinook salmon captured in the Klamath River in the reach from Shasta to Scott River confluences ranged from 60 percent in late April to 80 percent in early May (USFWS 2019b).

Polychaete Population Resilience to Flow-Mediated Disturbance

Several comments cite Malakauskas et al. (2013) and Shea et al. (2016) to assert that polychaete populations likely exhibit high resilience to flow-mediated disturbance, and that the flows that may be necessary to induce scour and disrupt polychaete habitat are above flow thresholds that are expected to be achieved following implementation of the Proposed Project. As discussed in Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites*, the highest densities of polychaetes have been observed in areas with stable substrates (Bartholomew and Foott 2010). The mobilization of particles on the bed of the channel downstream from Iron Gate Dam depends directly upon the size of the substrate and magnitude of peak flows. The greater the flows, the larger the particles likely to be moved, and the smaller the particles, the lower the flows required for mobilization. As assessed by Shea et al. (2016), under existing conditions with dams in place, sediment supply is reduced, flow variability is decreased, and conditions supporting the persistence of polychaetes are more prevalent (Shea et al. 2016).

The study cited by comments (Malakauskas et al. 2013) does not provide support for the suggestion that the relatively high flows that may be needed to scour polychaete habitat under current conditions are above thresholds of flows that are expected to be achieved under the Proposed Project. Furthermore, restoring natural sediment supply under the Proposed Project would reduce the threshold flow required to achieve effective surface flushing flows in the reach immediately downstream of Iron Gate Dam. While the Proposed Project itself does not substantially affect flows, it would contribute to the frequency with which flows result in bed mobilization.

Malakauskas et al. (2013) performed flume experiments to evaluate flow requirements for dislodging polychaetes. Their results highlight the resilience to flow-mediated disturbance, but the authors do not conclude that disruption is ineffective. Rather, their findings indicate that substrate size has a great influence of resilience of polychates to disruption (smaller particles, greater susceptibility), and that when sheer velocities are sufficient, polychaetes are dislodged. The authors speculate that dislodged polychaetes have high survival in the short-term but are more susceptible to predation, and to settling in suboptimal habitat, thus decreasing their longer-term survival.

Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* has been revised to include recent work by Malakauskas et al. (2013) as discussed above. Please see Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* for the revisions.

Water Temperature and Disease Risk Downstream of Iron Gate Dam

PacifiCorp and other commenters have asserted that water temperature changes under the Proposed Project would increase disease risk downstream of Iron Gate Dam and claim that the DEIR does not appropriately examine the potential for increased spring temperatures to exacerbate *C. shasta* infection prevalence.

The EIR includes a broad discussion of the effects of water quality (including water temperatures) on disease risk based on available scientific data. As discussed in Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Diseases and Parasites*, the water quality conditions that may increase fish stress levels (thereby reducing fitness and increasing risk of disease infection) include: (1) increased water temperatures in the late summer and fall; (2) swings in DO, pH, and ammonia levels associated with algal blooms in Lower Klamath Project reservoirs; and (3) effects of exposure to elevated levels of the algal toxin microcystin produced during intense blooms of blue-green algae (cyanobacteria) in Copco No. 1 and Iron Gate reservoirs, which may also result in direct mortality. Of these water quality factors; water temperature is the most directly studied and also is likely to have the greatest direct effect on disease transmission: it was also the parameter raised specifically in the comments this master response addresses. Thus, this master response focuses on water temperature-related disease risk, with the overall improvements expected from other parameters as background context. Volume III Attachment 1 Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* discusses increased risk of disease transmission with warmer water, and that dam removal would mean cooler temperatures in the late summer and fall, but slightly warmer temperatures during spring and early summer. Based on existing scientific assessments (e.g., FERC 2007, Bartholomew and Foott 2010), it appears that a reduction in temperature during late summer and fall would have the overall effect of reducing disease rates despite a slight increase in water temperatures during early spring.

Volume III Attachment 1 Section 3.3.5.3 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature* considers the potential that the presence of the Lower Klamath Project dams reduces fish stress during the spring by delaying the increase in water temperature. However, Bartholow et al. (2005) suggests that earlier warming of the river system may trigger juvenile salmonids rearing within the mainstem Klamath River to outmigrate earlier, which would allow them to avoid prolonged exposure to disease factors that are in part caused by the Lower Klamath Project dams.

Similarly, FERC concluded that more rapid cooling of river temperatures in the fall may also allow fall-run Chinook salmon in the mainstem to spawn earlier in the fall than observed under existing conditions with the Lower Klamath Project dams in place. More rapid cooling of river temperatures in the fall would likely result in earlier emergence and growth (for mainstem spawners), and encourage earlier emigration (FERC 2007). This is consistent with findings that accumulated temperature units are more important predictors of migration of juvenile Chinook salmon than flow or photoperiod (duration of day receiving sunlight) (Sykes et al. 2009). A predicted earlier outmigration in response to elevated water temperatures in the spring is also supported by a vast body of literature relating to increased growth rates and thermal response of emigrating salmonids (Hoar 1988). Many emigrants would avoid the unsuitably warm water temperatures that currently occur in late spring to midsummer in most years. This post-emergence growth and outmigration dynamic is predicted for all salmonids migrating in the mainstem Klamath River, regardless of whether they originated within tributaries or the mainstem Klamath River. Under the dam removal scenarios analyzed in the EIR, these emigrants would thus minimize their exposure to disease.

AQF-7 Bedload Sediment and Aquatic Habitat

Several comments assert that under the Proposed Project deposition of bedload sediment in the river reaches downstream of Iron Gate Dam would be detrimental to aquatic resources.

Bedload sediment is sediment that moves along the riverbed. The EIR assesses the potential for dam removal to release coarse sediment stored behind the dams to the Middle and Lower Klamath River, where it could be deposited on the riverbed and adversely impact aquatic habitat in the Middle and Lower Klamath River. For a discussion of how the EIR analyzes the potential impacts of fine sediment related to dam removal, please refer to Master Response GEO-1.

As described in Volume III Attachment 1 Section 3.3.5.2 *Aquatic Resources – Potential Impacts and Mitigation – Bed Elevation and Grain Size Distribution*, Volume II Appendix F *An Analysis of Potential Bedload Sediment Effects on Anadromous Fish in the Klamath Basin*, Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-265 to 3-776), and USBR (2012a), the reservoirs created by the Lower Klamath Project dams have trapped most of the fine sediment (silt and clay sized material) and all of the coarse sediment (sands, gravels, and cobbles) from upstream sources since their construction.

Interception of coarse sediment by the dams has caused the bed material in both riffle and pool sections downstream from the dams to be less mobile than it would be under natural conditions, creating conditions that increase the risk of fish disease (please refer to Master Responses AQF-5 and AQF-6), and that reduce salmonid spawning gravel quality. The presence of the dams has reduced the bed mobility of gravels and cobbles in the Klamath River between Copco No. 1 Reservoir and Cottonwood Creek (USBR 2012a).

AQF-8 Uncertainty in Fall-run Chinook Salmon Production and Recolonization

Several comments assert that the EIR does not adequately address uncertainty associated with fall-run Chinook salmon production and recolonization under the Proposed Project.

Please refer to Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 for a discussion of the best available and most current scientific and factual data on the likely response of fall-run Chinook salmon to the Proposed Project. In this section, the EIR states that no particular fall-run Chinook population change in abundance associated with dam removal is certain. In light of the uncertainty, the EIR predicts the *likelihood* of *increased* fall-run Chinook abundance under the Proposed Project based on multiple lines of evidence, including:

- limited duration of expected suspended sediment effects from dam removal;
- expected improved survival for both wild and hatchery-spawned juvenile salmonids after dam removal, based on improved water quality conditions and reduced disease;
- continued hatchery operations for eight years post-dam-removal;
- quantitative fish population modeling output from multiple studies;
- multiple overview studies, including Expert Panel consideration, indicating that dam removal is likely to result in increased anadromous fish abundance;
- availability of additional high-quality spawning and rearing habitat; and
- available observations in other watersheds of rates of recolonization after dam removal projects and other major habitat accessibility events.

The EIR does not solely rely on any one particular source.

As discussed in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, quantitative modeling of fall-run Chinook salmon populations predicts that the Proposed Project would increase Chinook salmon abundance. Modeling of dam removal and existing conditions by Oosterhout (2005) suggests that dam removal would substantially increase Chinook fall-run spawners over a 50-year period relative to other management scenarios. Additional population capacity and modeling efforts support this conclusion (Huntington 2006, Dunsmoor and Huntington 2006, Hendrix 2011, Lindley and Davis 2011).

Of the available models, the Hendrix (2011) life-cycle model (Evaluation of Dam Removal and Restoration of Anadromy [EDRRA]) approach is considered the most intensive and robust model undertaken to date, because it explicitly addressed the Proposed Project, used stock-recruitment data from the Klamath River, explicitly incorporated variability in watershed and ocean conditions, and notably, presented variance estimates of uncertainty. In the development of this model, Hendrix analyzed a time series of spawner and recruitment data from 1979 to 2000 in the Lower Klamath Basin (STT 2005) and used the results of this analysis to forecast future productivity of Chinook salmon in the Lower Klamath River Basin. Therefore, results of the EDRRA model implicitly incorporate varying ocean and freshwater conditions encountered in the Klamath Basin and nearshore ocean environment that influenced survival Chinook salmon historically.

As described in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, results of the model indicate that there is a substantial uncertainty in

Chinook salmon stock recruitment dynamics, resulting in uncertain escapement and harvest abundance forecasts. Despite this uncertainty, modeling results indicate that the Proposed Project would result in higher abundances of Chinook salmon relative to the No Project Alternative. The median numbers of adult spawners that return to the Klamath Basin are predicted to be higher under the Proposed Project than under existing conditions. Harvest is also predicted to be greater under the Proposed Project, and the probability of low escapement leading to fishery closures is less under the Proposed Project as compared with existing conditions. Finally, model simulations predict that there is approximately a 75 percent probability that there would be higher escapement, and approximately a 70 percent probability of higher annual harvest, under the Proposed Project as compared with existing conditions.

In addition to quantitative modeling results (Hendrix 2011), FERC (2007), Hetrick et al. (2009), and Hamilton et al. (2011) synthesized available information and concluded that increased habitat access following dam removal would result in an increase in the abundance of Chinook salmon population in the Klamath River Watershed.

The Expert Panel Reports are an important part of the diverse and extensive scientific record for the Klamath Basin. The Expert Panel reports, while acknowledging that there is a degree of uncertainty in their findings and identifying several challenges to restoration of fishery resources in the Klamath Basin, conclude an increased probability of successfully restoring Chinook, coho, and steelhead runs with dam removal.

The U.S. Fish and Wildlife Service (USFWS) convened the Expert Panels to review, evaluate, synthesize, and provide scientific assessments regarding the likely trajectories of fish populations with and without implementation of dam removal and other restoration actions. The Expert Panels provided valuable independent reviews in addition to the various studies, reports, and scientific information considered in this EIR. Having the Expert Panel reports as a part of the robust analyses considered when preparing the EIR provides increased confidence in the EIR findings regarding fish and fisheries.

In addition to quantitative and qualitative predictions of fall-run Chinook salmon abundance, Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 summarizes observations of fall-run Chinook salmon recolonization following dam removal in other watersheds. Recolonization success and rate is a function of fish straying into newly available habitats (Pess 2009). Typical stray rates for Chinook salmon are around six percent (Hendry et al. 2004), and 95 percent of strays migrate less than 20 miles from their natal area (Quinn and Fresh 1984, Quinn et al. 1991). However, following major changes in environmental conditions (e.g., dam removal, high SSC), salmonid stray rates have been observed to increase. The time period of colonization (historical or new habitat) has been reported to occur within months to years, and most typically within one to two decades (Withler 1982, Bryant 1999, Burger et al 2000, Glen 2002, Pess et al. 2003, Milner et al. 2008, Kiffney et al. 2009). Recolonization was observed for fall-run Chinook salmon within months of removal of Condit Dam on the White Salmon River, Washington (Allen et al. 2016). Fall-run Chinook salmon were observed to recolonize habitat upstream of the former location of the Elwha Dam within the first year of dam removal, and within five years of dam removal a majority of returning adults were spawning in newly accessible habitat upstream of the former dam location (Weinheimer et al. 2018).

As explicitly described in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, there is uncertainty in the response of fall-run Chinook salmon to the Proposed Project, as captured by the variance in predicted increases in abundance modeled by Hendrix (2011) and others. However, the preponderance of evidence considered by the Expert Panels and summarized in the EIR, and the observations of fall-run Chinook salmon recolonization following dam removal in other watersheds, support a prediction for increased fall-run Chinook salmon in the Klamath River under the Proposed Project.

AQF-9 Threshold for Impacts to Aquatic Species

Several commenters assert that the Draft EIR does not accurately assess the magnitude of impacts from the Proposed Project on coho salmon. They contend that substantial impacts are not accurately reflected in the threshold for a significant impact maintaining that the 50 percent reduction in the abundance of a year class is too high to use as a threshold, and that lesser impacts on coho salmon would still be substantial and should be considered a significant impact.

As discussed in Volume III Attachment 1 Section 3.3.3 *Aquatic Resources – Significance Criteria*, significance criteria thresholds used in the EIR are consistent with Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.). Analysis of coho salmon and other focal species in the EIR considers any impact that substantially reduces the abundance of a year class to be a significant impact. As described in Section 3.3.2.1 Aquatic Species [coho salmon], Williams et al. (2006) described nine population units of coho salmon in the Klamath Basin to support recovery planning for the listed coho salmon SONCC ESU. Analysis of coho salmon in the EIR considers impacts and benefits for each of the nine population units in the Klamath Basin separately but makes a significance determination for all population units combined within the Klamath Basin to be consistent with the approach to assessing other aquatic species populations, and to be consistent with the NMFS 2014 Southern Oregon/Northern California Coast (SONCC) Recovery Plan, which assesses all of the coho salmon in the Klamath River Basin as part of the same ESU. The EIR engages in a multi-factored analysis – both numeric and qualitative – to evaluate the significance of potential impacts to the species populations. This includes consideration of factors such as species life history, spatial distribution, population trends and variability, behavior, disease susceptibility and trends, and hatchery production for the species.

There is not a requirement under CEQA guidelines to establish a quantitative threshold for "substantial." In the EIR a numeric threshold of 50 percent was included as a number above which an aquatic species impact would necessarily be substantial.

Volume III Attachment 1 Section 3.3.3 *Aquatic Resources – Significance Criteria* has been revised to clarify that a reduction of less than 50 percent could also potentially be substantial, depending on a multifactored analysis. Please see below and refer to Volume III Attachment 1 Section 3.3.3 *Aquatic Resources – Significance Criteria* for the revisions.

"In the short term, effects of the Proposed Project would be significant if they:

- Substantially reduce the abundance~~(greater than 50 percent reduction)~~ of a year class for aquatic species, based on a comprehensive analysis that includes numeric analysis where available, qualitative analysis, and other relevant information. Any reduction of 50 percent or greater of a year class is necessarily a substantial reduction."

"In the long term; five years after removal of all dams, effects of the Proposed Project would be significant if they:

- Substantially reduce the abundance ~~(greater than 50 percent reduction)~~ of an adult population or year class for aquatic species, in any one generation, based on a comprehensive analysis that includes numeric analysis where available, qualitative analysis, and other relevant information. Any reduction of 50 percent or greater of a year class is necessarily a substantial reduction."

AQF-10 Potential Impacts to Fish of Sediment Release Due to Dam Removal

Several comments express concern regarding the volume of sediment that would be released under the Proposed Project, and the potential impacts of this release on fish in the Klamath River.

As discussed in Volume III Attachment 1 Section 3.3.5.1 *Aquatic Resources – Potential Impacts and Mitigation – Suspended Sediment* and Section 3.3.5.2 *Aquatic Resources – Potential Impacts and Mitigation – Bed Elevation and Grain Size Distribution*, there would be the following two major impacts on fish due to release of the stored fine reservoir sediment deposits: 1) short-term (dam removal year 1, dam removal year 2, and post-dam removal year 1) increase in suspended sediment concentrations (SSCs) in the Klamath River; and 2) short-term increase in the fine sediment content of the Klamath River bed material primarily from directly below Iron Gate Dam to the Klamath River confluence with Cottonwood Creek, as well as backwater areas and eddies. The estimated concentrations of suspended sediment in the Middle and Lower Klamath River downstream from the Hydroelectric Reach due to dam removal are discussed in Volume III Attachment 1 Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation –Suspended Sediment* Potential Impact 3.2-3. The elevated short-term SSCs resulting from dam removal are expected to be significantly above background levels downstream of the dams only for several weeks to months during and following reservoir drawdown.

There are three reasons why substantially elevated SSCs in the Klamath River are anticipated to be limited to this period. First, the majority of the erodible sediments are expected to erode during the reservoir drawdown period. Second, the KRRC is proposing a comprehensive revegetation plan for the reservoir footprint areas anticipated to stabilize the remaining sediment deposits with a goal of 90 percent ground cover within five years. Test plot evaluations conducted since publication of the Draft EIR indicate that this goal is achievable (KRRC 2019c). Finally, physical testing of reservoir sediments indicates that reservoir sediments become less erodible once dried (USBR 2012d). Drying of sediments is expected to occur within several months of sediment exposure depending on precipitation, at which point sediment resistance to erosion increases dramatically (see also Volume I Potential Impact 3.11-3).

Potential impacts on fish due to increases in SSCs in the Klamath River are expected to be greatest during the first year following dam removal, as detailed in Volume III Attachment 1 Section 3.3.5.1 *Aquatic Resources – Potential Impacts and Mitigation – Suspended Sediment* and Volume II Appendix E. Appendix E describes a modeling analysis of the potential impacts of suspended sediment on focal fish species under existing conditions, the Proposed Project, and the No Project Alternative. USBR used available data to characterize SSCs under existing conditions as information to model potential impacts. The type of model is an SRH-1D 2.4 sediment transport model. Using this model, USBR considered multiple drawdown scenarios for the Lower Klamath Project reservoirs (USBR 2012c). Application of the SRH-1D 2.4 to the analysis of SSCs during and following reservoir drawdown is considered “conservative,” because the model uses SSCs averaged laterally across the river channel (i.e., from river bank to river bank), whereas in actuality there are likely to be portions of the channel that exhibit lower concentrations of SSCs (e.g., along channel margins) that would potentially provide refuge for fish during periods of elevated SSCs. The approach therefore assumes a less-likely, greater-fishery-impact scenario, in light of the model limitations. Please see Master Response GEO-1 for further discussion of model selection including implications of applying a more precise two-dimensional model to assess the effects of dam removal on sediment transport and deposition downstream of Iron Gate Dam. Use of a more simplified model with conservative assumptions provides sufficient information regarding the potential extent of fisheries impacts.

Regarding the potential for impacts due to an increase in the amount of fine sediment present in the riverbed during and following dam removal, the likely physical impacts are described in Volume III Attachment 1 Section 3.3.5.2 *Aquatic Resources – Potential Impacts and Mitigation – Bed Elevation and Grain Size Distribution*. Volume II Appendix F addresses effects to fish as the result of anticipated bed material changes resulting from dam removal.

Overall, the EIR describes potential deleterious effects from fine and course sediment changes during the first year after dam removal, but the long-term benefits to fish would outweigh the short-term impairments from the Proposed Project.

For additional information regarding fine sediment erosion, transport, and deposition under the Proposed Project, please refer to Master Response GEO-1.

AQF-11 Coho Native Status in the Klamath River

Several comments have asserted that coho salmon are not native to the Klamath River, with some pointing to evidence that there have been stocking efforts in the past as an indication that the species did not occur prior to the stocking.

Coho salmon within the Klamath Basin are included within the Southern Oregon/Northern California Coast (SONCC) coho salmon ESU (NMFS 1997a); an inclusion that is predicated on coho salmon being native to the Klamath Basin. In addition, coho salmon in the Klamath Basin have been listed by the California Fish and Game Commission as threatened under the California Endangered Species Act (CESA) (CDFG 2002a), which is also predicated on coho salmon being native to the Klamath Basin.

Historical distributions of anadromous fish in the Klamath River are described in Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Anadromous Fish Species*. Credible scientific information describes the native North American range of coho salmon as extending from Alaskan coastal waters to the central California coast (Evermann and Clark 1931, Shapovalov and Taft 1954, Fry 1973, Moyle 1976, Sandercock 1991). This description is widely accepted by fishery biologists and ichthyologists. Brown and Moyle (1991) found records of the historic occurrence of coho salmon in 52 streams from the Smith River near the Oregon border to the Big Sur River on the central Coast. The largest concentration of wild coho occurs in the Eel River watershed (Brown and Moyle 1991), located just south of the Klamath Basin. The National Research Council (NRC) (2004a; 2008) lists coho salmon as a native species which occurred throughout the Klamath River and its tributaries at least up to the Oregon border. Hamilton et al. (2005) reports coho salmon in the Klamath were historically distributed upstream at least to the vicinity of Spencer Creek.

The fact that the Klamath River and tributaries: (1) are contiguous with documented historical coho rivers and streams both north and south of the Klamath River; (2) contain no natural barriers that would prevent their migration into the upper reaches and tributaries such as the Scott and Shasta rivers; (3) have physical attributes that would have produced suitable coho habitat in the past (e.g., gradient, morphology, and, in some cases like the Shasta River, spring sources that provide perennial flow); and (4) still contain suitable coho salmon habitat, is additional evidence that native coho salmon inhabited the Klamath River and its tributaries prior to any stocking.

Additionally, please note that the CEQA requires the Lead Agency to respond to comments on significant environmental issues related to the Public Draft EIR (CEQA Guidelines section 15088(a)). Although CEQA does not compel any further response to this type of comment, the above master response is provided to demonstrate the State Water Board's acknowledgement that there is continued concern regarding this issue despite the lack of evidence to support it.

AQF-12 KHSA Expert Panel Reports

Several comments assert that the Expert Panel Reports developed for the Klamath Hydroelectric Settlement Agreement (KHSA) highlight uncertainty in the outcome of the Proposed Project and the uncertainty is not acknowledged in the Lower Klamath Project EIR analyses.

The original KHSA terms sought legislation to grant the U.S. Secretary of the Interior the authority to make a "Secretarial Determination" regarding whether removing the J.C. Boyle, Copco No. 2, Copco No. 1, and Iron Gate dam complexes was in the public interest and would advance salmon restoration. The Expert Panel Reports were developed for the Secretarial Determination process. These reports, while acknowledging that there is a degree of uncertainty in their findings and identifying several challenges to restoration of fishery resources in the Klamath Basin, conclude an increased probability of successfully restoring Chinook, coho, and steelhead runs with dam removal. The Expert Panel Reports is one of many reference materials used in development of the EIR.

The U.S. Fish and Wildlife Service (USFWS) convened the Expert Panels to review, evaluate, synthesize, and provide scientific assessments regarding the likely trajectories of fish populations with and without implementation of dam removal and other restoration actions. The Expert Panels provide valuable independent reviews in addition to the various studies, reports, and scientific information considered in the science review process for the KHSA 2012 EIS/EIR and the Secretarial Determination Report. Further, having the Expert Panel reports as an additional set of analyses for consideration with respect to the Lower Klamath Project provides increased confidence in the Lower Klamath Project EIR findings regarding fish and fisheries. Please see Volume III Attachment 1 Section 3.3.6 *Aquatic Resources – References* for a list of all references used in developing Section 3.3 *Aquatic Resources*.

AQF-13 Ocean Conditions

Several comments noted that ocean conditions can have detrimental effects to anadromous salmonid populations in the Klamath River and that restoration of anadromous salmonid populations needs to consider ocean conditions.

Ocean conditions do play an important role in anadromous salmonid survival and productivity, as do several other factors, such as the condition of out-migrating juvenile salmonids (smolts) and freshwater habitat. Lawson (1993) used a conceptual model of declining freshwater habitat quality and cyclic ocean conditions to show that freshwater habitat is most critical during periods of depressed ocean survival and that improvements in ocean conditions can mask declines in freshwater habitat. Naturally functioning watersheds (freshwater environment) are important for wild salmon populations to persist.

Variable ocean conditions form part of the existing condition, which the Proposed Project is not anticipated to change. The Lower Klamath Project EIR considers ocean conditions while focusing on the effects of the Proposed Project on freshwater habitat conditions. The EIR addresses the influence of ocean conditions on anadromous salmonids in Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Anadromous Salmonids*. In addition, the influence of ocean conditions is included in the analysis of potential impacts on focal species in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*. Most notably, Potential Impact 3.3-7 includes the results of a population dynamics model (Hendrix 2011) that explicitly incorporated variability in ocean conditions when predicting the effects of dam removal consistent with the Proposed Project on fall-run Chinook salmon abundance.

2.2.6 Phytoplankton and Periphyton Master Responses

PAP-1 Influence of Upstream Sources of Algae and Associated Algal Toxin

Several commenters assert that toxic algae and associated algal toxins (e.g., microcystin) from upstream sources, including Upper Klamath Lake and Keno Reservoir, are not appropriately addressed in the EIR. Commenters express concern that toxic algae and associated toxins could be transported through the Hydroelectric Reach and downstream into the Middle and Lower Klamath River if the dams were to be removed. The commenters also assert that the Lower Klamath Project dams sequester or hold back the toxic algae, preventing its transport to the river downstream of the Lower Klamath Project dams.

Please refer to Potential Impact 3.2-6 for analysis of the potential for downstream transport of algal-derived (organic) suspended material due to the lack of interception and retention by the Lower Klamath Project dams. During the phytoplankton growth season (May through October), algal-derived (organic) suspended material is estimated using measurements of "Total Suspended Solids" (TSS) in the EIR since this is the primary component of TSS during this time of year. Under this approach, TSS includes all phytoplankton[5] as well as toxic blue-green algae. Accordingly, the analysis of TSS in the EIR evaluates the seasonal (May through October) transport of phytoplankton, including toxic algae, from upstream of the Lower Klamath Project reservoirs into the Hydroelectric Reach and the Middle and Lower Klamath River. As discussed in Potential Impact 3.2-6, the majority of the interception and retention of TSS that originates in Upper Klamath Lake during the late spring through early fall occurs in the Keno Impoundment/Lake Ewauna, which is upstream of the Hydroelectric Reach and will not be affected by the Proposed Project.

In addition to TSS measurements showing a downstream decrease in transport of phytoplankton, Appendix C, Section C.6.2.1 *Iron Gate Dam to Salmon River*, Figure C-54, shows microcystin concentrations measured between Keno Dam (i.e., RM 233 in Figure C-54) and the upstream end of Copco No. 1 Reservoir (i.e., RM 206.4 in Figure C-54) typically decrease with distance downstream in the Klamath River and microcystin concentrations in the Klamath River between Keno Dam and the upstream end of Copco No. 1 Reservoir are generally far less than the microcystin concentrations measured in the Klamath River downstream of Iron Gate Dam (i.e., RM 189.7 in Figure C-54). The consistently low microcystin levels above Copco No. 1 Reservoir along with genetic analyses of blue-green algae in Copco No. 1 and Iron Gate reservoirs indicate that microcystin measured in Copco No. 1 and Iron Gate reservoirs and downstream of Iron Gate Dam is being primarily produced by local *Microcystis aeruginosa* populations in Copco No. 1 and Iron Gate reservoirs. Section 3.2.5.6 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a* provide additional details on the genetic and toxins analyses of *Microcystis aeruginosa* in the Klamath River and the Lower Klamath Project reservoirs. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

The KHSA Interim Measure 15 (IM 15) microcystin data collected at multiple locations in the Klamath River and the Lower Klamath Project reservoirs from 2005 to 2015 are presented throughout Section 3.2.5.6 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a* and portions of Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting*, with Figure C-54 specifically showing the overall range of microcystin concentrations at individual monitoring locations by year from 2012 to 2015. To provide additional context, Figure PAP-1 below presents a time-series plot of the IM 15 microcystin data measured in the Klamath River between Keno Dam and the upstream end of Copco No. 1

[5] Defined in the EIR as aquatic microscopic organisms, including algae, bacteria, protists, and other single-celled plants, that obtain energy through photosynthesis and float in the water column of still or slowly flowing waters such as lakes or reservoirs.

Reservoir and downstream of Iron Gate Dam from 2008 through 2017, including all the data shown in Figure C-54 of the EIR as well as IM 15 data from Klamath River water quality sampling annual reports published after the issuance of the Notice of Preparation, which was issued on December 22, 2016. Figure PAP-1 further highlights how microcystin concentrations in the Klamath River between Keno Dam and the upstream end of Copco No. 1 Reservoir are usually far less than microcystin concentrations measured at the Klamath River monitoring site downstream of Iron Gate Dam. Public health microcystin monitoring data from within the Lower Klamath Project reservoirs were not plotted in Figure C-54, so these data also are not plotted in Figure PAP-1.

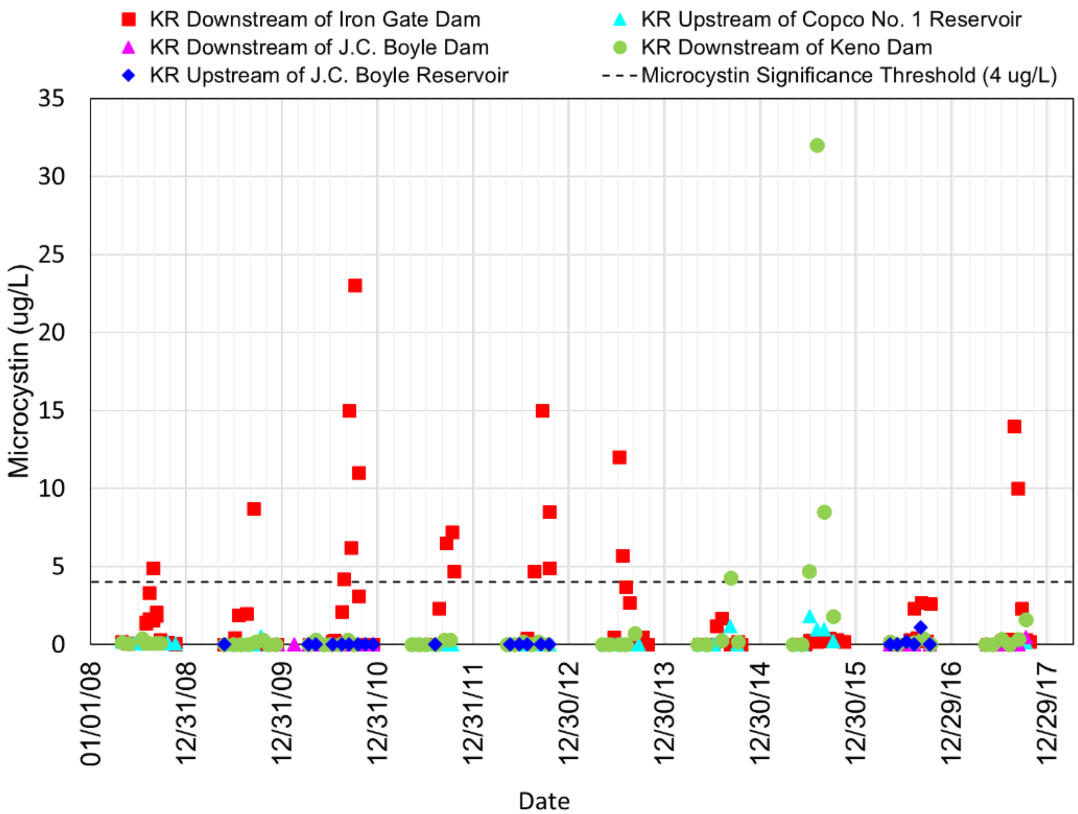

Figure PAP-1. Microcystin concentrations at monitoring sites in the Klamath River between Keno Dam and the upstream end of Copco No. 1 Reservoir along with downstream of Iron Gate Dam from 2008 through 2017. Source: PacifiCorp 2008b, 2009, 2010, 2011, 2012, 2013, 2014c, 2015b, 2016b, 2017b.

Data presented in Figure PAP-1 indicate that microcystin concentrations measured just downstream of Keno Dam exceeded the microcystin threshold of significance (4 ug/L) during two of the ten years plotted (20 percent), while microcystin concentrations measured at Klamath River monitoring sites from upstream of J.C. Boyle Reservoir to upstream of Copco No. 1 Reservoir did not exceed the microcystin threshold of significance in all 10 years of data. The decreases in microcystin concentrations in the Klamath River moving from Keno

Dam to upstream of Copco No. 1 Reservoir are likely due to degradation of the microcystin chemical in the free-flowing Klamath River reaches downstream of Keno Dam. In contrast, microcystin concentrations at the Klamath River monitoring site downstream of Iron Gate Dam exceeded the microcystin threshold of significance once or more in seven of the ten years (70 percent), supporting the conclusion that microcystin is being produced in Copco No. 1 and Iron Gate reservoirs.

The magnitude of phytoplankton and associated algal toxins transported into the Hydroelectric Reach from upstream sources would not be affected by dam removal since the Proposed Project would not alter conditions in the Klamath River upstream of J.C. Boyle Reservoir. The EIR analysis indicates that, absent any change in conditions in the Upper Klamath Basin, the same magnitude of phytoplankton (in the EIR this is typically referred to as algal-derived [organic] suspended material, TSS during the months of May through October, or biovolume) and associated algal-derived (organic) suspended material, nutrients, chlorophyll-*a*, and algal toxins measured between Keno Dam and J.C. Boyle Reservoir under existing conditions would be transported into the Hydroelectric Reach if the Lower Klamath Project dams were removed. Volume I Section 3.4.2.3 *Hydroelectric Reach – Phytoplankton* (pages 3-405 to 3-413) summarizes the existing phytoplankton conditions in the Klamath River between Keno Dam and J.C. Boyle Reservoir, including existing conditions for the toxin-producing blue-green algae *Microcystis aeruginosa*. Transport of the particular type of phytoplankton that produces the toxin microcystin (i.e., *Microcystis aeruginosa*) would continue to be limited under the Proposed Project, since this type of phytoplankton is infrequently detected between Keno Dam and J.C. Boyle Reservoir under existing conditions. Note that there were no measured detections of *Microcystis aeruginosa* in the Klamath River downstream of Keno Dam (approximately RM 238.4) or upstream of J.C. Boyle Reservoir (approximately RM 233.4) during 2002 to 2004, as shown in Figure 3.4-12 (page 3-409) and further documented in Kann (2006), cited in Volume I Section 3.4.2.3 *Hydroelectric Reach – Phytoplankton* (pages 3-405 to 3-413).

As discussed in Volume I Section 3.4.2.1 *Phytoplankton* (pages 3-392 to 3-403) and Volume I Section 3.4.2.3 *Hydroelectric Reach – Phytoplankton* (pages 3-405 to 3-413), the majority of blue-green algae cells being transported into the Hydroelectric Reach under existing conditions are the nitrogen-fixing blue-green algae *Aphanizomenon flos-aquae* and *Anabaena flos-aquae (Dolichospermum flos-aquae)*. *Aphanizomenon flos-aquae* has not been documented as a microcystin producing algae, and it is widely assumed that *Anabaena flos-aquae* is not responsible for the detected concentrations of microcystin in the phytoplankton and periphyton Area of Analysis because the measured amount (i.e., biovolume) of *Anabaena flos-aquae* is typically much less than that of *Microcystis aeruginosa* under existing conditions. Thus, similar to existing conditions, transport of these two types of blue-green algae into the Hydroelectric

Reach under the Proposed Project would not likely be the dominant source of microcystin to the Klamath River.

For those phytoplankton cells that do not settle out in the Keno Impoundment/Lake Ewauna, travel through the turbulent free-flowing reaches between Keno Dam and the upstream end of J.C. Boyle Reservoir under the Proposed Project would mechanically break apart colonies and cells such that they are no longer viable as intact blooms. As discussed in Potential Impact 3.2-6, mechanical breakdown of phytoplankton cells would continue in the turbulent reaches between J.C. Boyle and Copco No. 1 reservoirs, similar to existing conditions. The EIR analysis conservatively assumes that there would be no mechanical breakdown of phytoplankton cells in the new, free-flowing reaches of the Klamath River that replace J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoirs, which results in a slight relative long-term increase in algal-derived (organic) suspended materials under the Proposed Project (Potential Impact 3.2-6). Long-term increases in algal-derived (organic) suspended material under the Proposed Project are slight relative to existing conditions since the large, episodic increases in phytoplankton cells during in-reservoir blue-green algae blooms under existing conditions would be eliminated by dam removal and the anticipated increases of algal-derived (organic) suspended material would be well below the algal-derived (organic) suspended material produced in Copco No. 1 and Iron Gate reservoirs under existing conditions.

Combining information presented in Potential Impact 3.2-6 and Volume I Section 3.4.2.3 *Hydroelectric Reach – Phytoplankton* (pages 3-405 to 3-413), there could potentially be a small increase in algal-derived (organic) suspended materials moving into the Middle and Lower Klamath River primarily due to transport of *Aphanizomenon flos-aquae* and *Anabaena flos-aquae (Dolichospermum flos-aquae)* cells that do not settle out in the Keno Impoundment/Lake Ewauna, but the elimination of in-reservoir blue-green algae blooms that occur under existing conditions would decrease the biovolume and transport of *Microcystis aeruginosa* cells and associated microcystin toxin into the Middle and Lower Klamath River. Overall, the potential slight increase in the transport of *Aphanizomenon flos-aquae* and *Anabaena flos-aquae (Dolichospermum flos-aquae)* cells along with a decrease in transport of *Microcystis aeruginosa* cells and associated microcystin toxin would have a less-than-significant impact on toxic algae concentrations in the Klamath River downstream of the Hydroelectric Reach. Potential Impact 3.2-12 also provides an analysis of the changes in algal toxins that would occur due to dam removal under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Potential Impacts 3.2-6 and 3.2-12.

Overall, the existing data indicate that the magnitude of algal toxins that would be transported into the California portion of the Hydroelectric Reach under the Proposed Project would be less-than-significant (i.e., less than the significance threshold of 4 ug/L). The elimination of the slow-moving reservoir environment that currently supports seasonal growth of toxin-producing nuisance blue-green algae and periodically high concentrations of algal toxins (i.e., greater than 4 ug/L microcystin) would result in an overall decrease in the frequency of high algal toxin concentrations being transported into the Middle and Lower Klamath River downstream of Iron Gate Dam and this would be a beneficial effect of the Proposed Project compared to existing conditions.

Lastly, please also refer to Volume I Potential Impact 3.4-2 (pages 3-428 to 3-433) for further analysis of the alterations in the spatial extent, temporal duration, transport, or concentration of nuisance and/or noxious phytoplankton blooms and concentrations of algal toxins due to dam removal and elimination of reservoir habitat.

In summary, transport of phytoplankton, including blue-green algae, and associated algal toxins into the Hydroelectric Reach from upstream under the Proposed Project would be similar to existing conditions but, measurements of blue-green algae species between Keno Dam and J.C. Boyle Reservoir indicate transport of toxigenic *Microcystis aeruginosa* and associated algal toxin (i.e., microcystin) into the Hydroelectric Reach would be limited and unlikely to exceeded the microcystin threshold of significance (4 ug/L). Seasonal algal blooms and elevated microcystin concentrations in the Lower Klamath Project reservoirs along with *Microcystis aeruginosa* and microcystin concentrations measured downstream of Iron Gate Dam are primarily due to *Microcystis aeruginosa* growth within the slow-moving, calm Copco No. 1 and Iron Gate reservoirs rather than transport from upstream of the Hydroelectric Reach. While algae would continue to enter and be transported through the Hydroelectric Reach from upstream (similar to existing conditions), dam removal under the Proposed Project would eliminate the slow-moving habitat in calm Copco No. 1 and Iron Gate reservoirs that supports seasonal algae blooms and so would decrease transport of *Microcystis aeruginosa* and microcystin concentrations downstream of Iron Gate Dam. The conservative analysis used in the EIR assumes that there would be no breakdown of algae within the free-flowing Hydroelectric Reach under the Proposed Project, such that there would be potential for a slight relative long-term increase in algal-derived (organic) suspended material downstream of Iron Gate Dam because the reservoirs would no longer settle out algal-derived (organic) suspended material that is transported into the Hydroelectric Reach; however, such increases would be well below that produced by algae blooms in Copco No. 1 and Iron Gate reservoirs under existing conditions.

PAP-2 Phytoplankton and Periphyton Response to Nutrient Alterations

Several commenters assert that phytoplankton and periphyton growth downstream of the Lower Klamath Project dams would increase after dam removal due to increases in available nutrients, based on the belief that the dams would no longer trap nutrients originating from the Upper Klamath Basin.

Potential Impact 3.2-8 provides analysis of the alterations in nutrients in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean Nearshore Environment that would occur under the Proposed Project due to the lack of interception and retention by the dams and the conversion of the reservoir areas to a free-flowing river. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including clarifications to Potential Impact 3.2-8. Analysis of the nutrient interception and retention within Copco No. 1 and Iron Gate reservoirs using the Klamath River TMDL model output from calendar year 2000 determined that the annual (i.e., January to December 2000) modeled total phosphorus (TP) retention rate was approximately 6 percent of the incoming TP for Iron Gate Reservoir and approximately 1 percent for Copco No. 1 Reservoir, while the modeled total nitrogen (TN) retention rate was approximately 18 percent of the incoming TN for Iron Gate Reservoir and 4 percent for Copco No. 1 Reservoir. While the Klamath TMDL model results indicated that there was an overall annual nutrient retention, the monthly modeling results showed seasonal releases of nutrients, especially during reservoir turnover in late fall/early winter, with Iron Gate Reservoir releasing approximately 2 to 40 percent of incoming TP during late summer/fall and approximately 4 percent of incoming TN during winter and Copco No. 1 Reservoir releasing approximately 2 to 26 percent of incoming TP during late summer/fall and into winter months and approximately 3 to 14 percent of incoming TN during winter months (North Coast Regional Board 2010, Appendix 3).

In addition to the Klamath River TMDL model analysis of nutrient retention in the reservoirs, mass-balance nutrient budgets of the two reservoirs using approximately biweekly nutrient data from May 2005 through December 2007 have been used to estimate the nutrient interception and retention within Copco No. 1 and Iron Gate reservoirs (Asarian et al. 2009). Please note that estimates of annual nutrient retention in the reservoirs cannot be directly compared between the Klamath River TMDL model analysis discussed above and in Potential Impact 3.2-8 and the mass-balance nutrient budget analysis by Asarian et al. (2009) since the two analyses use different time periods for their calculations. The Klamath River TMDL model analysis is based on an annual period from January to December, but the nutrient budget analysis is based on an annual period from May of one year through April of the next year. The Klamath River TMDL model calculates results at a monthly time scale, but the nutrient budget analysis calculates results at a bi-weekly or seasonal (e.g., May to September) time scale.

On an annual basis (i.e., May 2005 to May 2006 or May 2006 to May 2007), the mass-balance nutrient budget analysis estimated the TP retention rate was approximately 3 to 6 percent of the incoming TP for Iron Gate Reservoir and approximately 6 to 8 percent for Copco No. 1 Reservoir, while the TN retention rate was approximately 4 to 7 percent of the incoming TN for Iron Gate Reservoir and approximately 5 to 10 percent for Copco No. 1 Reservoir. Similar to the

Klamath River TMDL model results for 2000, these results indicate an overall annual nutrient retention from May 2005 to May 2007. However, the nutrient budget analysis also indicates that there were periods of both retention and release during summer through winter, through analysis of bi-weekly nutrient budget values. More specifically, Iron Gate Reservoir releases for individual bi-weekly periods ranged from approximately 2 to 35 percent of incoming TP during late summer/fall and approximately 5 to 35 percent of incoming TN during mid-summer through mid-winter. Copco No. 1 Reservoir releases for individual bi-weekly periods ranged from approximately 2 to 35 percent of incoming TP during mid-summer to mid-winter months and approximately 3 to 14 percent of incoming TN during winter months. Average nutrient releases over the entire summer to winter period were much less than these amounts, since there were also periods of retention (Asarian et al. 2009).

Overall, the lack of nutrient retention in Copco No. 1 and Iron Gate reservoirs and the associated net annual increase in nutrients downstream of Iron Gate Dam due to removal of those reservoirs would be expected to be approximately 12 to 13 percent for TN and approximately 9 to 13 percent for TP based on the nutrient budget analysis results from May 2005 to May 2007. Note that the net annual nutrient increase from removal of both reservoirs is not equal to the sum of the annual nutrient retention from individual reservoirs since the individual reservoir results are reported as a percent of the incoming nutrients for the individual reservoir. Since much of the nutrient retention in Copco No. 1 and Iron Gate reservoirs occurs during winter and spring, much of this nutrient increase after dam removal (39 to 78 percent of TN and 92 to 116 percent of TP[6]) would occur during winter and spring (i.e., December to May) when water temperature, light levels, and high flows in the river do not support phytoplankton and periphyton growth (Asarian et al. 2009).

Further, as analyzed in Volume III Attachment 1 Potential Impact 3.2-8 and Volume I Potential Impact 3.4-2 (pages 3-428 to 3-433), Potential Impact 3.4-4 (pages 3-435 to 3-437), and Potential Impact 3.4-5 (pages 3-437 to 3-440), anticipated nutrient increases under the Proposed Project would not be expected to result in significant increases in overall algal biomass beyond levels experienced under existing conditions, so these additional nutrients would not be anticipated to result in exceedances of the California North Coast Regional Water

[6] Annual TP retention in Copco No. 1 and Iron Gate reservoirs was calculated as the sum of the TP retention from May of one year to May of the next year. Annual TP retention in Copco No. 1 and Iron Gate reservoirs during the one year period from May to May was less than December to May TP retention because there was a net release of TP downstream of Iron Gate Dam between May and December in that year. As such, the increase in TP between December and May downstream of Iron Gate Dam due to dam removal would potentially exceed the annual increase in TP, and the percentage of TP increase between December and May could exceed 100 percent.

Quality Control Board's Water Quality Control Plan for the North Coast Region (Basin Plan) water quality objectives for biostimulatory substances in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean Nearshore Environment. Please also refer to Volume III Attachment 1 Potential Impact 3.4-2 and Potential Impact 3.4-4 for minor revisions to these analyses that do not alter the significance determinations. Nutrient increases under the Proposed Project would only result in an exceedance of the Basin Plan biostimulatory substances water quality objective if those increases promote additional growth of algal biomass to the extent that such additional growth causes nuisance or adversely affect beneficial uses. Overall, the increase in nutrient concentrations under the Proposed Project would not result in significant biostimulatory impacts since these nutrient increases are not expected to result in an overall increase in algae biomass that exceeds existing conditions.

Phytoplankton would be limited in their ability to use increased nutrient levels for growth because elimination of the existing calm reservoir habitat under the Proposed Project would constrain habitat conditions that support large phytoplankton blooms in summer and fall, as discussed in Volume III Attachment 1 Potential Impact 3.2-8 and Volume I Potential Impact 3.4-2 (pages 3-428 to 3-433). Relatively high water velocity and constant mixing in the Klamath River does not typically support high levels of phytoplankton growth or reproduction under current conditions (Otten et al. 2015; Genzoli and Kann 2017). There are slow-moving habitats along the river edges that may be suitable for phytoplankton growth, but an increase in nutrients under the Proposed Project would not be expected to increase the overall biomass of nuisance and/or noxious blue-green algae compared to existing conditions. This is because available slow-moving river margin habitats suitable for phytoplankton growth are already typically occupied and periodically experience high concentrations of phytoplankton cells and algal toxins under existing conditions (Kann et al. 2010a; Genzoli and Kann 2017). While phytoplankton cells and algal toxins are measured in calm, slow-moving river margin habitats under existing conditions, growth and reproduction of phytoplankton in these habitats has not been documented. Phytoplankton cells and algal toxins in these habitats are generally attributed to entrapment and accumulation of cells and toxins transported downstream from the reservoirs rather than growth and/or reproduction within these habitats (Falconer et al. 1999; Kann et al. 2010a; State Water Board et al. 2010, updated 2016; Genzoli and Kann 2016, 2017). Longitudinal decreases in the measured *Microcystis aeruginosa* cell densities and microcystin downstream of Iron Gate Dam in both slow-moving shoreline and open channel habitats further suggest *Microcystis aeruginosa* cells and microcystin are being transported downstream into these shoreline habitats and phytoplankton growth is limited in these slow-moving shoreline habitats (Genzoli and Kann 2017). The removal of slow-moving reservoir habitats also would eliminate the primary source of *Microcystis aeruginosa* potentially transported into these river margin habitats, limiting the available *Microcystis aeruginosa* cells to uptake the additional nutrients.

Additionally, TN:TP ratios and a comparison of nutrient data measured at Klamath River monitoring sites from 2002 to 2017 downstream of Iron Gate Dam against phytoplankton half-saturation constants[7] for inorganic nitrogen and phosphorus suggest that nutrient availability is not the limiting factor that controls biomass from Iron Gate Dam (RM193.1) to approximately Seiad Valley (RM 132.7) under existing conditions. While nutrient concentrations vary widely across seasons (i.e., more than an order of magnitude), the minimum nutrient concentrations downstream of Iron Gate Dam were consistently greater than the phytoplankton half-saturation constants for inorganic nitrogen and phosphorus. The minimum inorganic phosphorus (i.e., orthophosphate) concentration (i.e., 0.019 mg/L) was approximately 6 times greater the inorganic phosphorus half-saturation constant (i.e., 0.003 mg/L) downstream of Iron Gate Dam, while the minimum TP concentration (i.e., 0.023 mg/L) was approximately 8 times greater than the inorganic phosphorus half-saturation constant. The minimum total inorganic nitrogen (i.e., ammonia/ammonium and nitrate+nitrite) concentration (i.e., 0.018 mg/L) was approximately 1.3 times greater than the inorganic nitrogen half-saturation constant (i.e., 0.014 mg/L) downstream of Iron Gate Dam, while the minimum TN concentration (i.e., 0.25 mg/L) was approximately 18 times greater than the inorganic nitrogen half-saturation constant. Furthermore, typical nutrient concentrations downstream of Iron Gate Dam are generally 3 or more times greater than the minimum nutrient concentrations. Since the measured nutrient concentrations under existing conditions are greater than the associated half-saturation constant from Iron Gate Dam to approximately Seiad Valley, there are currently more than sufficient nutrients to meet algal growth needs in this reach and additional nutrients under the Proposed Project would not correspond to an increase in algal biomass or an exceedance of the Basin Plan biostimulatory substances water quality objective.

Downstream of Seiad Valley, IM 15 data from 2009 to 2017 at Klamath River at Orleans (RM 58.9) and Turwar (RM 5.6) indicate that there are sufficient orthophosphate and total phosphorus to meet phytoplankton growth needs under existing conditions, but measured nutrient concentrations indicate inorganic nitrogen would likely limit phytoplankton growth. The total inorganic nitrogen in the Klamath River at Orleans and Turwar from 2009 to 2017 frequently was less than the inorganic nitrogen half-saturation constant during summer to early fall months. The abundance of nitrogen-fixing periphyton species in the Klamath River increases downstream of Seiad Valley and they become dominant, also

[7] The concentration of nutrient(s) at which the rate of uptake of those nutrients by phytoplankton (for growth) is one-half the maximum rate. Half-saturation constants for inorganic nitrogen and phosphorus also represent the highest concentration at which algae growth is directly proportional to nutrient concentrations (Cole and Wells 2015).

suggesting algal growth, including phytoplankton, becomes nitrogen-limited in the Klamath River downstream of Seiad Valley under existing conditions. While inorganic nitrogen is likely limiting growth of phytoplankton species that cannot fix nitrogen downstream of Seiad Valley, the growth of nitrogen-fixing phytoplankton species would be less limited by low inorganic nitrogen concentrations. While increases in nitrogen downstream of Seiad Valley under the Proposed Project would potentially result in some additional phytoplankton growth, the limited suitable habitat in the Klamath River downstream of Seiad Valley and the existing occupation of this limited suitable habitat would constrain increases in phytoplankton biomass under the Proposed Project compared to existing conditions. As such, nutrient increases under the Proposed Project still would not be anticipated to increase the overall phytoplankton biomass in the Klamath River or to result in an exceedance of the Basin Plan biostimulatory substances water quality objective due to the elimination of suitable reservoir habitat, the reductions in transport of *Microcystis aeruginosa* cells from reservoir habitats, and the presence of phytoplankton biomass in the remaining limited suitable habitat in the Klamath River, as discussed above.

In summary, some phytoplankton growth, including blue-green algae, may still occur after dam removal in the calm, slow-moving habitats along the margins of the Middle and Lower Klamath River, especially during low-flow periods, but nutrient increases under the Proposed Project are not expected to result in an overall increase algae biomass that exceeds existing conditions since a) dam removal would eliminate existing reservoir habitat that supports algal growth; b) the available suitable habitats in the Klamath River are already occupied and periodically experience high concentrations of phytoplankton cell and algal toxins concentrations under existing conditions; c) dam removal would reduce transport of *Microcystis aeruginosa* cells that could use the additional nutrients for growth into the available suitable habitats; and d) under existing conditions sufficient nutrients are already available to meet algal growth needs from Iron Gate Dam to Seiad Valley. Overall, the *Microcystis aeruginosa* and microcystin levels in Middle and Lower Klamath River under existing conditions are expected to decrease after dam removal because the decrease from reduced transport of *Microcystis aeruginosa* and microcystin into the Middle and Lower Klamath River under the Proposed Project is anticipated to be greater than potential growth within slow-moving habitats in the Middle and Lower Klamath River even with potential nutrient increases.

Lastly, please refer to Volume III Attachment 1 Potential Impact 3.2-8 and Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437) and Potential Impact 3.4-5 (pages 3-437 to 3-440) for the analysis of the influence of anticipated nutrient increases under the Proposed Project on periphyton biomass in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean Nearshore Environment. Please also refer to Volume III Attachment 1 Potential Impact 3.4-4 for minor revisions to these analyses that do not alter the significance determinations. Nutrient concentrations are high enough (i.e., greater than the half-saturation constants) that there are sufficient nutrients for periphyton growth from the upstream end of the Hydroelectric Reach (i.e., J.C. Boyle Reservoir) to Seiad Valley (RM 132.7) under existing conditions and nutrient increases downstream of Iron Gate Dam under the Proposed Project would not have a biostimulatory effect on periphyton growth. Potential increases in periphyton abundance upstream of Iron Gate Dam in the Hydroelectric Reach would be due to habitat increases (i.e., conversion of reservoir into river habitat) rather than nutrient increases. This additional periphyton growth would uptake some nutrients and likely decrease the magnitude of the upstream nutrients being transported through the Hydroelectric Reach into the Middle Klamath River, but the Yurok Tribe analysis (Asarian et al. 2010) still estimates a potential nutrient increase in the Middle and Lower Klamath River under dam removal even with this uptake by periphyton. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Potential Impact 3.2-8.

In the reaches where sufficient nitrogen is available to meet periphyton growth (i.e., upstream of Seiad Valley), the abundance of nitrogen-fixing species is low since nitrogen-fixing species primarily have a competitive advantage over other periphyton species when nitrogen concentrations are low. Downstream of Seiad Valley, the abundance of nitrogen-fixing species in the Klamath River increases and they become dominant, suggesting periphyton growth becomes nitrogen-limited in the Klamath River downstream of Seiad Valley under existing conditions. As such, increases in TN due to dam removal may alter the composition of the periphyton community (Asarian et al. 2010), but the increase in TN would likely just result in a change in the species of periphyton growing in the Klamath River and there is no anticipated overall increase in the periphyton abundance or biomass. Additionally, potential increases in TP due to dam removal under the Proposed Project are not expected to increase periphyton abundance or biomass because TP concentrations in the Middle and Lower Klamath River and the Klamath River Estuary suggest there is sufficient phosphorus to meet algal growth needs under existing conditions and additional phosphorus would not have a biostimulatory effect.

2.2.7 Terrestrial Master Responses

TER-1 Wildlife Habitat Effect of Removing Reservoirs

Several commenters indicate that the Iron Gate and Copco No. 1 reservoirs provide habitat for wildlife and removing the dams would destroy wildlife habitat. Commenters have noted, for example, that the area currently supports nesting bald eagles and pond turtles, and that the reservoir system has been long-established and supports both aquatic and terrestrial wildlife that sustain themselves on the reservoir systems.

Information on wildlife species at the Lower Klamath Project reservoirs is summarized in Volume I Section 3.5.2.4 *Terrestrial Resources – Environmental Setting – Non-special-status Wildlife* (pages 3-474 to 3-477) and Section 3.5.2.5

Terrestrial Resources – Environmental Setting – Special-status Species – Special Status Wildlife (page 3-478; see also Table 3.5-5, pages 3-501 to 3-513). As described therein, western pond turtles have been documented at Iron Gate Reservoir and Copco No. 1 Reservoir. The reservoirs and adjacent habitats also support migratory bird species (e.g., American white pelican, Barrow's goldeneye, common loon, black tern, black swift, Vaux's swift, olive-sided flycatcher, willow flycatcher, yellow warbler, and yellow-breasted chat) and year-round bird species (bald eagle, greater sandhill crane). The reservoirs and riparian areas provide foraging habitat for these species, by providing habitats that support fish, invertebrates, and reptiles for these birds to eat. Migratory birds use these reservoirs seasonally during their migrations and/or for overwintering, by supporting nesting, foraging, and/or loafing (resting on the water) habitat (see Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-21 [pages 3-562 to 3-563]). Surveys conducted by KRRC in 2017 and 2018 documented several osprey nests on platforms located on top of electrical poles in areas surrounding Iron Gate Reservoir, Copco No. 1 Reservoir, Copco No. 2 Reservoir, and along the Klamath River (CDM Smith 2018c, AECOM and CDM Smith 2019), and it is likely that osprey use the reservoirs for foraging on fish. The reservoirs also provide foraging habitat for bat species (e.g., Yuma myotis) that primarily prey on aquatic emergent insects (see Potential Impact 3.5-21). Project structures have been documented to support habitat for Yuma myotis (AECOM and CDM Smith 2019), and surrounding habitats, including project structures, may also support roosting for other special-status bat species (Western mastiff bat, Townsends's western big-eared bat, spotted bat, pallid bat, fringed myotis, and long-eared myotis) that may forage on terrestrial insects in more upland habitats.

The species discussed above, which include special-status species, are not exclusive to the Lower Klamath Project reservoirs, but rather they also have been documented in adjacent areas. For example, all of the bird species listed above have been either documented in habitats along the Klamath River upstream of Copco No. 1 Reservoir and downstream of Iron Gate Dam (see Volume I Section 3.5.2.5 *Terrestrial Resources – Environmental Setting – Special-status Species – Special Status Wildlife* Table 3.5-5), at Lower Klamath National Wildlife and Tule Lake National wildlife refuges, or at other nearby creeks, lakes, and reservoirs including Emigrant Creek, Emigrant Lake, Howard Prairie Lake City Park, and Hyatt Reservoir north of Iron Gate Reservoir (eBird 2019). Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-21 (pages 3-562 to 3-563) acknowledges that a loss of aquatic reservoir habitat would result in a loss of nesting, foraging, and loafing opportunities for fish-eating birds (e.g., bald eagle, osprey, and common merganser) and birds that consume aquatic vegetation and invertebrates (e.g., mallards). However, as discussed in Potential Impact 3.5-21, these impacts would be less than significant as these birds would continue to use the river or other aquatic habitat outside of the Proposed Project Primary Area of

Analysis for foraging once the reservoirs are removed. Aquatic insect foraging habitat for swifts and bats (Yuma myotis) would be reduced, as discussed in Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-17 (pages 3-559 to 3-560). However, once benthic macroinvertebrate populations reestablish after drawdown, swifts and bats would be able to forage over riverine habitat. Please also refer to Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-25 (pages 3-572 to 3-573), which analyzes the effects on wildlife that forage on fish (e.g., bald eagle, Barrow's goldeneye, common loon, and western pond turtle) from increased habitat for salmonids and changes in hatchery production.

Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-22 (pages 3-563 to 3-570) presents the analysis of potential short- and long-term impacts on western pond turtle from loss of aquatic reservoir habitat; based on this analysis, impacts would be less than significant with mitigation. Impacts on other wildlife species as a result of removal of reservoir habitat are discussed in Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status and Rare Natural Communities* Potential Impact 3.5-12 (pages 3-540 to 3-543), Potential Impact 3.5-13 *(*pages 3-543 to 3-547), Potential Impact 3.5-23 (page 3-570), Potential Impact 3.5-25 (pages 3-572 to 3-573), Potential Impact 3.5-29 (pages 3-575 to 3-576), and Potential Impact 3.5-30 (page 3-576). No special-status terrestrial invertebrates or amphibians would be affected by the removal of the reservoirs, as it is unlikely that reservoir habitat supports these species.

Please see Master Response AQF-1 for a discussion of how removal of the Lower Klamath Project reservoirs would affect Lost River and Shortnose sucker populations.

Consistent with CEQA Guidelines section 15088.5 (b), the EIR analysis characterizing potential short-term and long-term impacts on native special-status terrestrial species due to the loss of reservoir habitat has been clarified to include information regarding species' use of reservoirs and rivers within the Primary Area of Analysis, as well as in nearby wildlife refuges, creeks, lakes, and reservoirs outside of the Primary Area of Analysis. Please refer to Volume III Section 3.5 *Terrestrial Resources* for the associated revisions.

2.2.8 Flood Hydrology Master Responses

FLD-1 Downstream Flood Hydrology

Numerous commenters expressed concern regarding the potential for the Proposed Project to result in increased flooding and associated damage. This response summarizes key points from the EIR concerning the potential impacts related to the Proposed Project's changes to downstream flood hydrology, as well as the Proposed Project's proposal to reduce or avoid such impacts.

As discussed in Volume I Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain* (pages 3-630 to 3-635), J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams are not designed or currently operated as flood control facilities, although they do result in incidental and limited flood protection during certain flood events. Specifically, Volume I Table 3.6-12 (page 3-631) presents peak flood flows for the mainstem Klamath River and indicates that the 100-year flood is attenuated less than seven percent by Iron Gate and Copco No. 1 reservoirs under existing conditions, with J.C. Boyle and Copco No. 2 reservoirs providing negligible flood attenuation due to their substantially smaller volume and, in the case of J.C. Boyle, long distance upstream (USBR 2012a). Under the Proposed Project, there would be a minor increase in the 100-year floodplain elevations in the reach from Iron Gate Dam (river mile [RM] 193) to Humbug Creek (RM 174) following dam removal, with two additional legal habitable structures identified in the anticipated floodplain that are currently not within the existing floodplain. Additionally, peak flood flows downstream of Iron Gate dam would occur about 10 hours sooner if the dams were removed.

To address the minor increase in floodplain inundation below Iron Gate Dam, the KRRC proposes implementation of the Downstream Flood Control Project Component (Volume I Potential Impact 3.6-3 [pages 3-630 to 3-633]). This component of the Proposed Project includes working with landowners to move or elevate the 36 habitable structures (34 existing structures and 2 additional structures) located in the altered 100-year floodplain between Iron Gate Dam and Humbug Creek prior to dam removal, where feasible. This would reduce the risks of exposing people and/or structures to damage, loss, injury, or death due to flooding following dam removal.

As described in Volume I Potential Impact 3.6-3 (pages 3-630 to 3-633), final determination of the extent of the future 100-year floodplain following dam removal would be made by the Federal Emergency Management Agency (FEMA) and the KRRC is planning to coordinate with Siskiyou County and FEMA to initiate the map revision process (Appendix B: *Definite Plan*). Although the Downstream Flood Control Project Component would likely reduce potential flood hydrology-related impacts to less than significant, the State Water Board cannot ensure its implementation. Additionally, there may be new or increased potential for flood damage and/or loss of structures that are not feasible to move or elevate. Therefore, the State Water Board has concluded that impacts associated with exposing structures to a substantial risk of damage due to flooding are significant and unavoidable.

The Emergency Response Plan would ensure that potential effects related to exposing people and/or structures to a substantial risk of flooding related to flood forecasting would result in no significant impact. See Volume I Potential Impact

3.6-3 (page 3-632 to 3-633) for further discussion of the Emergency Response Plan.

2.2.9 Groundwater Master Responses

GRW-1 Effects on Groundwater Wells

Multiple comments expressed concern regarding the potential impact of removing Lower Klamath Project reservoirs on groundwater availability and quality, including the potential impact on residential or other private wells near the reservoirs.

Volume I Section 3.7 *Groundwater – Potential Impacts and Mitigation* Potential Impact 3.7-1 (pages 3-663 to 3-665) discusses the potential impacts of the Proposed Project on groundwater resources in the vicinity of the Lower Klamath Project reservoirs. As described in Volume I Section 3.7 *Groundwater* (starting on page 3-639), there is uncertainty regarding the extent to which wells may be impacted and the number of potentially impacted wells. However, available well record data (Section 3.7.2.2 *Groundwater – Environmental Setting – Local Groundwater Conditions* [pages 3-644 to 3-661] and Volume II Appendix L) indicate that some wells could be significantly impacted by dam removal unless measures are undertaken to protect groundwater supplies. Well records evaluated in the Groundwater analysis were obtained from the California Department of Water Resources and Oregon Water Resources Department (OWRD) databases. The records reviewed include sufficient detail to accurately locate the wells relative to the Lower Klamath Project reservoirs. These records include 25 wells near Iron Gate Reservoir and 22 near Copco No. 1 and Copco No. 2 reservoirs.

The Proposed Project includes implementation of the Groundwater Well Management Plan to offset potential adverse impacts. The Groundwater Well Management Plan requires monitoring to detect groundwater well impacts and identification of short and long-term measures to address such impacts as encountered. Under the Groundwater Well Management Plan, if groundwater levels in existing wells adjacent to the Lower Klamath Project reservoirs are found to be substantially depleted as a result of Project implementation, such that production rates drop to levels that do not support designated domestic or irrigation uses, the KRRC would undertake measures to return the production rates of the affected domestic or irrigation groundwater supply wells to conditions existing prior to dam removal. Additionally, short-term measures would include actions providing temporary water supplies until long-term measures such as pump motor replacement, well deepening, or full well replacement are identified and implemented.

Volume I Section 2.7.8.8 *Proposed Project – Proposed Project – Other Project Components – Groundwater Well Management* (page 2-99) and Volume II Appendix B: *Definite Plan* provide additional detail regarding the Groundwater

Well Management Plan. Further, the State Water Board has issued a draft water quality certification that sets forth monitoring and reporting requirements for groundwater wells surrounding the Lower Klamath Project reservoirs, including reporting that summarizes actions that KRRC has or will implement to address any impacts to groundwater supply associated with implementation of the Proposed Project.

GRW-2 Wells Missing from Groundwater Analysis

Some comments expressed concern that the EIR's groundwater analysis did not include the locations of all groundwater wells located within the groundwater Area of Analysis (Volume I Figure 3.7-1, page 3-640), and requested that additional information for missing wells be provided. Existing groundwater conditions in the Lower Klamath Project vicinity are presented in Volume I Section 3.7.2.2 *Groundwater – Environmental Setting – Local Groundwater Conditions* (starting on page 3-644) and the analysis of potential impacts of the Proposed Project on groundwater resources is presented in Volume I Potential Impacts 3.7-1 and 3.7-2 (starting on page 3-663 and 3-665, respectively). The section relies on information from the California Department of Water Resources well logs but notes that the available data on the location of existing wells is limited. In light of this limitation (and of limits on information regarding well-specific conditions other than location and water source that influence whether reservoir removal will impact a particular well), the EIR provides general information on potential impacts and measures to address groundwater wells within the groundwater Area of Analysis (Volume I Figure 3.7-1; page 3-640). Analysis provided in the EIR applies to both known and unknown wells within the Area of Analysis.

The analysis presented in the Lower Klamath Project EIR, as well as in previous studies conducted by USBR (2012a), conclude that while the direction of regional groundwater flow is toward the Lower Klamath Project reservoirs, local groundwater levels (i.e., locations immediately adjacent to the reservoirs) exhibit site-specific variability, with the majority of wells exhibiting water levels above those of the reservoirs such that groundwater would flow toward the reservoir, rather than away from the reservoir. A subset of groundwater wells located immediately adjacent to Copco No. 1 Reservoir exhibit water levels below those of the reservoir, such that groundwater would potentially flow from this reservoir toward these wells. In light of the potential for connectivity between groundwater and Copco No. 1 Reservoir for a subset of existing wells, and because well data are not readily available for every existing groundwater well in the vicinity of the Lower Klamath Project reservoirs, it is possible that removal of the reservoirs would cause a substantial decrease of groundwater levels and a corresponding decrease in production rates in existing wells to a degree that interferes with existing or planned uses. The inclusion of any other existing groundwater wells surrounding the Lower Klamath Project reservoirs in the groundwater analysis presented in the EIR, or in the analysis conducted by USBR (2012a), would not change the potential for the aforementioned impact.

Please also refer to Master Response GRW-1 for a discussion of the KRRC's Groundwater Well Management Plan, which would offset potential adverse impacts of Lower Klamath Project dam and reservoir removal on local groundwater supplies.

2.2.10 Water Supply/Water Rights Master Responses

WSWR-1 Potential Effects on Agricultural Water Supply for California Water Users in the USBR Klamath Irrigation Project

Some comments express concern that the Proposed Project will limit agricultural water supplies for farms upstream of the Hydroelectric Reach. Some comments refer specifically to operational coordination between the United States Bureau of Reclamation's (USBR) Klamath Project for irrigation and the Klamath Hydroelectric Project for hydropower production. Concerns specifically related to water supply on Klamath River tributaries are addressed in Master Response WSWR-2. Concerns specifically related to water supply within the Hydroelectric Reach and downstream of Iron Gate Dam are addressed in Master Response WSWR-3.

Volume I Section 3.8.2.1 *Upper Klamath Basin* (page 3-670 to 3-671) and Section 3.8.5 *Potential Impact 3.8-2* (pages 3-679 to 3-680) describe the role of the Lower Klamath Project in water diversions upstream of the Hydroelectric Reach, and potential impacts of the Proposed Project on those agricultural water supplies. As described more fully in the EIR, Upper Klamath Lake is the primary water supply for agricultural irrigation use in the Klamath River Basin. Approximately 98 percent of the available active surface water storage for irrigation uses along the Klamath River occurs in Upper Klamath Lake, which is regulated by Link River Dam. Keno Dam regulates water levels of the Klamath River upstream of the dam. The facility does not generate hydropower. PacifiCorp operates Keno Dam under an agreement with USBR to maintain stable water levels in Keno Impoundment/Lake Ewauna for irrigation uses. The Lower Klamath Project facilities have non-consumptive hydropower water rights (please also refer to Master Response WSWR-3), rather than water rights for the provision of irrigation supplies. Neither Link River Dam nor Keno Dam is being considered for removal under the Proposed Project.

As described in Volume I Section 3.8.5 *Potential Impacts* 3.8-1 and 3.8-2 (pages 3-676 to 3-680), during the extreme drought of 2014 to 2016, PacifiCorp coordinated late-2014 releases from Iron Gate and Copco No. 1 dams which resulted in a small degree of flexibility for managing irrigation water in the Upper Basin by allowing USBR to postpone releasing water for irrigation purposes at Keno Dam. A comparable water borrowing agreement between PacifiCorp and USBR for approximately 20,000 acre-feet also occurred in 2018. It is unclear if further water borrowing would occur in the future due to the multiple constraints detailed by USBR and discussed in Volume I Potential Impact 3.8-2 (pages 3-

679 to 3-680). The EIR's assessment of the unlikelihood of future water borrowing is further bolstered by USBR's elimination of this alternative from further consideration as part of its environmental assessment of the Klamath Irrigation Project operations (USBR 2019). Removal of the Lower Klamath Project dams would not affect USBR's central role in providing water to irrigators in the Upper Klamath Basin while also providing flows to the Klamath River as required by the current biological opinion.

WSWR-2 Water Availability on Klamath River Tributaries

Some comments raise concerns that removal of the Lower Klamath Project reservoirs would reduce the water supply available for environmental purposes in the mainstem Klamath River, and as a result, water diverters in tributaries to the Klamath River would be curtailed in order to increase mainstem surface water flows.

As described in Volume I Section 3.8.1 *Water Supply/Water Rights – Area of Analysis* (pages 3-667 to 3-669), there would be no water supply impact to tributaries to the mainstem Klamath River from implementation of the Proposed Project. Agricultural diversions within the Mid and Lower Klamath basins occur in tributaries including the Shasta, Scott, Salmon, and Trinity rivers. However, because the USBR maintains its biological opinion obligations for the mainstem Klamath River regardless of the existence of the Lower Klamath Project, dam removal would not alter the amount of water available for environmental purposes, or the source of that water.

WSWR-3 Downstream Water Rights, Lower Klamath Project Water Rights, and Hatchery Water Diversions

Some comments express concern that removal of the Lower Klamath Project facilities would adversely impact water supplies and/or water rights for beneficial uses including hydropower production, agriculture, hatcheries, and other downstream water diversions.

Please refer to Volume I Potential Impact 3.8-1 (pages 3-676 to 3-679) and Volume II Appendix M. The Lower Klamath Project reservoirs contain approximately two percent of the active surface water storage in the Klamath River watershed. The dams are operated for short-term water storage to be released for hydropower operations. As hydropower operations would cease at the Lower Klamath Project dams under the Proposed Project, use of these hydroelectric power-generation rights would cease. As described in Volume I Potential Impact 3.8-1 (pages 3-677 to 3-679) this cessation of diversion is not anticipated to have a significant impact on other domestic and agricultural diversions in the Klamath River downstream of the Hydroelectric Reach. With respect to the loss of hydropower generation associated with the Lower Klamath Project, this topic pertains to a portion of the Draft EIR that was recirculated on

December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Under the Proposed Project, diversions for Iron Gate Hatchery operations would decrease, and the point of diversion would change from Iron Gate Reservoir to Bogus Creek (Volume I Section 2.7.6.1 *Iron Gate Hatchery* [pages 2-77 to 2-80]). As identified in the EIR, there are no water diversions between the hatchery diversion location and the point of return for the water. The existing water flows that the California Department of Fish and Wildlife (CDFW) diverts into the Fall Creek Hatchery would increase under the Proposed Project as the hatchery is returned to operation for eight years following dam removal. Please refer to Volume I Potential Impact 3.8-1 (pages 3-676 to 3-679) and Master Responses WSWR-5 and WSWR-6 below for further discussion of the City of Yreka and hatchery water rights. Neither of these changes are anticipated to impact other water rights holders because there are no intervening diverters associated with the hatchery points of diversion and hatchery use is non-consumptive. Additionally, after eight years hatchery operations are planned to cease. Please refer to Master Response WSWR-1 for a discussion of potential effects on agricultural and downstream water supply.

WSWR-4 Potential Sediment Impacts on Water Diversions Downstream of the Lower Klamath Project

Some comments express general concern about potential impacts to diversion works downstream of the Lower Klamath Project that may result from increased sedimentation that is expected to occur during and following dam removal activities. Some of these comments have included concern that impacts to individual diversions were not evaluated with greater particularity. As described in Master Responses WSWR-1 and WSWR-3, the Proposed Project was not found to have a significant impact on water supplies or water rights. However, the EIR does evaluate and require mitigation for potential impacts related to sediment release and deposition.

Volume I Potential Impact 3.8-3 (page 3-680 to 3-682) evaluates the potential impact from releases of stored reservoir sediments during Proposed Project implementation to Klamath River water intake pumps downstream of Iron Gate Dam. USBR (2012a) conducted detailed hydraulic, hydrologic, and sediment transport modeling to determine the potential for sediment-related impacts due to removal of the Lower Klamath Project dams. This model does not address localized sediment deposition and erosion at a site-scale, which could affect existing diversion facilities.

No comments were received identifying individual diversion infrastructure that could be impacted due to sediment releases and deposition under the Proposed Project. The findings of Volume I Potential Impact 3.8-3 (pages 3-680 to 3-682) already discloses that sediment releases during reservoir drawdown could significantly affect the functionality of downstream diversion facilities. To address this potential impact, Mitigation Measure WSWR-1 (Volume I, page 3-681 to 3-682) requires individualized mitigation to address any impacts, with the option for diverters to engage in pre-project evaluations. With mitigation, the impact would be less than significant.

WSWR-5 City of Yreka Water Supply/Water Rights

Some comments express concern about potential impacts to the City of Yreka's water supply, which is diverted from Fall Creek (see also Volume I Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation* [pages 2-84 to 2-86]). Specific concerns include potential impacts from the pipeline alignment, instream bypass flow requirements in Fall Creek, PacifiCorp diversions from Spring Creek to Fall Creek, and the City's diversion intake structures on Fall Creek. Please refer to Master Responses WSWR-6 and WSWR-7 for a discussion of water availability and water rights in the Fall Creek watershed.

As described in Volume I Potential Impact 3.8-4 (pages 3-682 to 3-683), the existing water supply pipeline for the City of Yreka passes under Iron Gate Reservoir and would have to be relocated prior to reservoir drawdown to prevent potential damage. Three alternatives have been developed for proposed modifications to the pipeline, and the KRRC would determine the preferred alternative in consultation with the City of Yreka. During connection of a new pipeline, the KRRC anticipates that the existing pipeline would be disconnected for less than 12 hours during the winter season. The available water in the City of Yreka's storage facilities is able to supply the City of Yreka for up to 60 hours during the winter (see also Volume II Appendix B: *Definite Plan*).

In light of the lack of the specific construction detail necessary to fully support the KRRC's outage estimate, the EIR includes Mitigation Measure WSWR-2. Mitigation Measure WSWR-2 requires both coordination on the planned outage with City of Yreka and a separate approval for any outage longer than 12 hours and requires that the outage will not impair the City of Yreka's ability to supply water.

The 15 cubic feet per second (cfs) instream bypass flow requirement associated with the City of Yreka's water right is derived from provisions of the agreement between the City of Yreka and CDFW executed in 1967 and filed with the State Water Board. The condition was included in the amended permit for diversion and use granted by the State Water Board in 2012. There is no evidence that CDFW's 15 cfs bypass flow requirement is not suitable for potential future use of Fall Creek by salmonids, regardless of the entity that owns and operates Fall Creek hatchery, and no amendment to that obligation is part of the Proposed Project. CDFW has given no indication in its comments on the Draft EIR that a higher flow would be necessary in Fall Creek with access by anadromous fish or with hatchery operation. Additionally, under California water rights law, diversions under junior water rights must cease if demand under all senior water rights has not been met; exercise of a junior right cannot harm the senior right.

Concerns related to future increases of bypass flow requirements are speculative and not analyzed in this EIR.

With respect to concerns regarding potential impacts to the City of Yreka's water supply diversion intake structures, the Definite Plan (Volume II Appendix B: *Definite Plan*) indicates that the existing flat panel fish screens for the water supply intakes at Dams A and B may not meet current regulatory agency screen criteria for anadromous fish and may require updates (see also Volume I Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation* [pages 2-84 to 2-86]). Since issuance of the Draft EIR, the KRRC has proposed to include a permanent fish passage barrier at the Fall Creek Hatchery, located approximately 200 to 300 feet downstream of both Dams A and B (KRRC 2019a), such that there would be no need for updates to the City of Yreka's Dam A or B existing diversion intake structures and there would be no impacts.

WSWR-6 Fall Creek Hatchery Water Rights

Some comments express concern that increased water diversions from Fall Creek associated with re-opening the Fall Creek hatchery could preclude the City of Yreka from diverting their full water right.

Water diversions from Fall Creek associated with operation of the Fall Creek Hatchery would not impact the City of Yreka's water right, including its bypass flow requirement. CDFW's non-consumptive water right diverts water primarily downstream from the City of Yreka's diversion point with an optional 0.33 cubic feet per second (cfs) diversion above the City of Yreka's Dam B on Fall Creek. After passing through the hatchery, all diverted water (less evaporative losses) would be returned to Fall Creek upstream of the City of Yreka's bypass flow compliance point (i.e., location of USGS Gage No. 11512000 approximately 1,000 feet upstream of Daggett Road). Please refer to Volume I Section 2.7.6.2 *Fall Creek Hatchery* (pages 2-81 to 2-84) for further discussion. See also Master Response WSWR-5.

Since issuance of the Draft EIR, the KRRC has proposed to use 0.33 cfs from the optional diversion point located upstream of the City of Yreka's Dam B on Fall Creek. The KRRC proposes to use water from the optional diversion for egg incubation at Fall Creek Hatchery and proposes that this diversion would be part of the 10 cfs maximum diversion for operation of the hatchery. This diversion would also be non-consumptive. As noted above, all diverted water (less evaporative losses) would be returned to Fall Creek upstream of the bypass flow compliance point for the City of Yreka's water supply. Further, although the 0.33 cfs would be diverted upstream of the City of Yreka's Dam B, the amount of this diversion is relatively small compared with historical Fall Creek flows and historical City of Yreka diversions (Volume I Figure 2.7-16 [page 2-84]) and therefore the 0.33 cfs diversion would not preclude the City of Yreka from diverting their full water right.

WSWR-7 PacifiCorp Water Rights in Fall Creek and Spring Creek

Some comments express concern that reductions to PacifiCorp's water rights in Fall and Spring creeks could preclude the City of Yreka from diverting their full water right.

PacifiCorp's water diversions on Spring and Fall creeks and hydropower generation at the Fall Creek powerhouse are part of the Klamath Hydroelectric Project (KHP) and are not part of the Proposed Project. PacifiCorp's ownership and operation of the portions of the KHP that are not part of the four dams and the associated facilities proposed for removal (i.e., the Lower Klamath Project), or part of Parcel B lands, are not being changed under the Proposed Project. Whether the Federal Energy Regulatory Commission (FERC) would alter PacifiCorp's Spring Creek diversion in the future, as related to the KHP, is speculative and is not analyzed in this EIR. The State Water Board anticipates that any such change would be the subject of a future proceeding under FERC, which would include the opportunity for public and State Water Board input on decisions to continue or to change current operations.

2.2.11 Greenhouse Gas Emissions and Energy Master Responses

ENR-1 Rate Increases

Several comments state the belief that removal of the Lower Klamath Project facilities would result in power rate increases for PacifiCorp customers. Please note that under CEQA, potential effects from implementing a project that are solely social or economic in nature, such as reductions in property values, loss of property tax revenues, and increases in energy costs, do not constitute an effect (i.e., an impact) to the physical environment (see also Volume I Section 5.4 *Social and Economic Factors Under CEQA*).

Although under CEQA no further response is required, the following information is provided as context for power rates. The excerpt below is taken from the U.S. Bureau of Reclamation's (USBR's) response to public comments on this topic, as presented in Volume III of the 2012 KHSA EIS/EIR. This State Water Board is not aware of any limits to the applicability of the below analysis and conclusions regarding costs since its publication.

"Rates for PacifiCorp customers in the Klamath Basin are anticipated to rise even if the dams are retained. Any rate increase would be used to fund a portion of [dam removal], if approved, or the cost of relicensing, if not approved. Federal funds and California bond funds would be used to pay for the remainder of the costs associated with the Proposed [Project]. Rate increases for utility customers are controlled by public utility commissions to prevent price gouging and sudden harmful increases in power costs. Both the Oregon Public Utilities Commission (PUC) and the California PUC (CPUC) have determined that the cost to PacifiCorp customers would be less under a decommissioning scenario than a relicensing scenario."

According to the Oregon PUC hearings on the cost increases associated with the KHSA [Klamath Hydroelectric Settlement Agreement], PacifiCorp claimed that relicensing would cost their customers in excess of $400 million in capital costs and $60 million in operations and maintenance costs over a 40-year license term (Oregon PUC Order No. 10-364 can be found at https://apps.puc.state.or.us/orders/2010ords/10-364.pdf). In contrast, the cost of decommissioning the Lower Klamath Project has been capped at $450 million under the KHSA, and customer contributions have been capped at $200 million with up to $184 million coming from Oregon customers and up to $16 million from California customers. In California, the annual collection from PacifiCorp may not exceed two percent of their annual revenue, and it must be collected as a specified amount per kilowatt-hour billed to customers. The State of California is providing the remaining $250 million through Proposition 1 bond funding (Amended KHSA 2016 can be found at http://www.klamathrenewal.org/wp-content/uploads/2017/04/2016.12.31-Executed-and-Amended-Final-KHSA.pdf).

The CPUC also determined that the KHSA would provide more certainty to PacifiCorp customers in terms of cost than a relicensing scenario, as the KHSA mandates specific cost caps to PacifiCorp's customers. Without the KHSA, the CPUC finds that PacifiCorp's ratepayers would be subject to "an uncertain amount of cost in addressing what to do with PacifiCorp's Klamath assets" (CPUC Final Decision to Authorize a Surcharge to Recover the Costs of Removing the Klamath Assets can be found at http://docs.cpuc.ca.gov/PUBLISHED/FINAL_DECISION/134812-03.htm).

2.2.12 Geology, Soils, and Mineral Resources Master Responses

GEO-1 Fine Sediment Modeling and Analysis

Several comments were submitted regarding the EIR's overall approach to sediment modeling and analysis for the Proposed Project and alternatives, the downstream extent of potential fine sediment impacts during and following dam removal, and the analysis approach for addressing spatially discrete fine sediment impacts. These topic areas are discussed below.

1D and 2D Sediment Models

Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775), which is partially modified in Volume III Attachment 1, describes the results of sediment modeling for the Proposed Project undertaken by USBR (2012a). While not cited in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775), results of sediment modeling conducted by Stillwater Sciences (2008) are cited in USBR (2012a) and used towards analyzing how the rate of reservoir drawdown would affect the amount of erosion of the reservoir sediment deposits.

Stillwater Sciences (2008) originally used the peer-reviewed Dam Removal Express Assessment Model (DREAM-1) (Cui et al. 2006a,b) to identify preferred reservoir drawdown options for minimizing suspended sediment impacts to the Klamath River, especially biological resources, downstream of Iron Gate Dam. USBR (2012a) subsequently applied the one-dimensional (1D) Version (2.4) of the Sedimentation and River Hydraulics sediment transport model (SRH-1D), developed by Huang and Greimann (2010), to examine surface hydrology, groundwater hydrology, hydraulics, geomorphology, and sediment transport within the Klamath River Basin under the No Project Alternative (dams remain in place) and the Proposed Project (dam removal). Fine and coarse sediment were both modeled by USBR (2012a), including 48 two-year simulations (1961-2008) focused on suspended sediment, as well as three fifty-year simulations considering long-term evolution of the riverbed, with drawdown (3 ft/day maximum) modeled for dry, median, and wet water year types.

Information on the data and model parameters input to the SRH-1D model is included in USBR (2012a, pages 9-4 to 9-5). The sediment load inputs to the SRH-1D model are also described in USBR (2012a, pages 5-4 to 5-11), with additional information on tributary sediment loads provided in Stillwater Sciences (2010). In addition to the SRH-1D model, USBR (2012a, pages 9-56 to 9-85) also applied a two-dimensional (2D) model (SRH-2D v3) for Copco No. 1 Reservoir, which verified the erosional patterns predicted by the SRH-1D model for Copco No. 1 Reservoir.

The main difference between 1D and 2D sediment models is that 1D models consider flow velocity (i.e., the speed that water travels in the river channel) and water surface elevation (i.e., water level) as average values that remain constant across the width and depth of the river channel, whereas 2D models allow flow velocity and water surface elevation (also expressed as average values) to vary across the width of the river channel using a spatially distributed grid or mesh of input data. At an even finer scale, 3D models apply a mesh of input data across the width, depth, and upstream to downstream dimension of the river channel. 1D sediment models are technically sound for assessing sediment erosion, transport, and deposition, and associated channel change, in the upstream to downstream direction (i.e., the "longitudinal" dimension). For the purposes of Volume I Section 3.11 *Geology, Soils, and Mineral Resources*, the SRH-1D sediment model results were used to assess whether the Proposed Project would result in substantial deposition[8] of sediment in the Klamath River channel or Klamath River Estuary due to erosion of reservoir sediment deposits, and

[8] To affect the significance determinations for reaches downstream of Cottonwood Creek, a 2D model would have to find that there would be substantial deposition of sediment as defined in Volume III Attachment 1 Section 3.11.3 *Geology, Soils, and Mineral Resources – Significance Criteria*, where clarifying text has been added since the Draft EIR, or a risk to people and structures.

whether people and structures would be adversely affected (see Volume I Section 3.11.3 *Geology, Soils, and Mineral Resources – Significance Criteria* on page 3-759 and the modifications in Volume III Attachment 1). Although 2D sediment modeling would improve the understanding of sediment dynamics across the river channel (i.e., the "lateral" dimension), the results of such an undertaking would not change the EIR significance determinations presented in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) because the EIR already discloses that there would be short-term substantial deposition of sediment in the Klamath River channel between Iron Gate Dam and Cottonwood Creek in the short term (i.e., a significant and unavoidable impact) and recognizes the potential for spatially discrete fine sediment deposition in slack-water areas farther downstream. Additionally, 2D model results are usually consistent with 1D results as seen with 2D and 1D models used for reach-scale analyses of erosion and sediment deposition in river systems (Stillwater Sciences 2008; and the SRH-2D v3 model in USBR 2012a). The finer-scaled pattern of sedimentation across the river width (i.e., in slack water areas) downstream of Cottonwood Creek that could be predicted by a higher resolution 2D model would not affect the key findings of the EIR analysis or change the significance determinations.

The SRH-1D model simulations applied are considered appropriate for assessing the potential effects of dam removal in the context of CEQA. Furthermore, the advantage of 1D sediment modeling is that it is computationally less intensive and for assessing impacts from the Project, more efficient than 2D or 3D modeling. This allowed for SRH-1D models to be applied to the Klamath River from upstream of J.C. Boyle Dam (RM 229.8) to the Pacific Ocean using two-year simulations over a 48-year period (1961-2008), as well as using three separate 50-year simulations with reservoir drawdown modeled to occur in dry, median, and wet water year types (USBR 2012a). Modeling over this length of river and for this number of years would be impractical with 2D or 3D models, and modeling a fewer number of years would significantly reduce the probability that the hydrological conditions present during project implementation would be captured by any model predictions.

River Sediment Transport and Downstream Extent of Significant Short-term Sedimentation Impacts

The existing sediment deposits in J.C. Boyle, Iron Gate, and Copco No. 1 have a high water content (80 to 90 percent) and over 80 percent of the sediments are fine-grained (see Table 3.11-6 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [page 3-766]), which means that they are highly erodible. Based on the above described, technically sound, SRH-1D model simulations, USBR (2012a) estimated that between 5.4 and 8.6 million yd^3 [1.2 to 2.3 million tons], or 36 to 57 percent of the total reservoir sediment volume, is expected to be eroded and transported downstream during the drawdown period (see Table 3.11-7 in

Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [page 3-767 to 3-768]). Whether sediment eroded and transported would be within the lower, mid, or upper portion of this range is primarily related to whether drawdown occurs in a dry, normal, or wet water year, with more erosion and transport expected in a wet water year (see Figure 3.11-11 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [page 3-768]).

In addition to modeling the amount of sediment that would be eroded and transported downstream, the SRH-1D model simulated reach-averaged erosion of, and deposition on, the channel bed (USBR, 2012, pages 9-34 to 9-37). Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 has been clarified to discuss reach-averaged sediment deposition or erosion and bed elevation change results of both SRH-1D simulations (i.e., the 48 2-year simulations and three 50-year simulations) (USBR 2012a). The clarifying edits do not change the conclusions or significance determinations in Potential Impact 3.11-5. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 for the revisions.

The model simulations found that the reservoir sediment deposits would erode in the Hydroelectric Reach, with minimal deposition (see Figure 3.11-13 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [page 3-771]). The model also found that most of the fine-grained sediment would be transported downstream to the Pacific Ocean during the drawdown process (USBR, 2012, page 9-33). In the downstream direction, flows in the Klamath River increase due to tributary inflows (see Table 3.6-9 in Volume I Section 3.6.2.2 *Flood Hydrology – Environmental Setting – Basin Hydrology* [pages 3-616 to 3-617]), such that for the same riverbed slope there is greater stream power to hold sediment suspended in the water (see Table 3.11-3 in Volume I Section 3.11.4.2 *Geology, Soils, and Mineral Resources – Impacts Analysis Approach – Suspended Sediment* [pages 3-749 to 3-750]). Therefore, as the fine sediment load moves downstream during reservoir drawdown and in the short term following dam removal, it is not likely to be deposited in any substantial way unless there is a decrease of riverbed slope great enough to counter the power of water flow, which does not occur in the 193 river miles between Iron Gate Dam and the Pacific Ocean. USBR (2012a) modeled sediment deposition results are supported by Stillwater Sciences (2008) model results, which used the peer-reviewed Dam Removal Express Assessment Model (DREAM-1) (Cui et al. 2006a,b), and returned no discernable sediment deposition downstream of Iron Gate Dam for any simulations.

Based on the SRH-1D model results, the downstream extent of substantial sediment deposition would be Cottonwood Creek. The Klamath River reaches where sediment deposition is most likely to occur within two years of dam removal are Bogus Creek to Willow Creek and Willow Creek to Cottonwood Creek (RM 185.1), both of which have relatively low riverbed slope (approximately 0.2 to 0.4 percent within 5 miles of Iron Gate Dam) compared with upstream reaches, and are upstream of the first major tributary inflow–the Shasta River (RM 179.5) (see Figure 3.11-15 in Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5). Between Bogus Creek and Cottonwood Creek most of the predicted sediment deposition would be sand or larger, with fine sediments remaining in suspension in the water column through these reaches. The SRH-1D model simulation found that the streambed level could be raised (i.e., the process of 'aggradation') by 0.8 to 1.7 feet between Iron Gate Dam and Cottonwood Creek if drawdown occurs in a normal water year due to primarily coarse sediment deposition, with less in dry and wet water year types (USBR 2012a, pages 9-36 to 9-37). In these reaches, the greatest deposition is expected in a normal water year type, because less sediment would be eroded from the upstream reservoirs in a dry water year, and more sediment would remain suspended in the water column through these reaches in a wet water year. The potential effects of this deposition between Bogus Creek and Cottonwood Creek on aquatic habitat are described in Volume I Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Master Response AQF-7. Regarding geomorphic hazards, the flow of water and sediment is expected to follow existing and historic channels, which are reasonably confined and have sufficient width-depth ratios to allow for the predicted sediment deposition to occur within the channel.

Farther downstream, between Cottonwood Creek and the Shasta River, there is more likely to be minor scour than sediment deposition, and downstream of the Shasta River there would insignificant deposition (less than 0.1 feet) within two years following dam removal (see Figure 3.11-15 in Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5). Based on the SRH-1D model, downstream fluctuations of stream power (USBR 2012a, page 4-9) would not be substantial enough to result in suspended fine-grained load dropping out of the water column in reaches downstream of Cottonwood Creek. The estimated equivalent 10-year flood flow that would occur during reservoir drawdown would be large enough to spill onto lower elevation floodplains, with some spatially discrete sediment deposition expected in these locations. Although mitigation would be required to reduce the short-term impacts of elevated suspended sediment concentrations on coho salmon critical habitat and Chinook and coho essential fish habitat in the Klamath River between Cottonwood Creek and the Shasta River (see Potential Impacts 3.3-1 through 3.3-16 in Volume I Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*), return of more natural sediment loads to the Klamath River, which has been historically sediment starved by dams and hydraulic mining, would be beneficial for aquatic species in the long term (see Volume III Attachment 1 Section 3.3.5.2 *Aquatic Resources – Potential Impacts and Mitigation – Bed Elevation and Grain Size*

Distribution and Master Responses AQF-7 and AQF-10). Further, any fine sediment deposition that does occur in the short term or long term would have positive benefits for riparian vegetation establishment and would expand habitat suitable for larval rearing of Pacific lamprey (see Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Habitats* Potential Impact 3.3-11).

Short-term Spatially Discrete Sedimentation Impacts

As USBR (2012a) used a combined data reporting approach for the two-year model simulations, the report does not explicitly account for transient (i.e., temporary) sediment storage and erosion effects within the two-year period immediately following dam removal, or thereafter. Although most fine-grained sediment is expected to move downstream during drawdown (as described above) and Stillwater Sciences (2008) found that the amount of pool filling within the Klamath River bed would be small, there would be some spatially discrete sedimentation effects, such as deposition in slack water areas (e.g., pools, eddies, alcoves) (see Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [pages 3-772 to 3-773], which is partially modified in Volume III Attachment 1). This prediction was considered in the analyses of geology, soils, and mineral resources, hydrology, water quality, and aquatic biological resources for the Proposed Project and the alternatives, and is described as such in the Draft EIR.

The likely persistence of any fine sediment that does deposit along the Klamath River would be dependent on the flow magnitude required for remobilization of surface sediments. Shea (2016) summarized available information on this subject, and found the following:

- The flow required to mobilize fine sediments deposited in surface layers (i.e., exceed the shear stress) on 20-30% of the riverbed downstream of Iron Gate Dam is 5,000 cfs to 8,000 cfs (adapted from Holmquist-Johnson and Milhous 2010).
- The flow required to initiate slight mobilization of the riverbed (i.e., for the Shield’s parameter to reach or exceed the reference Shield’s stress), which would correspond to a small, but measurable, sediment transport rate, with potential flushing of sand to a depth of gravels and cobbles with a D_{90} particle size (i.e., the particle size diameter at which 90 percent of the riverbed’s sediment is comprised of particles with a diameter less than this value), downstream of Iron Gate Dam varies by reach and ranges from 5,800 cfs to 20,000 cfs (USBR 2012a).

Additionally, Ayres Associates (1999) provide geomorphologically specific information on the sediment motion associated with pools and riffles using a set of criteria related to grain shear stress, the specific weight of water, sediment size, and sediment density (termed “Shield’s criteria’) throughout the length of the Klamath River downstream of Iron Gate Dam, which are both considered here:

- Riffles comprise coarser sediment and conditions for sediment motion are frequently exceeded on parts of the riffle, even in low flows, because riffles are shallow with relatively high velocities and rough surfaces. Using Shield's criteria, the flow required for full mobility of the highest point on a riffle (i.e., riffle crests) at Little Bogus Creek (RM 187), which is upstream of Cottonwood Creek, is approximately 9,800 cfs, and this increases downstream to 147,000 cfs at Blue Creek (RM 16) using D_{50} (i.e., the particle size diameter at which 50 percent of the riverbed's sediment is comprised of particles with a diameter less than this value).
- Pools comprise finer sediment, and in the Klamath River the long-term capacity for storing fine sediment along the riverbed greatly exceeds the fine sediment supply. Using Shield's criteria, the flow required for sediment motion in pools at Little Bogus Creek is approximately 5,400 cfs, increasing downstream to 25,000 cfs at Blue Creek using D_{84} (i.e., 2 mm—the particle size diameter at which 84% of the riverbed's sediment is comprised of particles with a diameter less than this value). Using a smaller particle size (e.g., D_{50}) reduces the flow required for motion of fine sediment in pools.

In the reaches where significant sediment deposition is most likely to occur (Bogus Creek to Cottonwood Creek), the median estimate for initiation of mobilization of the existing bed substrate is a flow of approximately 10,250 cfs, which has a return period of approximately 4 years based on data from 1961-2008 (see Figure 3.11-6 in Volume III Attachment 1 Section 3.11.2.4 *Geology, Soils, and Mineral Resources – Impacts Analysis Approach – Sediment Load*) (USBR 2012a). As discussed in *Geology Soils and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 and USBR (2012a, pages 9-86 to 9-88), fining of the channel bed post dam removal is predicted to reduce the return period flow required to initiate mobilization of the channel bed to approximately 6,000 cfs from Bogus Creek to Cottonwood Creek. Therefore, controlled flushing flows in the order of 6,000 cfs (USBR 2018a; NMFS 2019; USFWS 2019a) may result in some bed mobilization from Bogus Creek to Cottonwood Creek. The amount of sediment deposition predicted by the SRH-1D model results between Bogus Creek and Cottonwood Creek, and the potential for these sediment deposits to remain in place for more than two years until a sufficiently large flow can mobilize them, led to the significant and unavoidable impact determination associated with Potential Impact 3.11-5 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* (page 3-765 to 3-775).

Downstream of Cottonwood Creek, the potential for impacts due to spatially discrete fine sediment deposition (i.e., deposition that occurs in slack water areas such as pools, eddies, and alcoves) would not be significant because the predicted sedimentation (described above) is sufficiently small and any sedimentation that does occur would be expected to mobilize during subsequent flood events. As described above, flows of 5,000 to 8,000 cfs could be sufficient to flush surface sediment downstream of Iron Gate Dam. Modeling by USBR

(2012a) produced reach-by-reach flow estimates, which were considered in preparing the EIR. Based on USBR (2012a), none of the reaches from Cottonwood Creek to Indian Creek have a median return period for initiation of sediment transport (i.e., surface flushing) greater than 4.5 years (see Figure 3.11-6 in Volume III Attachment 1 Section 3.11.2.4 *Geology, Soils, and Mineral Resources – Impacts Analysis Approach – Sediment Load*). No significant fining of the channel bed from Cottonwood Creek to Indian Creek is predicted that would alter the historic return period for sediment mobilization (USBR 2012a, pages 9-86 to 9-88). Under the USBR Klamath Irrigation Project 2019 BiOp (USBR 2018a; NMFS 2019; USFWS 2019a), flow releases of approximately 6,000 cfs would occur at Iron Gate Dam annually in spring, which would be expected to generate surface flushing in some reaches (i.e., reaches with the lowest shear stress) downstream of Iron Gate Dam. Although there are some differences between lower flows modeled by USBR (2012a) for the 1961−2011 period and lower flows that would occur with the 2019 BiOp (USBR 2018a; NMFS 2019; USFWS 2019a), the peak flows (>5,000 cfs) that would mobilize sediment are similar. Therefore, with the 2019 BiOp, the return periods modeled by USBR (2012a) for initiation of sediment transport continue to be relevant to this discussion and the EIR.

Should spatially discrete downwelling of sediment (i.e., downward movement of finer sediment into the matrix of larger particles on the riverbed) occur, the subsequent geomorphologically effective flow would redistribute (sort) the gravel and cobble layer on the riverbed, as well as widen the channel and remove aquatic vegetation. Shea (2016) estimates that this would occur with flows of approximately 15,000 cfs downstream of Iron Gate Dam, which have a return period probability of 10 years; although Ayres Associates (1999) suggest that geomorphic reworking of riffle crests may occur more frequently, and USBR 2012a (Figure 5-25 on page 5-8) indicate that slightly higher flows would be required for significant bed mobilization with return periods of 10.5 to 12.5 years. This is a cyclic geomorphic phenomenon, where sediment and vegetation build up until the next geomorphologically effective flow rejuvenates the reach, and the process repeats itself, maintaining approximate sediment equilibrium of free-flowing rivers at the time scale of decades. This process of sorting and redistributing sediment would reduce the impact of substantial short-term sediment deposition upstream of Cottonwood Creek in the long term. The Proposed Project would have the beneficial long-term (i.e., 50 years) effect of increasing sediment supply and transport and creating a more dynamic and mobile bed downstream of Iron Gate Dam. Farther downstream where no substantial short-term sediment deposition would occur, none of the reaches from Cottonwood Creek to Indian Creek have a median return period for significant (full bed) mobilization, which would sort the gravel and cobble layer, greater than 12 years (see Figure 5-25 in USBR 2012a, page 5-8). Downstream of Beaver Creek, significant bed mobilization would occur frequently, with the median estimate of every two to three years. Any potential small and spatially discrete fine-grained sediment deposition downstream of Cottonwood Creek is expected to have the longest residence time between the Shasta River and Beaver Creek.

Minimization and Monitoring Requirements

The EIR determined that potential sediment deposition between Iron Gate Dam and Cottonwood Creek would be significant and unavoidable (Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [pages 3-765 to 3-775]) because mitigation measures could not reduce deposition in the Klamath River channel between Bogus Creek and Cottonwood Creek to an amount that would not be substantial. The significance of potential sedimentation was, therefore, fully disclosed in the Draft EIR based on the best available science, and technically sound information, described above. This determination was made after accounting for Proposed Project measures to minimize ongoing sediment erosion and impacts. Mechanical methods for moving and stabilizing sediment have been avoided in the Proposed Project, in favor of softer measures to achieve the same objectives. Sediment jetting would be used to maximize sediment erosion during drawdown, thus minimizing potential future erosion of reservoir sediment deposits, and is described in Volume I Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3 (pages 3-84 to 3-106), which is revised and reprinted in Volume III Attachment 1. Additionally, during and after reservoir drawdown, hydroseeding would be used to stabilize sediments, with vegetation management for at least five-years following dam removal (see Volume II Appendix B: *Definite Plan*, pages 211-215).

The approach in the EIR does not affect monitoring that would be required under the Clean Water Act Section 401 certification for the Lower Klamath Project. The Definite Plan (see Volume II Appendix B: *Definite Plan – Appendix M*) includes a Water Quality Monitoring Plan to assess the Proposed Project's impacts to water quality, and this plan includes turbidity and suspended sediment concentration monitoring, along with adaptive management requirements. Please note that the State Water Board has authority to review and approve any final Water Quality Monitoring Plan through its water quality certification under the Clean Water Act, Section 401. The State Water Board released a Draft Water Quality Certification for public comment on June 07, 2018. The Draft Water Quality Certification sets forth water quality monitoring, adaptive management, and compliance requirements for any Water Quality Monitoring Plan to meet under Conditions 1 and 2. For informational purposes, note that the Draft Water Quality Certification requires quantification of the amount of sediment present in each Proposed Project reservoir footprint, the total amount of sediment exported from the Proposed Project reservoirs, and the amount of sediment that settles in the Klamath River between Iron Gate Dam and Cottonwood Creek following dam removal in the short term.

Conclusion

Although significant sediment deposition may occur between Iron Gate Dam and Cottonwood Creek, most eroded reservoir sediments are predicted to be transported to the Pacific Ocean as particles that remain suspended in the water during drawdown and in the short term following drawdown. The DREAM-1 model applied by Stillwater Sciences (2008) and the SRH-1D model applied by USBR (2012a) both indicate that fine sediment deposition in the Klamath River downstream of Cottonwood Creek would be minimal. Any spatially discrete fine sediment deposition (i.e., deposition that occurs in slack water areas such as pools, eddies, and alcoves) would also likely be transient (i.e., temporary), with remobilization occurring in near-term floods (i.e., for initiation of remobilization, 4.5-year probability or less).

The SRH-1D model, which is used as a basis for assessing downstream sediment impacts in the EIR, is technically sound and fit-for-purpose. The significance determinations in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 would not change with application of a different sediment model or more spatially discrete geomorphic analysis, because the existing sediment models were sufficient to assess potential sediment-related impacts of the Proposed Project against criteria relevant to CEQA, and the reach-by-reach significance of potential sedimentation was fully disclosed in the Draft EIR. Therefore, additional analysis of fine sediment erosion, transport, and deposition, as suggested by some commenters, is not necessary for the purposes of the EIR, and would be an unreasonable use of time and resources.

GEO-2 Potential For Slope Instability

Several commenters expressed concern about the potential for drawdown to trigger slope instability at specific locations around the Copco No. 1 Reservoir rim. Some slope stability-related comments also assert that existing and proposed geologic investigations and analyses to better define slope stability along the reservoir rim are inadequate to define the impacts and associated mitigation, and that monitoring of large, potentially unstable areas within Copco No. 1 Reservoir included in Mitigation Measure GEO-1 should be extended to a five-year period following drawdown.

Please refer to Volume I Section 3.11.2.3 *Slope Instability and Mass Wasting* (pages 3-747 to 3-748) for a general description of existing slope instability around the reservoirs and Volume III Attachment 1 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 for a detailed analysis of specific areas along the Copco No. 1 Reservoir rim where slope instability may occur during reservoir drawdown. Potential Impact 3.11-3 also includes a description of measures that KRRC will implement to mitigate the potential impacts of slope instability during drawdown (see also Volume II Appendix B: *Definite Plan*). Mitigation Measure GEO-1 specifies that KRRC shall implement these measures to mitigate the potential impacts of slope instability during reservoir drawdown; and specifies additional monitoring and inspection of unstable or potentially unstable areas throughout and following drawdown, as well as revegetation of affected areas.

For development of the Definite Plan (Volume II Appendix B of the EIR), the KRRC summarized existing geologic mapping, performed additional geologic mapping, conducted subsurface investigations with lab testing, and, using results of the testing, characterized and analyzed the stability of sediments in the reservoir rim and bed areas. Based on these analyses, KRRC identified certain areas that have the potential for slope instability as a result of proposed activities associated with dam removal. Where areas of potential instability occur above the current reservoir water surface, and where these instabilities could result in impacts to existing roads, private property, or structures during and following reservoir drawdown, KRRC would mitigate these impacts by implementing the below summarized actions, also specified in Mitigation Measure GEO-1.

Mitigation Measure GEO-1 specifies that KRRC will visually monitor potentially unstable areas along the Copco No. 1 Reservoir rim for the duration of reservoir drawdown and for two weeks following drawdown, or longer, if KRRC determines that a longer monitoring period is prudent. Depending on the location, monitoring may involve tribal monitors (see also Mitigation Measures TCR-1, TCR-2, and TCR-3 in Volume III Attachment 1). If slope failure related to Project activities is observed, an exclusion zone will be established around the unstable area and the KRRC will monitor the unstable area. Throughout drawdown activities, and once the areas are safe to inspect, the KRRC shall inspect any slope failures and implement slope stabilization measures, as appropriate. For any slope failure related to Project activities that occurs during drawdown or the year following drawdown and that adversely impacts a structure or public facility or impacts or has a material potential to impact water quality or volitional fish passage, KRRC will fund or implement the following actions:

1. By agreement with the property owner, repair or move affected structures and/or purchase affected property; or
2. Repair and/ or re-align affected road segments; or
3. Regrade and/or engineer structural slope improvements (e.g., retaining walls, buttresses, drilled shafts or other structural elements that could be installed to resist slope movement); and
4. Revegetate affected areas to the extent revegetation is feasible and appropriate.

As stated in Volume III Attachment 1 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3, implementation of the aforementioned measures would reduce the potential impacts to a less than significant level. Although KRRC may be conducting additional analyses to better understand the site-specific potential for slope failure, the results of these analyses would be intended to provide more refined information regarding how best to implement Mitigation Measure GEO-1 to reduce potential impacts to the less than significant or no impact level, and the results of these analyses would not change the determination of environmental impacts detailed in the EIR, nor would they change the actions stipulated in the mitigation measure.

With respect to comments asserting that monitoring under Mitigation Measure GEO-1 should be extended to a five-year period following drawdown, the following explanation is provided. When the water level in a reservoir is high, hydrostatic pressures (i.e., pressures exerted by the reservoir water at equilibrium at a given point, due to the force of gravity) help to stabilize the shoreline slope. A reduction in water level reduces the stabilizing external hydrostatic pressure and changes pore pressures (i.e., pressures in the small spaces between grains of sediment) inside the shoreline slope, which can lead to slope instability. Analyses by KRRC indicate the potential for slope instability in particular areas of the Copco No. 1 Reservoir rim during drawdown. The potential for slope instability in subsequent years following drawdown would be substantially lower, since groundwater related to reservoir inundation would have drained and pore pressures associated with that groundwater would have dissipated. Thus, any instabilities after the initial drawdown and draining of the reservoir slopes immediately following drawdown are anticipated to be unrelated to the Proposed Project. Consistent with the analysis described in Volume III Attachment 1 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3, throughout and immediately following reservoir drawdown is the reasonable and appropriate period within which to monitor and inspect potential slope instability related to the Proposed Project as this period allows for sufficient time for the conditions that may result in instability to resolve.

2.2.13 Recreation Master Responses

REC-1 Flatwater Fishing and Boating

Some commenters have expressed concern that the removal of the Lower Klamath Project facilities would result in a loss of flatwater fishing and boating at the reservoirs, and some of these commenters view the Iron Gate and Copco No. 1 reservoirs as rare/unique flatwater habitat within California. Some commenters indicate that a lack of recent data in the Draft EIR to characterize recreational use of the Lower Klamath Project reservoirs for flatwater activities is problematic. Other commenters are concerned that the KRRC's proposed new recreational facilities and the existing facilities may not be sufficient to minimize Proposed Project's impacts to flatwater recreation.

Section 3.20 *Recreation* has been updated to include the most recent recreational use data that are available (2015−2019). Please refer to Volume III Attachment 1 for the final Section 3.20 *Recreation*.

Section 3.20.2.1 *Recreation –Regional Recreation – Reservoir- and Lake-based Regional Recreation,* Table 3.20-4, indicates that there are 12 other lakes/reservoirs with similar facilities within 50 miles of the Lower Klamath Project reservoirs and another seven lakes/reservoirs within 100 miles, including California's Trinity Lake Unit, Whiskeytown Lake, Shasta Lake, and Willow Lake, such that the Lower Klamath Project reservoirs would not be rare or unique resources. Section 3.20.5 *Recreation – Potential Impacts and Mitigation* Potential Impact 3.20-2 discusses the impacts to flatwater fishing and boating. As discussed in Potential Impact 3.20-2, given that other regional facilities provide similar opportunities for reservoir-based recreation in an uncrowded setting, KRRC's proposal to retain and enhance most existing river access facilities, and Parcel B land transfer under the Proposed Project that would potentially allow for additional future river-based recreation opportunities, the Proposed Project would be highly unlikely to result in a loss of recreational facilities affecting a large area or substantial number of people.

Based on public comments on the Draft EIR, Section 3.20.3 *Recreation – Significance Criteria* has been revised to remove the requirement from the significance criteria for a recreational facility to be considered rare or unique before a change to or loss of a facility would be considered a significant impact. The particular revised criterion that would result in a significant impact to recreational resources is as follows: "Adverse changes to or loss of recreational facilities affecting a large area or substantial number of people." Please refer to Volume III Attachment 1 for the final Section 3.20 *Recreation*.

REC-2 Level of Detail in KRRC's Draft Recreation Plan

Some commenters have expressed concern regarding the analysis and/or significance determination for Potential Impact 3.20-4. Others request further details regarding any future site-specific review of the new recreation sites proposed in the KRRC's Draft Recreation Plan and details on the Proposed Project's mitigation measures that would help reduce potential impacts on recreation, consistent with CEQA Guidelines 15168(c).

The KRRC's Recreation Plan takes a programmatic approach to developing recreational facilities and mitigating any impacts attributable to these developments. Proposed new recreational facilities are being evaluated by KRRC, including consideration of public input on the potential types and locations of these facilities. A Final Recreation Plan would be submitted to FERC, and this plan would include any new recreation facilities that are proposed by the KRRC. The Final Recreation Plan would be subject to environmental review under NEPA, and mitigation measures would be determined by FERC. If implementation of the Final Recreation Plan (at FERC's direction) requires any further state or local approvals, then written checklists would be prepared pursuant to CEQA Guidelines sections 15162 and 15168(c) to ascertain whether further site-specific environmental review of individual reactional projects would be necessary. Such individual projects shall be subject to applicable best management practices and mitigation measures required by FERC, applicable mitigation measures in this EIR, such as Mitigation Measures WQ-1, TER-1,

TER-2, TER-3, TER-5, TCR-1, TCR-2, TCR-3, and HZ-1, and any other measures required by an agency with jurisdiction over those individual recreation projects. The potential environmental impacts of these new recreational facilities would be reviewed at a project level in subsequent evaluations prior to their implementation. Section 3.20.5 *Recreation – Potential Impacts and Mitigation* Potential Impact 3.20-4 has been removed in light of the discussion above. Please refer to Volume III Attachment 1 for the final Section 3.20 *Recreation*.

The EIR analyzes the potential environmental impacts of adding new recreational sites or expanding existing recreational sites for water quality (Potential Impact 3.2-4), aquatic resources (Potential Impact 3.3-21), terrestrial resources (Potential Impact 3.5-1, Potential Impact 3.5-7, Potential Impact 3.5-10), historical resources and tribal cultural resources (Potential Impact 3.12-1), and utilities (Potential Impact 3.18-1).

2.2.14 Hazards and Hazardous Materials Master Responses

HAZ-1 Identification and Disposal of Hazardous Materials due to Construction Activities

Numerous commenters expressed concern that hazardous materials associated with implementation of the Proposed Project, and their transport, use, disposal, accidental spill/release, handling, and/or emissions, have not yet been fully identified.

Please refer to a discussion of this topic in Volume I Section 3.21.2.1 *Hazards and Hazardous Materials – Environmental Setting – Transport/Releases of Hazardous Materials* (pages 3-1029 to 3-1031) and Volume I Section 3.21.2.3 *Hazards and Hazardous Materials – Environmental Setting – Contaminants/Contaminated Sites* (pages 3-1033 to 3-1035). Please also refer to Volume I Section 3.21.5 *Hazards and Hazardous Materials – Potential Impacts and Mitigation* Potential Impact 3.21-1, specifically pages 3-1042 to 3-1045, Potential Impact 3.21-2, specifically pages 3-1045 to 3-1046, and Potential Impact 3.21-4, specifically pages 3-1046 to 3-1047 for analysis of the potential impacts of the Proposed Project as related to the routine transport, use, disposal, accidental spill/release, handling, and/or emissions of hazardous materials. Pages 3-1043 to 3-1044 list federal and state regulations applicable to this project.

As discussed in Volume III Attachment 1 Section 3.21 *Hazards and Hazardous Materials*, after the Draft EIR was released for public comment, the State Water Board received a submittal from PacifiCorp (dated December 30, 2019) which included redacted versions of Phase I and Phase II Environmental Site Assessment (ESA) reports. As noted in the submittal, these reports included the following:

Phase I ESA documents

- Phase I ESA for the Lower Klamath Hydroelectric Project, Dated August 23, 2019
- Phase I ESA for the City of Yreka Diversion Dam, Dated July 10, 2019
- Phase I ESA for the Fall Creek Hatchery, Dated July 10, 2019

Phase II ESA documents

- J.C. Boyle Development, Hazardous Building Materials Survey (HBMS) Revision 1, Dated August 27, 2019
- Copco No. I Development, HBMS Revision 1, Dated August 22, 2019
- Copco No.2 Development, HBMS Revision 1, Dated August 22, 2019
- Iron Gate Development, HBMS Revision 1, Dated August 22, 2019
- Iron Gate Hatchery and Fall Creek Hatchery, HBMS Revision I, Dated August 22, 2019
- City of Yreka Diversion Dam, HBMS Revision 1, Dated August 27, 2019
- Iron Gate Hatchery Burn Pit, Phase II ESA, Dated September 13, 2019

These redacted reports confirm the findings in the Draft EIR, which disclosed the potential for certain types of hazardous materials (e.g., asbestos, heavy metals, polychlorinated biphenyls [PCBs] creosote-treated wood), at the various facilities as well as information in Appendix B: *Definite Plan – Appendix O-3 Hazardous Materials Management Plan*. Volume III Attachment 1 presents the final Section 3.21 *Hazards and Hazardous Materials*.

HAZ-2 Potential for Increased Wildfire Risk due to Loss of Lower Klamath Project Reservoirs

(A) Numerous comments expressed the generalized concern that the Lower Klamath Project reservoirs would no longer be available for fire response crews to use as a water source for firefighting if the dams were to be removed.

Please refer to a discussion of this topic in Volume I Section 3.17.2.1 *Public Services – Environmental Setting – Fire Protection* (pages 3-909 to 3-911) as well as Volume I Section 3.21.2.6 *Hazards and Hazardous Materials – Environmental Setting – Wildfires* (pages 3-1036 to 3-1040). Please also refer to Volume I Section 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17-2 (specifically pages 3-915 to 3-921), for an analysis of whether elimination of a long-term water source for wildfire services would substantially increase the response time for suppressing wildfires in the vicinity of the Lower Klamath Project, and Volume I Section 3.21.5 *Hazards and Hazardous Materials – Potential Impacts and Mitigation* Potential Impact 3.21-8 (specifically pages 3-1050 to 3-1053), for an analysis of whether dam removal construction-related activities and/or removal of the Lower Klamath Project reservoirs would substantially increase the public's risk of loss, injury, or death associated with wildland fires.

KRRC's most recent application for water quality certification of the Proposed Project, as submitted to the State Water Board in December 2019 (KRRC 2019a), includes the following additional information about the Fire Management Plan:

- "KRRC intends to avoid a material net increase of fire risk as compared to baseline conditions in the Project area as defined in the Definite Plan."
- "KRRC is developing an updated Fire Management Plan that will include effective and feasible strategies and concepts to enhance both short-term and long-term fire prevention, detection, and suppression in the Klamath River Basin, and will submit the updated Fire Management Plan with FERC in support of the pending surrender application."
- "The updated Fire Management Plan is being developed in consultation with federal, California, Oregon, and local fire agencies. During construction, these measures include, but are not limited to meeting or exceeding federal, Oregon, and California requirements for fire prevention and suppression during construction activities, implementation of best management practices following National Fire Protection Association standards, and the designation of a safety officer on site that is responsible for overseeing fire responsibilities for construction operations 24 hours a day, seven days a week. The Fire Management Plan will also address long-term fire management to ensure that the Klamath River Basin's fire-fighting resources are not diminished due to the implementation of the Project, including the potential deployment of technology that will rapidly detect wildfire ignitions in the Basin allowing fire agencies to respond quickly to fire ignitions. KRRC is also consulting with fire agencies on identifying replacement water sources and access, including identification of aerial river access points."
- "In addition, KRRC has also contracted with Reax, a leading fire engineering firm that has assisted utilities throughout California (including PacifiCorp) to reduce operational fire risk. Reax will assist KRRC with the development of the updated Fire Management Plan to ensure that the measures set forth in the updated Fire Management Plan will effectively reduce short- and long-term fire risk as a result of the implementation of the Project".

Section 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17-2 and Section 3.21.5 *Hazards and Hazardous Materials - Potential Impacts and Mitigation* Potential Impact 3.21-8 have been revised to include the additional information presented above. Please refer to Volume III Attachment 1 Sections 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17-2 and Section 3.21.5 *Hazards and Hazardous Materials - Potential Impacts and Mitigation* Potential Impact 3.21-8 for these revisions.

(B) Numerous comments expressed concern that Recommended Measure PS-1 is not an enforceable mitigation measure, the KRRC's Fire Management Plan (FMP) is a draft plan that has not yet been reviewed by fire suppression agencies, and coordination with CALFIRE regarding their specific needs and abilities has not yet occurred.

In CALFIRE's comment letter on the Draft EIR dated February 25, 2019 (please refer to comment SA4-1), CALFIRE notes *"…It is fair to say the possible impacts of the dam removal on firefighting would depend on a variety of factors including: Location of fire, type of fire, fire behavior, firefighting resources assigned to the fire, time of year when the fire occurs, the water flow of the Klamath River on the day of the fire, etc…. Ultimately the impact of the dam removals will have to be evaluated on a case by case basis. CAL FIRE is used to fighting wildland fires in a large variety of circumstances and will adapt to whatever conditions we encounter at each fire. Also CAL FIRE understands that the …(KRRC) will be working with CAL FIRE on KRRC's Fire Management Plan to address the analyzed issues."*

In KRRC's comment letter on the Draft EIR, dated February 26, 2019 (please refer to comment ORG47-3), KRRC states *"As a condition of license surrender, KRRC will address any potential increased response time and associated wildland fire risk due to implementation of the Proposed Project."* KRRC's EIR comment letter further states *"KRRC continues to work with CAL FIRE to identify not only replacement sources of water, but ways in which KRRC can facilitate the reduction of overall emergency response times through communications and roadway improvements."* KRRC goes on to describe specific steps that they would take to implement replacement sources and reduce overall emergency response times under the Proposed Project.

As mentioned above, the KRRC included additional information about its ongoing coordination with CALFIRE in its recent application to the State Water Board for water quality certification for the Proposed Project (KRRC 2019a). This and other clarifying information has been incorporated into Volume III Attachment 1 Section 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17-2 and Section 3.21.5 *Hazards and Hazardous Materials – Potential Impacts and Mitigation* Potential Impact 3.21-8 for the revisions.

The State Water Board appreciates KRRC's commitment to addressing any potential for increased response time and associated wildland fire risks due to implementation of the Proposed Project as a condition of license surrender, and notes that the ongoing discussion and hiring of a contractor to reduce fire risk are steps that further increase the likelihood that fire risk will not increase, and may improve as a result of the mitigation measures. The State Water Board also appreciates the aforementioned comment letter from CALFIRE affirming the agency's ability to adapt to myriad fire risk situations and its intent to work with the KRRC on the Fire Management Plan. However, the EIR significance determination related to this topic remains 'significant and unavoidable' since the terms of an updated Fire Management Plan and its incorporation of Recommended Measure PS-1 are not within the State Water Board authority, and the State Water Board therefore cannot ensure implementation of Recommended Measure PS-1. For additional discussion of preemption under the Federal Power Act, please refer to Master Response CEQ-2.

2.2.15 Master Responses for the Recirculated Portions of the Draft EIR

R-1 Comments Not Relating to Recirculated Portions of the Draft EIR

CEQA Guidelines section 15088.5 requires a lead agency to recirculate an Environmental Impact Report (EIR) when significant new information is added to the EIR, after public notice is given of the availability of the Draft EIR for public review but before certification of the Final EIR. If the revision is limited to a few chapters or portions of the EIR, the lead agency is only required to recirculate the chapters or portions that have been modified for public review. When the Draft EIR is revised only in part and the lead agency is recirculating only the revised chapters or portions of the EIR, the lead agency may request that reviewers limit their comments to the revised chapters or portions of the recirculated Draft EIR.

When a lead agency elects to partially recirculate an EIR, it can result in the lead agency receiving more than one set of comments from reviewers. In this case, the lead agency is only required to respond to: "(i) comments received during the initial circulation period [i.e., the Draft EIR, Volumes I and II circulation period] that relate to chapters or portions of the EIR that were not revised and recirculated, and (ii) comments received during the recirculation period [i.e., the Recirculated Draft EIR circulation period] that relate to the chapters or portions of the earlier EIR that were revised and recirculated." (CEQA Guidelines, section 15088.5, subd. (f)(2).)

On December 21, 2019, the State Water Board recirculated sections of the Draft EIR relating to air quality, greenhouse gas emissions and energy, and requested that reviewers limit their comments to the revised portions. The State Water Board is required to solicit and evaluate comments on the Recirculated Draft EIR, and to prepare written responses to significant environmental issues raised in those comments in accordance with section 15088 of the CEQA Guidelines. The comment period on the recirculated portions of the Draft EIR extended from December 21, 2019 until February 6, 2020.

Per section 15088.5 of the CEQA Guidelines, the State Water Board did not prepare written responses to comments received during the comment period for the recirculated portions of the Draft EIR, Volumes I and II if the comments do not pertain to the recirculated sections. However, such comments are included as part of the record and will be considered by the State Water Board before certifying the Final EIR.

R-2 Discussion of Windblown Dust from Recirculated EIR Section 3.9 (pages RE-3-29 to RE-3-30)

This master response addresses comments regarding drawdown of the Lower Klamath Project reservoirs and commenters' concerns that any subsequent exposure of sediments in the reservoir footprint could result in potential impacts relating to windblown dust and associated windblown dust related contaminates or other contaminates. Some commenters expressed concern regarding potential health impacts to surrounding residents. Additionally, commenters noted the Condit Dam removal had dust impacts and claim that similar impacts will occur with implementation of the Proposed Project. Also, commenters suggest that past drawdowns of Copco and Iron Gate Reservoir have resulted in increased dust exposure to residents around the reservoirs. As discussed herein and in the EIR, the character of the sediments, proposed revegetation measures, sampling of reservoir depositions, and other information, indicates that the potential impacts raised by commenters regarding windblown dust or related contaminates are unlikely to occur in a manner that would result in a change to the significance determinations.

With respect to comments regarding the potential for dust to be generated by sediment deposits remaining in the reservoir footprints following drawdown and dam removal, please refer to Volume III Attachment 1 Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, which discusses how sediments remaining in the reservoir footprints would strengthen (i.e., harden) as they dry out and thus would be unlikely to result in windblown dust following reservoir drawdown. This understanding of sediment properties during and following drying is based on reservoir sediment field sampling and laboratory testing in 2012 (USBR 2012a) and 2018 (Volume II Appendix B: *Definite Plan – Appendix H*).

Moreover, as explained in the impact analysis and in Section 2.7.4 *Restoration Within the Reservoir Footprint* (pages 2-69 to 2-71), the Proposed Project includes revegetation of reservoir sediments remaining on the floodplain and the surrounding slopes during and immediately following drawdown to stabilize the sediments. Stabilization of sediments through planting is expected to be effective since laboratory revegetation "grow tests" showed that vegetation stabilized sediments from Copco No. 1 Reservoir (Appendix B: *Definite Plan – Appendix H* – Section 8.1.1 *Reservoir Sediment Characteristics*). The Proposed Project Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*; see also Volume I Section 2.7.4 *Restoration Within the Reservoir Footprint* [pages 2-69 to 2-71]) includes activities to promote revegetation and sediment stabilization such as sediment preparation and amendment; irrigation; aerial seeding using pioneer seed mixes; planting of pole cuttings, acorns, and container plants; and adaptively re-seeding or re-planting areas that do not sufficiently establish following initial restoration activities. Aerial seeding of grass seed mixes would occur during the reservoir drawdown period (January to March), as the reservoir water levels drop, and before the exposed reservoir sediments dry and form a surface crust. During the dam removal period (March to December), additional seed plantings, irrigation, monitoring of plant growth and vegetation cover, re-seeding as needed, and maintenance of existing and previously planted vegetation would occur. Additionally, the Reservoir Area Management Plan includes relative vegetation cover targets for each year following dam removal; these targets are 70 percent cover for each planting zone by year 1, 75 percent by year 2, 80 percent by year 3, and 90 percent by year 5. Given the sediment properties, timing of reservoir drawdown, and the inclusion of a restoration plan, the potential for elevated levels of dust to be generated by sediment deposits remaining in the reservoir footprints following drawdown and dam removal is very low.

The use of revegetation efforts is well supported. As stated in Volume II Appendix B: *Definite Plan* (page 214), "The use of vegetation to stabilize reservoir sediments is a common practice and well documented approach to improve ecosystem processes. For instance, all of the dam removal and reservoir restoration plans that were reviewed as part of this work (Appendix H) had native vegetation establishment in reservoir areas as the primary component to provide long-term stabilization of exposed soils. Likewise, revegetation experiments, performed in 2008 by Ellen Mussman for the Elwha River dams, showed that vegetation reduced erosion of reservoir sediments by 33% and mulch could reduce erosion by as much as 99% (Mussman et al. Mussman et al. 2008)….KRRC also drew upon similar wildland restoration efforts found in wildfire area restoration, natural disaster areas (i.e. Mount St. Helens), and human-induced impacted areas since these altered and often barren landscapes are very similar to the remaining reservoir sediments. Establishment of native vegetation provides many important benefits for the stability of the remaining sediments in these disturbed areas."

Some commenters compare purported effects associated with the Lower Klamath Project reservoir sediments and the sediments remaining behind the Condit Dam (located in Oregon) following its removal. The two projects, however, are very different and it does not follow that the sediment deposits underlying the reservoirs would create the same degree of windblown dust. Specifically, the composition of the sediments of the two projects differs considerably, as does the timing of revegetation efforts following dam removal. The sediment deposits in Copco No. 1 and Iron Gate reservoirs contain approximately 14 to 16 percent sand (by mass) and 84 to 86 percent fine sediment (by mass) (Volume I Table 2.7-10 on page 2-67). In contrast, the sediment deposits behind Condit Dam contained a higher amount of sand (approximately 60 percent, by mass) and a lower amount of fine sediment (approximately 35 percent silt and clay, by mass) (Wilcox et al. 2014). The higher degree of fine sediment in the Lower Klamath Project deposits is aligned with the experimental observations of rapid strengthening (i.e., hardening) as these sediments dry out (see above), reducing the potential for windblown dust relative to the sediments that were originally behind Condit Dam. Furthermore, Condit Dam was breached in October 2011, and vegetation seeding did not begin until 11 months later in September 2012 (PacifiCorp 2016f). As noted above, hydroseeding of the sediment deposits in the Lower Klamath Project reservoir footprints would begin *during* drawdown, and revegetation efforts would continue throughout the year of drawdown and dam removal, with monitoring and adaptive management occurring throughout the first five years following dam removal and completion of revegetation, or until the performance criteria have been met.

Commenters noted past occurrences where Copco No. 1 reservoir water surface elevations decreased, which the commenters believe may have resulted in increased airborne dust, and they expressed concern that the same effect could occur under the Proposed Project. The water surface elevation decreases of Copco No. 1 Reservoir as a part of Klamath Hydroelectric Project operations, however, are quite different from the anticipated management of reservoir drawdowns under the Proposed Project. During the extreme drought of 2014-2016, PacifiCorp coordinated late-2014 water releases from Iron Gate and Copco No. 1 reservoirs to provide a small degree of flexibility for managing irrigation water in the Upper Klamath Basin. A comparable water borrowing arrangement also occurred in 2018. These water-borrowing operations reduced the water surface elevations of Iron Gate and Copco No. 1 reservoirs and occurred during dry periods where the sediments would have dried quickly and may have been mobilized during wind events. In contrast, the Proposed Project's drawdown is scheduled to occur during January-March which is a period of cool temperatures and precipitation which is likely to reduce the speed at which sediments dry in comparison to sediment drying under past Klamath Hydroelectric Project operations. Additionally, as explained above, the Proposed Project includes restoration actions such as aerial seedings to help stabilize the sediments and prevent windblown dust. Water surface elevation changes under current Klamath Hydroelectric Project operations did not include restoration and seeding actions to reduce windblown dust to residents near Copco reservoir.

In the comments received related to windblown dust, there were several references to other dam removal projects or bodies of water in the West where commenters believe that windblown dust was an issue. These included Condit Dam (addressed above), Owens Lake, and the Salton Sea. The available information, however, does not indicate that the Proposed Project is similarly situated in either geography or operations. The Klamath Hydroelectric Reach during implementation of the Proposed Project is characterized by differing wind patterns, soil types, physical properties of reservoir sediments, topography, and the implementation of a robust reservoir restoration plan designed to stabilize remaining sediments and exposed areas after drawdown. Past drawdown events in the Klamath Hydroelectric Reach where residents have stated that windblown dust was an issue would be prevented during implementation of the Proposed Project due to implementation of the restoration plan. These efforts to stabilize reservoir sediments and exposed areas were not implemented during past drawdowns. As noted above, the restoration plan for the reservoir areas is based on current knowledge of reservoir restoration and experience gained from recent dam removal projects. This includes designing a restoration plan intended to minimize the potential for undesirable sediment releases that would also reduce the potential for windblown dust.

As explained herein, the likelihood of substantial amounts of windblown dust occurring as a result of dam removal under the Proposed Project are low. Nonetheless, the EIR adequately disclose the potential contaminants associated with the Proposed Project. Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* provides a general summary of the inorganic and organic contaminants measured in the Klamath River waters, the reservoir sediments, and aquatic biota. Please also refer to Volume III Attachment 1 Appendix C, Section C.7 *Inorganic and Organic Contaminants* for further details about the inorganic and organic contaminants measured in the reservoir sediments. Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* includes the chemicals of potential concern detected in reservoir samples and comparisons of detected chemical concentrations with USEPA and California Environmental Protection Agency (CalEPA) human health screening levels to assess human health risk.

For example, as stated in Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants*, 4,4'-dichlorodiphenyltrichloroethane (DDT), 4,4'-dichlorodiphenyldichloroethane (DDD), 4,4'-dichlorodiphenyldichloroethylene (DDE), dieldrin, and 2,3,7,8-tetrachlorodibenzodioxin (TCDD) were detected only in J.C. Boyle sediments. Additionally, no PCBs were found above U.S. Army Corps of Engineers (USACE) Puget Sound Dredged Disposal Analysis Program (PSDDA) screening levels (Shannon & Wilson, Inc. 2006), and the degree of exceedance for total PCBs may reflect regional background conditions. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Additionally, Volume III Attachment 1 Section 3.2 *Water Quality*, Volume II Appendix B *Definite Plan* (pages 148 to 150), and Volume III Attachment 1 Appendix C discuss the levels of contamination measured in the reservoir sediment deposits. Volume III Attachment 1 Section 3.2 *Water Quality* discusses the potential impacts from human exposure to inorganic and organic contaminants in the reservoir sediment deposits. Concentrations of inorganic and organic contaminants in the reservoir sediments mean that the potential for problematic levels of human exposure to these compounds once reservoir drawdown occurs is unlikely. As stated in Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-13, for the Lower Klamath Project reservoir sediments remaining in the reservoir footprint and along the river banks, detected levels of dioxin, furan, and dioxin-like PCBs are only slightly above regional background concentrations, and arsenic and nickel are the only compounds detected at levels exceeding USEPA and/or CalEPA residential screening levels to protect human health. The section also states that exposure to arsenic in these areas would be constrained by short-term activities and long-term future land use that would support only limited exposure patterns, such that human exposure to arsenic and nickel in sediments in the reservoir footprint would be a less-than-significant impact. The USEPA and CalEPA screening levels used in the analysis in Potential Impact 3.2-13 relate to the ingestion of soil, which differs from the inhalation of airborne dust. However, estimating exposure from both pathways is dependent on the concentration of contaminants and the timeframe over which exposure occurs. In sum due to the mitigating factors noted above (i.e., physical properties of reservoir sediments, level of contamination in reservoir sediments, seasonally wet conditions during drawdown, and implementation of the restoration plan immediately following reservoir drawdown), it is not anticipated that any additional emissions from windblown dust would result in a change to the significance determinations in recirculated Section 3.9 *Air Quality* related to the emissions of particulate matter and potential health effects.

Although there is the potential that criteria air pollutants and GHG emissions may be generated during any efforts to reduce windblown dust during restoration activity, these emissions are not anticipated to be substantial enough to result in a change in the significance determinations in recirculated Section 3.9 *Air Quality* and Section 3.10 *Greenhouse Gas Emissions and Energy*. Due to the conservative assumptions used to estimate the criteria air pollutant and GHG emissions from construction activity, any emissions generated to address windblown dust would be accounted for in the emissions estimates related to restoration activities.

2.3 Written Comments and Responses – Draft EIR

This section presents written comments received on the Draft EIR and the State Water Board's responses to those comments. Written comments and responses in this section are organized by comment affiliation type. To determine which affiliation your comment is associated with, please refer to Table 2-1 or Table 2-2.

Table of Written Comments and Responses

2.3.1 State Agencies

This section presents written comments received on the Draft EIR from state agencies and the State Water Board's responses to those comments. Written comments and responses in this section are organized alphabetically by agency name. To determine whether your comment is associated with an affiliation type other than state agencies, please refer to Table 2-1 or Table 2-2.

Table of Written State Agency Comments and Responses

CAL FIRE, Mike Hebrard

Comment SA4-1

The Water Board Environmental Impact Report found that the removal of the dams would have a "significant and unavoidable" impact due to the "elimination of a long-term water source for wildfire services" and a potential substantial increase in response time for suppressing wildfires.

The possible impact of the dam removals on CAL FIRE's wildland firefighting is a very complicated issue. It is fair to say the possible impact of the dam removal on firefighting would depend on a variety of factors including: Location of fire, type of fire, fire behavior, firefighting resources assigned to the fire, time of year when fire occurs, the water flow of the Klamath River on the day of the fire, etc.

Ultimately, the impact of the dam removals will have to be evaluated on a case by case basis. CAL FIRE is used to fighting wildland fires in a large variety of circumstances and will adapt to whatever conditions we encounter at each fire. Also, CAL FIRE understands that the Klamath River Renewal Corporation (KRRC) will be working with CAL FIRE on KRRC's Fire Management Plan to address the analyzed issues.

Please feel free to contact me with any questions regarding this letter.

Response to Comment SA4-1
Thank you for your comment. The information provided in this comment was used to help develop Master Response HAZ-2.

California Department of Fish and Wildlife, Tina Bartlett, Jeffrey Stoddard, Tiffanny Manko

Comment SA3-1
The California Department of Fish and Wildlife (Department) appreciates the opportunity to comment on the Draft Environmental Impact Report (DEIR) for the Lower Klamath Project License Surrender (Project). The proposed Project consists of the decommissioning and removal of the J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities located on the Klamath River. The Project implements portions of the Klamath Hydroelectric Settlement Agreement (KHSA), as amended. The Department is a signatory to the KHSA and has been actively participating in matters related to the Project since December 2000.

The Department provided a letter to the State Water Resources Control Board (SWRCB) on the Notice of Preparation for the subject DEIR on February 1, 2017. In addition, the Department provided a letter to the SWRCB regarding our support of the draft 401 water quality certification on June 26, 2018, and the aquatic resource measures as described in the Definite Plan on November 9, 2018. We hereby incorporate the comments provided in those letters by reference. The Department worked closely with the Klamath River Renewal Corporation (KRRC) on the development of the restoration plan, the terrestrial resource measures, and the aquatic resources measures as they are presented in the Definite Plan and we support their implementation. Department personnel have reviewed the DEIR and offer the following comments.

KRRC proposes to remove three dams in California and one in Oregon to create a free-flowing Klamath River in the Hydroelectric Reach and provide for volitional fish passage in accordance with the terms of the KHSA. Currently, the Klamath Hydroelectric Project is causing irreparable harm to the State's fish and wildlife resources. The dams alter the flow of the river, block fish passage, and create poor water quality conditions that cause toxic algal blooms, low dissolved oxygen(DO), and high-water temperatures. The dams also contribute to conditions that foster fish disease and result in high juvenile salmon mortality in *the Klamath River. The Project, if approved and implemented, will return the Klamath River in the Hydroelectric Reach to natural riverine conditions resulting in improved water quality and a more natural range of water temperatures. The Project will benefit anadromous fish populations by increasing access to historical habitat, restoring mainstem and tributary habitat, and improving biological and physical factors that heavily influence fish populations (e.g., flow conditions, sediment and bedload transport, water quality, fish disease, toxic algal blooms, and water temperature).*

The Department supports the establishment of a free-flowing Klamath River and volitional fish passage through implementation of the proposed Project, specifically as it relates to the recovery and conservation of fish and wildlife resources. Although we recognize that the SWRCB's analysis indicates that the Project will result in short-term significant and unavoidable impacts, these impacts would largely be limited to the time frame of direct dam deconstruction actions and sediment release.

The short-term aquatic effects of the Project will primarily occur from the release of sediment during reservoir drawdown. These effects include high concentrations of suspended sediment, bedload mobilization and deposition, and low DO levels, all of which are well described in the DEIR. It is the Department's position that the measures proposed to minimize impacts to aquatic resources from these short-term effects are adequate.

The short-term effects of the Project on terrestrial resources will primarily occur due to construction related activities and noise-levels. Again, it is the Departments position that these effects will be adequately off-set by the measures proposed. We concur with the list of short-term effects identified in the DEIR and summarized on page ES-12.

The long-term benefits of the Project will ultimately outweigh the short-term impacts. The Department concurs with the list of the long-term benefits of the proposed Project provided in the DEIR starting on page ES-9. The Project would significantly improve Klamath River water temperatures and DO conditions, reduce algal toxins, reduce the incidence of fish disease in juvenile salmon, restore historical anadromous fish habitat, and eliminate fish passage barriers. In addition, the Project would result in long-term beneficial effects to terrestrial resources. Some of those benefits include, increased wildlife movement opportunities, and increased distribution of riparian habitat, which, in turn, will lead to beneficial effects on willow flycatcher (Empidonax trail/ii), a species listed as threatened under the California Endangered Species Act. We provide greater detail regarding the long-term benefits of dam removal below.

There has been an increase in dam removal projects over the last five years (O'Conner et al. 2015) and studies have demonstrated the following benefits: the successful establishment of self-sustaining populations of salmonids in *previously inaccessible habitat (Anderson et al. 2015), and the proportion of returning fish born in upstream reaches increasing over time (Engle et al. 2013; Hatten et al. 2015; Allen et al. 2016). On the Elwha River, the total escapement of Chinook Salmon (Oncorhynchus tshawytscha) (4,243 adults) approximately doubled over the 20-year average immediately following dam removal and, after the Savage Rapids Dam was removed from the Rogue River (2009), salmonid redds were documented within the bounds of the former reservoir in one year, and over twice that many redds were identified within the former reservoir in two years (ODFW 2011). Recent dam removal efforts show that the rivers are healing very quickly, and fish are instinctively repopulating historic habitat. In a comprehensive synthesis of dam removal literature prepared by O'Conner et al. (2015) they state that a major finding of dam removal research is that rivers are resilient with many responding quickly to dam removal by trending towards their pre-dam states.*

Response to Comment SA3-1

Thank you for your comment. A response to this comment is not required under CEQA because the comment does not raise a significant environmental issue (CEQA Guidelines, section 15088) and/or would not change an environmental impact or mitigation measure analyzed in the EIR. This comment is included as part of the record and will be considered by the State Water Board before certifying the EIR (CEQA Guidelines section 15090).

Comment SA3-2

There are a number of peer-reviewed scientific and engineering studies that document the Project's benefits. The following documents more thoroughly discuss the Project's long-term benefits:

- *Klamath Dam Removal Overview Report for the Secretary of the Interior- an assessment of science and technical information (March 2013)*
- *Definite Plan for the Lower Klamath Project (Appendix I and Appendix J) (June 2018)*
- *The Joint Preliminary Biological Opinion on the Proposed Removal of Four Dams on the Klamath River, Conducted by: National Marine Fisheries Service and Fish and Wildlife Service Region 8 (November 2012).*
- *Klamath Facilities Removal Environmental Impact Statement/ Environmental Impact Report (EIS/EIR). (The Department and the Bureau of Reclamation were co-leads, 2012)*
- *Summary of Findings Informing the Secretarial Statement of Support (A transmittal to FERC from the Department of the Interior 2016)*
- *Preliminary Comments and Recommendations on PacifiCorp's Application for New Major License, Klamath River Hydroelectric Project, FERC No 2082, Klamath and Siskiyou Counties (a letter prepared by CDFW and submitted to FERC on March 27, 2006)*

In general, the Department concurs with all the benefits to natural resources from dam removal identified in the above referenced documents. Although this letter highlights some of the benefits identified in those documents, we want to emphasize that our silence as to any natural resource benefits described in any of the above identified documents should not be interpreted as a rejection or disagreement with any such benefits. We have drawn from the above listed documents to prepare the following section of this letter.

Response to Comment SA3-2

Please refer to response to comment SA3-1.

Thank you for providing a list of peer-reviewed scientific and engineering studies that document the Proposed Project's beneficial effects. During draft EIR development, the State Water Board considered all of the sources cited in California Department of Fish and Wildlife's (CDFW's) February 21, 2019 letter in addition to other resource materials included in reference sections for each resource area of the Draft EIR.

Comment SA3-3

The construction of PacifiCorp's hydroelectric dams on the Klamath River has blocked fish passage to the upper basin for nearly 100 years. The lack of fish passage at the hydroelectric facilities has resulted, and continues to result, in direct adverse impacts on anadromous fish resources of the Klamath Basin. Long-term declines of Klamath Basin fisheries have been estimated at 92 percent to 96 percent for wild fall-run Chinook Salmon, 98 percent for spring-run Chinook Salmon, 67 percent for steelhead trout (0. mykiss) (since 1960), 52 percent to 95 percent for Coho Salmon (0. kisutch), and 98 percent for Pacific Lamprey (Lampetra tridentata) (Overview Report). The research suggests that salmonids will benefit from a host of ecological improvements resulting from dam removal including access to miles of spawning and rearing habitat upstream from Iron Gate Dam. It is estimated that the Project will result in access to 76 miles of habitat for Coho Salmon, 300 miles for Chinook Salmon (Huntington 2004), and 420 miles for steelhead (Huntington 2004; 2006). In addition, recolonization of previously inaccessible reaches of the river will also restore the flow of marine-derived nutrients to upstream portions of the watershed resulting in an overall boost to ecosystem nutrient budgets and productivity (Tonra et al. 2015).

Water Quality and Water Temperature

The long-term benefits of dam removal include overall increases in DO concentrations. The reach of the Klamath River downstream of Iron Gate Dam is predicted to have a DO level increase of 3 to 4 mg/L during the summer and late fall (PacifiCorp 2005), which will reduce stresses to juvenile salmonids rearing in the mainstem.

In the long-term, it is anticipated that water temperatures downstream of the Iron Gate Dam site will be 2°c to 10°C lower during August through December and 2°c to 5°C higher during January through March than under the existing conditions. The generally warmer spring temperatures and cooler summer and fall temperatures are likely to benefit salmonid species. In addition, the more natural diurnal water temperature variation will be more synchronous with historical migration and spawning periods for salmon species. Benefits associated with increased spring water temperatures include increased growth rates for juveniles (Dunne et al. 2011) which has been shown to increase ocean survival (Bilton et al. 1982, Henderson and Cass 1991, Lum 2003, Jokikokko et al. 2006, Muir et al. 2006).

Hydrograph

Increased (i.e., natural) flow variability in the Klamath River mainstem will increase the effectiveness of environmental cues and better enable juvenile salmonids to adapt to changes in flow. Juveniles make localized movements in response to changes in environmental conditions at temporal scales of hours to months. Increased flow variability therefore is expected to increase the likelihood of juvenile survival due to their redistribution to suitable refugia sites upstream or downstream when they detect changes in flow.

Disease

Outmigrating juvenile salmonids within the Lower Klamath River Basin currently experience significant mortality from infectious disease, with recent estimates of disease-related mortality in downstream migrants as high as 90 percent, in specific areas for specific times (CDFW 2006). The Project will restore flows in the Klamath River that create channel bed scour. This bed scour will result in habitat disturbance of the polychaete worm that hosts Ceratonova shasta (FERC 2007), a myxosporean parasite that infects salmonids and can lead to mortality. In the long-term, reducing polychaete habitat will likely lead to an increase in the abundance of salmonids by increasing outmigration survival, particularly for juvenile Coho Salmon (FERC 2007).

Nuisance Algae

The Project will eliminate the habitat for the toxic blue-green algae (Dunne et al 2011, Hamilton et al. 2011). Blue-green algae thrives in stagnant water and is intolerant of turbulent water. The elimination of the reservoirs will result in an immediate and long- term reduction in toxic algal blooms which will improve long-term water quality (pH and DO) in the mainstem Klamath River.

Sediment and Debris Transport

The Project will result in a more natural sediment transport regime (Reclamation 2011, Hamilton et al. 2011, USDOI and CDFG 2012), which will increase the complexity in the channel bed. It is anticipated that these changes will enhance spawning, incubation, and rearing habitat for salmonids and reduce fish disease prevalence in the Klamath River. Increased delivery rate of debris will result in large wood deposition which has also been shown to increase salmonid abundance, survival, and production (Keeley et al. 1996, Solazzi et al. 2000, Roni and Quinn 2001, Whiteway et al. 201O, White et al. 2011).

Climate change

Based on the climate change model prediction of increasing water temperatures in the Klamath River watershed, access to the cold-water tributaries in the Hydroelectric Reach will improve salmonid population resilience and increase the probability of long-term persistence. The National Research Council (2004) wrote, "For salmonids, the most important potential changes [in the Klamath River aquatic environment due to climate change] include altered timing of snowmelt, lower base flows, and additional warming of water in summer." Access to spring-fed tributaries of the Klamath River in the Hydroelectric Reach will provide important refugia for salmonids as the climate continues to change.

In sum, the improved mainstem aquatic habitat conditions that will result from implementation of the Project (e.g., increased DO concentrations, increased flow variability, more natural water temperature patterns, decreases in disease, and increased gravel and large wood recruitment) and increased spatial distribution of habitat for native fishery resources are expected to improve ecosystem function and the survival of all fishery resources in the Klamath River in the long-term.

We look forward to working closely with KRRC and the SWRCB on an adaptive management and monitoring program for the Project. There are a number of plans that will require coordination with and approval from the Department prior to Project implementation including:

1. *Water Quality Monitoring Plan*
2. *Fish Presence Monitoring Plan*
3. *Tributary Mainstem Connectivity Plan*
4. *Spawning Habitat Availability Report and Plan*
5. *Juvenile Salmonid Rescue and Relocation Plan*
6. *Hatchery Operations and Maintenance Plan*
7. *Restoration Plan*
8. *Recreation Facilities Plan*
9. *Hydropower Operations Plan*

In closing, we would like to emphasize that the Department is committed to building and maintaining partnerships that achieve comprehensive and collaborative solutions to fisheries restoration and recovery in the Klamath River watershed. The Department will continue to coordinate with agricultural and water user communities, Tribes, Siskiyou County, our fish agency partners, commercial fishing interests, and conservation groups, to achieve that end. The Department continues to look for solutions to difficult natural resource issues by staying engaged with various stakeholders in the Klamath River Basin. Ultimately, the Department is interested in the long-term success of these holistic efforts beyond just dam removal.

Response to Comment SA3-3
Please refer to response to comment SA3-1.

2.3.2 Local Agencies

This section presents written comments received on the Draft EIR from local agencies and the State Water Board's responses to those comments. Written comments and responses in this section are organized alphabetically by agency name. To determine whether your comment is associated with an affiliation type other than local agencies, please refer to Table 2-1 or Table 2-2.

Table of Written Local Agency Comments and Responses

Board of Harbor Commissioners of the Crescent City Harbor District, James Ramsey

Comment LA5-1
The Board of Harbor Commissioners of the Crescent City Harbor District wishes to voice their support for the removal of the dams located on the Klamath River.

The Board of Harbor Commissioners further supports the Klamath River Renewal Corporation's (KRRC) application to the State Water Board for a Clean Water Act section 401 certification for the Federal Energy Regulatory Commission Project No. 14803 license surrender of the Lower Klamath Project. The beneficial results *of the dam removal project include positively affecting the water quality of the Klamath River and by doing so, taking an historic step toward restoring traditional salmon runs. Dam removal is crucial to restoring the natural ecosystem that existed before construction of the dams.*

Response to Comment LA5-1
Thank you for your comment. Please refer to Master Response GEN-1.

City of Crescent City, Blake Inscore

Comment LA7-1
Crescent City supports removal of the Klamath River dams as analyzed in the State Water Resources Control Board's recent Draft Environmental Impact Report (DEIR).

Crescent City serves as the home port for numerous commercial and recreational fishing vessels. The fishing industry is a major source of income for the City and includes fishing, seafood markets, seafood processing and support for local businesses like marine repair and supply services, restaurants and grocery stores. Many of our residents depend on these industries for their livelihood.

The Klamath River was once the third-largest salmon-producing river on the West Coast, and salmon played a large part in our fishing industry's prosperity. However, Klamath River dams blocked the migration of adult fish to historic upstream spawning grounds, greatly reducing salmon populations, and the region's commercial fishing industry has been severely compromised by these reduced salmon runs.

Crescent City-based recreational fishing has suffered as well, putting an unwelcome drag on our economy and pressuring city budgets and services.

We strongly believe, based on the DEIR, that a free-flowing Klamath will revitalize both segments of our fishing industry, and in turn create jobs and bring revenue to Crescent City that will allow us to better serve our residents.

For the reasons outlined above, Crescent City supports the Proposed Project reviewed in the DEIR and looks forward to the benefits it will provide to our region.

Response to Comment LA7-1
Thank you for your comment. Please refer to Master Response GEN-1.

City of Yreka, Steven Baker, Don Henion

Comment LA8-1

The State Water Resources Control Board ("SWRCB") has circulated for public comment (State Clearinghouse No. 2016122047) a Draft Environmental Impact Report (DEIR; KRRC 2018; hereafter known as the "DEIR") which sets forth the fact that PacifiCorp has applied to the Federal Energy Regulatory Commission ("FERC") for authority to decommission and remove four PacifiCorp owned and operated Klamath Hydroelectric Project dams, the flow of which is regulated by the Bureau of Reclamation ("BOR"). The application requests a substitution of permitees from PacifiCorp to the Klamath River Renewal Corporation, a 501(c)(3) corporation formed to potentially oversee the project ("KRRC").

The dams proposed to be decommissioned are the Iron Gate Dam, the Copco No. 1 Dam, the Copco No. 2 Dam, the J.C. Boyle Dam, and various appurtenant facilities, such as the removal and relocation of most of the infrastructure of the Iron Gate Fish Hatchery to a new fish hatchery located on Fall Creek immediately adjacent to the City of Yreka's diversions for its municipal water supply (collectively, the "Lower Klamath Facilities").

Response to Comment LA8-1

Thank you for your comment. This comment concerns a summary of the Lower Klamath Project.

Comment LA8-2

In significant part, the application has requested FERC to divide the Klamath River Basin Hydroelectric Project license into two separately designed projects: 1) The four lowermost dams on the Klamath River to a separate Lower Klamath Facilities project license; 2) The other PacifiCorp hydroelectric owned or operated facilities that are not proposed to be decommissioned. FERC has granted this request. The application also requests that FERC allow the transfer of the Lower Klamath Project license from PacifiCorp to KRRC. KRRC would then implement FERC approved steps to remove/decommission those facilities. Finally, the application requests that FERC stay its proceedings on PacifiCorp's (the current licensee) pending application for license renewal until FERC takes final action on the application. ("Proposed Project").

PacifiCorp's FERC license on the Lower Klamath Project expired in March 2006. FERC has not yet approved the Proposed Project, the transfer of the license, nor indicated what steps, if any, it will require should it approve the decommissioning of the Lower Klamath Facilities. FERC has referred the Proposed Project to an Independent Board of Consultants ("BOC") to fully review the Klamath Renewal Project and make its recommendations upon which FERC will base its ultimate decision to approve, disapprove or order modifications to the Proposed Project. The individuals on the BOC have expertise in dam construction and removal, engineering, aquatic and terrestrial biology, financial feasibility, construction cost estimating, insurance, and bonding for large infrastructure projects.

Response to Comment LA8-2
This comment concerns the Federal Energy Regulatory Commission (FERC) application for Lower Klamath Project and related issues.

Comment LA8-3
Significantly, although FERC has ultimate control over the nature and scope to the Proposed Project the DEIR is not being jointly submitted for comment with a NEPA environmental study. A NEPA Final Environmental Impact Study ("FEIS") was circulated and approved in 2012 but this study is outdated and FERC has required additional studies and information before that process can proceed.

Response to Comment LA8-3
Comment noted. Please see Master Response CEQ-1 for additional information.

Comment LA8-4
The Proposed Project is the product of an agreement between the United States Department of the Interior (which is the overseeing agency for the Bureaus of: Indian Affairs; Land Management; Reclamation; Park Service; U.S. Fish and Wildlife and U.S. Geological Survey), United States Department of Commerce's National Marine Fisheries Service, State of California, California Natural Resources Agency (which is the umbrella agency for Department of Water Resources, Department of Fish and Wildlife, Department of Conservation), California Department of Fish and Wildlife, the State of Oregon, Oregon State of Environmental Quality, Oregon Department of Fish and Wildlife, Oregon Water Resources Department and the permittee/owner PacifiCorp (a subsidiary of Berkshire Hathaway) as well as 35 other tribal, fish and conservation related NGOs, irrigation entities and water users. This agreement is entitled the Klamath Hydroelectric Settlement Agreement, dated February 18, 2010, as amended April 6, 2016 and November 30, 2016 ("AKSA"). The AKSA has not been sanctioned by the U.S. Congress nor ratified by state or federal law. It is an agreement whose validity has not been tested in Court and we are not aware of any pending litigation in that regard.

Response to Comment LA8-4
This comment concerns the Klamath Hydroelectric Settlement Agreement (KHSA).

Comment LA8-5
The federal compact to implement the 2010 agreement, was introduced and reintroduced to the House of Representatives and the U.S. Senate and variously referred to as S.1851 the "Klamath Basin Economic Restoration Act of 2011" and HR.3398, S2739 – the "Klamath Basin Water Recovery and Economic Restoration Act of 2014" and S.133 – the "Klamath Basin Water Recovery and Economic Restoration Act of 2015." None of these bills were signed into law and, accordingly, federal funds were not appropriated for its implementation.

Implementation of the AKSA is now being funded with a surcharge on PacifiCorp customers ($200 million) and by California State water bond funds ($250 million). It is estimated that if this agreement is not implemented, and FERC proceeds to relicense the dams, that PacifiCorp projects that it will incur a loss estimated at 20 million dollars per year on the Klamath Hydroelectric Project, which loss, PacifiCorp will be entitled to recover from its ratepayers under PUC regulatory standards.

Response to Comment LA8-5

This comment concerns the Klamath Hydroelectric Settlement Agreement (KHSA).

Comment LA8-6

Yreka's sole concerns, as related in these comments, are to ensure that the Proposed Project does not, in any manner, presently or consequently in any future period, adversely affect Yreka's right to divert and consumptively use water for municipal purposes under its Water Right Permit.

The possible areas that Yreka can presently identify through the data and plans proposed thus far, related to the following areas:

1. The replacement and reconstruction of its water transmission pipeline with a water transmission pipeline that is safe and secure from external threats that could cause any interruption in municipal water service.

2. The lack of specificity of the exact improvements to be made to Yreka's water diversion facilities on Fall Creek. The lack of such concrete specificity renders it premature and impossible to adequately address those particular impacts of the Proposed Project.

3. The effects of the proposed location, construction and expansion of a defunct fish hatchery and reconstruction of rearing ponds at Fall Creek, which are proposed to divert water under a junior water permit and further proposed to rear and release endangered species which could, in the future, cause further water restrictions upon Yreka's right to take under its consumptive water permit.

4. The effect of the project on PacifiCorp's pre-1914 water right to divert water from Spring Creek (16.5 cfs) and from Fall Creek to its Fall Creek Hydroelectric Facility upon which adequate water flow to Yreka's water diversion is predicated.

Response to Comment LA8-6

This comment summarizes some of the major concerns in the City of Yreka's letter. Please refer to Master Responses WSWR-3, WSWR-5, WSWR-6, WSWR-7, and responses to comments LA8-20 and LA8-22. Please also see responses to individual comments in this letter for more detailed information on the issues summarized here.

<u>Comment LA8-7</u>

5. The proposed deconstruction of the majority of the existing fish hatchery located at Iron Gate together with the lack of adequate studies and analysis of maintaining, improving and expanding hatchery activities at Iron Gate Hatchery or all other alternative locations which would thereby obviate any possible additional future adverse impacts on Yreka's right to divert or restrict the flow to such diversion, on Yreka's consumptive municipal water diversion from Fall Creek.

6. The data-deficient basis, lack of specificity and procedural compliance with applicable law in prematurely requiring Yreka to provide comments on a project that is still subject to change in the proceedings before the Federal Energy Regulatory Commission.

Response to Comment LA8-7

This comment summarizes some of the major concerns in the City of Yreka's letter. Please see responses to individual comments in this letter for more detailed information on the issues summarized here. Additionally, please see response to comment LA8-40 and Master Response CEQ-1.

<u>Comment LA8-8</u>

7. The assumption by the SWRCB of lead agency status when this status properly rests with the Klamath River Basin Compact Commission which has not been consulted, held public hearings, received public input or made any determinations regarding the Proposed Project.

Response to Comment LA8-8

Please refer to Master Response CEQ-4.

<u>Comment LA8-9</u>

Fall Creek is a tributary of the Klamath River and part of the Klamath Water Basin network. As stated in the DEIR, the City of Yreka, operates a public municipal water supply system and takes its normal water supply exclusively from Fall Creek under the allowance granted under California State Water Right Permit 15379, Application #22551, a water right that allows the diversion and consumption of up to 15 cubic feet per second ("cfs") (9.7 mgd) and allows diversion of 6,300 acre/feet annually for domestic and municipal water uses (the "Permit"). Yreka's water supply originates from two diversion impounds whose points of diversion are specified on the Permit. During extreme drought emergencies Yreka selectively provides other smaller municipalities with a small allocation of water in order for those municipalities to supply clean water to their inhabitants and businesses for subsistence purposes. No elaboration on the environmental impacts on humans would seem necessary if Yreka was deprived of its water supply. The effect of a project on humans is considered in the NEPA process.

The primary point where the city takes its water is known as the "A" Dam and is located directly below the tailrace of the PacifiCorp's Fall Creek Hydroelectric Facility. This powerhouse is fed by a penstock which receives water from a diversion canal from Fall Creek. The City "A" Dam is upstream of the intake of the California Department of Fish and Wildlife rearing ponds which the state ceased all operations in 2004.

City operations occasionally require adjustment due to the operational aspects of the powerhouse. Primarily, this happens when the PacifiCorp's powerhouse trips offline, or is taken offline for maintenance. PacifiCorp will then change the gates at the Fall Creek Diversion Dam to send water down the natural channel of Fall Creek to Yreka "B" Dam instead of the penstock to the powerhouse. The "B" Dam is located in the natural channel of Fall Creek directly below the lower set of barrier falls.4 City Staff must then manually install boards and open a valve to allow water from the "B" Dam to be gravity piped to the intake of the "A" Dam. This operational situation alters the flow over to the "A" Dam. Water from the tailrace of the powerhouse slowly reduces and depending on the situation, may cease entirely. It is important to understand that the convergence of the natural channel of Fall Creek and the tailrace section is located below the former rearing pond intake.

Yreka's headworks is located at the "A" Dam. It is this location where water enters the singular intake point of a 24" pipe of Yreka's water transmission system. From the headworks, gravity conveys the water to a pump station to the West. From that point the pipe lays on the bottom of Iron Gate Reservoir thence on to Yreka's water storage tanks and purification plant. The City's water conveyance pipeline is 23 miles long.

SWRCB required in Yreka's amended water diversion permit that 15 cfs or more must flow past the Dams "A" and "B" combined for fish and wildlife purposes (See Attachment 1). When this requirement was requested in 1967 by the California Department of Fish and Wildlife the Department had not yet sought its own water appropriation of 10 cfs, which was CWRQCB permitted in 1979. The bypass measurement is taken downstream of the confluence of the tailrace section and the natural watercourse of Fall Creek. The amount and quality of water for the California Department of Fish and Wildlife ("CDFW") operations will hinge upon the ability of the rearing pond intake to divert water from both the "A" Dam and "B" Dam to ensure flows are present at all times. It is rare to have 15 cfs flowing past both dams at the same time. Flow past the "A" dam varies depending on how many and of what size generators are online at PacifiCorp's Fall Creek Hydroelectric Facility. In the current configuration, Yreka has two options for flow into its headworks. It is believed that CDFW owns a pipe diversion from the "B" Dam to the rearing ponds but its condition, sizing, and ability to provide required flows for hatchery and rearing pond operations are unknown to this commenting party.

PacifiCorp diverts water from Fall Creek under Statements of Diversion and Use S015372 and S0153736. PacifiCorp claims a maximum non-consumptive diversion right to about 75 cfs based on a pre-1914 claim.

Yreka's diversion from Fall Creek is presently subject to a permit condition that requires the City of Yreka to bypass a minimum flow of 15.0 cfs or the natural flow of the stream whenever it is less than 15.0 cfs. The intent of the flow bypass is to benefit fish and wildlife purposes. Accordingly, without consideration for any diversion from Fall Creek or Spring Creek for the proposed 10 cfs permit allocation on its junior and subordinate priority Fall Creek Fish Hatchery, Fall Creek must have 30 cfs flowing through it for Yreka to divert its entire 15 cfs for its water supply.

Of primary significance to Yreka's ability to take its full appropriation is PacifiCorp's right to divert up to 16.5 cfs from Spring Creek to Fall Creek for the use of its power generation facilities which is also the product of a State of Oregon pre-code water right. After this 16.5 cfs is diverted from Spring Creek, it flows through PacifiCorp's Fall Creek Hydroelectric facility (the "Facility") and flows into Fall Creek thereby increasing Fall Creek's flow by 16.5 cfs, which then continues to flow on to the point of Yreka's water diversion. While PacifiCorp appears to have secured a right to divert up to 16.5 cfs under Oregon law, during FERC's earlier consideration of relicensing of the Facility, it was considered but not yet implemented, that PacifiCorp's Spring Creek diversion be greatly restricted. FERC's 2012 Final Environmental Impact Study determined to impose two conditions on PacifiCorp's federal power permit – no diversions from Spring Creek to Fall Creek from June 1 through September 15 and a reduction from 16.5 cfs to 4 cfs the remainder of the year. Accordingly, to great extent, the necessary volume of Yreka's water source is dependent on water that is diverted from Spring Creek to the Facility. When the flow of Fall Creek is at its lowest the demand by municipal water users is at its highest. Any implementation of a reduction to Spring Creek's diversion to the Facility, under present permitting conditions, would prevent Yreka from the benefit of its full 15 cfs allocation for domestic and municipal water uses.

Response to Comment LA8-9

The State Water Board acknowledges the detailed description of the City of Yreka's water supply diversions at Dam A and Dam B. These are also described and noted in figures within Volume I Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* (pages 2-81 to 2-84) and Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* (pages 2-84 to 2-86). Please also refer to Master Response WSWR-7 and Volume I Section 3.6.2.2 *Flood Hydrology – Environmental Setting – Basin Hydrology – Spring, Fall and Jenny Creeks* (pages 3-606 to 3-607). Reference to the Spring Creek diversion has been added to Section 3.8.2.1 *Water Supply/Water Rights – Environmental Setting –*

Upper Klamath Basin – Fall Creek Water Rights – City of Yreka. Please refer to Volume III Attachment 1 Section 3.8.2.1 *Water Supply/Water Rights – Environmental Setting – Upper Klamath Basin – Fall Creek Water Rights – City of Yreka* for the revisions.

Comment LA8-10

Table 2.7-16 of the DEIR purports to demonstrate "historical Fall Creek flow," which table, merely shows the flows during a short two-year period spanning 10/01/2003 through 9/01/2005. As discussed below, this data inaccurately describes the actual long-term flows especially as it would regard multiple-year low-flow periods, in which the 2012 FEIS proposed action by FERC to discontinue all flow diversion from Spring Creek to the Facility during the critical low-flow periods (and Yreka's high-use periods) and reduce Spring Creek's diversion to the Facility the rest of the year from 16.5 cfs to 4 cfs—Yreka would not have sufficient water for domestic/municipal use five months the first dry year, six months the second year and five months the third year. This is the case even if all consideration of the proposed diversion of up to 10 cfs for the newly erected Fall Creek Hatchery were disregarded.

With 30 cfs as a baseline for Yreka to fully take under its present permit, together with the year around flow to the PacifiCorp Facility from Spring Creek (16.5 cfs) to Fall Creek, flow records at the USGS operated Gage 11512000 near the confluence of Fall Creek and the Klamath River exist for the period April 1933 to September 1959. As shown in Table 1, the mean monthly flow for the period in August was 33 cfs.

Table 1. Monthly Mean Flow at USGS Gage 11512000 (1933–1959).

Month	***Calculated Flow (cfs)***
January	*46*
February	*51*
March	*49*
April	*45*
May	*38*
June	*35*
July	*34*
August	*33*
September	*34*
October	*35*
November	*37*
December	*43*

In 2018 the maximum flows decreased from the historical average high of 51 cfs down to 41 cfs. Although the low flow was greater that year, increasing in that one year from a mean average in august from 33 cfs to 38 cfs, one can objectively determine that, without the Spring Creek diversion, or if the CDWF *junior water right of 10 cfs depleted water flow at Yreka's point of diversion, there would be insufficient water for Yreka to divert enough flow under its permitted allocation even at Yreka's present population. See Table 2 below:*

Table 2. Fall Creek—Annual Water Level Log Sheet Year: 2018. FALL CREEK MEASUREMENT PROCEDURE: Reads will be taken monthly on or near the 1st of each month.

1st of Month	Fall Creek Gaging Station Level (ft – no pumps running)	Calculated Flow (cfs)
January	1.10	41.0
February	1.09	40.5
March	1.08	40.0
April	1.08	40.0
May	1.07	39.0
June	1.04	37.6
July	1.06	38.6
August	1.06	38.6
September	1.06	38.6
October	1.06	38.6
November	1.08	40.0
December	1.08	40.0

Table 3. Illustrates the Maximum Rate of Water Diverted and used from Fall Creek by Yreka in the Year 2017.

Month	Maximum Rate of Diversion (cfs)
January	10.9
February	10.8
March	10.7
April	11
May	11
June	11
July	11.7
August	13.7
September	11
October	11
November	5.8
December	13.8

Table 4 demonstrates the monthly divertible flow for a multiple dry year period. PacifiCorp's present bypass flow requirement of 5.0 cfs is considered, and the City of Yreka's 15.0 cfs bypass flow requirement is included. Table 4 shows total divertible flows dipping to a low of 9.0 cfs in the first dry year, 8.0 cfs in the *second dry year, and 9.0 cfs in the third dry year. Yreka would not have enough water for its municipal use five months the first dry year, six months the second year and five months the third year. As we will go into in more detail later in these comments, SWQCB's consideration of this DEIR is premature when it is unknown all the conditions that FERC will approve/impose, should the Proposed Project be allowed to proceed in any manner.*

Response to Comment LA8-10

The commenter is expressing concern that flow information included in the EIR for Fall Creek is insufficient for analyzing long-term low flow conditions in Fall Creek and the impacts to the City of Yreka's water right associated with long-term low flow conditions and the Proposed Project's hatchery operations. Specifically, the commenter notes the "2012 FEIS" proposed action by Federal

Energy Regulatory Commission (FERC) to discontinue all flows diversions from Spring Creek during critical low flow periods. Additionally, the commenter provides flow data from 1933 to 1959.

Historical United States Geological Survey (USGS) gage data from Fall Creek are consistent with Figure 2.7-16 in Volume I Section 2.7.8.3 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* (page 2-84) and illustrate that mean monthly flows in Fall Creek exceed 30 cubic feet per second (cfs) in all months, which indicates the City of Yreka's diversion of 15 cfs, with a bypass flow of 15 cfs, could have occurred. However, it is possible that during historical multi-year drought periods mean monthly flows in Fall Creek could be lower and potentially affect any water right holder on Fall Creek. Please note that the Proposed Project's water diversion at Fall Creek Hatchery (FCH) would be non-consumptive, primarily diverted downstream of the City of Yreka's diversion point, and returned to Fall Creek upstream of the City of Yreka's bypass flow compliance point. Therefore, the Proposed Project's water diversion at Fall Creek Hatchery would not impact the City of Yreka's water right or bypass flow requirements. Please refer to Master Response WSWR-5 for further information on the City of Yreka's water supply and water rights. Please refer to Master Response WSWR-6 for further information on Fall Creek Hatchery water rights. Please refer to Master Response WSWR-7 for further information on PacifiCorp water rights in Fall Creek and Spring Creek.

Comment LA8-11

If the FERC determines, as it did in its 2012 FEIS, to curtail the diversion from Spring Creek to the Facility from June 1st through September 15th together with a 4 cfs diversion limit the remainder of the year – with the present 15cfs bypass in effect – Yreka would rarely be able to divert the 15 cfs it requires for domestic/municipal uses. As further discussed in these comments, the circulation of this DEIR is premature, in part because it is not clear what proposed action the presently designated federal lead agency, FERC, will propose as its Preferred Alternative. If FERC continues to pursue restrictions to the Spring Creek diversion to the Facility, Yreka recommends that the effects of the Proposed Project be mitigated by action through SWQCB to amend Yreka's permit to entirely eliminate the 15 cfs bypass (15 cfs – 16.5 cfs = -1.5 cfs). It is precisely these types of unknowns that the requirement that a joint DEIR/DEIS be submitted for circulation.

Response to Comment LA8-11

Please refer to Master Responses WSWR-7 and CEQ-1.

Comment LA8-12

Water Laws Granting Domestic Water Use as the State's Highest Priority

According to California, Oregon and the United States Code, municipal water use has the highest priority of any other use, including those uses related to fish and wildlife considerations.

First, California Water code §106 provides:

"It is hereby declared to be the established policy of this State that the use of water for domestic purposes is the highest use of water ..."

Water Code §106.3 provides, in part:

"(a) It is hereby declared to be the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes.

(b) All relevant state agencies, including the department, the state board, and the State Department of Public Health, shall consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria when those policies, regulations, and criteria are pertinent to the uses of water described in this section. [Emphasis added]

(e) The implementation of this section shall not infringe on the rights or responsibilities of any public water system."

Thus, it is clear under California water law that municipal water use has the priority of any other use and that the SWQCB is statutorily bound to afford Yreka with its "highest use" priority.

However, there is even a more specific statutory scheme affirming this principal which is specifically applicable to the use of water from the Klamath River Basin. Those principals are set out in Federal, California and Oregon laws collectively known as the Klamath River Basin Compact, Public Law 85-222, ratified by Congress and signed into law by the President on August 30, 1957, colloquially dubbed "The Law of the River" (the "Compact"). The law creates a federally designated commission to implement its provisions called the "Klamath River Compact Commission" (the "Commission.") Each of the ancillary state laws also refer to, and are members of, the Commission.

Oregon has adopted the KORS 542.610 which provides:

"The Legislative Assembly of the State of Oregon hereby ratifies the Klamath River Basin Compact set forth in ORS 542.620 (Klamath River Basin Compact), and the provisions of such compact hereby are declared to be the law of this state upon such compact becoming effective as provided in subsection (2) of this section.

(2) The compact shall become effective when it has been ratified by the legislatures of the States of California and Oregon, and has been consented to by the Congress of the United States as provided in Article XIII of the compact. [1957 c.142 §1]"

The compact was ratified by the State of Oregon by Chapter 142, Oregon Laws 1957 (signed by Governor on April 17, 1957).

The State of California has adopted the Compact at Water Code §5900, et seq. The Compact was ratified by the State of California by Chapter 113, California Statutes 1957 (signed by Governor on April 17, 1957, and effective on September 11, 1957). The provisions of said Klamath River Basin Compact reiterated in California Water Code 5901 are:

Article I. Purposes

The major purposes of this compact are, with respect to the water resources of the Klamath River Basin:

A. To facilitate and promote the orderly, integrated and comprehensive development, use, conservation and control thereof for various purposes, including, among others: the use of water for domestic purposes; the development of lands8 by irrigation and other means; the protection and enhancement of fish, wildlife and recreational resources; the use of water for industrial purposes and hydroelectric power production; and the use and control of water for navigation and flood prevention.

B. To further intergovernmental co-operation and comity with respect to these resources and programs for their use and development and to remove causes of present and future controversies by providing (1) for equitable distribution and use of water among the two states and the Federal Government, (2) for preferential rights to the use of water after the effective date of this compact for the anticipated ultimate requirements for domestic and irrigation purposes in the Upper Klamath River Basin in Oregon and California, and (3) for prescribed relationships between beneficial uses of water as a practicable means of accomplishing such distribution and use.

Article II. Definition of Terms

As used in this compact:

A. "Klamath River Basin" shall mean the drainage area of the Klamath River and all its tributaries within the States of California and Oregon and all closed basins included in the Upper Klamath River Basin.

B. …

C. "Commission" shall mean the Klamath River Compact Commission as created by Article IX of this compact.

D. "Klamath Project" of the Bureau of Reclamation of the Department of the Interior of the United States shall mean that area as delineated by appropriate legend on the official map incorporated by reference under subdivision B of this article.

E. "Person" shall mean any individual or any other entity, public or private, including either state, but excluding the United States.

F. …

G. "Water" or "waters" shall mean waters appearing on the surface of the ground in streams, lakes or otherwise, regardless of whether such waters at any time were or will become ground water, but shall not include water extracted from underground sources until after such water is used and becomes surface return flow or waste water.

H. "Domestic use" shall mean the use of water for human sustenance, sanitation and comfort; for municipal purposes; for livestock watering; for irrigation of family gardens; and for other like purposes.

I. …

J. …

Article III. Distribution and Use of Water

A. There are hereby recognized vested rights to the use of waters originating in the Upper Klamath River Basin validly established and subsisting as of the effective date of this compact under the laws of the state in which the use or diversion is made, including rights to the use of waters for domestic and irrigation uses within the Klamath Project. There are also hereby recognized rights to the use of all waters reasonably required for domestic and irrigation uses which may hereafter be made within the Klamath Project.

B. Subject to the rights described in subdivision A of this article and excepting the uses of water set forth in subdivision E of Article XI, rights to the use of unappropriated waters originating within the Upper Klamath River Basin for any beneficial use in the Upper Klamath River Basin, by direct diversion or by storage for later use, may be acquired by any person after the effective date of this compact by appropriation under the laws of the state where the use is to be made, as modified by the following provisions of this subdivision B and subdivision C of this article, and may not be acquired in any other way:

1. In granting permits to appropriate waters under this subdivision B, as among conflicting applications to appropriate when there is insufficient water to satisfy all such applications, each state shall give preference to applications for a higher use over applications for a lower use in accordance with the following order of uses:

(a) Domestic use,

(b) …

(c) Recreational use, including use for fish and wildlife,

(d) …

(e) Generation of hydroelectric power,

(f) These uses are referred to in this compact as uses (a), (b), (c), (d), (e) and (f), respectively. Except as to the superiority of rights to the use of water for use (a) or (b) over the rights to the use of water for use (c), (d), (e) or (f), as governed by subdivision C of this article, upon a permit being granted and a right becoming vested and perfected by use, priority in right to the use of water shall be governed by priority in time within the entire Upper Klamath River Basin regardless of state boundaries. The date of priority of any right to the use of water appropriated for the purposes above enumerated shall be the date of the filing of the application therefor, but such priority shall be dependent on commencement and completion of construction of the necessary works and application of the water to beneficial use with due diligence and within the times specified under the laws of the state where the use is to be made. Each state shall promptly provide the commission and the appropriate official of the other state with complete information as to such applications and as to all actions taken thereon."

Response to Comment LA8-12

The EIR finds no significant impact with mitigation to the City of Yreka's water supply. Please see Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683) and Master Response WSWR-5 for further discussion. In the absence of a conflict between water uses – and any potential environmental impacts from an ensuing need for one right holder to curtail use – it is not necessary for the EIR to address the City's statements concerning use priorities in the Klamath River Basin Compact and in California Water Code sections 106 and 106.3. Please also refer to Master Response CEQ-4.

Comment LA8-13

Why does the Compact matter? The interstate compacts clause of the United States Constitution, Article I, §10, cl. 3, which states in pertinent part: "No State shall, without the Consent of Congress . . . enter into any Agreement or Compact with another State, or with a foreign Power." Since a Compact has already been entered regarding the exact prioritization of the use of Klamath River Basin waters in Oregon, California and throughout the federal reservations (i.e., the U.S. Forests, the Wildlife Refuges, the Tribal Nations, the Bureau of Reclamation, etc.) it is required that to encroach on the jurisdiction of the Compact requires the consent of the Commission.

Prior to the entry of the AKSA there were many attempts to gain the "consent of Congress." Each of those attempts failed. Nowhere in the provisions of the Compact is there any time-limitation that causes the compact to expire. It is not clear whether the Congress even has the authority under the Constitution to reserve to itself in compact legislation the ability to "alter, amend, or repeal" the terms of a compact. Litwak, Compact Law 33, 241, notes:

After Congress gives its consent to a compact, two questions arise relating to the relationship between the compact and the federal government. First, does that consent limit the ability of the federal government to enact subsequent law that might affect the implementation of the compact? . . . Second, does consent alter the responsibilities of the federal government under existing federal law that relates to the subject matter of the compact?

Consent matters not only because it satisfies the constitutional requirement but also because it makes clear the fact that, in addition to whatever specific interests the two states might have in a given situation, there is a national interest in the matter that is critical. The states are not free to assert that only their particular concerns count, either at the time of the agreement or later when disputes may arise over its terms. As the Supreme Court made clear in Dyer v. Sims: "A compact is more than a supple device for dealing with interests confined within a region. That it is also a means of safeguarding the national interest is well illustrated in the Compact now under review." West Virginia ex rel. Dyer v. Sims 341 U.S. 22, 27 (1951). In Hess v. Port Authority Trans-Hudson Corp., Justice Ginsburg echoed the Dyer language., 341 U.S. 22, 27 (1951).

Litwak explains at length, and with excerpts from a variety of key cases, this national interest and the constitutional consent requirement that protects it. This doctrine allows Congress to ensure that agreements among states do not injure either other states or the nation as a whole, and is key to understanding why states cannot act unilaterally with respect to existing compacts. He stresses that: "Dyer v. Sims is the Supreme Court's clearest statement on holding states to their obligations under a compact, even if a state believes its constitution restricts the state's ability to fulfill the compact."

The Dyer Court held that it would not be states that would decide, but the federal courts.

“But a compact is after all a legal document. Though the circumstances of its drafting are likely to assure great care and deliberation, all avoidance of disputes as to scope and meaning is not within human gift. Just as this Court has power to settle disputes between States where there is no compact, it must have final power to pass upon the meaning and validity of compacts. It requires no elaborate argument to reject the suggestion that an agreement solemnly entered into between States by those who alone have political authority to speak for a State can be unilaterally nullified, or given final meaning by an organ of one of the contracting States. A State cannot be its own ultimate judge in a controversy with a sister State. To determine the nature and scope of obligations as between States, whether they arise through the legislative means of compact or the "federal common law" governing interstate controversies (Hinderlider v. La Plata Co., 304 U.S. 92, 110), is the function and duty of the Supreme Court of the Nation. Of course, every deference will be shown to what the highest court of a State deems to be the law and policy of its State, particularly when recondite or unique features of local law are urged. Deference is one thing; submission to a State's own determination of whether it has undertaken an obligation, what that obligation is, and whether it conflicts with a disability of the State to undertake it is quite another.”

The Commission’s exercise of powers is conditioned on the ability of “any interested party [to] have the opportunity to present his views on the proposed action” before Commission action, after “reasonable” advance notice of the action. (71 Stat. at 505.) Decision-making by the compact entity is thus nothing like the negotiation of a settlement agreement without such opportunity for public comment. The Supreme Court has confirmed that the requirement of decision-making by a compact entity involves a different sort of “political accountability;”

“An interstate compact, by its very nature, shifts a part of an authority to another state or states, or to the agency the several states jointly create to run the compact. Such an agency under the control of special interests or gubernatorially appointed representatives is two or more steps removed from popular control, or even of control by a local government.”

Hess v. Port Auth. Trans-Hudson Corp., 513 U.S. 30, 42 (1994) (quoting M. Ridgeway, Interstate Compacts: A Question of Federalism 300 (1971)).

Moreover, compact issues under agreements to which the Congress has consented are matters of federal, not state law, known generally as the “Law of the Union” doctrine. This critically important doctrine is one that many state officials do not appear to understand, but the Supreme Court has made the point clearly in Cuyler v. Adams 449 U.S. 433 (1981). “Because congressional consent transforms an interstate compact within [the Compact] Clause into a law *of the United States, we have held that the construction of an interstate agreement sanctioned by Congress under the Compact Clause presents a federal question." The Court added "[W]here Congress has authorized the States to enter into a cooperative agreement, and where the subject matter of that agreement is an appropriate subject for congressional legislation, the consent of Congress transforms the States' agreement into federal law under the Compact Clause."*

In addition to the obvious points, Litwak stresses that because compact law is federal law, the usual considerations of federal preemption are not present and the compact law "supersedes the party states' statutes and constitutions." That being understood, the Compact Commission itself is not always an agency of the United States but, can be, depending on the language of the compact itself, a regional planning agency.

Statutes are exercises of the legislative power to prescribe or prohibit public or private conduct, establish policy, or mandate processes by which public agencies operate and are part of the body of positive law. Compacts are agreements that represent a meeting of the minds among different parties and are interpreted today against a longstanding common law tradition.

An interstate compact is clearly an agreement among states, but it is also statutory, both in terms of the legislation adopted by the participating states to sanction the agreement but also because of the critically important fact that Congress adopts legislation consenting to the agreement. The congressional action is not only an exercise of its authority under the interstate compact clause of the Constitution, but also transforms issues that arise under the compact into federal questions under the Law of the Union doctrine.

If the focus is on statutory interpretation and if the issues are matters of federal law, compact agencies may be entitled to deference by courts in their interpretation of the legislation they implement and administer under the Supreme Court's Chevron doctrine. Indeed, the Oregon Supreme Court recognized that Chevron deference is due to the Gorge Commission. Litwak even notes that a number of compacts empower the compact agency "to provide guidance on compact responsibilities and interpretation of compact provisions."

Response to Comment LA8-13

Comment noted. Comment refers to interstate compacts and related legal analysis. Please see Master Response CEQ-4.

Comment LA8-14

The California and Oregon state statutes and the United States Code make it clear that the Compact's application not only applies to the Upper Klamath Basin, which is defined as the portion of the Klamath Project within Oregon commencing at the Stateline, but also to the entire Klamath River Basin in California; which, *without question and specifically, includes the Klamath River's tributaries such as Fall Creek. California Water Code § 5901, Article II(H) defines "domestic use" among other uses as "municipal use." Thus, the California Water Code specifically provides that the use of water for "domestic purposes," that being, the use of water for "municipal purposes" has the first priority in the allocation of Klamath Basin water usage.*

Response to Comment LA8-14
Please refer to response to comment LA8-12 and Master Response CEQ-4.

Comment LA8-15
Significantly, public policy specifically declares water for municipal use to be of a higher priority than water use for fish and wildlife purposes. That does not mean that Yreka is opposed to the use of conservation hatcheries, just that any operational conflicts which negatively impacts Yreka's present or future right to take water must be resolved in favor of the protection of Yreka's municipal usage.

Response to Comment LA8-15
Please refer to response to comment LA8-12 and Master Response CEQ-4.

Comment LA8-16
As set out in the Compact itself, the purpose of the Compact is to further intergovernmental co-operation and comity with respect to these resources and programs for their use and development and to remove causes of present and future controversies by providing (1) for equitable distribution and use of water among the two states and the Federal Government, (2) for preferential rights to the use of water after the effective date of this compact for the anticipated ultimate requirements for domestic and irrigation purposes in the Upper Klamath River Basin in Oregon and California, and (3) for prescribed relationships between beneficial uses of water as a practicable means of accomplishing such distribution and use.

This provision encompasses this exact circumstance – one in where it is being determined how the SWQCB shall determine, in the context of the Proposed Project, whether Yreka's municipal use of water is of a higher priority than that of any other use, regardless of when the right was appropriated. It goes without saying that any portion of the Proposed Project that could impact or adversely affect Yreka's right to utilize its fully permitted allocation must be adequately studied and modified so that Yreka's municipal water use is not adversely impacted. Thus, when considering whether the relocation of a fish hatchery that propagates ESA designated threatened species would detrimentally affect the city's right to take in the future, it is clear that any wildlife consideration must give way to the priority granted to municipal water usage.

Accordingly, SWQCB is constrained to construe the laws and environmental regulations of the State of California in a manner that is consistent with the provisions and existence of the Compact. No joint or individual action by Oregon, California or any of the parties to the Proposed Project, can take lawful action other than to prioritize Yreka's water use as the highest priority use in the Klamath River Basin.

Response to Comment LA8-16

Please refer to response to comment LA8-12 and Master Response CEQ-4.

Comment LA8-17

It is equally clear that the Commission is the proper lead agency to the Proposed Project as the regional planning agency. The circulation of this DEIR by an agency without authorization, public hearings before the Commission and delegation under the Compact is premature as the Commission is the appropriate regional planning agency to circulate it. Any other course of conduct would constitute a violation of both the "Law of the River" and the "Law of the Union." The correct application of these doctrines make crystal clear that the DEIR must be circulated for comment as a joint state and federal DEIR/DEIS.

Response to Comment LA8-17

Please refer to Master Responses CEQ-1 and CEQ-4.

Comment LA8-18

The Preservation of Yreka's Right to Take as Agreed by the Parties to the Amended Klamath Settlement Agreement

As noted in the preface to these comments the Proposed Project is the genesis of the AKSA. The SWRCB, if it proceeds to the stage of a FEIR, must make its determinations regarding the Proposed Project by construing the AKSA as providing Yreka's municipal water use with the highest priority use over lesser priorities set out in the Compact. Fortunately, the AKSA contains multiple provisions intended to protect Yreka's municipal water supply. The provision relating to the protection of Yreka's municipal water permit and its water conveyance infrastructure as follows:

AKSA ¶ 7.2.3 "Assessment and Mitigation of Potential Impacts to the City of Yreka The Parties understand that actions related to this Settlement may affect the City of Yreka. In recognition of this potential, the Parties agree to the following provisions, which shall remain in effect so long as this Settlement remains in effect.

A. The Parties collectively and each Party individually shall agree not to oppose the City of Yreka's continued use of California State Water Right Permit 15379, which provides for the diversion of up to 15 cfs for municipal uses by the City of Yreka.

B. As part of implementation of this Settlement, an engineering assessment to study the potential risks to the City of Yreka's water supply facilities as a result of implementation of Facilities Removal shall be funded and conducted by the Secretary. Actions identified in the engineering assessment necessary to assure continued use of the existing, or equivalent replacement, water supply facilities by the City of Yreka shall be funded from the California Bond Measure and implemented. Actions that may be required as a result of the engineering assessment and in consultation with the City of Yreka include, but are not limited to:

(1) Relocation, replacement, and/or burial of the existing 24-inch diameter water line and transmission facilities from the City of Yreka's Fall Creek diversion;

(2) Assessment, mitigation, and/or funding to address potential damage to the City of Yreka's facilities located along the Klamath River, including mitigation of potential impacts that may occur as a result of a dam breach. Such assessment, mitigation, and/or funding shall include consideration of the cathodic protection field located near the north bank of the Iron Gate crossing and the facilities that house the City's diversion and pump station; and

(3) Assessment, mitigation, and/or funding to address any impacts resulting from implementation of the Settlement, on the ability of the City to divert water consistent with its Water Right Permit 15379.

C. As part of implementation of this Settlement, an assessment of the potential need for fish screens on the City of Yreka's Fall Creek diversion facilities was completed in the Detailed Plan and it identified the need for fish screens on Dam A and Dam B. As a result of implementation of this Settlement, in order to meet regulatory requirements and screening criteria, construction of the required fish screens, including, but not limited to, necessary costs to preserve City facilities with additional species protection, shall be funded through the California Bond Measure pursuant to Section 4.2.3, or through other appropriate sources." [Emphasis added]

Since the State of California, SWQCB and the Department of Fish and Wildlife are all parties to this agreement, the parties have agreed that all their actions will support the continued and unimpaired use of Yreka's 15 cfs water diversion. This would include all determinations made on the Proposed Project and on the DEIR.

Response to Comment LA8-18

Please note that the State Water Resources Control Board is not a signatory to the amended Klamath Hydroelectric Settlement Agreement (KHSA). The provision of the KHSA related to City of Yreka's water supply is noted.

Please refer to Volume I Section 3.8.4 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 and 3-683), which analyzes the potential impact of relocating the City of Yreka's water supply pipeline under the Proposed Project on the City's water supply. Potential Impact 3.8-4 includes Mitigation Measure WSWR-2, which would ensure that there would be uninterrupted water supply during replacement of the pipeline section, any required intake screen modifications, and throughout Project implementation. Potential Impact 3.8-4 concludes that with mitigation there would be no significant impact to the City of Yreka's water supply. Please also refer to Master Responses WSWR-5 and WSWR-6.

Comment LA8-19
ASKA Interim Measure 17 states in relevant part:

"Additionally, if anadromous fish have passage to the Fall Creek following removal of the California dams, flows will be provided in the Fall Creek bypass reach to provide for the appropriate habitat needs of the anadromous fish species of any kind that are naturally and volitionally present in the Fall Creek bypass reach. Flows will be based on species specific habitat needs identified by the IMIC. The operation will also avoid and minimize take of any listed species present."

Accordingly, if anadromous fish take passage into Fall Creek, processes must be put into place to ensure that Yreka receives its full allocation of water as well as any additional water needed for the anadromous fish. This should not be interpreted to imply that anadromous fish should be encouraged to take passage into Fall Creek through the imprinting of being raised in a hatchery located there. In fact, use of the words "naturally and volitionally" should be correctly interpreted as those anadromous fish that are the product of the natural production of fish occupying the Klamath River Basin rather than those caused to immigrate to Fall Creek after their rearing as hatchery Yearlings. There is no reason to single out Fall Creek from any of the other Klamath tributaries except for the purpose of the protection of Yreka's water diversion. Another provision of the Fish and Game Code that could apply is section 5937, which requires the owner of any dam to "allow sufficient water at all times to pass through …to keep in good condition any fish …below the dam…." This section is notable because third-parties like environmental groups can bring lawsuits against public entities that own dams to enforce this duty, which appears to be frequently occurring.

Response to Comment LA8-19
The provision of the Klamath Hydropower Settlement Agreement (KHSA) relating to PacifiCorp's obligation to continue to provide 5 cubic feet per second (cfs) in the Fall Creek bypass reach is noted. Please also refer to Master Responses WSWR-5 and WSWR-6.

Comment LA8-20

The DEIR Fails to Select a Preferred Alternative of Three Types of Replacement to Yreka's Water Transmission Pipeline and the Improvements That Will be Made to Yreka's Water Diversion Facilities Thereby Rendering Yreka's Ability to Comment Impossible

Yreka's water transmission pipeline lays along the bottom of Iron Gate Reservoir. When the reservoir is drawn down, it will be subject to high velocity waters and scouring that will be harmful to it. The DEIR states that a replacement pipe crossing is needed before dam removal and reservoir drawdown to ensure an uninterrupted water supply to the City of Yreka. The DEIR generally opines that, as a result of any chosen alternative, excepting the no removal alternative, that Yreka's water transmission pipeline, must be reconstructed in one of three methods:

1. A new buried pipeline by micro-tunneling in the immediate vicinity of the existing waterline crossing.

2. A new aerial pipeline on a dedicated utility pipe crossing in the immediate vicinity of the existing waterline crossing.

3. A new buried pipeline and an aerial pipeline crossing on the existing timber traffic bridge along Daggett Road located approximately 2,000 feet upstream of the existing waterline crossing.

How this pipeline is replaced is of vital importance to Yreka. No selection is made even though the DEIR states that this is one of the first projects that must be completed before the water in Iron Gate Reservoir is drawn down.

Response to Comment LA8-20

The comment expresses concern that a final water supply pipeline alignment has not yet been selected, inhibiting the commenter's ability to accurately comment on pipeline alignment options.

The commenter notes that the EIR explains that the City of Yreka's water transmission pipeline lays along the bottom of the Iron Gate Reservoir, that a replacement pipe crossing would need to be installed before dam removal and reservoir drawdown, to prevent damage to the pipeline, and that the pipe crossing would consist of one of three options. (please refer to Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* [pages 2-84 to 2-85.). Volume I Potential Impact 3.8-4 (3-682 to 3-683) evaluates the potential environmental impacts of replacing the City of Yreka water supply pipeline regardless of which pipeline alignment alternative is selected, consistent with CEQA Guidelines section 15126. A number of resource areas consider potential construction-related impacts of replacing the pipeline, including Water Quality (Section 3.2.5.2 *Water Quality – Potential Impacts and*

Mitigation – Suspended Sediments Potential Impact 3.2-4 and Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-15 [please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality]*), Aquatic Resources (Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-21, Potential Impact 3.3-22, and Potential Impact 3.3-24 [please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*]), Water Rights/Water Supply (Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 [pages 3-682 to 3-683], which includes Mitigation Measure WSWR-2), recirculated Air Quality (Potential Impact 3.9-1 and Potential Impact 3.9-4), recirculated Greenhouse Gas Emissions (Potential Impact 3.10-1), Aesthetic Resources (Section 3.19.5 *Aesthetics – Potential Impacts and Mitigation* Potential Impact 3.19-6 [please refer to Volume III Attachment 1 for the final Section 3.19 *Aesthetics*]), Cumulative Effects (Volume I Section 3.24.17 *Cumulative Effects – Public Services* Potential Impact 3.24-8 [pages 3-1160 to 3-1161], Potential Impact 3.24-55 [pages 3-1205 to 3-1206], Potential Impact 3.24-59 [pages 3-1210 to 3-1211 as modified in Volume III Attachment 1 Potential Impact 3.24-59], and Potential Impact 3.24-64 [pages 3-1215 to 3-1216]). The EIR also analyzes the potential for long-term (permanent) visual changes resulting from the proposed removal of the existing, submerged portion of the pipeline and replacement with new bridge or aerial pipeline infrastructure in Section 3.19.5 *Aesthetics – Potential Impacts and Mitigation* Potential Impact 3.19-5. Please refer to Volume III Attachment 1 for the final Section 3.19 *Aesthetics*.

The three pipeline alignment options came from the project proponent, which has not yet committed to a specific option. The impact analyses referenced above provide ample basis for the City of Yreka to provide public comments and other input on the ultimate method of reconstructing its water supply pipeline, notwithstanding that three potential methods remain available.

Comment LA8-21

A DEIR must consider all phases of project planning, implementation, and operation. Cal Code Regs §15063(a)(1). It is referred to as Potential Impact 3.8-4. The DEIR states merely that it will determine the preferred alternative in consultation with the City of Yreka. Consultation is not the equivalent of consent and deprives Yreka of any ability to comment. It concludes that any of the selections made will result in the same quantity and quality of water conveyed to the city. However, because the exact plans for pipeline re-routing are incomplete, it is not possible to determine the reasonableness of the assumed timeframe for pipeline disconnection. An interruption in service is not limited to the time it takes to reconnect a water line. If the pipeline is constructed in a manner that permits service interruption in the future it is also an environmental consideration that must be considered. Environmental Protection Inf. Ctr. v Department of Forestry & Fire Protection (2008) 44 C4th 459, at 503. The level *of specificity required in the DEIR regarding this part of the Proposed Project is therefore inadequate.*

Response to Comment LA8-21
Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* (pages 2-84 to 2-86) and Potential Impact 3.8-4 (pages 3-682 to 3-683) describe the need for replacement of a section of the City of Yreka's water supply pipeline, and present three potential options for such replacement, based on the options under discussion between the City and the applicant, as presented in the Definite Plan.

The potential for service interruption under the Proposed Project is analyzed in Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* Potential Impact 3.8-4 (pages 3-682 to 3-683). There is no evidence that any of the pipeline configurations would have greater or lesser ability to avoid a service disruption. Regardless, Potential Impact 3.8-4 describes Mitigation Measure WSWR-2, which avoids future service interruptions regardless of how the City of Yreka's supply pipeline is replaced, by setting a performance standard.

Comment LA8-22
In regard to the replacement of the water diversion fish screens, the DEIR states: "While the fish screens have recently been updated, their compliance to NMFS, USFWS, and CDFW screen criteria for anadromous fish still needs to be confirmed. These fish screens would require updates, if found to be non-compliant." To mitigate the impact the DEIR states: "Any work the KRRC undertakes to ensure that the City of Yreka water supply intakes' screens comply with fish screen criteria shall be completed within the water delivery outage period specified above." This lack of specifics in the DEIR impermissibly disables Yreka to comment.

Response to Comment LA8-22
Please refer to Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683) for discussion of fish screens as part of the Proposed Project. Mitigation Measure WSWR-2 permissibly requires a performance standard which would mitigate the potential significant effect of a Project, and which may be accomplished in more than one specified way.

Comment LA8-23
The DEIR circulated is required to avoid vagueness, incompleteness, or untested mitigation measures. Mitigation measures must not be remote and speculative. Federation of Hillside & Canyon Assn's v City of Los Angeles (2000) 83 CA4th 1252, 1260. Here the mitigation measures are inadequate because they are so undefined that it is impossible to gauge their effectiveness. Preserve Wild Santee v City of Santee (2012) 210 CA4th 260 San Franciscans for Reasonable

Growth v City & County of San Francisco (1984) 151 CA3d 61, 79); Kings County Farm Bureau v City of Hanford (1990) 221 CA3d 692, 727.

Response to Comment LA8-23
Please refer to response to comments LA8-20 and LA8-22.

Comment LA8-24
Yreka's present water pipeline is buried or covered with many feet of water. It is of critical importance that the reconstruction of the pipeline be done in a manner that ensures that water service will remain as uninterrupted as it was before the Proposed Project. Yreka is concerned about possible terrorist attacks on exposed portions of the pipeline (if simply suspended over the riverbed or placed in open view under a bridge structure) and simple vandalism with rural citizens sporting .50-caliber rifles. Thus, Yreka recommends the imposition of a mitigation measure which requires the selection of a new buried pipeline by tunneling in the immediate vicinity of the existing waterline crossing or that the DEIR be recirculated with the proper amount of specificity required to enable Yreka to comment.

Response to Comment LA8-24
The existing water supply pipeline for the City of Yreka is primarily under ground and under water between the Fall Creek diversion and the City's treatment plant, although portions of the pipeline are exposed above ground in accessible areas. Bridge crossings in rural and urban areas commonly have attached and exposed utility lines (see, e.g., CalTrans 2018 [providing standards of construction for utility bridge crossings].) The California Division of Drinking Water (DDW) has no evidence that any vandalism or terrorist acts have been perpetrated against any utilities in the vicinity of the Proposed Project. Therefore, concerns anticipating such acts are speculative, and it is not necessary to impose further mitigation for replacing a segment of the City of Yreka's water supply pipeline.

Please also refer to responses to comments LA8-20 and LA8- 21 regarding specificity.

Comment LA8-25
The same situation applies to the Fish Screens that the DEIR indicates need to be replaced but does not provide any specificity as to what improvements or modifications will be undertaken.

Response to Comment LA8-25
If the existing fish screens at the City of Yreka water supply pipeline are found to be non-compliant, as described in Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* (page 2-85) the existing screens would be replaced with screens that meet modern criteria from NMFS (National Marine Fisheries Service), USFWS (United States Fish and Wildlife Service), and CDFW (California Department of Fish and Wildlife). Please

refer to Volume III Attachment 1 Section 3.3.4 *Aquatic Resources – Potential Impacts and Mitigation* Potential Impact 3.3-22 for a discussion of the potential impacts of replacing the existing fish screens at the City of Yreka water supply pipeline. In this discussion, the potential impacts of the Proposed Project are assessed with and without installation of fish screens to allow for the possibility that the screens would not need to be replaced. If screen replacement is necessary, standard construction best management practices would be applied, as described in Volume 1 Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs*. Therefore, sufficient specificity is available to assess the potential impacts to environmental resources from installation of fish screens at the City of Yreka water supply pipeline (if they are found to be non-compliant).

Further, the Klamath River Renewal Corporation (KRRC) has recently indicated that the Proposed Project would involve installation of a permanent fish passage barrier just downstream of the confluence of Fall Creek and the Fall Creek powerhouse tailrace to prevent fish entrainment in the existing City of Yreka diversions (KRRC 2019a). A permanent fish passage barrier at this location would negate the need for fish screen installation at the existing City of Yreka water diversions. Although details surrounding the proposed design and implementation of a permanent fish passage barrier associated with the Fall Creek Hatchery (FCH) are not yet available, they would be required to adhere to all construction Best Management Practices (BMPs) and relevant mitigation measures associated with all construction for larger Proposed Project, including requirements tailored for in-stream work. Construction of a barrier would also eliminate the potential need for construction associated with modifying or replacing the existing fish screen. Thus, should a barrier be constructed instead of modifying or replacing the City of Yreka's fish screen, the EIR analyses of potential impacts and significance determinations associated with the City of Yreka's water supply infrastructure would not require revision. Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* has been revised to note the permanent fish passage barrier. Please refer to Volume III Attachment 1 Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* for the revisions.

Comment LA8-26

The lack of concrete specificity of the exact improvements to be made to Yreka's water pipeline and water diversion facilities on Fall Creek renders it premature and impossible to adequately address those particular impacts of the Proposed Project.

Response to Comment LA8-26

Please refer to Master Response WSWR-5, Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683), and Section 7.5 *Yreka Water Supply* in Volume II

Appendix B: *Definite Plan*. Please also refer to comment responses LA8-20 through LA8-25.

Comment LA8-27
The Decommissioning of the Iron Gate Hatchery and the Construction of the Fall Creek Hatchery

The ASKA contains the following provisions regarding the fish hatcheries.

7.6.6 PacifiCorp Hatchery Facilities:

A. Hatchery Funding

"PacifiCorp will fund 100 percent of hatchery operations and maintenance necessary to fulfill annual mitigation objectives developed by the California Department of Fish and Wildlife in consultation with the National Marine Fisheries Service. This includes funding the Iron Gate Hatchery facility as well as funding of other hatcheries necessary to meet ongoing mitigation objectives following Facilities Removal…"

B. Hatchery Production Continuity

"PacifiCorp will fund a study to evaluate hatchery production options that do not rely on the current Iron Gate Hatchery water supply. The study will assess groundwater and surface water supply options and water reuse technologies that could support hatchery production in the absence of Iron Gate Dam. The study may include examination of local well records and increasing production potential at existing or new facilities in the Klamath Basin as well as development of a test well or groundwater supply well. Based on the study results and with the approval of the California Department of Fish and Wildlife and the National Marine Fisheries Service, PacifiCorp will provide one-time funding to construct and implement the measures identified as necessary to continue to meet current mitigation production objectives for a period of eight years following the Decommissioning of Iron Gate Dam….Production facilities capable of meeting current hatchery mitigation goals must be in place and operational upon removal of Iron Gate Dam. PacifiCorp shall not be responsible for funding hatchery programs, if any, necessary to reintroduce anadromous fish in the Klamath basin."

Response to Comment LA8-27
The comment's recitation of Klamath Hydropower Settlement Agreement (KHSA) provisions is noted.

Please note that the State Water Resources Control Board is not a signatory to the amended KHSA.

<u>Comments LA8-28 and LA8-29</u>

The DEIR Proposes to Construct a new Fall Creek Hatchery adjacent to Yreka's Municipal Water Supply Improvements located at Fall Creek. The DEIR proposes to reopen Fall Creek Hatchery with upgraded facilities (e.g., install circular tanks, UV treatment system, renovate existing raceways, upgrade plumbing, provides for settling ponds, etc.) for raising coho salmon (an ESA designated "threatened" species) and Chinook salmon yearlings within the existing facility footprint and an area adjacent to the upper raceways (Figure 2.7-15 in the DEIR). Additional space requirements needed for most operations (e.g., vehicle parking, pertinent buildings, tagging trailer, etc.) can be accommodated on existing developed or disturbed areas around the hatchery and powerhouse, but the settling pond would need to be located outside of this area. The settling pond would be constructed on one of two potential nearby sites located on Parcel B lands downstream of the Fall Creek Hatchery, with a minimally buried or at-grade conveyance pipeline transporting flows from the hatchery to the settling pond.

The AKSA does not obligate PacifiCorp to fund the study of the construction of a hatchery at Fall Creek adjacent to Yreka's water diversion facilities in particular. One study opines that once Iron Gate Dam is removed the river will have cooler water, which cooler water could supply IGH. It does not consider any filtering methods to improve IGH water quality. The DEIR does not reference any studies undertaken to generate further cooling of the water that IGH uses. It would appear that geothermal cooling could be studied. If geothermal cooling were not sufficient for optimal fish propagation, it could be supplemented with water cooler. PacifiCorp has access to the cheapest source of power than anyone else.

How was FCH selected when it is known that there are other better sources of cool water in the area which would sustain a fish hatchery. Under the "dams out" alternative, adult salmon access will be provided to cool water tributaries (i.e., Shovel Creek, 2.1 mi; and upper/middle Spencer Creek, 7.1 mi) above the dams, springs currently inundated by reservoirs, and groundwater areas above the Keno Reservoir (the Wood River, the Williamson River, and springs on the west side of Upper Klamath Lake). In addition, a large spring complex discharging directly to the mainstem Klamath River downstream from JC Boyle Dam provides ~225 cubic feet per second of cool water year-round (USDI Bureau of Land Management 2003), creating a large thermal refuge area currently unavailable to salmon, particularly during summer and fall months. Accordingly, Yreka requests further studies be conducted before the selection of a site adjacent to Yreka municipal water source and the construction of FCH is implemented.

Response to Comments LA8-28 and LA8-29

The comment requests that further studies be conducted regarding the water source for Iron Gate Hatchery and further studies be conducted prior to selection of a hatchery location adjacent to the City of Yreka's water supply intake.

Please refer to Volume I Section 2.7.6 *Proposed Project – Proposed Project – Hatchery Operations* (pages 2-77 to 2-84) for a discussion of the Proposed Project hatchery operations, including production goals and water supply. Please refer to Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 for an analysis of the water temperature in the Klamath River in the vicinity of the Iron Gate Hatchery (i.e., downstream of Iron Gate Dam) after dam removal. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*. Overall, dam removal under the Proposed Project would result in warmer water temperatures adjacent to Iron Gate Hatchery (i.e., downstream of Iron Gate Dam) earlier in the spring, cooler temperatures earlier in the fall, and increased daily variability compared to existing conditions. These changes would be consistent with a more natural thermal regime for the Klamath River (refer also to Volume III Attachment 1 Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature*). Currently, water temperatures delivered to Iron Gate Hatchery from Iron Gate Reservoir range from 38 to 45°F (3.7 to 7.2°C) and 50 to 60°F (10 to 15.7°C) in the winter and summer months, respectively (CDFW and PacifiCorp 2014). As analyzed in Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-1 and shown in Figure 3.2-8, modeled Klamath River water temperature downstream of Iron Gate Dam after dam removal under the Proposed Project would typically be greater than 50 to 60°F (10 to 15.7°C) during summer, so Klamath River water could not provide a similar level of cold water to Iron Gate Hatchery as Iron Gate Reservoir does under existing conditions.

Note that the Klamath River Renewal Corporation (KRRC) originally considered the following potential water supply options for Iron Gate Hatchery:

- direct diversion from the Klamath River,
- groundwater,
- Fall Creek diversion and transfer, and
- Bogus Creek diversion.

Based on further exploration of the feasibility of each of the aforementioned options, KRRC proposed that water for Iron Gate Hatchery would be diverted from Bogus Creek within 1,000 feet of the confluence with the mainstem Klamath River. Diversion from Bogus Creek represents the Proposed Project As discussed in Volume I Section 2.7.6.1 *Proposed Project – Hatchery Operations – Iron Gate Hatchery* (pages 2-77 to 2-80), if Bogus Creek flows are insufficient to meet minimum operational needs while balancing flow requirements in the creek, water reuse (recirculation) from the rearing raceways could be utilized. In addition to recirculation, early release of smolts (i.e., prior to April 1) may occur to reduce water use requirements in the hatchery. The effectiveness of recirculation and early smolt release would be studied to determine whether they could be used to meet minimum operational flow and water temperature needs in the hatchery given annual variations in Bogus Creek flow and water temperature during the early release period. Thus, based on the studies and modeling already conducted and the alternatives already vetted for feasibility and effectiveness, the additional studies requested by the comment would not uncover additional feasible alternatives.

Comments on the Definite Plan (i.e., the Proposed Project), including the approach for supplying cold water to Iron Gate Hatchery and the selection of the location for Fall Creek Hatchery (FCH), should be submitted to the KRRC. As described in Volume I Potential Impact 3.8-4 (pages 3-682 to 3-683), with mitigation the EIR does not find a significant impact on the City of Yreka's water supply.

Comment LA8-30

The Fall Creek Hatchery was originally built in 1919 and operated until 1948. The facility thereafter consisted of rearing ponds used from 1979 to 2003 to raise 180,000 chinook salmon which were released at the Iron Gate Hatchery. Chinooks are not an ESA listed species. There are six raceways that remain, unused since 2003. Photographs taken on February 21, 2019 of the current state of what remains of the "hatchery" are attached as Attachment 4. The hatchery itself is completely demolished. Since the DCFW 10 cfs junior and subordinate water appropriation was acquired in 1979[21], it could not have been used for hatchery purposes, only for the rearing ponds from 1979 through 2003. This CDFW permits the diversion of 5,463 acre-feet per year while Yreka's permit allows 6,300 acre-feet per year. If CDFW were to fully use its permitted allocation Yreka would not be able to take under its permit as agreed by the parties to the ASKA.

Response to Comment LA8-30

Please refer to Master Response WSWR-6 and response to comment LA8-10.

Comment LA8-31

To operate the Fall Creek Hatchery, up to 10 cfs of water would be diverted from the PacifiCorp Fall Creek powerhouse return canal downstream of the City of Yreka's diversion facility at Fall Creek Dam A. Hatchery water would be diverted from Fall Creek Dam B to Dam A during periods when the powerhouse return canal is not flowing. While the Definite Plan specifies diverted water would be returned to Fall Creek at the fish ladder located in the lower tank area or the settling pond location (Appendix B: Definite Plan −Section 7.8.3), an October 2018 update specifies the upper rearing tank would discharge diverted water directly to Fall Creek, the lower rearing tank would discharge to the fish ladder adjacent to the tank, and the settling pond would discharge to Fall Creek further down, but upstream of the USGS 11512000 gage on Fall Creek (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., October 2018). Fall Creek diverted water would be gravity fed and plumbed to each rearing location and all circular tanks.

It is proposed that the hatchery diversion would not significantly alter Fall Creek flows measured at the USGS 11512000 gage or compliance with minimum Fall Creek flow requirements since the diversion flows for Fall Creek Hatchery would be diverted and returned (less evaporative losses) to Fall Creek upstream of the USGS 1151200 gage under the Proposed Project. This action would return most hatchery flows to Spring Creek before the point where the CDFW imposed Yreka's Fall Creek bypass is measured.

However, the effect, if any, that Mitigation Measure 17[22] has at this point, is relevant because it is not clear where the flows will come from to satisfy the concept that "flows will be provided in the Fall Creek bypass reach to provide for the appropriate habitat needs of the" fish. Is this phrase meant to apply to Yreka's municipal diversion or PacifiCorp's 75 cfs Fall Creek and 16.5 cfs Spring Creek right to take? There is no explanation of how these flows can be created and not affect Yreka's diversion.

Response to Comment LA8-31
The cited provision is not a Mitigation Measure under the EIR: the text is from the Klamath Hydropower Settlement Agreement's (KHSA's) Interim Measure 17. The 5 cubic feet per second (cfs) minimum flow in the Fall Creek bypass reach described in KHSA Interim Measure 17 is a continuation of PacifiCorp's existing operations of Fall Creek powerhouse. No change to this bypass reach flow is anticipated under the Proposed Project. Please also refer to Volume I Section 2.7.9 *Proposed Project – Proposed Project – KHSA Interim Measures* Table 2.7-19 (pages 2-103 to 2-107), Volume I Section 3.6.2.2 *Flood Hydrology – Environmental Setting – Basin Hydrology – Spring, Fall, and Jenny Creeks* (page 3-606), and Master Response WSWR-7.

Comment LA8-32
Further, unless Yreka's permit is amended, the permit's Condition F provides:

"This permit does not authorize any act which results in the taking of a threatened or endangered species or any act which is now prohibited, or becomes prohibited in the future, under either the California Endangered Species Act (Fish and Game Code sections 2050 to 2097) or the federal Endangered Species Act (16 U.S.C.A. sections 1531 to 1544). If a "take" will result from any act authorized under this water right, the permittee shall obtain authorization for an incidental take prior to construction or operation of the project. Permittee shall be responsible for meeting all requirements of the applicable Endangered Species Act for the project authorized under this permit."

Response to Comment LA8-32
Comment noted. The comment refers to Condition F of the City of Yreka's water right permit. Please refer to LA8-37 for response to related comments.

<u>Comment LA8-33</u>

The KRRC Definite Plan set out that the intention is to raise 75,000 Coho Yearlings and 115,000 Chinook Yearlings at the proposed Fall Creek Hatchery ("FCH").23. These Coho Yearlings are now being raised at Iron Gate Hatchery ("IGH"). The DEIR 2.3.4, et seq. summarizes that the IGH, now raises steelhead, coho salmon, and Chinook salmon. The hatchery includes a warehouse, a hatchery building, four fish-rearing ponds, a fish ladder, a visitor center, and four employee residences. It has a fish trapping and holding facility including a fish ladder, holding tanks, and a processing facility at the downstream base of Iron Gate Dam. It is supplied by water from the present reservoir.

The objectives of the AKSA as detailed in the Definite Plan present imminent risks for the City of Yreka's Fall Creek water right. Specifically, the broad objective of the AKSA Fisheries Program is intended to reintroduce anadromous fish species which could migrate into Fall Creek. Reintroduction of fish species could lead to the increased prevalence of threatened or endangered species in and around the City of Yreka's points of diversion. Also, various habitat restoration requirements could have an impact on the nature of the flow in Fall Creek. CDFW's proposal to construct a new hatchery facility at the site of its defunct fish hatchery is adjacent to Yreka's points of diversion will likely cause the hatchery raised fish to return to Fall Creek due to these species homing mechanisms. The objective of the AKSA is for the reintroduction of anadromous species throughout their historic range above Iron Gate Dam and provides that the focus of habitat restoration and monitoring is to be the Upper Klamath River Basin. Retaining coho prorogation at the IGH is directly in line to the Upper Klamath Basin and must remain the place of propagation of coho hatchery production. Instead the majority of this hatchery is proposed for demolition and eliminates coho production.

Response to Comment LA8-33

Please refer to responses to comments LA8-28/29 and LA8-37. Additionally, please refer to Volume I Section 2.7.6 *Proposed Project – Proposed Project – Hatchery Operations* (pages 2-77 to 2-86) for a detailed description of both the Fall Creek Hatchery (FCH) and the Iron Gate Hatchery plans.

<u>Comment LA8-34</u>

The data clearly demonstrates that Yreka would only receive its fully permitted water allocation one month out of the three-year period during low flow years if CDFW's junior, lower priority appropriation was permitted for the use of a Fall Creek hatchery/rearing ponds and if CDFW did not be return its hatchery flows above the gage as is presently proposed or if more water is used by the hatchery than is proposed CDFW. If CDFW is allowed to construct a hatchery at Fall Creek, the return of its flows above the gage must be a made condition of that allowance.

Response to Comment LA8-34
As described in Volume I Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* (pages 2-81 to 2-84), diversions associated with California Department of Fish and Wildlife's (CDFW's) non-consumptive water right on Fall Creek would return to the creek upstream of the United States Geological Survey [USGS] gage (Gage no. 11512000). Additionally, please refer to Master Responses WSWR-5 and WSWR-6.

Comment LA8-35
Further, as noted in the DEIR, it is "unclear" how the Fall Creek Hatchery would be "decommissioned" or "repurposed" at the expiration of the eight-year PacifiCorp financial commitment. What is known to this commentator is that at least one Indian Tribe desires to take over the operation of the hatchery. Should the State transfer its operation to a sovereign nation the next step, five years later, is for that tribe to request the Bureau of Indian Affairs to transfer the property into trust for the benefit of the Tribe. At that point neither the State, nor Yreka, would have any degree of control over the diversion to the hatchery and one would have to assume that, rather than the projected monthly Fall Creek Hatchery diversions set out in the DEIR, that the full allocation of 10 cfs would be used year around. On the basis of "federal reservation" arguments, some additional extraction might occur.

Response to Comment LA8-35
Please refer to Master Response WSWR-5 and WSWR-6. The comment's hypothetical series of events in which a Native American tribe would take ownership of Fall Creek Hatchery (FCH) after it is decommissioned, take the property into trust to remove it from state authority, and operate it using a greater amount of water than the current proposal and in violation of the principles of seniority to the detriment of a municipal diversion is speculative.

Comment LA8-36
Accordingly, the threat to Yreka's continued extraction of 15 cfs is clear and imminent unless a mitigation measure is placed into effect that the Fall Creek Hatchery be decommissioned at the end of PacifiCorp's financial commitment. The State of California should be required to set aside sufficient revenues to adequately finance this obligation.

If the Proposed Fall Creek Hatchery is allowed to be constructed, given this consideration, Yreka requests that the effects of the Proposed Project be mitigated by action through SWRCB to amend Yreka's permit to reduce the present 15 cfs bypass to 5 cfs (15 cfs – 10 cfs = 5 cfs). As previously mentioned, when Fish and Wildlife requested this bypass flow it did not then have its own 10 CFS appropriation intended for its rearing ponds/raceways. If the Fall Creek Hatchery is permitted to be constructed, the rationale for the bypass is then mooted since proactive propagation measures would be in effect through the *operation of the Fall Creek Hatchery and there would be no additional environmental need for the bypass.*

Response to Comment LA8-36
Similar to the discussions in responses to comments LA8-10, LA8-28, LA8-29, LA8-34, LA-37,and LA8-40, no Mitigation Measure is required to protect City of Yreka's ability to divert for municipal supplies, because the Proposed Project does not have a significant impact on the City's water supply or use. Please also refer to Master Responses WSWR-5 and WSWR-6.

Comment LA8-37
The Definite Plan and DEIR propose hatchery propagation of threatened Coho salmon at the proposed FCH to the stage of yearling maturation. By hatchery raising cohoes to the yearling stage it is certain that they will be imprinted to return to Fall Creek as their "home" rather than where they are actually planted in the various tributaries, the Klamath River itself or within the Upper Klamath River Basin – which is the actual objective of the Proposed Project. This imprinting occurs at different times caused by differing hormonal conditions in natural salmon, but in hatchery raised salmon, the homing mechanism is almost certainly imprinted between the fry and smolt stages. Thus, not only is Yreka's water diversion suddenly directly in conflict with protections for ESA species but the objectives of the Proposed Plan themselves are not accomplished. As a consequence, Fall Creek is likely to be designed as "critical habitat" for the cohoes in a creek that does not itself provide good habitat for spawning, in which previous studies have shown varying returns between 0 to 10%. What data does the latest Biological Opinion have to say about this effect? "Little is known about juvenile coho salmon movement into, out of, and within the mainstem of the Klamath River. The analysis for this BA assumes similar movement patterns as nearby drainages, where data is available."

Response to Comment LA8-37
Comments regarding coho imprinting and juvenile salmon movement are noted. These comments and references are consistent with the analysis in Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries*, which analyzes the rate of recolonization based on observed stray rates of coho salmon produced at Iron Gate Hatchery; and assumes that fish return to natal streams unless straying occurs. Impacts associated with hatchery operations including coho straying is discussed in Potential Impact 3.3-9. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*. Additionally, please refer to Volume I Section 3.8.4 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683) for a discussion of fish screen assessments and potential upgrades as part of the Proposed Project.

No critical habitat for coho salmon is currently designated upstream of Iron Gate Dam. Following dam removal, National Marine Fisheries Service (NMFS) may consider whether to designate the newly available habitat as critical habitat as part of its five-year status review or as a separate reconsideration of the critical habitat designation for the species (J. Simondet, NMFS, pers. comm., 2011). It is speculative at this point to prejudge the outcome of any such consideration. Adult coho salmon that return to Fall Creek would presumably be collected for hatchery brood stock, potentially locate suitable spawning habitat, or may stray to other tributaries upstream of Iron Gate Dam.

Comment LA8-38

The ESA, enacted in 1973, tasked all federal agencies with the protection of endangered species, declaring: "the policy of Congress that all Federal departments and agencies shall seek to conserve endangered species and threatened species and shall utilize their authorities in furtherance of the purposes of this chapter." Early litigation clarified that species protection occupied a position of utmost priority, superseding other policy and economic considerations.

Two federal agencies—the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS)—are primarily responsible for implementing the ESA, under authority delegated by the U.S. Department of the Interior and the U.S. Department of Commerce, respectively.

To oversimplify how ESA operates, endangered or threatened species are first recognized and listed through a science-based administrative process, and the implementing agencies also identify their critical habitat. Federal agency actions that might adversely affect a listed species can proceed only after consultation with either the FWS or NMFS (depending on the species involved), which then advise the federal agency through a Biological Opinion (BiOp) whether the proposed action would jeopardize the continued existence of the species or damage or destroy its critical habitat, and what "prudent and reasonable alternatives" might be available.

Response to Comment LA8-38

Comment noted. The comment relates an overview of the Endangered Species Act (ESA).

Comment LA8-39

Coho salmon once existed throughout the Basin but are now extinct above Iron Gate Dam, the lowermost Klamath mainstem dam that blocks fish passage. This salmon species was listed as threatened in 1997 and is NMFS's responsibility to manage and recover.

Meanwhile the BOR BiOp contains a request for formal consultation under section 7(a)(2) of the ESA with NMFS relating to coho salmon and their designated critical habitat. Until this occurs, it is premature to circulate this DEIR *because it is impossible for Yreka to comment upon the Proposed Project with that issue unresolved.*

Response to Comment LA8-39

The 2013 BiOp Flows served as the United States Bureau of Reclamation (USBR) Klamath Irrigation Project operational flow requirements for the Klamath River and specified the minimum flow requirements downstream of Iron Gate Dam at the time of the Notice of Preparation (NOP) for the Lower Klamath Project EIR (i.e., December 22, 2016) and the Draft EIR considered the potential effects of dam removal using the 2013 BiOp Flows to represent existing hydrology. In 2017, re-consultation on revisions to the biological opinion began again. After the issuance of the Lower Klamath Project Draft EIR on December 27, 2018, the applicable biological opinion and the operational flow requirements for the Klamath River changed again in March 2019, when the new biological opinions were issued by the National Marine Fisheries Service [NMFS] (2019) and United States Fish and Wildlife Service [USFWS] (2019). The 2019 Biological Opinion flows (2019 BiOp Flows) are now the current operational flow requirement for the Klamath River.

However, the fact that the flow schedules required for the USBR's Klamath Project were being revisited did not render CEQA analysis for the Klamath River Renewal Corporation's (KRRC's) project speculative so as to require a delay in CEQA review. Therefore, it was not premature to circulate the Draft EIR.

Please refer to Volume III Attachment 1 Section 3.1.6 *Introduction – Summary of Available Hydrology Information for the Proposed Project* for a comparison of the 2019 BiOp Flows, the 2013 BiOp Flows, and the Klamath Basin Restoration Agreement (KBRA) Flows, and a discussion of how the 2019 BiOp Flows are analyzed in the Lower Klamath Project Final EIR as a second CEQA baseline, representing flows under newly defined existing conditions. Please note that there are no changes in significance determinations relating to the inclusion of the 2019 BiOp Flows in the Final EIR analyses. For additional detail, please refer to Master Response HYD-1.

Comment LA8-40

Because of the inherent conflict between Yreka's right to take water for municipal purposes and the potential effect of the propagation of threatened species negatively affecting that right to take its full 15 cfs, as the parties agreed in the AKSA, Yreka requests that a mitigation measure be imposed that, should the FCH be constructed, no ESA endangered or threatened species be propagated at FCH.

Response to Comment LA8-40

The commenter is expressing concern regarding hypothetical future water diversion restrictions for the City of Yreka, based on the presence of a larger number of threatened species (coho salmon) in Fall Creek than would occur due to fish barrier removal alone and due to the operations of the Proposed Project's coho salmon conservation program at Fall Creek Hatchery (FCH). Based on this concern, the commenter is requesting that mitigation measures be added to the Proposed Project for Fall Creek Hatchery operations.

Mitigation measures requested by the commenter to protect their water supplies are not required because there is no significant impact to the City of Yreka's water supply associated with Proposed Project's Fall Creek Hatchery operations (please also refer to responses to comments LA8- 10, LA8-28, LA8-29, LA8-34, LA8-37, LA8-41, and Master Responses WSWR-5 and WSWR-6). As described in Potential Impact 3.3-24, there is no evidence that the existing 15 cubic feet per second (cfs) bypass requirement is insufficient to supply adequate flows for listed salmonids that would use Fall Creek to access the Proposed Project's Fall Creek Hatchery. During the period of coho salmon migration and spawning (December through early winter), flows are typically much higher than the minimum 15 cfs bypass flow as a result of precipitation. If coho salmon adult returns were to become relatively high in Fall Creek as a result of hatchery returns, there is no basis to speculate that increased instream flows from reduced water diversions would be a reasonable or effective means to reduce crowding. Furthermore, the current program at Iron Gate Hatchery does not indicate that a similar program at Fall Creek Hatchery become high enough to induce "crowding." At Iron Gate Hatchery from 2004 to 2016, from zero to around 350 hatchery return spawners were observed, without crowding issues noted (Knechtle and Chesney 2011, 2016a, 2017). In addition, the proportion of anadromous salmonids anticipated to use the habitat in Fall Creek is relatively minor in comparison with the totality of newly accessible habitat upstream of Iron Gate Dam under the Proposed Project. The state (California Department of Fish and Wildlife [CDFW]) and federal (National Marine Fisheries Service [NMFS]) resource managers responsible for hatchery operations and the recovery of coho salmon have not indicated the release location of coho salmon smolts from the Fall Creek Hatchery, and it is speculative to assume that releases would occur in a location that would lead to adult crowding.

The 15 cfs is a flat bypass requirement that applies regardless of whether the City of Yreka's consumptive diversion is increased to 15 cfs (as was assumed for purposes of the flow analysis for salmonids in the EIR (please refer to Volume III Attachment 1 Section 3.3.5 *Aquatic Resources – Potential Impacts and Mitigation* Potential Impact 3.3-24). Additionally, NMFS and CDFW were involved in developing the hatchery proposal for Fall Creek, and these agencies have not indicated concern that the existing flows or that the City Yreka's bypass requirements in Fall Creek (negotiated with CDFW) are insufficient. The comment's concern that a greater number of listed coho salmon will return to Fall Creek and subsequently require restriction of City of Yreka's diversions is speculative (please also refer to response to comment LA8-37).

Additionally, the mitigation requested—that no threatened species be raised at Fall Creek Hatchery—does not appear to be feasible under CEQA. The goals for coho production are for a conservation hatchery and require a year-round supply of cold water which may not be available at Iron Gate Hatchery.

Comment LA8-41

It has been found that it is possible to prevent imprinting by treating water with activated carbon and ion-exchange resin, insoluble in petroleum-ether, dialyzable, non-volatile, and heat-stable and then imprinted with ÃŸ-phenylethyl alcohol (PEA) or morpholine for at least 14 days during smoltification and lured into unfamiliar streams scented with these odors during homing migration a few years later. Alternatively, in a natural stream environment, however, after preventing imprinting in the hatchery environment, smolts should be imprinted immediately by different odors when they encounter a branch stream that flows into a main stream during downstream migration as in the sequential imprinting hypothesis. If construction of the FCH is approved, and further if CDFW is not prohibited from raising ESA threatened species at FCH, this mitigation measure must be imposed to mitigate the probability that the cohoes will be imprinted to return to Fall Creek as a result of their rearing at the FCH.

To further prevent Fall Creek from becoming a magnet for salmonid spawning, Yreka seeks a mitigation condition that all fish propagated at FHC be planted at other tributaries and areas where they will be likely to return and that they not be released at Fall Creek itself.

This means planting the yearlings where the habitat is favorable to coho spawning propelling spawning upward into the Upper Klamath Basin. However, Oregon and California do not agree on whether hatchery fish should be propagated to accomplish the objectives of the Proposed Project. Oregon endorses a policy of native fishery production while CDFW originally proposed a "wait and see" approach before engaging in hatchery operations. All parties agree that hatchery fish compete with native fish, could create increased risk of disease, and could negatively affect natural fish production. In this regard the latest BiOp states:

"Uncertainty exists concerning the interrelationship of hatchery produced fish with the naturally produced coho salmon when both are present in the natural environment (i.e., after the hatchery fish are released into the Klamath River). This includes the role of hatchery produced salmon in the spread and proliferation of fish disease. The effects of hatchery operations are included as a Baseline condition."

Yet, CDFW is proposing to directly and immediately proceed with the demolition of IGH and construction of FCH. While it is understandable that CDFW desires to proceed while the project funding is occurring, PacifiCorp's commitment for *funding would remain in place in the event that "waiting and seeing" proves out to require hatchery produced fish following dam decommissioning.*

Response to Comment LA8-41

Klamath River Renewal Corporation's (KRRC) Definite Plan (Section 7.8.3 *Proposed Fish Hatchery Plan*) describes the proposed Fall Creek Hatchery (FCH) facilities and improvements, water supply requirements, and operations including the production of coho salmon. As described in Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project Fish – Hatcheries*, coho salmon hatchery operations are proposed to continue operating as a conservation hatchery under a Hatchery Genetic Management Plan, including specific assessment of hatchery impacts on species spatial structure and operation of Fall Creek Hatchery with a particular emphasis on recolonization, including rearing and release techniques. The proposed fish hatchery plan states that California Department of Fish and Wildlife (CDFW) and National Marine Fisheries Service (NMFS) are evaluating release strategies for coho salmon produced at Fall Creek Hatchery. The state and federal agencies responsible for managing the recovery of coho salmon would continue to adjust hatchery operations, including release strategies, to maximize production, recovery, and recolonization while minimizing crowding and other potential issues in Fall Creek, in the operations of the facility under the Hatchery Genetic Management Plan. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* analyzes the effect of continued hatchery production of coho salmon. Impacts associated with hatchery operations including coho straying are discussed in Potential Impact 3.3-9. Potential Impact 3.3-9 was not found to be significant in the short term and to be beneficial for coho salmon populations in the long term. Under CEQA, mitigation measures are not required for impacts that are not found to be significant. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Regarding recolonization without hatchery operations, please refer to Section 4.7.3 Alternatives – *Aquatic Resources – No Hatchery Alternative.* Please also refer to Master Response AQF-2 for general discussion of future hatchery operations, and response to comment LA8-40 for further discussion of crowding concerns.

Comment LA8-42

While Yreka is neutral on whether or not the Proposed Project dams are decommissioned, it is interesting that it has been determined that the parasites that are largely creating the mortality of the salmon can be obviated by simply flushing the parasites off the rocks on the bottom of the river. While it is proposed that this flushing will naturally occur through flooding once the dams are decommissioned, there are no studies presented in the Definite Plan nor any *proposed alternative in the DEIR, that suggests that the BOR cannot simply perform this task though the rapid release of water with the dams intact. This is one of the functions of the BOR – to regulate the flow of water while balancing water usage with species recovery alternatives.*

Response to Comment LA8-42

United States Bureau of Reclamation (USBR) regulates flows released at Link River Dam in the Upper Klamath Basin, including the provision of flushing flows for the Middle Klamath River to address polychaete habitat. The flushing flows prescribed in the 2017 court order and incorporated in the 2019 Biological Opinion (BiOp) could be achieved with dams in place or with dams removed. As described in Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments to disrupt the periphyton intermediate host (discussed below). The court-ordered flushing flows and emergency dilution flows are not modeled as part of existing conditions hydrology under the Proposed Project. As described in Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, the 2017 court-ordered flows included a requirement to ensure that certain high flows are reached each winter, and they also included an emergency dilution requirement if juvenile fish disease reached high levels in the infection nidus. The emergency dilution flows were used in 2018. In March 2019, the court-required re-initiation of USBR consultation with National Marine Fisheries Service (NMFS) and United States Fish and Wildlife Service (USFWS) was completed and new biological opinions (BiOps) were issued by NMFS (2019) and USFWS (2019a). The 2019 BiOp flow requirements include annual surface flushing flows of at least 6,030 cubic feet per second (cfs) for 72 hours at Iron Gate Dam between March 1 and April 15, and the potential for dilution flows and/or enhanced spring flows should water be available and disease conditions support their use. Dilution flows also occurred in June 2019 under the new BiOp flow requirements. While there has not been sufficient time to collect data characterizing the efficacy of the flushing flows since they were initiated in 2017, the necessity to use dilution flows in 2018 and 2019 suggests that flushing flows are insufficient on their own to resolve the issue of fish disease downstream of Iron Gate Dam.

Please refer to Volume III Attachment 1 Section 3.3.5.5 *Fish Disease and Parasites* and Master Response AQF-6 for a discussion of the multiple additional factors (in addition to flushing flows and the resulting bed mobilization) that affect fish disease and parasite prevalence in the Klamath River that potentially would be altered by the Proposed Project. The Lower Klamath Project EIR has been updated to reflect the 2019 BiOp Flows as an additional CEQA baseline for both the Proposed Project and the alternatives, as applicable. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment LA8-43

There is no study, proposal requiring or discussion that hatchery raised fish be genetically diversified to assure they do not pose a risk to wild populations. This mitigation is requested.

Response to Comment LA8-43

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* analyzes the effect of continued hatchery production of coho and Chinook salmon on wild populations of these species. Potential Impact 3.3-7 (Effects on the fall-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal) and Potential Impact 3.3-9 (Effects on coho salmon populations due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal) were not found to be significant in the short term and were found to be beneficial for these populations in the long term. Under CEQA, mitigation measures are not required to be included for impacts that are not found to be significant. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

As described in Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project Fish – Hatcheries*, the Hatchery Genetics Management Plan (HGMP) for the Iron Gate Hatchery (CDFW and PacifiCorp 2014) specifically addresses conservation of genetic resources for hatchery produced coho salmon. The hatchery program will operate in support of the basin's coho salmon recovery efforts by conserving a full range of the existing genetic, phenotypic, behavioral, life history, and ecological diversity of the run.

Comment LA8-44

The characterization in the DEIR that there would be "upgraded plumbing" with the construction of a new Fall Creek Hatchery is a gross minimization of the water facilities that would be constructed. Attachment 5 demonstrates the last water layout design plan provided to Yreka by KRRC's engineers. Attachment 6 is the latest Fall Creek Hatchery layout provided to Yreka. The DEIR Should Yreka's water diversion impounds be altered in any manner, coordination between all parties would be absolutely necessary to maintain operations. In fact, the same coordination from all who are diverting water from Fall Creek (including any newly constructed fish hatchery) is necessary when Yreka performs periodic maintenance on its diversion impounds and fish screens.

Response to Comment LA8-44

Comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation (KRRC). The figure shown in Attachment 5 is generally consistent with information provided in the KRRC's Definite Plan and the EIR. Please note that the figure shown in Attachment 6 of this comment is also provided in Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* as Figure 2.7-15 (page 2-83). The caption for Figure 2.7-15 has been revised to note that specific details regarding the location of facilities at the re-opened hatchery are subject to minor changes within the Limits of Work. Further, as described in Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Mitigation Measure WSWR-2 (pages 3-682 to 3-683) is consistent with CEQA Guidelines section 15126.4, and in particular subdivision (a) (1) (B), which states that a mitigation measure may specify performance standards which would mitigate the significant effect of the project and which may be accomplished in more than one specified way. Additionally, Mitigation Measure WSWR-2 states that a short water delivery outage is necessary to make the final connections following construction of the new pipeline; the KRRC shall limit the water delivery outage to a maximum of 12 hours, unless the KRRC receives prior approval for a longer outage from the State Water Board, based on detailed information that the outage proposed will not interfere with City of Yreka's ability to supply water; and the KRRC shall coordinate the water delivery outage period with the City of Yreka to ensure the City of Yreka has an adequate supply of water stored to cover the maximum water delivery outage period, with adequate buffer.

Comment LA8-45

The Consequences of the Proposed Spring Creek Flow Restriction Condition Taken Together with Yreka's Water Permit Bypass Condition Will Restrict Yreka From Taking its Permitted Allocation

In the conditions proposed for renewal of the hydroelectric licenses, it has been proposed that PacifiCorp's 16.5 diversion from Spring Creek to its Fall Creek Hydroelectric facility be discontinued during the low-flow months of the summer. These are also Yreka's highest demand months. If this condition were implemented, together with the consequences of the CDFW 15 cfs bypass, Yreka would be deprived of its municipal water source during its most critical period. Accordingly, Yreka requests that a mitigation measure be imposed that SWQCB recommend to FERC that it not impose the proposed restriction of the diversion of Spring Creek water to the Facility.

Response to Comment LA8-45

Please refer to Master Response WSWR-7.

Comment LA8-46

The Klamath River Basin Compact Commission is an Essential party and is Properly the Lead Agency for the Purposes of this Circulating the DEIR and making Determinations Upon it.

Section 1.1 of the Draft Environmental Impact Report (DEIR; KRRC 2018; hereafter known as DEIR) states that the Klamath River Renewal Corporation (KRRC) has applied to the Federal Energy Regulatory Commission (FERC) to decommission and remove the four Lower Klamath Project dams (Proposed

Project). Section 1.1 further states that FERC is the federal lead agency that licenses the construction, operation, and decommissioning of most hydroelectric dams in the United States. However, in the DEIR we are now required to comment upon, the SWRCB has assumed the lead agency role and prepared the Lower Klamath Project License Surrender Project DEIR without following the legislative intent of CEQA, CEQA Guidelines, and CEQ NEPA regulations and, equally significant, the state and federal laws relating to the Klamath River Compact.

Response to Comment LA8-46
Please refer to Master Response CEQ-4.

Comment LA8-47
This is a logical non sequitur under the law since the project is intended to be carried out by the KRRC, a non-public 501(c)(3) organization. If 14 Cal Code Regs §15051(a) applies at all, it does not apply to SWQCB but to the Compact Commission. Pursuant to the Law of the River and the Law of the Union, the Commission is specifically designated as the regional planning agency with the greatest responsibility for supervising or approving the project as a whole pursuant to 14 Cal Code Regs §15051(b).

Article IX (Administration) of the Compact creates the Klamath River Compact Commission. (See 69 Stat. 613, 71 Stat. 497 [1957]; Cal. Water Code §§ 5900-5901 and ORS 542.610 to 542.630) Under Article IX subparagraph 1 creates the commission to administer the compact (the "Commission"). The Commission consists of three: a ex officio representative designated by the State of Oregon Water Resources; an ex officio representative designated by the SWRCB and a nonvoting Chair of the Commission designated by the President of the United States. Action is effective only if it is unanimously affirmed by both voting members. The Commission is required to appoint an executive director. Subparagraph 8 requires the Commission to be subject to open meeting laws.

The Commission is obligated to hold public hearings and to submit to the Governor of each state a budget of its estimated expenditures for such period as required by the laws of that state for presentation to the legislature thereof. Each state pledges itself to appropriate and pay over to the commission one-half of the amount required to finance the commission's estimated expenditures as set forth in each of its budgets. The Commission is required to transmit to the legislature and Governor of each state and to the President of the United States an annual report covering the finances and activities of the Commission and embodying such plans, recommendations and findings as may have been adopted by the Commission and to be annually audited by a Certified Public Accountant.

The Commission has monetary restrictions. It is prohibited from pledging the credit of any government except by and with the authority of the legislative body thereof given pursuant to and in keeping with the constitution of such government *and is also prohibited from incurring any obligations prior to the availability of funds adequate to meet them. The Commission is empowered to: 1) borrow, accept or contract for the services of personnel from any government or agency thereof, from any intergovernmental agency, or from any other entity; 2) Accept for any of its purposes and functions under this compact any and all donations, gifts, grants of money, equipment, supplies, materials and services from any government or agency thereof or intergovernmental agency or from any other entity; 3) Acquire, hold and dispose of real and personal property as may be necessary in the performance of its functions; and 4) Make such studies, surveys and investigations as are necessary in carrying out the provisions of this compact. Obviously, the studies relevant to the Proposed Project and the preparation of the related environmental DEIR fall within these categories.*

Response to Comment LA8-47
Please refer to Master Response CEQ-4.

Comment LA8-48
The DEIR and the DEIS Should be Required to be jointly Submitted

The National Environmental Policy Act (NEPA) (42 USC §§4321-4370h), was adopted to mandate public agencies to consider the environmental impacts of their actions, to document those impacts, and to disclose that documentation to the public. See No Oil, Inc. v City of Los Angeles (1974) 13 C3d 68, 86 n21, 118 CR 34; Friends of Mammoth v Board of Supervisors (1972) 8 C3d 247, 261, 104 CR 761; Selmi, The Judicial Development of the California Environmental Quality Act, 18 UC Davis L Rev 197 (1984).

If a project requires approvals from a California public agency but will also be carried out, financed, or approved in part by a federal agency, preparation of a joint EIR/EIS may be required (see 14 Cal Code Regs §§15220-15228), and the joint document must usually meet the requirements of both CEQA and NEPA. This is particularly applicable where projects that have a significant impact on matters within federal jurisdiction, such as some projects that require a permit to fill wetlands or that may affect waters that are subject to United States jurisdiction under §404 of the Federal Water Pollution Control Act (Federal Clean Water Act) (33 USC §1344).

This project expressly concerns the flow of navigable water between Oregon and California and through federal (US Forest Service) and Tribal reservations Klamath Tribe, Karuk Tribe, Hoopa Tribe and Yurok Tribe). Each of these tribes are federally recognized. Not only is an express federal approval an integral part of the implementation of this plan, the deconstruction of four hydroelectric dams, under FERC required considerations, significantly affects the quality of the human environment which separately requires NEPA environmental assessment. 42 USC §4332(2)(C), 40 CFR §§1501.4(b), 1508.9.

The National Environmental Policy Act (NEPA), is intended to ensure that Federal agencies actively participate as cooperating agencies in other agency's NEPA processes. The CEQA regulations addressing cooperating agencies status (40 C.F.R. §§ 1501.6 & 1508.5) implement the NEPA mandate that Federal agencies responsible for preparing NEPA analyses and documentation do so "in cooperation with State and local governments" and other agencies with jurisdiction by law or special expertise. (42 U.S.C. §§ 4331(a), 4332(2)).

Response to Comment LA8-48
Please refer to Master Response CEQ-1.

Comment LA8-49
The Intergovernmental Cooperation Act contains specific coordinated planning requirements for local, state and federal agencies. Presidential Executive Order 12372 requires federal agencies to coordinate actions and projects with local governments so that local impacts arising from federal projects may be identified.

The National Environmental Policy Act (NEPA) applies to projects that are carried out, financed, or approved in whole or in part by federal agencies; therefore, FERC must prepare an environmental impact statement prior to acting with respect to the Proposed Project.

Yreka respectfully requests SWQCB to take the action above stated.

Response to Comment LA8-49
Please refer to Master Response CEQ-1.

County of Siskiyou, Ashley J. Remilllard

Comment LA9-1
On behalf of Siskiyou County ("County"), we are writing to express our significant concerns regarding the Draft Environmental Impact Report ("DEIR") for the Lower Klamath Project License Surrender ("Proposed Project") prepared by the California State Water Resources Control Board ("State Board") pursuant to the California Environmental Quality Act, Cal. Pub. Res. Code, § 21000 et seq. ("CEQA"). As the State Board is aware, the Klamath River Renewal Corporation ("KRRC") and PacifiCorp have submitted applications to the Federal Energy Regulatory Commission ("FERC") for hydropower license transfer and surrender. Together, these applications propose to transfer, decommission, and remove four lower Klamath River dams—Iron Gate, Copco I, Copco II, and J.C. Boyle. Three of these dams are located within Siskiyou County. The County has, on multiple occasions, expressed its concerns regarding the potential impacts of dam removal on imperiled species, water quality, and the overall health of the Klamath River ecosystem, as well as other environmental and societal impacts, including air quality, climate change, cultural resources, hazardous materials, and traffic impacts, in addition to socioeconomic impacts on the local community. See, e.g., PacifiCorp, 162 FERC 61,236 at 28 (Mar. 15, 2018). Accordingly, the

County has a vested interest in ensuring that the public is appropriately and lawfully informed of the consequences of the Proposed Project.

As part of the license surrender process, and pursuant to section 401 of the Clean Water Act, 33 U.S.C. § 1341 et seq., KRRC must also obtain a water quality certification from the State Board. Because the section 401 certification must be based on a finding that the Proposed Project will meet water quality standards and other applicable requirements, the State Board must comply with CEQA. Here, however, the State Board has failed to do so.

As further set forth in the Technical Memorandum attached hereto as Exhibit A, the DEIR fails to satisfy the requirements of CEQA and its implementing guidelines, 14 Cal. Code Regs. §§ 15000 et seq. ("CEQA Guidelines"), and therefore fails to provide the public with an adequate assessment of the significant environmental effects associated with implementation of the Proposed Project. The County's concerns include, among other things, the following:

As the State Board is aware, FERC is required under the National Environmental Policy Act ("NEPA") to prepare an environmental impact statement to evaluate the potential environmental impacts of the Proposed Project. Various provisions of the CEQA Guidelines, as well as NEPA's implementing regulations, state that lead CEQA and NEPA agencies should avoid duplication and jointly prepare one environmental document. Such an approach improves efficiency, preserves public resources, and avoids public confusion and complexity. Here, the State Board's failure to prepare a joint environmental document with FERC is problematic. For example, the fact that FERC has not begun the NEPA process reinforces the uncertain nature of the Proposed Project description (also discussed below). Likewise, having two documents with multiple alternatives makes the Proposed Project unnecessarily complex and risks causing unneeded public confusion. Thus, the County requests that the State Board issue a revised DEIR prepared in coordination with FERC.

Response to Comment LA9-1

Thank you for your comment. Please refer to Master Response CEQ-1.

<u>Comment LA9-2</u>

The State Board has improperly failed to consult with responsible agencies and other local agencies that exercise authority of the resources that will be affected by the Proposed Project. See Cal. Pub. Res. Code § 21104; 14 Cal. Code Regs. § 15086(a). Specifically, the State Board has taken the position that the County is not a responsible agency because the County's local permitting requirements will be preempted by federal law. This determination is improperly premature. Not only has FERC required compliance with all local permitting requirements in other dam removal contexts, Arizona Public Service Co., 109 FERC ¶ 61,036 (2004); Wisconsin Electric Power Co., 94 FERC ¶ 61,038 (2001), but this is a determination to be made by FERC—not the State Board. In addition, FERC has *made it clear that KRRC must comply with state and local laws to the extent practicable. E.g., Definite Plan at 38, citing PacifiCorp, 115 FERC ¶ 61,194 (2006) ("We prefer for our licensees to be good citizens of the communities in which projects are located, and thus to comply with state and local requirements, where possible.") Unless and until FERC makes a determination regarding preemption, it is improper for the State Board to assume that the County is not a responsible agency under CEQA.*

Response to Comment LA9-2

Please refer to Master Response CEQ-2 for a discussion of the effect of Federal Power Act preemption on responsible agencies.

Comment LA9-3

The purpose and objectives of the Proposed Project are improperly narrow. More specifically, the purpose and objectives foreclose meaningful consideration of alternatives that should properly be considered under CEQA. For example, the objective to '[r]estore volitional anadromous fish passage in the Klamath Basin to viable habitat currently made inaccessible by the Lower Klamath Project dams' is narrower than, and not justified by, the project purpose (i.e., improving water quality and upstream access). This objective essentially preselects the preferred alternative-dam removal-thereby precluding consideration of other alternatives that could significantly improve fish passage and survival (e.g., trap and haul, or other means of assisted migration). Likewise, the purpose and objectives improperly focus exclusively on improving "anadromous fish passage." This ignores the fact that multiple other non-anadromous species inhabit the Proposed Project area, including imperiled shortnose and Lost River suckers. It is improper for the purpose and objectives to be defined so narrowly as to exclude consideration of alternatives that would benefit other Klamath Basin aquatic species.

Response to Comment LA9-3

The State Water Board has set forth an underlying purpose and project objectives that are reasonably focused on restoration goals related to the Lower Klamath Project facilities (see Volume I *Executive Summary* page ES-4). The Proposed Project purpose and objectives are not improperly narrow or conflated, nor do they preclude meaningful consideration of a reasonable range of alternatives to the Proposed Project in the EIR.

Specifically, the objective specifying volitional anadromous fish passage is aligned with the requirements of National Marine Fisheries Service's (NMFS) Biological Opinion issued to the Klamath Hydroelectric Project (KHP) in prior proceedings regarding these facilities – while being broader than the four-dam-removal goal stated by the applicant and included in the Klamath Hydroelectric Settlement Agreement (KHSA).

Long-term declines in Klamath Basin fisheries have been observed for wild fall-run Chinook salmon, spring-run Chinook salmon, steelhead, coho salmon, and Pacific lamprey. These declines, which are attributable to the cumulative effects of a multitude of changing conditions including dam construction, hydrologic modifications, changing ocean conditions, and land use changes, have created hardships for commercial fisheries and tribal communities that depend on these fisheries as an important cultural resource. Commercial fishery trollers in the Pacific Ocean that catch coho and fall- and spring-run Chinook salmon originating from river systems including the Klamath River have suffered severe economic impacts due to decreases in fish numbers and related harvest limitations in the past several decades (see also Volume I Section 5.4.1.1 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA – Consideration of Economic Information for Resources Potentially Affected by Dam Removal – Commercial Fishing* [pages 5-5 to 5-7]). A lack of access to native food sources, including an inability to get salmon due to poor river conditions, is primary among the reasons that Klamath Basin Native community food assistance users report a reliance on food assistance, with 70 percent of all surveyed households reporting that they rarely or never have access to their desired foods including salmon (Sowerwine et al. 2019). Salmon are also ecologically important to the Klamath River Basin, providing a nutrient-rich food source for terrestrial species, including bald eagles, osprey, and many other species of birds and mammals. The declines in coho salmon in the Klamath Basin have contributed to the listing of this species as threatened under the Endangered Species Act (ESA) (Volume III Attachment 1 Section 3.3 *Aquatic Resources* Table 3.3-2). Improvements to listed suckers in this reach would not be an appropriate objective for the Hydroelectric Reach because, as further discussed in response to comment LA9-19, the sucker populations in Iron Gate and Copco No. 1 reservoirs are "sink populations" and are not likely to be self-sustaining.

The Lower Klamath Project EIR presents a range of reasonable alternatives to the Proposed Project that meet most of the project objectives. As described in Volume I Section 4.1 *Alternatives Selection/Overview* (pages 4-1 to 4-15), the State Water Board considered all of the potential alternatives discussed in the 2007 FERC EIS and the 2012 KHSA EIS/EIR and evaluated them as potential objectives, including consideration of their ability to meet the Proposed Project's underlying purpose and objectives. In addition to revisiting the alternatives considered for the prior related environmental reviews, the State Water Board considered three additional potential alternatives raised in Lower Klamath Project scoping, including a fish passage alternative that looks at a combination of trap and haul, fish cannons (a new technology since 2012), and other mechanisms for fish passage without dam removal proposed by Siskiyou County and others.

Ultimately, the State Water Board brought forward six alternatives for detailed analysis in the EIR. Of these, two involve removal of all four Lower Klamath Project Dams, and four involve some or all of the dams remaining in place with mandatory fishway prescriptions. While none of the additional proposals for fish passage were found to be feasible alternatives for review, the EIR notes where the potential impacts of trap and haul might differ from the impacts of the mandatory fishway prescriptions in the Continued Operations with Fish Passage and Two Dam Removal alternatives (Volume I Section 4.4 *Alternatives – Continued Operations with Fish Passage* [pages 4-99 to 4-180] and Section 4.5 *Alternatives – Two Dam Removal* [pages 4-100 to 4-246]).

There are potential impacts and beneficial effects identified for each of these alternatives in the EIR and each will be fully considered by the State Water Board before certifying the EIR (CEQA Guidelines section 15090).

Comment LA9-4

The Proposed Project is improperly defined. Specifically, the DEIR defines the Proposed Project as the project set forth in the Definite Plan for the Lower Klamath Project ("Definite Plan") that was submitted to FERC in June 2018. As the State Board is aware, the Definite Plan is currently under review by FERC, and has not been deemed technically or financially feasible. Furthermore, KRRC has indicated that the Definite Plan will be revised and reissued in April 2019. See http://www.klamathrenewal.org/wp-content/uploads/2018/12/2018-12-12-Letter-Report-BOC-Mtg-No-1.pdf; see also November 2018 Comments from Siskiyou County re Definite Plan (attached hereto as Exhibit B). The State Board's use of a tentative, yet-to-be-vetted project as the Proposed Project is contrary to CEQA. See Washoe Meadows Community v. Department of Parks and Recreation, 17 Cal.App.5th 277 (Cal. Ct. App. 2017).

Response to Comment LA9-4

Prior to issuance of the Draft EIR in December 2018, the Klamath River Renewal Corporation (KRRC) indicated that updates to the Definite Plan primarily would be focused on updating cost information associated with the Proposed Project and that any updates to the proposed activities and/or project components would be minor.

In July 2019 and February 2020, KRRC provided updates to the Definite Plan, in which KRRC provided cost-related information, including funding for mitigation surety, which is not integral to the analyses in the EIR. KRRC (2019b) also proposed that pre-drawdown construction activities would occur in 2021 and primary reservoir drawdown and dam removal would occur in 2022, which does not constitute significant new information. Please refer to KRRC (2019b) here: http://www.klamathrenewal.org/wp-content/uploads/2019/07/KRRC-July-29-FERC-Filing.pdf. Please refer to KRRC (2020) here: http://www.klamathrenewal.org/wp-content/uploads/2020/02/Public-02-28-2020-Supp-Response-Letter.pdf

CEQA does not require that a lead agency delay environmental review until a federal agency makes particular determinations regarding a proposed project. Therefore, the project description is not improper.

Comment LA9-5

Throughout the DEIR, the State Board refers to "measures that would not be considered feasible for the purposes of CEQA because the SWRCB cannot ensure that they would occur." The State Board's approach with respect to these measures is improper. Where mitigation measures can be devised consistent with CEQA, the State Board cannot lawfully shirk its responsibility to identify such measures and require compliance with them in order to reduce impacts to less than significant. Importantly, "a condition requiring compliance with regulations is a common and reasonable mitigation measure, and may be proper where it is reasonable to expect compliance." Oakland Heritage Alliance v. City of Oakland, 195 Cal. App. 4th 884, 906 (Cal. Ct. App. 2011), cited in Center for Biological Diversity v. Department of Fish & Wildlife, 234 Cal. App. 4th 214, 246 (Cal Ct. App. 2015). It is reasonable to expect compliance with, for example, the federal Endangered Species Act, pertinent provisions of the California Fish and Game Code, and other federal and state laws. Therefore, the State Board should revise the DEIR to incorporate mitigation measures (rather than recommended measures) wherever possible.

Response to Comment LA9-5

Please refer to Master Response CEQ-2.

Comment LA9-6

The State Board acknowledges that the Proposed Project will result in exceedances of air quality thresholds established by the Siskiyou County Air Pollution Control District ("SCAPCD"), including with respect to NOX, PM10, and PM2.5. DEIR at 3-703, citing SCAPCD Rule 6.1, Construction Permit Standards for Criteria Pollutants. The State Board further concludes that, based on those exceedances, construction emissions for the Proposed Project would be significant. Id. In Section 2.8 of the Project Description, however, the State Board has not identified SCAPCD as a responsible agency that will rely on the DEIR for permitting or other regulatory purposes. See, e. g., SCAPCD Rule 2.1(A), Permits Required. This contravenes CEQA Guidelines section 15124, subdivision (d). The State Board should revise the DEIR to properly comply with this requirement.

Response to Comment LA9-6

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (Air Quality). With respect to the comment's concern that the EIR does not identify the Siskiyou County Air Pollution Control District (SCAPCD) as a responsible agency that will rely on the EIR for permitting or other regulatory purposes, please refer to Master Response CEQ-2.

<u>Comment LA9-7</u>

The DEIR's analysis of greenhouse gas emissions is inadequate. For example, the impact analysis indicates that emissions have not been quantified since the 2012 EIR/EIS, despite significant changes to the Proposed Project. The State Board should either perform a new analysis to quantify emissions or explain why it has not performed such an analysis. See Cleveland Nat'l Forest Found. v. San Diego Assn. of Governments, 3 Cal. 5th 497, 515-516 (Cal. Ct. App. 2017). Furthermore, the DEIR's 10,000 MT threshold of significance is contrary to recent court decisions holding that, without an analysis explaining why the data is relevant to a particular project, reliance on statewide data or other regional data to prepare significance thresholds is improper. E.g., Golden Door Properties, LLC v. Cty. of San Diego, 27 Cal. App. 5th 892 (Cal. Ct. App. 2018); Ctr. for Biological Diversity v. Dep't of Fish & Wildlife, 62 Cal. 4th 204 (Cal. 2015). Thus, at a minimum, the State Board should revise the DEIR to include an additional analysis demonstrating why the data that it used is relevant to the Proposed Project, including with respect to both its type and location. Id.; see also DEIR at 3- 720. Moreover, because of the burden and risk associated with tailoring thresholds to particular projects, many local agencies have instead adopted a net zero threshold. See, e.g., Newhall Ranch Project, https://netzeronewhall.com/. This is also the approach recommended by the California Air Resources Board. See, e.g., https://www.arb.ca.gov/cc/scopingplan/scoping_plan_2017.pdf at 101. The County encourages the State Board adopt a net zero threshold for the Proposed Project. In any event, the County reaffirms its position that the DEIR must include mitigation measures to reduce air quality impacts to less than significant rather than simply allowing KRRC to endanger public health by proceeding with an action that has unmitigated, significant air quality impacts.

Response to Comment LA9-7

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (Greenhouse Gas Emissions and Energy).

<u>Comment LA9-8</u>

Section 1.1 of the Draft Environmental Impact Report (DEIR) states that the Klamath River Renewal Corporation (KRRC) has applied to the Federal Energy Regulatory Commission (FERC) to decommission and remove the four Lower Klamath Project dams (Proposed Project). Section 1.1 further states that FERC is the federal lead agency that licenses the construction, operation, and decommissioning of most hydroelectric dams in the United States.

The National Environmental Policy Act (NEPA) applies to projects that are carried out, financed, or approved in whole or in part by federal agencies; therefore, FERC must prepare an Environmental Impact Statement (EIS) prior to taking action with respect to the Proposed Project. California Environmental Quality Act (CEQA) Guidelines Section 15006, Reducing Delay and Paperwork, *states that lead agencies should eliminate duplication with federal procedures by providing for joint preparation of environmental documents with federal agencies and by adopting documents prepared in fulfillment of NEPA and its implementing regulations. In addition, CEQA Guidelines Section 15222, Preparation of Joint Documents, states that a lead agency should try to combine an Environmental Impact Report (EIR)/EIS to avoid the need for the federal agency to prepare a separate document for the same project. According to CEQA Guidelines Section 15222 this involvement is necessary because federal law generally prohibits a federal agency from using an EIR prepared by a state agency unless the federal agency was involved in the preparation of the document. Furthermore, Council on Environmental Quality (CEQ) NEPA Regulations encourage cooperation with state and local agencies in an effort to reduce duplication in the NEPA process (40 Code of Federal Regulations [C.F.R.] § 1506.2). The CEQ NEPA regulations state that cooperation shall include joint planning processes, joint environmental research and studies, joint public hearings, and joint environmental assessments (Id. § 1506.2(b)(1-4)).*

The State Water Resources Control Board (SWRCB) has prepared the Lower Klamath Project License Surrender Project DEIR without following the legislative intent of CEQA, CEQA Guidelines, and CEQ NEPA regulations. The SWRCB has created undue confusion and complexity for the public, local agencies, and other state and federal agencies involved in reviewing the project by initiating two separate, duplicative environmental review processes. Thus, it's recommended that the SWRCB issue a revised DEIR in coordinating with FERC.

Although the County clearly outlines the need for a revised EIR, it is important to note that due to SWRCB's failure to follow the process outlined above the potential for future amendments to the DEIR, requiring recirculation, results in financial hardship to economically stressed stakeholders and local agencies, such as Siskiyou County, who will be obligated to expend further limited resources to review and respond to the new documents the SWRCB circulates. Had the SWRCB followed typical and acceptable procedural steps in developing this DEIR, there would have been a significant decrease in the financial strain experienced by affected stakeholders and local agencies, including Siskiyou County.

Response to Comment LA9-8
Please refer to Master Response CEQ-1.

Comment LA9-9
Under Public Resources Code section 21104, "[p]rior to completing an environmental impact report, the state lead agency shall consult with, and obtain comments from, each responsible agency, trustee agency, any public agency that has jurisdiction by law with respect to the project, and any city or county that borders on a city or county within which the project is located unless otherwise designated annually by agreement between the state lead agency and the city or

county, and may consult with any person who has special expertise with respect to any environmental impact involved." Under 14 California Code of Regulations (CCR) § 15086(a), the lead agency "shall consult with and request comments… from" responsible agencies and other local agencies that exercise authority over resources that may be affected by the project, and "may consultant directly with: (1) Any person who has special expertise with respect to any environmental impact involved, (2) Any member of the public who has filed a written request for notice with the lead agency or the clerk of the governing body." Here, SWRCB has taken the position that Siskiyou County is not a Responsible Agency because FERC will preempt all of Siskiyou County's local permitting requirements. However, FERC has, in some dam removal cases, required licensees to obtain all local permits. See Arizona Public Service Co., 109 FERC 61,036 (2004), and Wisconsin Electric Power Co., 94 FERC 61,038 (2001). As FERC has explained to PacifiCorp in the past, "federal preemption does not necessarily mean that the Commission will not elect to require PacifiCorp to comply with those of the Counties' requirements that the Commission concludes will not interfere with the company's ability to carry out the Commission's orders"; rather, "[i]t only establishes that it is within the Commission's sole discretion to determine the extent to which such compliance will be required." (PacifiCorp Project No. 2342-18; Order available at: https://www.ferc.gov/whats-new/comm-meet/051806/H-2.pdf.) Given that counties may be permitted to exert regulatory authority to the extent its regulations do not make compliance with FERC orders impossible or unduly difficult, and given that FERC prefers licensees to be good citizens of the communities in which projects are located, and thus to comply with all local requirements, where possible, the SWRCB is in error in not consulting with the County as a Responsible Agency so that the EIR would be useful for its purposes as well.

Response to Comment LA9-9
Please refer to Master Response CEQ-2.

Comment LA9-10
Section 2.1 of the DEIR, Project Purpose and Objectives, outlines the SWRCB identified objectives of the Proposed Project as well as the underlying purpose. The purpose is "timely improving water quality related to the Lower Klamath Project within and downstream of the current Hydroelectric Reach and restoring anadromous access upstream of Iron Gate Dam." This purpose is unduly narrow. It appears the SWRCB and KRRC have conflated the underlying purpose, objectives, and Proposed Project. This is contrary to CEQA. North Coast Rivers Alliance, et al. v. A.G. Kawamura/Our Children's Earth Foundation, et al. v. California Department of Food and Agriculture (2015) 243 Cal.App.4th 647 (opining that failing to properly distinguish between the project purpose, project objectives, and project violates CEQA).

The four project objectives outline improvements to water quality and fish populations, but notably absent are considerations by the lead agency of any *consideration of the potential benefits for and costs to local communities, including but not limited to agricultural and ranching interests. The SWRCB should consider the interest of the citizens of Siskiyou County in their project objectives.*

Furthermore, the objective to "Restore volitional anadromous fish passage in the Klamath Basin to viable habitat currently made inaccessible by the Lower Klamath Project dams" is narrower than, and not justified by, the project purpose (improving water quality and upstream access). This objective can be used to justify dam removal over any other alternative including trap and haul or other means of assisted migration. Restoring volitional anadromous fish passage rather than conserving wild salmonid populations, for example, gives the appearance of purposefully manipulating the objectives in order to identify the applicant's long-preferred alternative of dam removal as the preferred alternative.

Response to Comment LA9-10

Please refer to response to comment LA9-3. Please also refer to Volume I Section 5.4 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA*. Additionally, please refer to Master Responses WSWR-1, WSWR- 2, WSWR-3, and WSWR-4, and to Volume 1 Section 3.15.5 *Agriculture and Forestry Resources – Potential Impacts and Mitigation* for further discussion regarding potential impacts to agriculture.

Comment LA9-11

Section 2.7 of the DEIR, Proposed Project, states that the Detailed Plan and Definite Plan constitute the applicant's Proposed Project. As the SWRCB is aware, the Definite Plan is currently being reviewed by FERC and the Independent Board of Consultants for technical adequacy. In fact, the project proponent has committed to revise the Definite Plan, issuing a new document in April 2019. See http://www.klamathrenewal.org/wp-content/uploads/2018/12/2018-12-12-Letter-Report-BOC-Mtg-No-1.pdf. According to Washoe Meadows Community v. Department of Parks and Recreation (2017) 17 Cal.App.5th 277, an EIR must contain an "accurate, stable, and finite" project description. Given the potential changes to the Proposed Project as a result of the commitment to issue revised documents, additional pending review and subsequent comments, using the draft plan as a basis for the project description and baseline for analysis is inadequate. Further, as FERC is the lead federal agency for the project, SWRCB should wait for their input on the Definite Plan before having forged ahead on the DEIR (CEQA Guidelines 15223). SWRCB's release of the DEIR precluded FERC's ability to review and comment on the project itself.

Section 2.7.8 of the DEIR, Project Component, summarizes project components outside of the major dam and powerhouse deconstruction. These components primarily address environmental, safety, and quality of life issues and are *outlined in the appendices to the Definite Plan. Siskiyou County has provided substantive comments on the Definite Plan (and appendices). As these components are instrumental in the mitigation of environmental impacts, please ensure that our comments are addressed in subsequent drafts of these essential components of the Proposed Project.*

Response to Comment LA9-11

Comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation (KRRC). Please refer to response to comment LA9-4 regarding sufficient stability of the Proposed Project and to Master Response CEQ-1 for a discussion of the relationship between the CEQA and the National Environmental Policy Act (NEPA).

Comment LA9-12

Section 15126.4(a) of the CEQA Guidelines states "(a) An EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, from both a local and regional perspective. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant."

There are many sections in the DEIR that rely on future surveys or studies to be prepared to identify resources or habitats that may be present in the project impact area. Without quality data that allow for an assessment of baseline conditions of resources within the project area, the impact analysis is unreliable. The impacts of a Proposed Project must be evaluated by comparing expected environmental conditions after project implementation to conditions at a point in time referred to as the baseline. The changes in environmental conditions between those two scenarios represent the environmental impacts of the Proposed Project. The adequacy of a document's baseline is a factual issue to be determined based on whether there is substantial evidence in the record supporting the agency's determination.

Baseline is not a policy choice to be made at the end of CEQA Review (Save Our Peninsula Committee v. Monterey County (2001) 87. Cal. App. 4th 99). For a new project, courts have required that the baseline reflect actual existing physical conditions at the start of environmental review. The DEIR relies on future surveys and studies to identify wetlands, special-status plants, culturally significant resources, special-status wildlife, groundwater wells, and other affected resources. The impact determination directly correlates to the existing or baseline conditions. If those conditions are unknown then making a determination of significance is not possible or reliable. The SWRCB has abdicated its responsibility in providing quality data regarding the baseline/existing conditions so that realistic and accurate impact determinations can be made. We have noted specifically in Table 1, below, where individual *resource topics do not have the adequate environmental setting information to make an informed impact analysis.*

Response to Comment LA9-12

As described in Volume I Section 3.1.2 *Introduction – Environmental Setting*, the EIR establishes and evaluates the relevant baseline as part of each resource area. The EIR incorporates available existing information to describe the baseline under CEQA. The environmental setting analysis relies on a range of available information, including studies that are relevant to the description of existing conditions. In some instances, the analyses discuss new or updated studies like those noted in the comment, to confirm the presence and/or extent of a particular resource that has been identified as potentially present using existing information, or to confirm whether associated impacts have the potential to occur. These additional studies can be relevant for a range of reasons, including the abundance of available data for characterizing a resource, the likelihood that data collected in prior studies would change over time and the rate of that change, and the degree of granularity in the existing data. Where the analyses discuss new or updated studies, the EIR conservatively assumes the presence and extent of resources in light of available information, and appropriately evaluates the breadth of potential impacts as well as feasible mitigation. This approach is consistent with CEQA's requirement to describe the environmental setting in order to "give the public and decision makers the most accurate and understandable picture practically possible of the project's likely near-term and long-term impacts" (CEQA Guidelines section 15125, subd. (a)).

Referencing ongoing studies related to current conditions or requiring further, more exact information regarding resources prior to implementation of a project does not constitute an impermissible delayed policy decision regarding establishment of a baseline.

The comment notes that Table 1 raises specific allegations of lack of specificity in the baseline. Please see the responses to those more specific comments, below.

Comment LA9-13

(1) An EIR shall describe feasible measures which could minimize significant adverse impacts, including where relevant, inefficient and unnecessary consumption of energy.

(A) The discussion of mitigation measures shall distinguish between the measures which are proposed by project proponents to be included in the project and other measures proposed by the lead, responsible or trustee agency or other persons which are not included but the lead agency determines could reasonably be expected to reduce adverse impacts if required as conditions of approving the project.

(B) This discussion shall identify mitigation measures for each significant environmental effect identified in the EIR.

(2) Mitigation measures must be fully enforceable through permit conditions, agreements, or other legally-binding instruments. In the case of the adoption of a plan, policy, regulation, or other public project, mitigation measures can be incorporated into the plan, policy, regulation, or project design.

Throughout the DEIR, the SWRCB refers to "measures that would not be considered feasible for the purposes of CEQA because the SWRCB cannot ensure that they would occur." In these cases, recommended measures are provided that would reduce potential impacts if implemented by KRRC. However, the impact analysis herein cannot rely on the implementation of these measures. In many of these cases the DEIR concludes that a significant and unavoidable impact would result. It is unclear why the SWRCB has taken this position with so many of the impacts. The excerpt below is from pages ES-9–ES-15.

"[T]he determination of whether a project will have significant environmental impacts, and the formulation of measures to mitigate those impacts, must occur before the project is approved." California Native Plant Society v. City of Rancho Cordova (2009) 172 Cal.App.4th 603, 621. Here, the SWRCB has failed to formulate mitigation measures, arguing time and again, it is not feasible to do so. For example, with respect to terrestrial resources, the SWRCB states: "implementation of terrestrial resources measures would be not be considered feasible for the purposes of CEQA because the State Water Board cannot ensure that they would occur. In these cases, recommended measures are provided that would reduce potential impacts if implemented by KRRC" (DEIR, p. 3-516). Where mitigation measures can be devised consistent with CEQA Guidelines Section 15126.4, the SWRCB cannot lawfully shirk its responsibility to identify such measures and require compliance with them in order to reduce impacts to less than significant. Importantly, "a condition requiring compliance with regulations is a common and reasonable mitigation measure, and may be proper where it is reasonable to expect compliance." Oakland Heritage Alliance v. City of Oakland (2011) 195 Cal. App. 4th 884, 906 cited in Center for Biological Diversity v. Department of Fish & Wildlife (2015) 234 Cal. App. 4th 214, 246. It is reasonable to expect compliance with the federal Endangered Species Act, pertinent provisions of the Fish and Game Code, and other federal and state laws. Therefore, the SWRCB must revise the DEIR to incorporate mitigation measures rather than recommended measures wherever possible. In those circumstances where the SWRCB believes it is not possible, it must comply with CEQA Guidelines Section 15126.4(a)(5) by explaining the reasoning for its determination. Simply reciting the conclusory claim that there are no feasible mitigation measures does not suffice. "The failure to provide enough information to permit informed decision-making is fatal." Napa Citizens for Honest Government v. Napa County Bd. of Supervisors (2001) 91 Cal. App. 4th 342,

361. Furthermore, in those circumstances where the SWRCB proposed recommended measures, consistent with Public Resources Code section 21081(a)(2), the SWRCB should clearly identify other public agencies that have the responsibility and jurisdiction to require implementation of those recommended measures.

Response to Comment LA9-13
Please refer to Master Response CEQ-2.

Comment LA9-14
The Executive Summary to the DEIR states:

Below is a summary, by resource area, of impacts found to be 'significant and unavoidable' with or without mitigation (Table ES-1). Please note, the KRRC proposes to further develop Proposed Project actions relating to certain state and local regulatory requirements for several resource areas that fall outside of State Water Board's water quality certification authority. The State Water Board anticipates implementation of additional measures (e.g., good neighbor agreements between the KRRC and relevant state or local agencies, recommended measures in this EIR, and any modifications developed through the FERC process that provide the same or better level of protection for the resource in question) would reduce impacts. The EIR notes where such protection would eliminate the potential for a significant impact. However, the State Water Board cannot ensure implementation of good neighbor agreements, recommended measures included in this EIR, or modifications anticipated to be developed through the FERC process. Therefore, the State Water Board has identified impacts that rely on implementation of such agreements or recommended measures in this EIR as significant and unavoidable.

DEIR at ES-11.

This section included significant and unavoidable impacts on the following resources: Water Quality, Aquatic Resources, Phytoplankton and Periphyton, Terrestrial Resources, Flood Hydrology, Air Quality, Historical Resources and Tribal Cultural Resources, Public Services, Aesthetics, Recreation, Hazards and Hazardous Substances, Transportation and Traffic, and Noise. Most of the resource areas also included recommended mitigation measures that the SWRCB states are not enforceable and therefore cannot be relied upon. In some cases the recommended measures are under the purview of other state or federal agencies that may require those measures through their permits or consultations that must be completed as part of the project permitting process and that may be enforceable by the permitting agency (e.g. California Department of Fish and Wildlife [CDFW] for special-status terrestrial species and rare natural communities or state-listed species; U.S. Fish and Wildlife Service [USFWS] and/or National Marine Fisheries Service [NMFS] for federally listed species, etc.).

The DEIR does not rely on other trustee or lead agency authority in cases where it reasonably could to ensure that these measures would be implemented to reduce impacts to less than significant. Part A of the above statute clearly indicates that "mitigation measures shall distinguish between" (1) "measures which are proposed by project proponents to be included in the project," and (2) "other measures proposed by the lead, responsible or trustee agency or other persons which are not included but the lead agency determines could reasonably be expected to reduce adverse impacts if required as conditions of approving the project."

The SWRCB asserts its authority to enforce or require mitigation for certain resources. As an example, the DEIR asserts that it has jurisdiction over wetlands and waterways and can enforce that mitigation, therefore concluding that it can imposed mitigation measures to mitigate effects to reptiles and amphibians so that they are less than significant (based on Mitigation Measure TER-2 − Amphibian and Reptile Management). This measure, just as any terrestrial mitigation measure, will require approval by CDFW and normally would be included in a Streambed Alteration Agreement (SAA) and, in the event any reptiles are listed as threatened or endangered, in a California Endangered Species Act (CESA) permit.

The SWRCB has interpreted law with respect to CEQA to provide that any required mitigation measures would have to be fully enforceable through SWRCB permit conditions. Therefore, where mitigation cannot be enforced by SWRCB under its non-CEQA authorities, such as the Porter Cologne Water Quality Control Act, the SWRCB must make significant and unavoidable impact determinations rather than identifying mitigation to mitigate effects to less than significant. The SWRCB goes on in these significant and unavoidable impact determinations to refer to "recommended measures" that if implemented would reduce impacts to less than significant. In many cases these measures would be reasonably expected to be conditions of approving the project by another trustee or responsible agency. One such example is CDFW through their responsibilities under Lake and Streambed Alteration Program. Section 1600 of the Fish and Game Code states:

The Legislature finds and declares that the protection and conservation of the fish and wildlife resources of this state are of utmost public interest. Fish and wildlife are the property of the people and provide a major contribution to the economy of the state, as well as providing a significant part of the people's food supply; therefore their conservation is a proper responsibility of the state.

The Lake and Streambed Alteration Program establishes a regulatory scheme to protect and conserve fish and wildlife resources, and the habitats upon which they depend. This includes notification to CDFW and a procedure to reach agreement with CDFW. This regulatory program codifies CDFW's responsibility *to protect public trust resources. The SWRCB, being a state agency likewise charged with protection of public trust resources, is responsible to ensure that conservation of fish and wildlife is part of any project it authorizes or acts as lead agency with respect to under CEQA. Because CDFW and the SWRCB are both state agencies, the EIR should require mitigation measures that avoid violation of state laws. The Water Board cannot simply determine that impacts are significant and unavoidable in violation of state law.*

The DEIR also includes significant and unavoidable impact determinations for several federally listed species using the same reasoning that SWRCB cannot enforce mitigation measures outside the water quality certification conditions. However, the significant and unavoidable impacts that would result from the Proposed Project to listed species (including Bald and Golden Eagle Protection Act [BGEPA] species) without USFWS consultation and approved avoidance, minimization and mitigation would be in violation of the ESA. Because the project will require both a U.S. Army Corps of Engineers (USACE) Section 404 permit and FERC surrender license, there is a federal nexus and both will require a Section 7 consultation with the USFWS. The SWRCB analysis should require:

1) implementation of Recommended Terrestrial Measures 3–12,
2) acquisition of an SAA from CDFW, and
3) consultation with the USFWS to secure a Biological Opinion or Letter of Concurrence to avoid violation of state and federal law.

Section 15126.2 of the CEQA Guidelines states:

(a) The Significant Environmental Effects of the Proposed Project. An EIR shall identify and focus on the significant environmental effects of the Proposed Project on the environment. In assessing the impact of a Proposed Project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published, or where no notice of preparation is published, at the time environmental analysis is commenced. Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects. The discussion should include relevant specifics of the area, the resources involved, physical changes, alterations to ecological systems, and changes induced in population distribution, population concentration, the human use of the land (including commercial and residential development), health and safety problems caused by the physical changes, and other aspects of the resource base such as water, historical resources, scenic quality, and public services. The EIR shall also analyze any significant environmental effects the project might cause or risk exacerbating by bringing development and people into the area affected. For example, the EIR should evaluate any potentially significant direct, indirect, or cumulative environmental impacts of locating development in areas susceptible to hazardous conditions (e.g., floodplains,

coastlines, wildfire risk areas), including both short-term and long-term conditions, as identified in authoritative hazard maps, risk assessments or in land use plans, addressing such hazards areas.

Response to Comment LA9-14

Please refer to Master Response CEQ-2 regarding preemption under the Federal Power Act including the effects of preemption on mitigation measures and responsible agencies. As discussed in Master Response CEQ-2, recommended measures to reduce impacts on federally-listed species to less than significant have been modified to be mitigation measures; coordination with applicable federal and state agencies has been incorporated within these mitigation measures, as appropriate. To reduce impacts on bald and golden eagles to a less than significant level, Recommended Terrestrial Measure 11 has been revised to be a Mitigation Measure (Mitigation Measure TER-7). To reduce impacts on grey wolf, Recommended Measure 8 has been revised to be a Mitigation Measure (Mitigation Measure TER-6). Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-Status Species and Rare Natural Communities* for these revised measures.

Additionally, this comment provides a summary introduction of items raised, with more specific items listed in commenter's Table 1. For a response to the more specific items raised in commenter's Table 1, please see the individual responses below.

<u>Comment LA9-15</u>

Data relied upon for the water quality analysis is too old to adequately assess existing conditions of the project area. The information relating to total phosphorus, total nitrogen, dissolved oxygen, pH, inorganic and organic matter, sediment contaminants, and aquatic biota contaminants is all over ten years old and does not represent the current environment, particularly given alterations in climate and surrounding land uses.

Response to Comment LA9-15

Please refer to Master Response WQ-4.

<u>Comment LA9-16</u>

The Klamath River Water Quality Model (KRWQM) includes the assumption that all waters that enter the state of California are fully compliant with applicable Total Maximum Daily Loads (TMDLs). That is, the model assumes that reservoir conditions and waters that flow into California meet all water quality standards for water temperature, organic enrichment/dissolved oxygen, nutrients, pH and microsystins. As such, the effects of dam removal on the TMDL target constituents are underestimated, since it's likely that the TMDLs will not be being met upstream. The DEIR then states: "dam removal would rapidly and substantially move the Hydroelectric Reach towards achieving California TMDL

Compliance." This is disingenuous, as it relies heavily on the improper and unsupported assumption that waters entering California will be TMDL-compliant. It also ignores the short term effects and the consequence of sending a huge, contaminated debris flow that will end up downstream of the Hydroelectric Reach, the Klamath River estuary, and the Pacific Ocean. The DEIR should analyze water quality constituents without assuming TMDL compliance upstream.

Response to Comment LA9-16
Please refer to Master Response WQ-5.

The language quoted in the comment – "dam removal would rapidly and substantially move the Hydroelectric Reach towards achieving California TMDL compliance" – is part of Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature*, so it is specifically referring to achieving California Total Maximum Daily Load (TMDL) compliance for water temperature. Additionally, it is the final sentence in the first full paragraph in Volume I page 3-76 describing why this conclusion is accurate for water temperature despite the California Klamath River TMDL model's assumption of compliance. Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* has been revised to clarify that dam removal would rapidly and substantially move the Hydroelectric Reach towards achieving California TMDL compliance for water temperature. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Sediment impacts are addressed in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments*, not in the cited temperature section. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment LA9-17
The KRWQM model notes that removal of the dams would increase water temperatures in the spring, with climate change possibly resulting in a 1.8˚F to 5.4˚F increase in water temperatures. With increases in temperatures between 1.8˚F to 5.4˚F, conditions for spring spawners and adult/juvenile migration would potentially be worse than with the dams in place, as the dams are able to release deeper, cold water during the spring and summer months. Also, for the Middle and Lower Klamath, Estuary, and Pacific Nearshore environment, the KRWQM predicts warmer water during April through August (migration/spring spawning) and warmer (4–18˚F) water during August through November (fall spawning time). The DEIR should consider the negative effects of warmer water on migrating and spawning salmonids.

Response to Comment LA9-17
Please refer to Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 for a discussion of the potential

impacts of the Proposed Project on water temperature in the Klamath River. The model results discussed in the comment are not from the Klamath River Water Quality Model (KRWQM). The model results are from the River Basin Model-10 (RBM-10) model that estimates Klamath River water temperature conditions from Link River Dam to the Pacific Ocean over the next 50-years under climate change for a scenario with the Lower Klamath Project dams remaining in place (i.e., "dams-in") under 2010 BiOp Flows and for a scenario with the Lower Klamath Project dams removed (i.e., "dams out") under Klamath Basin Restoration Agreement Flows (KBRA Flows). In addition to water temperature changes due to the dams remaining in place or the dams being removed, water temperature was predicted to increase 1.8ºF to 5.4ºF under both "dams in" and "dams out" scenarios over the next 50-years due to climate change (Perry et al. 2011). Water temperature increases under climate change generally resulted in a progressive, nearly uniform increase in water temperature throughout the modeled Klamath River reaches over time, suggesting variations in the flow between the "dams-in" and "dams-out" scenarios did not influence the predicted increase in water temperature from climate change.

Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Water Temperature* provides an analysis of water temperature dynamics and effects on aquatic resources under existing conditions. Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature* provides an analysis of the potential influence of warmer water on salmonids, including the potential for adverse impacts to aquatic resources due to increased water temperatures during spring and summer under the Proposed Project. The Chinook Salmon Expert Panel concluded that Lower Klamath Project dam removal offers greater potential than the existing conditions for Chinook salmon to tolerate climate change and changes in marine survival (Goodman et al. 2011). Similarly, the Coho Salmon and Steelhead Expert Panel concluded that dam removal would provide greater mitigation to climate change for coho salmon and steelhead than existing conditions (Dunne et al. 2011). Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impacts 3.3-7, 3.3-9, and 3.3-10 provide discussion of the effects of dam removal on Chinook salmon, coho salmon, and steelhead populations, including changes in water temperature under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Please also refer to Master Response WQ-2.

Comment LA9-18

If barriers are removed to allow upstream access by Oncorhynchus mykiss irideus (steelhead), the potential effects of this subspecies on O. mykiss newberrii, and vice versa, needs to be analyzed in the DEIR. Hatcheries have had a large influence on the genetic structure of salmonids in the basin, and *thought should be given to how restoring upstream passage may affect the resident trout population.*

- "In addition, non-native stocks of O. mykiss have been widely planted in the basin, and large hatcheries exist on both the Klamath (Iron Gate Hatchery) and Trinity (Trinity River Hatchery) rivers. The extent of their genetic impact on wild, naturally-spawning, O. mykiss is not known." (Pearse et al 2007)

Response to Comment LA9-18

Volume I Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-18 discusses how removal of Lower Klamath Project dams under the Proposed Project and resulting habitat access to steelhead (*O. mykiss*) would affect resident redband trout. Because these two species evolved together in the Upper Klamath Basin of the Klamath River and co-existed prior to the construction of dams (Goodman et al. 2011), there is no predicted significant impact to either species from restoring the potential for interactions. Pearse et al. (2007) does not raise concerns about genetic implications from interactions between *O. mykiss* downstream and upstream of Iron Gate Dam, and their research did not include collection of samples upstream of Iron Gate Dam. Both populations have already been subjected to hatchery trout genetics, there have been no steelhead hatchery releases from Iron Gate Fish Hatchery since 2012, and the comment presents no information that is not already included in the EIR appropriate for assessing species interactions. Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-18 has been revised to include discussion of the information presented in Pearse et al. (2007). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment LA9-19

California Fish and Game Code 2081.11 states that "(a) The department may authorize, under this chapter, the take or possession of the Lost River sucker (Deltistes luxatus) and shortnose sucker (Chasmistes brevirostris) resulting from impacts attributable to or otherwise related to the decommissioning and removal of the Iron Gate Dam, Copco 1 Dam, Copco 2 Dam, or J.C. Boyle Dam, consistent with the Klamath Hydroelectric Settlement Agreement, if all of the following conditions are met:

- (1) The department determines the authorized take will not jeopardize the continued existence of the Lost River sucker or shortnose sucker.

- (2) The impacts of the authorized take are minimized.

- (3) The take authorization provides for the development and implementation of an adaptive management plan, approved by the department, for monitoring the effectiveness of, and adjusting as necessary, the measures to minimize the impacts of the authorized take.

- (b) This section shall not be construed to exempt the project described in subdivision (a) from any other law."

Most work with these species is centered on their status in Upper Klamath Lake and the tributaries that feed the lake. There is no recent information presented addressing the status of the population in the downstream reservoirs. The KRRC cites work conducted by Desjardins and Markle (2000), which was approximately 20 years ago. Desjardins and Markle (2000) indicated that further studies were needed to investigate recruitment of adults and juveniles. Therefore, there is a data gap on the current status of these species in these downstream reservoirs. If adequate recruitment to spawning age is an issue in both the Upper Klamath Lake and downstream areas, it is improper to sacrifice the downstream population as a "sink population" without adequately understanding and describing the justification (i.e., genetics, current population structure). As stated in the U.S. Geological Survey (USGS) Report (Hewitt et al 2018), "Despite relatively high survival in most years, we conclude that both species have experienced substantial decreases in the abundance of spawning adults because losses from mortality have not been balanced by recruitment of new individuals." Furthermore, this position is reflected in another USGS Report (Burdick et al. 2018), which states: "Upper Klamath Lake populations are decreasing because adult mortality, which is relatively low, is not being balanced by recruitment of young adult suckers into known spawning aggregations. Most Upper Klamath Lake juvenile sucker mortality appears to occur within the first year of life."

Response to Comment LA9-19

Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Fish – Resident Riverine Fish Species – Lost River and Shortnose Suckers* provides a comprehensive summary of recent information used to inform the USFWS (2013) revised recovery plan, which determined that the populations in Iron Gate and Copco No. 1 reservoirs are "sink populations" and are not likely to be self-sustaining. The issues noted in the comment regarding a reduction in survival of the sucker population in Upper Klamath Lake (citing recent reports) are not potentially alleviated by the existing sucker populations in Iron Gate and Copco No. 1 reservoirs. Low recruitment in the reservoir populations is due to the lack of access to spawning habitats, as described in Moyle (2002) and NRC (2004), and as determined through extensive sampling conducted by Oregon State University, citing Desjardins and Markle (2000). No data are available, and United States Fish and Wildlife Service (USFWS) has released no information to suggest that the sink populations in Iron Gate and Copco No. 1 reservoirs are a viable source for supporting the Upper Klamath Lake population.

The issues of poor recruitment, reduced survivorship of adults, and low age class diversity are discussed in the recovery plan for these species (USFWS 2013), and the discussion is consistent with the information included in the Hewitt et al.

(2018) and Burdick et al. (2018) United States Geological Survey (USGS) reports mentioned in the comment.

Comments regarding the summary of Fish and Game Code 2081.11 noted.

Comment LA9-20

In the DEIR, the Resident Fish Panel Expert states that the Upper Klamath Lake populations are self-sustaining. However, both reports from the USGS on adult (Hewitt et al 2018) and juvenile status (Burdick et al. 2018) indicate inadequate numbers of new spawning recruits. Therefore, the Panel's findings are inconsistent with current science on the Lost River and shortnose Suckers. This inconsistency should be acknowledged and discussed.

Response to Comment LA9-20

The comment claims that recent United States Geological Survey (USGS) reports (Hewitt et al. 2018 and Burdick et al. 2018) demonstrate that the Upper Klamath River sucker populations are no longer "self-sustaining." However, this appears to be a misunderstanding of the term "self-sustaining". The cited reports affirm that the status of the Lost River and Shortnose sucker populations in Upper Klamath Lake remains distressed. "Self-sustaining" simply means that the population is capable of occurring without influence from other sucker populations. The endangered status of these species clearly speaks to the United States Fish and Wildlife Service (USFWS) position that the population abundances are in decline. The issues of poor recruitment, reduced survivorship of adults, and low age class diversity are discussed in the recovery plan for these species (USFWS 2013).

Comment LA9-21

If the USFWS or other agencies are worried about hybridization of Klamath smallscale suckers (Catostomus rimiculus) with the other sucker species, as detailed in the 2013 Biological Opinion (USFWS 2013), removal of barriers such as J.C. Boyle Dam could allow access of Klamath smallscale suckers to migrate upstream where Lost River and Shortnose suckers more commonly occur. This could potentially increase incidences of hybridization. This is further stated as a concern by Buettner et al. (2006) and others to caution against supporting migration of individuals from Iron Gate and Copco Reservoirs into the Upper Klamath Lake population.

Response to Comment LA9-21

Hybridization of Klamath smallscale suckers is directly addressed in the EIR through the discussion of implementing Klamath River Renewal Corporation's (KRRC's) proposed Aquatic Resource Measures. The Aquatic Resource Measures are summarized in Section 2.7.8.1 *Proposed Project – Proposed Project – Other Project Components – Aquatic Resource Measures* and detailed in Volume II Appendix B: *Definite Plan − Appendix I*. The Proposed Project includes Aquatic Resource Measure AR-6 (*Suckers*) to reduce the short- and long-term effects of reservoir removal (including increased connectivity to upstream habitats). Aquatic Resource Measure AR-6 involves the following two primary actions: reservoir and river sampling to estimate the abundance of suckers in the Hydroelectric Reach and to conduct genetic testing for hybridization; and, sucker salvage and release into waterbodies isolated from the Upper Klamath Lake populations. The proposed actions are anticipated to increase the survival of individual Lost River and shortnose suckers currently inhabiting the Hydroelectric Reach, without increasing exposure of the Upper Klamath Lake population to adults that possess a high degree of hybridization.

Smallscale sucker have been found to be common in J.C. Boyle Reservoir (Buettner et. al 2006) and improving connectivity in the Hydroelectric Reach through dam removal has not been identified as a short-term or long-term concern with respect to the potential for increasing hybridization between smallscale sucker and federally listed Lost River and shortnose suckers. Buettner et al. (2006) note that Miller and Smith (1981) claimed that hybridization was pronounced in the hydroelectric reservoirs, but Buettner et al. (2006) do not provide evidence, or state a concern, with hybridization resulting from potential upstream habitat connectivity. The USFWS Biological Opinion (2013) does not state a concern with removal of J.C. Boyle Dam, or suggest a link between increased habitat connectivity and hybridization, both as suggested in the comment. USFWS (2013) states that hybridization among Klamath Basin suckers is consistent with a pattern of historical intercrossing.

In addition, minor typographical errors in the section this comment refers to, Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species,* have been corrected. Please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species* for the revisions.

Comment LA9-22

The USFWS logic in the 2013 Revised Recovery Plan to not include the downstream reservoirs, downstream of Keno Dam, under Critical Habitat designation for the Lost River Sucker and Shortnose Sucker are based on Primary Constituent Elements. However, data on the population status of the Lost River Sucker and Shortnose Sucker should be updated prior to assuming the sucker populations downstream of Keno Dam are part of a sink population. During sampling in 1998 and 1999, Desjardins and Markle (2000) found all developmental stages of Shortnose Sucker at J.C. Boyle and Copco Dams. The downstream reservoirs, while artificially created, currently provide some level of habitat for these sucker species. In a Joint Press Release dated February 20, 2014 between the USFWS and PacifiCorp (USFWS and PacifiCorp 2014), it is stated that "the majority of remaining affected suckers are not part of reproducing populations since they reside in downstream reservoirs, which are outside of their historic range." While these suckers may not have been present in these areas prior to dam installation, the installation of dams and the associated reservoirs now provide some level of habitat for these ESA sucker species.

Response to Comment LA9-22

Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Lost River and Shortnose Suckers* provides a comprehensive summary of the best available scientific information on sucker populations in the Lower Klamath Project hydroelectric reservoirs, including a detailed summary of the results of the sampling conducted by Desjardins and Markle (2000) in 1998 and 1999 that documented multiple life stages of suckers in the hydroelectric reservoirs. This section reflects the information used to inform the 2013 revised recovery plan. The federal agency responsible for the recovery of the Lost River and Shortnose suckers concluded in the recovery plan that the populations in Iron Gate and Copco No. 1 reservoirs are "sink populations" and are not likely to be self-sustaining, nor do they contribute to the recovery goals for the sucker populations. Low recruitment in the reservoir population is due to the lack of access to spawning habitats, as described in Moyle (2002) and NRC (2004), and as determined through extensive sampling conducted by Oregon State University, citing Desjardins and Markle (2000). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources.*

Comments regarding USFWS's process of critical habitat designation are noted. Designation of critical habitat by USFWS is not under the purview of the State Water Board and is not part of the Proposed Project analyzed in this EIR.

Comment LA9-23

Similar to Impact 3.3-1, the DEIR concludes that there is no significant impact to EFH with implementation of AQR-1 and AQR-2. However, these mitigation measures (MMs) are directed at species rather than EFH. The impact to EFH occurs even with implementation of mitigation and should be considered significant.

Response to Comment LA9-23

In addition to addressing impacts to species, Klamath River Renewal Corporation's (KRRC's) proposed Aquatic Resource Measures AR-1 and AR-2 include components that directly alleviate impacts to fish habitat (including essential fish habitat; EFH), including spawning and migratory habitat. Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resources Impacts* describes potential impacts on Chinook and coho salmon EFH (and critical habitat) quality and quantity due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal (see Potential Impact 3.3-4).

Proposed Aquatic Resource Measure AR-1 (Mainstem Spawning) would improve habitat connectivity from the Klamath River into tributaries by addressing sediment and debris obstructions that block volitional upstream passage, thereby increasing and improving access to fish habitat. Aquatic Resource Measure AR-1 also includes an evaluation and proposal of other actions to improve rearing and spawning habitat such as large woody material installation, riparian plantings, or cattle exclusion fencing. Additional actions would be implemented if spawning habitat conditions following dam removal do not meet target metrics including gravel augmentation in the mainstem, with additional spawning habitat actions in tributaries, thereby directly improving EFH and critical habitat.

Proposed Aquatic Resource Measure AR-2 (Juvenile Outmigration) would require actions to maintain connectivity to EFH and critical habitat to ensure volitional fish passage between tributaries and the Klamath River, and it would provide for the development of a water quality monitoring network, trigger thresholds, and plan for relocating juvenile fish from tributary confluence areas to cold water tributaries or nearby off-channel ponds.

As described in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resources Impacts*, in addition to the KRRC's proposed measures the EIR includes Mitigation Measures AQR-1 and AQR-2 to increase certainty of the effectiveness of the Aquatic Resource Measures AR-1 and AR-2. EIR Mitigation Measures AQR-1 and AQR-2 specify that monitoring shall also be conducted following a significant (5-year) flow event, even if that flow event occurs more than two years following dam removal. Implementation of Mitigation Measures AQR-1 and AQR-2 would increase the frequency of monitoring and extend the monitoring period for implementing proposed Aquatic Resource Measures AQ-1 and AQ-2. Increasing the frequency of monitoring and extending the monitoring period would improve EFH and critical habitat conditions for Chinook and coho salmon by ensuring that the actions specified under proposed Aquatic Resource Measures AR-1 and AR-2 are protective for a longer duration if necessary. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources.*

Comment LA9-24

The SWRCB relies on Mitigation Measure AQR-1 − Mainstem Spawning, and Mitigation Measure AQR-2 − Juvenile Outmigration, to reduce impacts to coho critical habitat to less than significant. These measures reduce impacts to the species. Also, the question remains as to why the SWRCB believes that the salvaging and relocation of a listed species that is both federally and state-listed as threatened (under the purview of NMFS and CDFW) is enforceable as part of the Water Quality Certification conditions but cannot do the same for other species or habitats (e.g. terrestrial special-status plants or species).

Response to Comment LA9-24

Please refer to response to comment LA9-23 for discussion of how AQR-1 and AQR-2 will protect habitat for fish species. Please also refer to Master Response CEQ-2 for discussion of the effect of federal preemption on the enforceability of mitigation measures and how mitigation for potential impacts to some terrestrial species can be accomplished pursuant to federal authorities.

Comment LA9-25
Similar to Impact 3.3-1, the DEIR concludes that there is no significant impact to EFH with implementation of AQR-1 and AQR-2. However, these mitigation measures (MMs) are directed at species rather than EFH. The impact to EFH occurs even with implementation of mitigation and should be considered significant.

Response to Comment LA9-25
The comment's assertion that Mitigation Measures AQR-1 and AQR-2 are not directed at fish habitat is incorrect. Please refer to response to comment LA9-23 for discussion of how potential impacts to Essential Fish Habitat (EFH) and critical habitat will be mitigated to less than significant levels.

Comment LA9-26
The SWRCB relies on Mitigation Measure AQR-1 − Mainstem Spawning, and Mitigation Measure AQR-2 − Juvenile Outmigration, to reduce impacts to coho critical habitat to less than significant. These measures reduce impacts to the species, and not the critical habitat.

Response to Comment LA9-26
Please refer to responses to comments LA9-23 and LA9-25.

Comment LA9-27
The DEIR states that "cool groundwater spring inputs in the Williamson River and the south side of Upper Klamath Lake would likely provide thermal refugia for the non-migratory juvenile salmonid rearing life stages." However, this statement overlooks the fact that juveniles will be forced into crowded conditions with many other species of native and non-native fishes and these crowded conditions would likely increase the potential for disease outbreaks. Furthermore, these spring inputs should be counted, identified, and quantified in a way that substantiates this conclusion.

Response to Comment LA9-27
Please refer to Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites* for a discussion of disease risk in the Williamson River following the Proposed Project. There is some concern regarding a disease zone in the lower Williamson River downstream from the confluence with the Sprague River, where there are currently high parasite densities observed (Hurst et al. 2012). However, maximum temperatures in the Williamson River do not exceed the disease threshold of 59°F in all years analyzed (Bartholomew and Foott 2010, Hamilton et al. 2011). Overall, the risk of a juvenile salmon disease response in the Williamson River would be lower than under existing conditions in the Middle Klamath River, but not negligible in all water years (S. Foott, USFWS, pers. comm., 2012). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources.* Please also refer to

Master Response AQF-5 for a discussion of potential for conditions upstream of Iron Gate Dam to result in a new disease nidus.

Please refer to response to comment ORG46-235. Please also refer to Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-8 and Volume I Section 3.7.2.1 *Groundwater – Environmental Setting – Regional Groundwater Conditions* (page 3-641), which cite the work of Gannet et al. (2007), for the most recent and comprehensive attempt to estimate the groundwater level gradients and flow patterns within the vicinity of the Lower Klamath Project reservoirs.

Comment LA9-28

The statement regarding young salmon having the option to feed at night when water temperatures are cooler fails to recognize that the primary feeding times for juveniles is the crepuscular hours and they do not typically feed at night because of low light visibility (Schabetzberger, et al. 2003). Young salmon, not being able to consume adequate amounts of food on a daily basis, will compromise their ability to be fit for migration to the ocean and still experience average survival rates. This data is not taken into account and would conflict with the Proposed Project's purported benefits to salmonids due to reductions in minimum daily temperatures.

Response to Comment LA9-28

Section 3.3.5.4 *Aquatic Resources – Environmental Setting – Potential Impacts and Mitigation – Water Temperature* provides additional supporting information for the overall conclusion that reductions in minimum daily temperatures below those under existing conditions would benefit salmonids in the Klamath River mainstem, helping them to tolerate the warmer periods of the year when dwelling in the mainstem, but also allowing feeding excursions when confined to refugia during the warmer times of the day. NRC (2004) concludes that cooler temperatures at night may allow rearing fish to move out of temperature refugia to forage at night, allowing growth to occur even when ambient day time temperatures are above optimal. Foott et al. (2012) directly tested the effect of diurnal (including nighttime conditions) fluctuating water temperature profiles similar to what would be observed in the Klamath River under the Proposed Project, and the authors observed positive growth and no apparent effect of elevated temperature on immune function or fitness in Klamath River juvenile Chinook salmon held over a 23-day period under conditions in a laboratory. Feeding apparently did not decrease enough under nocturnal conditions to substantially affect growth. Salmonids in the Klamath River have been observed to use cooler hours to migrate between thermal refugia (Belchik 2003), and the decrease in minimum temperatures during the spring, summer, and fall under the Proposed Project would be beneficial for fish (Figure 3.3-3). Increased nighttime cooling of water temperatures is important to salmonids in warm systems, providing regular thermal relief, time for repair of proteins damaged by thermal stress, and significant bioenergetic benefits that help fish persist under marginal conditions despite the potential for reduced nighttime feeding (Schrank et al. 2003, NRC 2004). In addition, Dunsmoor and Huntington (2006) suggest that lower nighttime temperatures with dam removal would allow fish to leave thermal refugia in the Klamath River to forage and thereby allow more effective use of the available refugia habitat. Overall, the Proposed Project reductions in minimum daily temperatures below those under existing conditions would benefit salmonids in the Klamath River mainstem, helping them to tolerate the warmer periods of the year when dwelling in the mainstem, but also allowing feeding excursions when confined to refugia during the warmer times of the day. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources.*

Comment LA9-29

Significant impacts associated with critical habitat are related to potential effects or impairment of the Primary Constituent Elements (PCEs) within the Action Area of the Proposed Project. The impact determination on critical habitat PCEs includes salvaging and relocating fish. Yet, the DEIR states that the Proposed Project would have no significant impact on coho salmon critical habitat in the short term. This is not accurate.

Response to Comment LA9-29

The comment appears to misunderstand the EIR analysis regarding coho salmon critical habitat. Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-1 concludes there would be no significant impact *with mitigation*. Primary Constituent Elements (PCEs) for Southern Oregon/Northern California Coast (SONCC) coho salmon are described in National Marine Fisheries Service [NMFS] (1999b) as follows: "In addition to these factors, NMFS also focuses on the known physical and biological features (PCEs) within the designated area that are essential to the conservation of the species and that may require special management considerations or protection. These essential features may include, but are not limited to, spawning sites, food resources, water quality and quantity, and riparian vegetation."

The effects on PCEs and critical habitat are analyzed in EIR Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation –Aquatic Resource Impacts* (Potential Impact 3.3-1). The EIR states that: "Based on the substantial short-term decrease in quality of the features of critical habitat and PCEs supporting SONCC coho salmon, there would be a significant impact to coho salmon critical habitat under the Proposed Project in the short term. However, the Proposed Project includes aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on coho salmon PCEs of critical habitat."

With implementation of Mitigation Measures AR-1 and AR-2, the Proposed Project would have no significant impacts to coho salmon critical habitat in the short term.

Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment LA9-30

The SWRCB relies on Mitigation Measure AQR-1 − Mainstem Spawning, and Mitigation Measure AQR-2 − Juvenile Outmigration, to reduce impacts to coho critical habitat to less than significant. These measures reduce impacts to the species. Also, the question remains as to why the SWRCB believes that the salvaging and relocation of a listed species that is both federally and state-listed as threatened (under the purview of NMFS and CDFW) is enforceable as part of the Water Quality Certification conditions but cannot do the same for other species or habitats (e.g. terrestrial special-status plants or species).

Response to Comment LA9-30

Please refer to the responses to comments LA9-23 and LA9-24. Please also refer to Master Response CEQ-2.

Comment LA9-31

Dam removal and fish passage projects in Washington are used as examples of "rapid recolonization" following implementation. These examples are inapposite to the Proposed Project, however, because they included good water quality as a baseline condition. That is not the case here. To the contrary, it is unlikely the Klamath River will ever achieve the level of water quality that was achieved in those sample projects. This was recognized by the Chinook Salmon Expert Panel (page 3-301): "While the Chinook Salmon Expert Panel agreed that there was also evidence that potential dramatic increases in abundance associated with potential fish passage upstream of Keno Dam as well, they cautioned that achieving substantial gains in Chinook salmon abundance and distribution in the Klamath Basin is contingent upon successfully resolving key factors that would continue to affect the population, including water quality in Upper Klamath Lake and Keno Reservoir, disease, colonization of the Upper Klamath River Basin, harvest and escapement, hatchery interactions, predation by resident fish, climate change, instream flows, and impacts from dam removal."

Response to Comment LA9-31

As noted in the comment, Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* (Potential Impact 3.3-7) describes potential differences between the Proposed Project and examples of dam removal and fish passage projects that occurred elsewhere. Multiple examples of dam removals conducted elsewhere are provided in the Draft EIR as examples, not as the sole or primary evidence for recolonization in the Klamath Basin. Rather, the Draft EIR uses multiple lines of evidence, including the Evaluation of Dam Removal and Restoration of Anadromy (EDRRA) approach to inform and support the recolonization analysis.

Similarities and differences between the Proposed Project and examples of dam removal and fish passage projects from elsewhere are described and these comparisons provide valuable context. The differences between the Proposed Project and other project examples were considered when predicting potential outcomes of dam removal under the Proposed Project.

As noted by the Chinook Salmon Expert Panel, water quality is a concern under existing and dam removal conditions and was considered in assessing the effects of the Proposed Project. Section 3.3.5.3 *Aquatic Resources – Potential Impacts and Mitigation – Water Quality* describes potential impacts related to water quality conditions that were considered when analyzing the potential impacts of the Proposed Project on aquatic resources, and includes discussion of the water quality concerns raised by the Expert Panel. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment LA9-32

On February 8, 2019, the California Fish and Game Commission declared a finding of emergency and statement of proposed emergency regulation relating to the Upper Klamath-Trinity Spring Chinook Salmon. The proposed emergency regulations will make the Klamath River Basin Spring Chinook Salmon a candidate species under the California Endangered Species Act receiving full take protection while the Department of Fish and Wildlife considers a 'threatened' or 'endangered' listing. The DEIR should provide an update to the environmental setting and impact analysis assuming the spring-run Chinook Salmon would be listed under the California Endangered Species Act and provide any mitigation to limit impacts per presumed compliance with an Incidental Take Permit (California Fish and Game Code Section 2081).

Response to Comment LA9-32

Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species* has been revised to describe the recent decision by the California Fish and Game Commission to consider listing Upper Klamath Trinity River Spring Chinook. Please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species* for the revisions.

Listing of spring-run Chinook by California Department of Fish and Wildlife (CDFW) would not change the existing physical conditions of the environmental setting or the conclusions of the analysis of potential impacts to spring-run Chinook that are set out in the EIR Section 3.3.2.1 *Aquatic Species – Spring-Run Chinook Salmon – Anadromous Fish Species*. The analysis of potential impacts of the Proposed Project on spring-run Chinook salmon is presented in Potential Impact 3.3-8. The EIR concludes no significant impact for spring-run Chinook salmon populations in the short term, and beneficial for spring-run Chinook salmon populations in the long term. Although the EIR finds no significant impact on spring-run Chinook salmon, the Klamath River Renewal Corporation (KRRC) proposes Aquatic Resource Measure AR-2 (Juvenile Outmigration), which would further reduce the potential for short-term effects of suspended sediment concentrations (SSCs) on salmonid juveniles and smolts, including spring-run Chinook salmon. In addition, although CEQA Guidelines section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, Mitigation Measure AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would further reduce the potential for short-term, less than significant effects of the Proposed Project on spring-run Chinook salmon.

Comment LA9-33

Citing other Klamath River documents, the authors of the DEIR accepts the statement that clams live in buried sediment and therefore are not affected by the sediment loads that will inundate the Klamath River bed. However, studies have shown that organisms like the razor clam can only tolerate single events of additional sediment (12 cm or less) for a short period (Vavrinec, et al. 2007) and events that introduce more than 26 cm of sediment over the top of an existing clam bed can result in greater than 70 percent mortality.

Response to Comment LA9-33

As described in Potential Impact 3.11-5, Sedimentation and River Hydraulics sediment transport model (SRH-1D) model simulations project up to approximately 1.7 feet of reach-averaged dam-released sediment deposition between Bogus Creek (river mile [RM] 192.68) and Willow Creek (RM 187.8) in the short-term (less than 2 years) and up to 0.9 feet between Willow Creek and Cottonwood Creek (RM 185.1). SRH-1D model simulations did not project any significant sediment deposition downstream of Cottonwood Creek. This deposition will occur during and following drawdown, with further remobilization and deposition in association with precipitation-driven flow events following dam removal, typically lasting for several hours and separated by several days or weeks. The results of Vavrinec et al. (2007) suggest that clams may not survive deposition over 0.9 feet in the reach between Bogus Creek (RM 192.68) and Willow Creek (RM 187.8), where Anodonta spp. populations closest to Iron Gate Dam are likely to be most affected (as described above). The results of Vavrinec et al. (2007) further suggest that for clams downstream of Willow Creek there is likely to be high survival following deposition of 0.9 feet or less, especially if there is at least 24 hours between burial events. Therefore, it is predicted that freshwater clams located downstream of Willow Creek (RM 187.8) can survive deposition events such as those predicted to occur following dam removal (Vavrinec et al. 2007) and are expected to avoid impacts from bed deposition. While the comment uses razor clams as an example species, razor clams are marine bivalves that are not found in the freshwater reaches of the Klamath River analyzed under Potential Impact 3.3-19.

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-19 has been revised to incorporate the Vavrinec et al. (2007) results. Please refer to Volume III Attachment 1 Section

3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-19 for the revisions.

Comment LA9-34

Absent a wetland delineation, impacts to wetlands are unknown, avoidance cannot be assured and therefore impacts cannot be quantified.

Response to Comment LA9-34

As discussed in Volume I Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-1 (pages 3-518 and 3-519), a wetland delineation was anticipated within the limits of construction around the dams and facilities, access and haul roads, and disposal sites prior to the initiation of construction; this delineation was completed in July of 2019 (KRRC 2019c). The results of the wetland delineation will be incorporated into the Proposed Project design to avoid and minimize direct impacts on wetlands to the maximum extent feasible, and wetland areas adjacent to the construction Limits of Work (Volume I Section 2.2 *Proposed Project – Project Location* Figure 2.2-5 and Volume 1 Section 2.7.1 *Proposed Project – Proposed Project – Dam and Powerhouse Deconstruction* Figures 2.7-2, and 2.7-4) would be fenced to prevent inadvertent entry. Implementation of Mitigation Measure TER- 1 would require the use of sufficient buffers to ensure no significant environmental impacts to wetlands. Furthermore, for those wetlands that cannot be avoided, the Reservoir Area Management Plan includes details for the installation of native plants and aerial, barge, or hand seeding in appropriate areas to re-vegetate all areas disturbed during construction with a goal of no net loss of wetland or riparian habitat acreage and functions. Potential Impact 3.5-1 has been clarified to indicate that the amount of wetland and riparian habitat created through dam removal and revegetation efforts would far exceed the acreage of any existing, fully established wetlands and/or riparian vegetation for which a small portion of wetlands and/or riparian vegetation would not be avoided during construction activities. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-35

Potential Impact 3.5-1 is related to construction impacts however, the text goes back and forth between long- and short-term impacts and it is difficult to decipher what is being analyzed as an effect in this section. Discussing the Reservoir Area Management Plan and no net loss of wetlands in a construction impact is confusing.

Response to Comment LA9-35

Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* has been revised to clarify the definition of short-term effects. Please refer to Volume III Attachment 1 Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* for the revisions.

Potential Impact 3.5-1 in Volume I Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* (pages 3-518 and 3-519) addresses potential short-term impacts due to construction; this impact analysis does not address potential long-term impacts due to the Proposed Project. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-36

Mitigation Measure TER-1 provides buffers for avoiding existing wetlands during construction. It is unclear if the SWRCB is relying on the Reservoir Area Management Plan as mitigation for this impact. This should be clarified.

Response to Comment LA9-36

If a wetland is identified and avoidable, implementation of Mitigation Measure TER-1 would ensure that there would be no significant impacts to wetlands; the wetland would be fenced with appropriate buffers to avoid inadvertent entry. The State Water Board has the authority to include this mitigation measure in its water quality certification for the project. Please see Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the final Mitigation Measure TER-1. If a wetland cannot be avoided, the Reservoir Area Management Plan, which is part of the Proposed Project rather than a mitigation measure, includes measures to revegetate all areas disturbed during construction. Potential Impact 3.5-1 has been clarified to indicate that the amount of wetland and riparian habitat created through dam removal and revegetation efforts would far exceed the acreage of any existing, fully established wetlands and/or riparian vegetation for which a small portion of wetlands and/or riparian vegetation would not be avoided during construction activities. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-37

Surveys for these species have not yet occurred so presence and quantification of these species is not known.

Response to Comment LA9-37

As discussed in Volume I Section 3.5.5.2 *Terrestrial Resources – Potential Impacts and Mitigation – Culturally Significant Species* Potential Impact 3.5-6 (page 3-524), as part of the Proposed Project, updated inventories of wetland and riparian vegetation around the reservoir perimeters were anticipated; these inventories were completed in 2019 (KRRC) Potential Impact 3.5-6 in Section 3.5.5.2 *Terrestrial Resources – Potential Impacts and Mitigation – Culturally Significant Species* (page 3-524) has been clarified in light of this data. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-38

The mitigation includes several actions to survey for wetlands and encourage rapid revegetation with native riparian species in the reservoir footprints as defined in the Reservoir Area Management Plan (Appendix B: Definite Plan – Appendix H) to ensure no net loss of wetland or riparian habitat acreage and functions. These measures, however, only address long term impacts, and ignore short term impacts.

Response to Comment LA9-38

Potential Impact 3.5-6 in Section 3.5.5.2 *Terrestrial Resources – Potential Impacts and Mitigation – Culturally Significant Species* has been clarified. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-39

Surveys for special-status species and rare natural communities should be conducted prior to ground disturbance, but impacts cannot be quantified, or significance determinations made, absent a baseline.

Response to Comment LA9-39

The Draft EIR identified special-status plant species and rare natural communities with the potential to occur within the Primary Area of Analysis. The Draft EIR anticipated that comprehensive floristic surveys would be conducted prior to ground disturbance within the construction Limits of Work plus an established buffer.

Since the Draft EIR was released for public comment, those floristic surveys have been conducted. The mid-season (May) and part of the late season (July) floristic surveys were conducted in 2018 and the early-season (April) and follow-up late season surveys were completed in 2019. Additionally, vegetation surveys were completed in 2018 for upland areas and 2019 for wetland areas. Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special status Species and Rare Natural Communities* Potential Impact 3.5-7 has been clarified in light of these surveys. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special status Species and Rare Natural Communities* for the revisions.

The survey results do not change the significance determinations in Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special status Species and Rare Natural Communities* Potential Impact 3.5-7 (pages 3-524 and 3-525). As explained in the Draft EIR, where feasible the Proposed Project design would preserve any documented special-status plants in place. If avoidance is not feasible, a combination of relocation, propagation, and establishment of new populations in designated conservation areas would be implemented, as determined in coordination with the resource agencies, and invasive plant species would be controlled by implementing measures such as routine washing of construction vehicles and equipment (Volume II Appendix B: *Definite Plan – Appendix J*). As noted in Potential Impact 3.5-7, there could be significant impacts on special-status plants in the short-term where avoidance is infeasible and if replanting does not succeed in re-establishment of new populations at a 1:1 ratio such that there is no net loss of individuals. If implemented as part of the Final Restoration Plan, Recommended Terrestrial Measure 1 would reduce impacts to less than significant. This conclusion remains the same.

Also, the Proposed Project includes avoidance and minimization measures as well as provisions for the establishment of wetland and riparian areas and other sensitive vegetation communities within the project area to result in no net loss of habitat acreage (Volume II Appendix B: *Definite Plan – Appendix J*); therefore, impacts to rare natural communities would not be significant.

Comment LA9-40

Resources within the construction envelope will be temporarily impacted even with establishment of revegetated areas. This should be considered a significant short-term impact based on the SWRCB's own significance criteria (up to 2 years of loss). The no net loss through re-establishment addresses long term impacts only.

Response to Comment LA9-40

Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* has been revised to clarify the definition of short-term effects. Please refer to Volume III Attachment 1 Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* for the revisions.

Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-1 has been clarified to indicate that the amount of wetland and riparian habitat created through revegetation efforts would far exceed the acreage of any wetlands and/or riparian vegetation that cannot be avoided during construction activities and that it is anticipated that at least 70 percent cover would achieved by post-dam removal year 1. Please refer to Volume III Attachment 1 Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Comment LA9-41

The DEIR indicates that because the SWRCB cannot ensure implementation of the terrestrial aspects of the Final Restoration Plan, it is analyzing the impact in this DEIR as significant and unavoidable. This is improper. It is reasonable to expect implementation of, and compliance with, the plan. Oakland Heritage Alliance v. City of Oakland (2011) 195 Cal. App. 4th 884, 906 cited in Center for

Biological Diversity v. Department of Fish & Wildlife (2015) 234 Cal. App. 4th 214, 246. As such, the State Board is obligated under CEQA to require such implementation and compliance as a mitigation measure. Furthermore, a CDFW SAA could be reasonably expected to include conditions to address impacts to special-status plants and rare natural communities.

Response to Comment LA9-41

Please refer to Master Response CEQ-2, Effect of Federal Power Act preemption on mitigation measures.

Comment LA9-42

Flood frequency analysis for the 10-year to 100-year events was performed for seven USGS gages along the Klamath River. The analysis used a Log-person III distribution method consistent with USGS Bulletin 17B (USGS 1982). The Bulletin 17B methods have been updated to Bulletin 17C. The updated version (Bulletin 17C) replaces statements to acknowledge climate variability and climate change. The peak discharge frequency analysis is should be revised to utilize the updated methods in Bulletin 17C.

Response to Comment LA9-42

United States Geological Survey (USGS) Bulletin 17C acknowledges climate variability and climate change; however, the guidelines assume time invariance and do not evaluate methods to account for climate variability in flood frequency analyses. Bulletin 17C guidelines retain the same statistical framework used in Bulletin 17B, such that there would be consistency in results generated by the two methods. The main differences between Bulletin 17B and 17C are 1) incorporation of interval peak flow data and historical flood information, and 2) identification of potentially influential low floods in the gage record. These additions to Bulletin 17C would not impact the flood frequency analyses for the Klamath River gages because they possess continuous periods of record over many decades and thus do not require consideration of interval peak flow data, and because the Klamath River gage data are censored to remove low outlier peak flows that result from hydroelectric regulation. It is therefore not necessary to change the analysis in the EIR.

Comment LA9-43

The KRRC proposes to work with willing landowners to implement a plan to address the significant flood risk following dam removal for the 36 habitable structures (including permanent and temporary residences) located in the altered 100-yr floodplain between Iron Gate Dam and Humbug Creek. However, the potential impacts to environmental resources, or identification of potentially hazardous materials from relocating, elevating, or other methods to relocate, or remove these structures is not identified. The DEIR should be revised to identify these impacts.

Response to Comment LA9-43
Potential environmental impacts related to the Downstream Flood Control Project Component are analyzed throughout the EIR. The potential impact analyses and mitigation measures listed below consider the broad set of ground-disturbing activities associated with the Proposed Project – including moving or elevating habitable structures downstream of Iron Gate Dam, as needed, as part of the proposed Downstream Flood Control Project Component.

Impact analyses and mitigation measures in the EIR that consider the broad set of ground-disturbing activities associated with the Proposed Project are:

<u>Volume III Attachment 1</u>
Potential Impact 3.2-4 Increases in suspended material from stormwater runoff due to pre-construction, dam deconstruction and removal, and restoration activities in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam.

Mitigation Measure WQ-1 Best Management Practices to reduce potential impacts to water quality due to pre-construction, dam removal, and restoration-related activities.

Volume III, Attachment 1 Section 3.6.4 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities*

Mitigation Measure TER-6 Gray Wolf.

Mitigation Measure TER-7 Bald and Golden Eagle.

<u>Volume I</u>
Potential Impact 3.5-1 (pages 3-518 to 3-519) Construction-related impacts on wetland and riparian vegetation communities.

Mitigation Measure TER-1 (page 3-519) Establish a 20-foot buffer around delineated wetlands.

Potential Impact 3.5-7 (page 3-524 to 3-525) Short-term impacts on special-status plants and rare natural communities from construction-related activities.

Recommended Terrestrial Measure 1 (page 3-525) Establish Mitigation Ratios for Special-Status Plants.

Potential Impact 3.5-9 (page 3-527) Short-term impacts on special-status terrestrial invertebrates from construction-related activities.

Potential Impact 3.5-10 (pages 3-527 to 3-535) Short-term impacts on special-status amphibian, reptiles, and mammals from construction activities.

Mitigation Measure TER-2 (page 3-530) Amphibian and Reptile Management.

Mitigation Measure TER-3 (pages 3-530 to 3-531) Western Pond Turtle Pre-Construction Surveys.

Recommended Terrestrial Measure 3 (pages 3-532 to 3-533) On-site Biologist/Construction Monitoring Plan.

Recommended Terrestrial Measure 4 (page 3-533) Biological Resources Education and Awareness Training.

Recommended Terrestrial Measure 5 (page 3-533 to 3-534) Requirements for Construction Personnel.

Recommended Terrestrial Measure 6 (pages 3-534 to 3-535) Wildlife Exclusion and Entrapment.

Recommended Terrestrial Measure 7 (page 3-535) General Special-status Wildlife Surveys and Pre-construction Surveys.

Potential Impact 3.5-11 (pages 3-536 to 3-540) Short-term impacts on nesting birds from construction-related noise and habitat alterations.

Recommended Terrestrial Measure 9 (pages 3-538 to 3-540) Nesting Birds.

Potential Impact 3.5-12 (pages 3-540 to 3-543) Effects on willow flycatcher from short-term construction-related noise and short-term and long-term habitat alterations.

Recommended Terrestrial Measure 10 (page 3-543) Willow Flycatcher

Potential Impact 3.5-13 (pages 3-543 to 3-547) Short-term impacts on bald and golden eagles from construction-related noise and nesting habitat alterations.

Potential Impact 3.5-14 (pages 3-547 to 3-553) Short- and long-term impacts on bats from construction noise and loss of roosting habitat.

Recommended Terrestrial Measure 12 (pages 3-551 to 3-553) Roosting Bats and Habitat.

Potential Impact 3.5-15 (pages 3-554 to 3-555) Impacts on northern spotted owl and critical habitat from construction-related noise and habitat alterations.

Potential Impact 3.21-1 (pages 3-1042 to 3-1045) Proposed construction-related activities could result in substantial exposure to hazardous materials through the routine transport, use, or disposal of hazardous materials.

Mitigation Measure HZ-1 (pages 3-1044 to 3-1045) Hazardous Materials Management. (See also Volume III Attachment 1 for modifications.)

Potential Impact 3.23-8 (page 3-1100) Construction activities associated with the Downstream Flood Control Project Component (moving or elevating legally established structures with flood risk) could produce noise and vibration associated with construction activities.

Please also note that, since issuance of the Draft EIR, the Klamath River Renewal Corporation (KRRC) has clarified that the Proposed Project "Limits of Work" include the following:

- 34 small areas ranging from 0.02 acres to 6.5 acres in size, with most parcels less than 0.03 acres, all of which are located within the altered 100-year floodplain of the Middle Klamath River between Iron Gate Dam (river mile [RM] 193) and Humbug Creek (RM 174) and have existing legally-established habitable structures that may require relocation or elevation prior to dam removal;
- 1,300 linear feet of the south shore of Copco No. 1 Reservoir inclusive of the adjacent twelve parcels that possess existing habitable structures, which potentially could be impacted by slope failure during or immediately following reservoir drawdown;
- 480 linear feet of Copco Road (unpaved) located on the north shore of Copco No. 1 Reservoir which has the potential to experience slope failure during or immediately following reservoir drawdown.

The EIR Project Boundary, which is inclusive of the Proposed Project's Limits of Work, as well as PacifiCorp owned and managed lands immediately surrounding the Lower Klamath Project ("Parcel B lands") that would be transferred as part of the Proposed Project, has been updated accordingly. The clarifications to the Limits of Work are relatively minor and are included in Volume III Attachment 1 *Executive Summary* Figure ES-2 *Proposed Project Boundary − California Portion*. The updated Proposed Project Boundary shown in Figure ES-2 applies to all figures in EIR Volume I that include the Project Boundary.

Comment LA9-44

It is unclear whether the proposed Federal Emergency Management Agency (FEMA) 100-year floodplain boundary impact potentially developable lands that would otherwise be outside of the FEMA 100-yr floodplain under existing conditions. Figure 7.7-1 displays structures in the 100-year floodplain following dam removal; sheets 1 of 8, and 3 of 8 show post-dam increases in flood depths that may be within areas with planned developments and may impact private property potential. The impact analysis should include impacts to habitable *structures, along with any planned development, private property, or land uses that would allow for future development (or use).*

Response to Comment LA9-44

Please refer to Volume I Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain* Potential Impact 3.6-3 (pages 3-630 to 3-633) for discussion of potential flooding impacts to habitable structures. The analysis assesses the potential impacts of the Proposed Project and feasible alternatives against existing environmental conditions, consistent with CEQA Guidelines section 15125 (a). Additionally, please refer to Volume I Section 3.24.6 *Cumulative Effects – Flood Hydrology* (pages 3-1181 to 3-1182) for discussion of potential cumulative impacts related to development projects, including reasonably foreseeable projects (see Volume I Table 3.24-1), and flood hydrology. The comment mentions planned developments but provides no specific reference for the plans, therefore, it is unclear what potentially developable lands and planned development are being referred to. Note that Volume I Section 3.24.6 *Cumulative Effects – Flood Hydrology* (pages 3-1181 to 3-1182) does take approved and reasonably foreseeable projects into account. Potential future uses and development in floodplains in the existing Federal Emergency Management Agency (FEMA) 100-year floodplain or the altered floodplain following dam removal (USBR 2012a) would be speculative.

Comment LA9-45

The wells illustrated in Cross-Section A-A', B-B', C-C' (page 3-648+) show wells with water table below the Copco No. 1 reservoir level. This information indicates that the wells may still be recharged from water seepage from the base of the reservoir, not from lateral regional groundwater flow. Drawdown of the Copco No. 1 reservoir may decrease or eliminate the source of groundwater recharge for at least a dozen wells.

The data presented for wells near the Iron Gate reservoir suggest that the groundwater table is higher than the reservoir. Drawdown of the surface water within the reservoirs have the potential to impact adjacent groundwater levels, regardless of whether the groundwater water levels are higher or lower than the current reservoir levels. However, the wells with water levels below the reservoir level, i.e., the Copco No. 1 reservoir, may be more reliant on the reservoir as a source of groundwater recharge, and therefore these wells may be more affected by the reservoir drawdown.

As the wells are all drilled wells set within fractured bedrock, each well will have a unique response to the reservoir drawdowns, depending on the fracture orientation and hydraulic properties. Each well's sensitivity to the drawdown will also rely on the current well yield and availability of water-bearing fractures. For instance, a low yield well where the recharge is low may be more sensitive to the reservoir drawdown, especially if the well is hydraulically connected to the surface water in the reservoir.

Response to Comment LA9-45
The impact analysis associated with the comment's statements regarding existing groundwater wells in the vicinity of Copco No. 1 and Iron Gate reservoirs can be found on Volume I Section 3.7.5 *Groundwater – Potential Impacts and Mitigation* Potential Impact 3.7-1 (pages 3-663 to 3-665).

Comment LA9-46
"No significant impact" as asserted on Page 3-665, cannot be claimed until drilling occurs to remedy the loss of a well's capacity to serve its intended use.

Response to Comment LA9-46
Please refer to Master Response GRW-1.

Comment LA9-47
Page 3-665 "Potential Impact 3.7-2 The Proposed Project could interfere with groundwater recharge and adversely affect surface water conditions in the Klamath River" states no significant impact based on the findings of Gannett et al. (2007) where 92 cubic feet per second of groundwater is predicted to discharge to surface water within the reach between Iron Gate dam and the upper reservoirs. However, the well data presented within the DEIR demonstrates a large degree of variability with regard to vertical groundwater flow, where some areas with low water levels relative to the reservoir water level may be reliant on the reservoir as a groundwater recharge source. Any significant impact will be determined on a case-by-case basis and should be adequately addressed within the Groundwater Well Management Plan.

Response to Comment LA9-47
Volume I Section 3.7.5 Groundwater – *Potential Impacts and Mitigation* Potential Impact 3.7-2 (page 3-665) analyzes the potential for impacts to Klamath River surface flows to occur due to the Proposed Project. As described in Section 3.7.2 *Groundwater – Environmental Setting* (pages 3-641 to 3-661) and in Gannett et al. (2007), the Klamath River in the groundwater Area of Analysis is made up of 'gaining' reaches where natural groundwater flow moves *into* the river. Although there is localized site-specific variability in groundwater levels immediately adjacent to the reservoirs, as noted in Sections 3.7.2.1 *Groundwater – Environmental Setting Regional Groundwater Conditions* and 3.7.2.2 *Groundwater – Environmental Setting Regional Groundwater Conditions* (pages 3-641 to 3-661), removal of the Lower Klamath Project dams is not expected to alter the existing condition of groundwater moving into the Hydroelectric Reach because Lower Klamath Project reservoirs do not substantially alter regional and local groundwater conditions, and thus, surface flows would not be impacted in the Klamath River under the Proposed Project. Any significant impact to individual groundwater wells would be determined on a case-by-case basis, as described in the Groundwater Well Management Plan (see Volume II Appendix B: *Definite Plan*).

Comment LA9-48

The DEIR concludes that impacts to water supply and/or water rights are considered significant if they result in: (1) Causing unreasonable injury to existing water rights; or (2) Decreasing water supplies beyond what is needed for public health and safety (human consumption, cooking, and sanitation) for the current population.

These two criteria do not explicitly address resiliency or reliability, which could experience significant impacts, as indicated below.
The phrase "unreasonable injury" in the first criterion is not well explained. Under California law, the so-called "no-injury rule" (see Water Code, Sections 1702, 1706) can be triggered by almost any change in the point of diversion, place of use, or purpose of use of a water right that causes "injury" to, e.g., another water rights holder. The no-injury rule does not have any "reasonableness" threshold. Perhaps the word "unreasonable" is intended to reference the constitutional reasonable use doctrine (Cal. Const., art X, § 2), but if so, it's not clear why the two concepts should (or could) be combined together The second criterion, including the reference to "public health and safety," sets an extremely low bar for impacts to water supply/rights. This criterion is unusual, and does not appear to be based on typical or standard water rights principles. It sets much too low of a bar to protect vested property interests or to maintain statutory priorities/preferences for municipal and domestic uses (e.g., Water Code, Sections 106, 106.5) over, e.g., environmental or irrigation uses.

Response to Comment LA9-48

CEQA charges the lead agency with identifying and analyzing potentially significant impacts to the physical environment from a proposed project. A minor change in the exercise of a water right would not be a reasonable threshold to define a significant impact under CEQA. CEQA impacts are based on a physical change to the environment rather than on any potential legal infringement. Unreasonable interference with water right uses means that the extent of the interference would support a complaint made under Article 10 Section 2 of the California Constitution. All diversions and beneficial uses of water must be reasonable given all other needs of water, including instream and off-stream uses, and some level of minor inconvenience is acceptable in light of the constitutional policies promoting shared use of water. Such a minor change in water availability and usage would be unlikely to result in significant water-supply-related environmental impacts.

The significance criteria necessarily encompass potential impacts to resiliency and reliability of water rights because these aspects of a right to divert can be subject to unreasonable interference, and changes to resiliency and reliability can cause public health impacts. Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impacts 3.8-2, 3.8-1, and 3.8-

4 analyze potential reliability and resiliency effects from Proposed Project implementation.

The additional criterion regarding public health and safety is based on the human right to water, as expressed in Water Code section 106.3, and on the direct potential for public health impacts from a change in water supply. As noted above, significance criteria are set to evaluate environmental impacts and, as such, setting forth a water supply criterion related to public health and safety is appropriate.

Comment LA9-49

There is inadequate consideration of supply system resiliency or reliability, both of which might experience significant impacts. For example, even if the Lower Klamath Project reservoirs were not designed or operated as seasonal storage reservoirs to maintain downstream flows (page 3-674), these facilities undoubtedly provide some level of physical capability to store water and control/time releases, which will be lost with dam removal. The DEIR's discussion of coordinated releases during the "extreme drought" of 2014-2015 illustrates this capability (pages 3-678–3-680).

Response to Comment LA9-49

Please refer to Volume I Section 3.8.2.1 *Water Supply/Water Rights – Environmental Setting – Upper Klamath Basin* regarding the Lower Klamath Project for a discussion of the available active surface water storage of the Lower Klamath Project reservoirs. Please also refer to Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impacts 3.8-1 and 3.8-2 (pages 3-676 to 3-680) for discussion of surface water flow available for diversion along the Klamath River under the Proposed Project, including consideration of the United States Bureau of Reclamation's (USBR's) Klamath Irrigation Project located in the Upper Klamath Basin. Please also refer to Master Response WSWR-1 for additional discussion of potential effects on agricultural water supply and coordinated releases and Master Response WSWR-3 for additional discussion of potential effects on water supply downstream of Iron Gate Dam. Additionally, note that Keno Dam possesses the ability to coordinate timed releases in rare cases such as the 2014 – 2015 drought.

Further, the reliability of the City of Yreka's water supply is evaluated in Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683). Please also refer to Master Responses WSWR-5 and WSWR-6 and responses to the City of Yreka's comments on future water availability (i.e., comments LA8-6, LA8-7, LA8-9, LA8-10, LA8-11, LA8-14, LA8-15, LA8-19, LA8-24, LA8-28, LA8-30, LA8-31, LA8-32, LA8-33, LA8-35, LA8-36, LA8-40, LA8-44, and LA8-45).

Comment LA9-50

The impacts analysis is not sufficiently detailed to show that Yreka's water rights will not be injured or otherwise impaired in dry or drought conditions. In particular, the analysis does not discuss the total downstream demands with legal priority and/or seniority ahead of Yreka's rights versus the anticipated flows.

Response to Comment LA9-50

It is possible that drought conditions could impact any water right holder on Fall Creek. However, water demands associated with the Proposed Project would not impact water availability for the City of Yreka's water right. California Department of Fish and Wildlife's (CDFW's) non-consumptive water right on Fall Creek diverts water primarily downstream from the City of Yreka's diversion point with an optional 0.33 cubic feet per second (cfs) diversion upstream of the City of Yreka's Dam B. After passing through the hatchery, all diverted water (less evaporative losses) would be returned to Fall Creek upstream of the City of Yreka's bypass flow compliance point (i.e., location of United States Geological Survey (USGS) Gage No. 11512000 approximately 1,000 feet upstream of Daggett Road). Please refer to Volume I Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* (pages 2-81 to 2-84) for further discussion.

PacifiCorp's water diversions on Spring and Fall creeks and hydropower generation at the Fall Creek powerhouse are part of the Klamath Hydroelectric Project (KHP) and are not part of the Proposed Project. PacifiCorp's ownership and operation of the portions of the KHP that are not part of the four dams and the associated facilities proposed for removal (i.e., the Lower Klamath Project), or part of Parcel B lands, are not being changed under the Proposed Project. Whether the Federal Energy Regulatory Commission (FERC) would alter PacifiCorp's Spring Creek diversion in the future, as related to the KHP, is speculative and is not analyzed in this EIR.

For additional details refer to Master Responses WSWR-5, WSWR-6, and WSWR-7.

Comment LA9-51

The project is potentially subject to 17 CCR 93105, but lack of detail in the Environmental Setting section makes it difficult to ascertain if the project is subject to this requirement. This should be analyzed and discussed. Additionally, the project must comply with California Health and Safety Code §41700 and §41701 regarding nuisance discharges and opacity limitations. It is unclear whether the project would violate these standards The DEIR should be revised to address this issue.

Response to Comment LA9-51

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-52

A significant and unavoidable impact was identified for Potential Impact 3.9-2, Section 3.9.5. Page 3-704 states that "the analysis in this section does not include mitigation to minimize impacts from construction emissions generated by the Proposed Project activities. Since similar minimization measures may be implemented during project construction…" This is in direct conflict with the CEQA Guidelines. A few mitigation measures are proposed in the Air Quality Appendix in Section N.4 (Page N-21 of the air quality Appendix – Appendix N). Additionally, there are numerous dust control measures discussed in 17 CCR 93105 (CARB 2011) and there are other feasible and reasonably achievable dust control measures that could be implemented and should therefore be discussed. Since the project must comply with the requirements of California Health and Safety Code §41700 and §41701 and is potentially subject to 17 CCR 93105 as well as SCAPCD Rule 4.1 and 4.2, it is reasonable to assume that any mitigation measures proposed would be enforceable under these regulations. See Oakland Heritage Alliance v. City of Oakland (2011) 195 Cal. App. 4th 884, 906 cited in Center for Biological Diversity v. Department of Fish & Wildlife (2015) 234 Cal. App. 4th 214, 246.

Response to Comment LA9-52

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-53

Impact 3.9-2 was found to be significant and unavoidable, but the analysis does not specify whether the impacts would be cumulatively considerable and does not address whether cumulative impacts would result from the project. Discussion of cumulative impacts of a project is required as stated in section 15130 in the CEQA Guidelines.

Response to Comment LA9-53

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-54

Regional haze is discussed generally in a broader context in Section 3.9.3, then in the Potential Impacts and Mitigation Section (section 3.9.5), conformance with the California Regional Haze Plan is evaluated and there was a finding of no significant impact since the project would be in conformance with the regional haze plan. CEQA Guidelines state in Section 15125(e) that where a Proposed Project is compared with an adopted plan, the Environmental Setting shall contain an examination of the existing physical conditions as well as potential future conditions discussed in the plan. The DEIR should give a more thorough description of the Regional Haze Plan to provide context for the reader, and inform the impact analysis.

Response to Comment LA9-54

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-55

Note that Section 3.9.1 of the DEIR states that the Area of Analysis includes Siskiyou County as a whole and there are two Class I areas within Siskiyou County as well as two associated IMPROVE monitoring stations (TRIN1 and LABE1). Discussion of the IMPROVE monitoring station data should be included in discussion of the Environmental Setting Section for regional haze. Sources that may be used as a basis for discussion of monitoring include the Western Regional Air Partnership (WRAP) Regional Haze Rule Reasonable Progress Summary Report (WRAP 2013), the California Regional Haze Plan (CARB 2009), and California Regional Haze Plan 2014 Progress Report (CARB 2014). Additionally, visibility trends by year and various summaries of light extinction and haze distributions can also be located on the Federal Land Manager Environmental Database (2019) Website under Air Quality Related Values (AQRV) Summaries, Visibility (Colorado State University 2019). Including this information would inform the analysis and how the Proposed Project could affect haze.

Response to Comment LA9-55

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-56

The Air Quality impact section discusses the justification of using stationary source operational emissions "significance thresholds" to assess impacts from the project's construction emissions. These values are taken from Siskiyou County Air Pollution Control District (SCAPCD) Rule 6.1. This rule applies to the levels of emissions above which stationary sources would be subject to implementation of Best Available Control Technology (BACT) and emission offsets. This rule does not apply to construction emissions, but the DEIR states that use of these values is conservative when used to assess construction impacts and then asserts that if emissions from construction were to exceed these thresholds, "an air quality standard" would be violated and a significant air quality impact would result. This creates several uncertainties regarding the analysis. The analysis should be revised to address the following:

What precisely is the impact of exceeding these thresholds and what is the "air quality standard" that would be violated? Has this been quantified? The SWRCB should explain why the stationary source "thresholds" are used to assess impacts and what exceedance of these thresholds means in terms of impacts, not just that exceedance of these thresholds results in significant impacts without further explanation. CEQA Guidelines state in Section 15064.7 *that "a threshold of significance is an identifiable quantitative, qualitative or performance level of a particular environmental effect, non-compliance with which means the effect will normally be determined to be significant by the agency" and, that thresholds of significance must be adopted by ordinance, resolution, rule, or regulation and be supported by substantial evidence. The "thresholds" used to assess significance in the DEIR document are air permitting thresholds which were not developed for purposes of CEQA's environmental review process, and do not meet the definition of a threshold of significance. In other words, exceeding this air permitting threshold does not necessarily indicate that a project would cause an air quality standard to be violated and conversely, meeting the air permitting threshold does not guarantee compliance with air quality standards. In addition, the current version of the document clearly does not meet the requirements in Section 15126.2 of the CEQA Guidelines that "direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects." Since it is unclear to a reader what precisely the impacts are, the DEIR documentation obviously falls short of the requirement to clearly identify and describe the significant effects of the project on the environment.*

The language throughout the document and technical appendix refer to these levels of emissions as "significance thresholds," implying that these values are CEQA significance thresholds developed by the Air District, which is not the case—these are air permitting thresholds. This should be clarified throughout the relevant documentation.

Response to Comment LA9-56
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-57
The impact section needs to specify whether fugitive dust is likely to exceed 40% opacity for a period or periods aggregating more than three minutes in any one hour. If so, the project would be out of compliance with SCAPCD Rule 4.1 and would likely require mitigation of construction emissions to reduce the impact of the construction project to comply with this rule.

Further, it is unclear whether the emissions will (1) cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public, (2) endanger the comfort, repose, health or safety of any such persons or the public, (3) cause or have a natural tendency to cause injury or damage to a business or property? If so, the project would be out of compliance with SCAPCD Rule 4.2 and would likely require mitigation of construction emissions to comply with this rule.

Response to Comment LA9-57
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-58
Section 3.9.4 describes the impact analysis approach and indicates that emissions have not been quantified since the 2012 EIR/EIS analysis, despite changes to the project. Despite the assertion that a quantitative assessment was made for the analysis, there was by necessity, some qualitative assessment of the likely similarity of impacts from the originally Proposed Project. The approach itself is not necessarily problematic. However, the fact that there were significant impacts found, there was not originally adequate mitigation proposed, and there are several instances where emission calculation software has been updated since the original analysis was completed, makes the original emission quantifications and the impacts determination invalid for assessing the potential impacts of the project in the context of the current environmental and regulatory setting.

Response to Comment LA9-58
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-59
The determination of significant and unavoidable impacts necessitates a more substantial investigation of potential project emissions and mitigation measures. It appears that impact 3.9-2 discussed in Section 3.9.5 was deemed significant and unavoidable based on violation of a quantitative threshold, but quantification of changes to emission rates were admittedly not completed. Additionally, the original emissions quantifications were done in part using CARB's OFFROAD 2007 software and CAPCOA's CALEEMOD version 2011.1.1. There have been updates to these programs (OFFROAD 2017 and CALEEMOD version 2016.3.2, respectively) which include changes to vehicle emission factors. It is possible that these software updates could substantially change the outcome of the significance determination. This analysis should be performed, or the State Board should explain why it has not performed it. See Cleveland Nat'l Forest Found. v. San Diego Assn. of Governments (2017) 3 Cal. 5th 497, 515-516.

Response to Comment LA9-59
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-60
The DEIR states that "the current proposal for the Proposed Project lacks sufficient detail concerning construction activities and it is too speculative to determine whether the mitigation measures proposed in the 2012 KHSA EIS/EIR are feasible and enforceable." Therefore, the analysis assumes that no mitigation

would be implemented. At the very least, mitigation measures should be discussed given the finding of a significant and unavoidable impact, it is reasonable to interpret that the project should implement mitigation measures to comply with California Health and Safety Code §41700 and §41701.

Response to Comment LA9-60
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-61
There are some obvious flaws and invalid assumptions that were noted in Appendix N, which is based on the quantification of emissions from the 2012 analysis. The text of Appendix N, section N.2.1.5 regarding unpaved road dust states that "natural mitigation" from rainfall occurs but this would only be true over the course of an entire year. It is unclear if this was applied to daily emission rates, but it is safe to assume that the answer is yes, since this is included in the methods section and results are only presented in pounds per day. Applying a "natural mitigation" percentage based on annual rainfall information is not appropriate for assessing impacts on a pound-per-day basis which is the basis for the significance determination. The section also claims that "natural mitigation" from rainfall is 76–77%whereas an accurate value would be more like 24 or 23% and, as previously noted, that would only be on an annual basis. Since background documentation and calculations were not available for the purposes of this review, it is difficult to see if there are errors in the calculations and results, or if this is just a misstatement in the text of Appendix N. It would be prudent to redo the analysis based on the new project details and reevaluate some of the faulty assumptions made concerning road dust and verify that the original assumptions in the 2012 analysis are accurate, up-to-date, and appropriate.

Response to Comment LA9-61
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-62
In Section 3.9.2 – the Environmental Setting, Naturally Occurring Asbestos should be discussed in more detail. CEQA Guidelines Section 15125(a) states that the Environmental Setting Section should include a description of the physical environmental conditions in the vicinity of the project, which would include whether any portion of the disturbed area will be located in an area where the provisions of California Air Resources Board Airborne Toxic Control Measure under 17 California Code of Regulations (CCR) 93105 (California Air Resources Board [CARB] 2011) are potentially applicable. This regulation is designed to mitigate emissions of naturally occurring asbestos which may be emitted when the disturbed area contains naturally-occurring asbestos, serpentine, or ultramafic rock. Siskiyou County has several areas where ultramafic rock and

naturally occurring asbestos have been discovered (Van Gosen and Clinkenbeard 2011), so enough information needs to be included in the Environmental Setting to determine if this rule is applicable.

Response to Comment LA9-62
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-63
If the project is found to be subject to the requirements of 17 CCR 93105 and does not obtain an exemption under paragraph (c) 93105, then requirements for road construction and maintenance in paragraph (d) and requirements for construction and grading operations in paragraph (e) apply. These potentially applicable dust control measures are not included as mitigation measures. The DEIR needs to discuss section 93105, including whether an exemption applies, and, if needed, include measures to control fugitive dust emissions from construction activities. This is particularly important because potential impact 3.9-2, discussed in Section 3.9.5 regarding project impacts was determined to be significant and unavoidable due in part to emissions of particulate matter (PM)10 and PM2.5. The CEQA Guidelines clearly state in Section 15126.4(a)(1)(B) that each measure available to mitigate an impact should be discussed and the basis for selecting a particular measure should be identified. Note that, if the requirements of 17 CCR 93105 apply, these mitigation measures would be enforceable as described in Section 15126.4(a)(2) of the CEQA Guidelines.

In Section 3.9.2.2 of the Environmental Setting regarding Criteria Air Pollutants, National Ambient Air Quality Standards (NAAQSs) are mentioned, but California Ambient Air Quality Standards (CAAQS), which are more stringent for certain pollutants, are not discussed. CAAQS should be added to the discussion.

Response to Comment LA9-63
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment LA9-64
Section 3.10.4 describes the impact analysis approach and indicates that emissions have not been quantified since the 2012 EIR/EIS analysis, despite changes to the Proposed Project. The State Board should either perform a new analysis to quantify emissions or explain why it has not performed such an analysis. See Cleveland Nat'l Forest Found. v. San Diego Assn. of Governments (2017) 3 Cal. 5th 497, 515-516. Furthermore, in addition to the deficiencies in the GHG emission quantification methodologies discussed above, it seems strange that only the direct construction emissions are assessed based on a quantitative threshold, but the ongoing indirect impacts are only assessed qualitatively. It would be more appropriate to use the 10,000 MT threshold of significance to evaluate the indirect impacts since those are likely to occur over a

longer timescale. The 10,000 MT CO2e threshold was developed to assess operational impacts (ongoing sources of emissions) so use of this threshold is more conducive to evaluate the lasting impacts of non-renewable power generation than construction emissions. Typically, construction emissions are amortized over the life of the project in order to assess impacts, or some other qualitative means of assessment are used.

Additionally, the original emissions quantifications were done in part using CARB's OFFROAD 2007 software and CAPCOA's CALEEMOD version 2011.1.1. There have been updates to these programs (OFFROAD 2017 and CALEEMOD version 2016.3.2, respectively) which include changes to vehicle emission factors. It is possible that these software updates could impact the significance determination since impacts for these emission sources are being assessed quantitatively in the DEIR.

It would be prudent to redo the analysis based on the new project details and make a good-faith effort to quantify all direct and indirect emissions of GHGs resulting from the project in accordance with the CEQA Guidelines.

Response to Comment LA9-64

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment LA9-65

The impact being evaluated is whether the GHG emissions from the project, direct or indirect, would exceed 10,000 MT CO2e. Yet, this question is simply not answered with respect to indirect emissions. Instead, on page 3-727 the replacement of the hydroelectric energy is discussed, and it is stated that 65 MW of electricity, 52% of the Lower Klamath electricity production, would be replaced with electricity generated from a resource mix which would be majority non-renewable. It is then stated that over the next 20 years this would be offset by PacifiCorp (which provides power to multiple states) increasing the renewable source electricity generation. Though it is true that generally, PacifiCorp will be replacing non-renewable sources with renewable sources in coming years, this is not an impact of the Proposed Project. Therefore, it is inappropriate to frame the impacts assessment of the Proposed Project within the context of PacifiCorp's long term, broad goals, which have no bearing on the impacts of this individual project. The fact is that the Proposed Project will likely result in 65 MW of 100% renewable energy being replaced with 65 MW of some mixture of non-renewable and renewable energy and the impacts of this must be assessed based on likely power generation portfolios over the short and long term.

PacifiCorp's Integrated Resource Plan is cited in the DEIR and therefore, it follows that a good faith effort could be made to determine what mixture of resources would be representative for the replacement of the hydroelectric power *generation (or reasonable assumptions could also be made based on the Renewable Portfolio Standard goals) over the short and long term. To adequately convey the impacts of this project to the public, an attempt to quantify the increase in GHG emissions from non-renewable sources that would be required to replace the 100% renewable energy source of the dams must be made.*

Response to Comment LA9-65

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

<u>Comment LA9-66</u>

In the Impacts Analysis Approach Section 3.10.4, it is specified that there were "minor" changes between the 2012 EIS/EIR analysis and the Proposed Project, primarily due to timing. However, there are no statements specifying whether the emissions of greenhouse gases will increase, decrease, or stay the same. This analysis should be added.

Response to Comment LA9-66

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

<u>Comment LA9-67</u>

In Section 3.10.4, page 3-722, it is stated that "It is likely that sulfur hexafluoride (SF6) would be released during deconstruction because the circuit breakers from the power facilities would be emptied. Although SF6 has a relatively high GWP, sufficient data was not available at the time of this writing to quantify emissions".

Not only does SF6 have a "relatively high GWP", it has the highest global warming potential (GWP) of any compound quantified by human-kind. SF6 has a lifetime of 3,200 years in the atmosphere (Blackman, Averyt, and Taylor 2016), and a GWP of 23,500 over a 100-year time horizon (IPCC 2014). Based on this GWP value, just one pound of SF6 released is equivalent to over 10.7 metric tons of carbon dioxide equivalent (CO2e). Therefore, a good-faith effort must be made to quantify these emissions particularly since charge sizes for gas insulated switchgear equipment rated 50 kV or more can range from hundreds to thousands of kg per installation, and low voltage switches contain 1-2 kg per installation (IPCC 1997) depending on the model year. In addition to the 9,455 MT CO2e already quantified, the emissions from SF6, depending on the type and quantity of circuit breakers, could easily be exceeded. There is no information provided on the type of equipment in Appendix O or DEIR section 3.10.4.

Response to Comment LA9-67

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment LA9-68

One source of emissions mentioned was that currently sequestered organic carbon would be released when sediments including biological material are released from their current anoxic environment upon the commencement of the Proposed Project activities. This was mentioned in the environmental setting, but never mentioned again and the magnitude of emissions were not described or quantified. It should be. Additionally, changes in vegetation associated with construction activities, revegetation efforts, and changes in recreational area extents and locations were not assessed with respect to climate impacts. The impacts due to net vegetation changes and associated changes to carbon sequestration should be described or quantified as deemed appropriate based on a good-faith effort.

Response to Comment LA9-68

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment LA9-69

Sediment transport modeling was performed from 2002 survey data (USBR 2012), and the volume of sediment transport is assumed to be explicit of sediment volume, as it relies on the rate of drawdown dictated by the hydrology (dry/normal/wet). The volume and spatial extent of sediment transported for the project is based on the USBR 2012 model results. The DEIR proposes to perform sediment jetting to maximize erosion of reservoir deposits; anticipated to mobilize an additional 13–41% of the sediment volume expected to erode during dam removal (DEIR Table 3.2-12). Although the estimated volume (USBR 2012) is predicted through year 2020 based on sediment trapping/sampling for accumulated sediments between the time of survey and proposed actions, inputs from sediment jetting are not considered in the model. The spatial and temporal extents in the USBR 2012 may not adequately describe the additional input of fine sediment.

Response to Comment LA9-69

Comment noted. For information on sediment transport modeling and associated sensitivity and uncertainty, please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and revisions to this section in Volume III Attachment 1, as well as to Master Response GEO-1, and response to comment ORG46-8. Sediment volumes presented in the EIR are sourced from USBR (2012a) model results. Lower Klamath Project reservoir sediment cores collected in 2006 (Shannon & Wilson, Inc. 2006) and 2009 and 2010 (USBR 2011), and used to estimate reservoir sediment thickness and volumes, are described in Section 5.6.1.2 of USBR (2012a, pages 5-18 to 5-28). Additionally, development of the hydraulic model is described in detail in Section 4.1 of USBR (2012a, pages 4-1 to 4-7), including use of 2001 and 2009 bathymetric survey data and 2010 Light Detection and Ranging (LiDAR) data.

With respect to the potential for additional mobilization of sediment due to the proposed sediment jetting during reservoir drawdown, please refer to response to comment ORG46-132. As stated in ORG46-132, Section 3.2.5.2 *Water Quality Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3 – Table 3.2-12 summarizes the range of reservoir sediment volume estimated to be potentially transported by sediment jetting during drawdown and compares this sediment volume with the USBR (2012a) sediment transport model estimate of the potential range of total 2020 sediment volume anticipated to erode under dam removal without sediment jetting. The maximum and minimum sediment volume transported by sediment jetting is based on maximum and minimum potential sediment depths measured in the areas where sediment jetting would occur. Sediment is anticipated to erode from these reservoir areas under drawdown without sediment jetting (UBSR 2012), so sediment jetting would primarily transport reservoir sediments that are already anticipated to be eroded during drawdown; the maximum and minimum sediment volume estimated to be transported by sediment jetting during drawdown in Table 3.2-12 is not in addition to the sediment volume estimated to be transported by drawdown alone. The column in Table 3.2-12 titled "Percentage of 2020 Sediment Volume Transported by Sediment Jetting (%)" presents the amount of sediment that would be potentially mobilized via sediment jetting as a fraction of the total reservoir sediment deposits anticipated to be eroded. While sediment jetting would primarily transport reservoir sediments that are already anticipated to be eroded during drawdown, some additional reservoir sediments may be transported by the combination of drawdown and sediment jetting flows compared to only drawdown flows. Potential increases in the total reservoir sediment estimated to erode under the Proposed Project due to the combination of reservoir drawdown and sediment jetting flows would likely be small compared to the total reservoir sediment volume estimated to erode due to drawdown alone by USBR (2012a). As such, the assessment in Potential Impact 3.11-5 in Volume 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* (pages 3-765 to 3-775), and modified in Volume III Attachment 1, is accurate. The analysis in Potential Impact 3.11-5 is consistent with both USBR (2012a) and Section 3.2 *Water Quality*. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment LA9-70

The DEIR acknowledges fine sedimentation as a short-term impact to aquatic resources, anticipating impacts to occur within the first year following the proposed drawdown and dam decommissioning. The DEIR proposes to release *flows up to the 10-year recurrence interval flood. Flows of this magnitude are likely to deposit fine sediment at diversion head gates, tributaries, in side channels, and overbank floodplain habitats, potentially causing vertical and oblique accretion of the floodplain and point bars. Vertical accretion has potential to raise the elevation of backwater habitats causing for a higher flow to reactivate them. Oblique accretion has potential to enlarge point bars. Vertical accretion may occur at the floodplain fringe where low velocities and backwater areas exist. The DEIR proposes to survey the river bed downstream of Iron Gate to Humbug Creek, and adaptively manage aggradation and tributary barriers by mechanical removal outside of the main channel. The reach between Iron Gate and Humbug Creek is within a narrow and confined valley, the reach exhibits long riffle-runs and deep pools in a canyon section with little to no floodplain that would accrete fine sediments. Reaches downstream of Humbug Creek are in a much less confined valley and the morphology of the channel is an alluvial meandering channel dominated by riffle-pools, point bars, and an active floodplain. The upstream canyon reach has a higher transport capacity and fine sediment is anticipated to transport out of this reach to downstream reaches. The DEIR does not describe the potential short-term impacts to stream morphology of the lower reaches of the Klamath River. The downstream reaches are more sensitive to changes in sediment loading and flow, and have higher potential for vertical, lateral and oblique accretion of fine sediments. Accretion of sediments may cause short-term impacts to stream morphology, which could potentially lead to long-term impacts. For example, oblique accretion of lateral bars downstream of the Humbug Creek Confluence, has potential to adversely direct the lower stage flows towards the opposite bank, and repositioning of the thalweg. During successional high seasonal flow periods, the channel may take this new thalweg position and exacerbate the erosional forces along the opposite bank. Lateral accretion may also exacerbate the situation, as excessive deposition of fine sediment deposits near the floodplain fridge could grow in with vegetation. Impacts to stream morphology associated with fine sediment accretion downstream of Humbug Creek are recommended to be evaluated and adaptively managed. The downstream reaches have an active floodplain, where excessive fine sediment would deposit onto the floodplain and channel bars and have potential to cause impacts to stream morphology.*

The reservoir drawdown analysis should be revisited to justify the specified rate of 2 feet to no greater than 5 feet per day for the drawdown. A slower drawdown would likely decrease the episodic nature of the reservoir sediment erosion, pending further analyses on the sediment slope stability Landslides may be promoted by the drawdown by virtue of the ground water levels within adjacent hillside being out of equilibrium with the lower hydraulic heads produced during the reservoir lowering. The elevated pore pressures produced by the negative stress of the proposed rapid drawdown will create a lower coefficient of internal friction within the soil/sediment, which will enhance the potential for slope failure within the reservoir sediment and adjacent hillside.

Response to Comment LA9-70

Regarding fine sediment erosion, transport, and deposition, as well as potential stream morphological change, please refer to Master Response GEO-1. For potential related impacts to aquatic resources, please refer to Master Responses AQF-7 and AQF-10. In the reaches where significant sediment deposition is most likely to occur (Bogus Creek to Cottonwood Creek), vertical and/or oblique accretion of channel bars may occur, resulting in changes to channel morphology. The potential for morphological change associated with sediment deposition in this reach is disclosed in Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* – Potential Impact 3.11-5 as *significant and unavoidable*. Please refer to Volume III Attachment 1 for the final Potential Impact 3.11-5. Downstream of Cottonwood Creek, the potential for impacts due to spatially discrete fine sediment deposition, including accretion of bars, would not be significant because the predicted sedimentation is sufficiently small and any sedimentation that does occur would be expected to mobilize during subsequent flood events.

Please refer to Volume I Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* (pages 2-54 to 2-60), as well as to Volume II Appendix B: *Definite Plan*, for explanations of reservoir drawdown periods and rates. Please also refer to Section 3.2.4.2 *Water Quality – Impact Analysis and Approach – Suspended Sediments* for a discussion of the reservoir drawdown rate in relation to sediment discharge and to Volume III Attachment 1 for the final Section 3.2 *Water Quality*. Faster reservoir drawdown would reduce the period of elevated sediment load and the duration of elevated suspended sediment concentrations (SSCs) in the Klamath River during and following dam removal. A slower drawdown rate is unlikely to decrease the episodic nature of sediment erosion, as the comment suggests, because there will be episodic sedimentation at any of the identified rates (2-5 feet per day) and the nature of sediment erosion, transfer, and deposition would be more dependent on the water year type than the rate of drawdown.

Regarding potential hillslope instability, including landslides, please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* – Potential Impact 3.11-3, as well as to Master Response GEO-2.

Comment LA9-71

Potential Impact 3.11.3 notes that reservoir drawdown could result in hillslope instability in reservoir rim area. The geologic assessment and slope stability analysis conducted by KRRC indicated that certain segments along the Copco No. 1 Reservoir rim have a potential for slope failure that could impact existing roads and/or private property. These areas included 3700 linear feet of slopes along Copco Road and approximately 2800 linear feet of slope adjacent to private property. Up to eight parcels in these areas have existing habitable structures that could potentially be impacted. However, KRRC has only *proposed to complete additional field geologic investigation and laboratory testing of material properties to better understand the potential for slope instability in these areas. A future study is not adequate to define the impact and associated mitigation that would be necessary for the project.*

Response to Comment LA9-71

Please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 (pages 3-761 to 3-765) and modifications to this impact in Volume III Attachment 1, and to Master Response GEO-2, relating to hillslope stability around the reservoirs during drawdown. In the Draft EIR, Mitigation Measure GEO-1 was not limited to investigations and testing and included monitoring and mitigation for slope failure. Since the Draft EIR, Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 Mitigation Measure GEO-1 has been updated. Revised Mitigation Measure GEO-1 includes monitoring and mitigation for slope failure. The mitigation covers any slope failure related to Project activities that adversely impacts a structure or public facility, or impacts or has a material potential to impact water quality or volitional fish passage. The Klamath River Renewal Corporation (KRRC) will fund or implement actions listed in Mitigation Measure GEO-1, including structure repair, relocation, or purchase; road repair and/ or re-alignment; engineering of structural slope improvements; and revegetation of affected areas to the extent feasible and appropriate. The monitoring and mitigation for Project-related slope failures specified in final Mitigation Measure GEO-1 (see paragraphs 2 and 3) are required regardless of the outcome of potential future studies. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 Mitigation Measure GEO-1 for the revisions.

Comment LA9-72

As a result Mitigation Measure GEO-1 Slope Stabilization was recommended, which consists of the following (from Page 3-765): "For any large slope failure that occurs during drawdown or the year following drawdown, KRRC will offset potential impacts by implementing the following actions: 1.Move affected structures or purchase affected property, 2.Re-align affected road segments, 3.Engineer structural slope improvements (e.g., drilled shafts or other structural elements that could be installed to resist slope movement), and 4.Revegetate affected areas. The monitoring period of "only during drawdown or the year following" for potential mass-wasting impacts is not adequate. The potential for landslides will continue beyond that time, until potential stabilization by natural vegetative growth will require longer period of time. Depending on climate and weather events, the period could be extended to five (5) years after the drawdown. The planned monitoring period should be extended, that the slopes at risk in other reservoirs be monitored, and that the engineering solutions could be more aggressive.

Response to Comment LA9-72

Please refer to Master Response GEO-2, relating to slope stabilization and the period of monitoring and mitigation for potentially unstable slopes surrounding Copco No. 1 Reservoir.

Comment LA9-73

The DEIR cultural resources section relies upon records searches conducted as part of the Klamath Hydroelectric Project Relicensing (FERC 2007) and 2012 EIR/EIS studies (PacifiCorp 2004 and Cardno Entrix 2012), with an updated records search in 2017 by KRRC which included the study area from the Oregon-California state line downstream to Humbug Creek. In addition, KRRC conducted a heritage search at the Klamath National Forest in 2017. However, the DEIR does not indicate whether archaeological surveys have been conducted as part of this project to identify resources within the Area of Analysis which may not be previously recorded. In section 3.12.2.3, the DEIR states "The majority of the past surveys involve pedestrian field survey and cultural resources monitoring. Overall, an estimated 8,189 acres of federal, state, and/or private lands have been previously surveyed within the records search area and except for some proposed disposal sites, encompasses the current boundaries of the Proposed Project." This language is not clear on the extent to which the study area has been subject to intensive pedestrian survey or how recently those surveys were conducted. Generally accepted professional practice is that areas that have not been surveyed within the past 5-10 years should be resurveyed to ensure adequate identification efforts. Site records should be updated to record current conditions and integrity of previously recorded resources. Changes in environmental conditions over time can lead to changes in visibility allowing for the identification of resources; the same environmental factors can change the condition and integrity of known cultural resources as well. The Cultural Resources Plan (attached to the Definite Plan but not to the DEIR) suggests that a survey was conducted in 2004; such survey is now 15 years old and should be updated. The DEIR should be revised to include detailed information on the timing, coverage, and results of the pedestrian survey to identify archaeological resources.

Response to Comment LA9-73

Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of the Proposed Project* has been revised to clarify complete versus incomplete inventory efforts.

Additionally, although previously stated in various locations throughout the EIR, the introductory text of Section 3.12 *Historical Resources and Tribal Cultural Resources* has been clarified to acknowledge that not all of the cultural resources inventories and evaluations required pursuant to section 106 of the National Historic Preservation Act (NHPA) will be completed prior to certification of the Final EIR.

The decision regarding whether to update surveys would be made during pre-survey record searches and outreach with local tribes. Mitigation Measure TCR-1 states that the Tribal Cultural Resources Management Plan (TCRMP) shall include an inventory of known and potential Tribal Cultural Resources (TCRs) that could be affected by the Project. Appendix B: *Definite Plan – Appendix L* includes a preliminary inventory of such resources. Klamath River Renewal Corporation (KRRC) will continue to develop the inventory through the consultation process for the license surrender application.

Please refer to Volume III Attachment 1 Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of the Proposed Project* for the revisions.

Comment LA9-74

The DEIR discussed KRRC's updated records search at the Northeast Information Center of the California Historical Resources Information System (CHRIS) which was conducted in 2017. This 2017 updated records search included the study area from the Oregon-California state line downstream to Humbug Creek. Appendix L of the Definite Plan indicates that an expanded records search was conducted in 2018 for an area encompassing a 0.5-mile wide zone on either side of the Klamath River from below Humbug Creek to the mouth of the river at the Pacific Ocean. Appendix L of the Definite Plan indicates that the results of that 2018 expanded records search would be incorporated into future reports. If downstream cultural resources in that zone have the potential to be affected by the Proposed Project, then those records search results should be incorporated into the DEIR and that area should be considered part of the Area of Analysis for the DEIR. Some of those records would be on file with the Northwest Information Center at Sonoma State University which houses records for Del Norte and Humboldt Counties. Consideration of potential project impacts to downstream historical resources and tribal cultural resources is critical.

Response to Comment LA9-74

Volume I Section 3.12.1 *Historical Resources and Tribal Cultural Resources – Area of Analysis* does consider the area 0.5 miles on either side of the river from downstream of Humbug Creek to the mouth of the Klamath River. Please refer to Figure 3.12-5, which defines Subarea 4. Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* has been revised to clarify the area's consideration in the analysis of Potential Impact 3.12-3. Please refer to Volume III Attachment 1 Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* for the revisions. Notwithstanding the 2018 expanded records search, the determination that drawdown and dam removal are unlikely to increase erosion or flood-related risk of damage to cultural resources downstream from Humbug Creek remains unchanged.

Comment LA9-75

The document does not include any discussion of whether resources might qualify as "unique archaeological resource" under PRC § 21083.2. It should be revised to do so. It only mentions archaeological resources as California Register of Historical Resources (CRHR)-eligible historical resources or as tribal cultural resources.

Response to Comment LA9-75

The introductory text of Section 3.12 *Historical Resources and Tribal Cultural Resources;* Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of the Proposed Project*; and Section 3.12.3 *Historical Resources and Tribal Cultural Resources – Significance Criteria* have been revised to address unique archaeological resources. These revisions clarify that for the purposes of this analysis, all known and unknown prehistoric archaeological sites in the Proposed Project area, including those that may meet the criteria for unique archaeological resources, are considered Tribal Cultural Resources (TCRs). Please refer to Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources* for the revisions.

Comment LA9-76

In the section labeled "Historical Landscape Analysis" on page 3-813, it is not clear whether a historical landscape has been identified which warrants consideration as a historical resource under CEQA. The DEIR needs to be clear if the project area is considered a historical landscape, which should then potentially be considered as a historical resource under CEQA.

Response to Comment LA9-76

The Historical Landscape Analysis has been completed and no Historical Landscapes have been defined in the project area. The EIR has been clarified by including a statement regarding the results of the historical landscape analysis. Please find the revision in Volume III Attachment 1 Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of the Proposed Project.* This revision does not constitute significant new information (CEQA Guidelines Section 15088.5(a)).

Comment LA9-77

Table 3.5-3 in Appendix W lists previously recorded archaeological sites and built environment resources and indicates their National Register of Historic Places (NRHP) eligibility status. Under CEQA, resources that are eligible for listing in the CRHR are also historical resources for which impacts must be analyzed. The DEIR needs to describe whether there are resources which are CRHR eligible or eligible for local listing but not NRHP eligible (also known as "CEQA only" resources). If so, these would not be addressed in the Historic Properties Management Plan (HPMP) under development by KRRC for FERC to comply *with Section 106 (because such resources would not be historic properties under Section 106). The DEIR does not identify such resources or address mitigation of impacts related to those resources.*

Response to Comment LA9-77

The introductory text in Section 3.12 *Historical Resources and Tribal Cultural Resources* has been revised to clarify that (1) for the purposes of the EIR analysis, all known and unknown built environment and historic archaeological resources are assumed to be significant historical resources under CEQA and (2) some of these resources may not be National Register of Historic Places (NRHP)-eligible. Please refer to Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources* for these revisions. Please note that some historical resources may not be identified on Table 3.5-3 in Volume II Appendix W, which addresses only NRHP-eligible resources. As stated in Section 3.12.5.2 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Built Environment and Historic-period archaeological Resources*, the Klamath River Renewal Corporation (KRRC) has initiated a process through the Cultural Resources Working Group and Federal Energy Regulatory Commission (FERC) to develop and implement a Historic Properties Management Plan (HPMP) and a Programmatic Agreement. KRRC has committed to including protection of both National and California-eligible cultural resources (i.e., historic properties and historical resources) in the Historic Properties Management Plan (KRRC 2019a). At this time, however, the Historic Properties Management Plan and the Programmatic Agreement are not finalized and the State Water Board cannot require their implementation. In addition, the EIR analysis concludes that even with inclusion of the KRRC's proposed protection measures, some impacts to historical resources would be significant and unavoidable.

Comment LA9-78

Mitigation Measures TCR-1 through TCR-3 refer to development of an HPMP which will include a Tribal Cultural Resources Management Plan (TCRMP), a Looting and Vandalism Prevention Program (LVPP), and an Inadvertent Discovery Plan (IDP). However, as disclosed under discussion of Impact 3.12.5.2, FERC and KRRC are initiating the development of these plans under the Section 106 process and "the State Water Board cannot require their implementation." It's not acceptable to defer mitigation during future consultation processes under CEQA (CEQA Guidelines Section 15126.4(a)(1)(B)). Mitigation measures, and their effect on the impacts of the project, should be clearly stated in the DEIR for consideration by stakeholders, the public, Native American Tribes, and others.

Response to Comment LA9-78

Please refer to Master Response CEQ-2 and ORG46-302.

The State Water Board developed tribal cultural resources mitigation measures in formal Assembly Bill 52 (AB 52) government-to-government consultation with Native American Tribes that have tribal cultural resources which could be impacted by the Proposed Project. To ensure implementation of the mitigation measures, the Klamath River Renewal Corporation (KRRC) was included in AB 52 consultations for development of tribal cultural resources mitigation measures. On October 17, 2018 and November 30, 2018 the KRRC confirmed their agreement with the mitigation measures, thus ensuring feasibility for implementation under CEQA.

Please note that although Section 106 requirements are not required to extend to non-federally recognized Native American Tribes, CEQA does not require that Tribal Cultural Resource (TCR) impacts be dependent on a Native American Tribe's federal recognition status as such, and TCR mitigation measures identified in the EIR apply to both federal and non-federally recognized tribes. Efforts currently occurring in the Section 106 process are separate and complementary to the TCR mitigation measures developed and committed to by the KRRC.

Mitigation Measures TCR-1, TCR-2, and TCR-3, which require development and implementation of a Historic Properties Management Plan (HPMP) that includes a Tribal Cultural Resources Management Plan (TCRMP), a Looting and Vandalism Prevention Program (LVPP), and an Inadvertent Discovery Plan (IDP), respectively, do not improperly defer formulation of mitigation measures. For this project, formulation of the precise means of mitigating project impacts to all potentially affected historic and cultural resources before the EIR is certified is infeasible and impractical for a number of reasons, including the nature and magnitude of the project, the quantity of cultural resources that could be impacted, the current inaccessibility of many of those resources, and the need for the State Water Board to issue or deny water quality certification for the project within the statutory time limit.

Numerous surveys and studies have been conducted, compiled, and evaluated, and the State Water Board has engaged in an extensive and productive consultation process with affected Native American tribes pursuant to AB 52, which resulted in the development of detailed mitigation measures. The consultation process pursuant to section 106 of the National Historic Preservation Act is ongoing, and may result in additional cultural resource surveys and evaluations. In particular, the KRRC has agreed to conduct intensive surveys to identify Tribal Cultural Resources (TCRs), archaeological, and other historical resources following reservoir drawdown, and to conduct a data gap analysis to ensure that all of the areas within the limits of work are surveyed to the extent feasible. The KRRC has committed to develop and implement a HPMP for protection of both federally and California-eligible historical properties (KRRC 2019a). The additional information developed through the section 106 consultation process will be incorporated into the HPMP and TCRMP.

Under CEQA, deferral of the specifics of mitigation is permissible where a commitment exists to implement the mitigation, specific performance standards are identified, and the types of actions that will be considered and potentially incorporated into a mitigation plan are identified. (*Sacramento Old City Assn. v. City Council* (1991) 229 Cal.App.3d 1011, 1028-1030; Cal. Code Regs., tit. 14, § 15126.4, subd. (a)(1)(B).) Those requirements are satisfied here. First, the KRRC has committed to implementing Mitigation Measures TCR-1, TCR-2, and TCR-3. The TCRMP (which will include the LVPP and IDP) will be developed in consultation with affected tribes and submitted to Federal Energy Regulatory Commission (FERC) as part of the HPMP for approval.

Specific performance standards for the mitigation of significant impacts to historic and cultural resources are established by applicable federal and state laws and guidelines, which are identified in the EIR and Appendix L to the Definite Plan. These include Public Resources Code section 21084.3, section 106 of the National Historic Preservation Act, the Advisory Council on Historic Preservation's Section 106 Archaeology Guidance, and the Native American Graves Protection and Repatriation Act. The purpose of the HPMP, TCRMP, LVPP, and IDP is to ensure that potential significant impacts to historic and cultural resources are mitigated in accordance with those legal standards.

The types of actions that will be considered and potentially incorporated into the TCRMP, LVPP, and IDP are identified in TCR-1, TCR-2, and TCR-3. Those mitigation measures list the elements that must be included in the respective plans, and identify specific measures that must be implemented or considered, including field worker training, limits to worker and public access, tribal monitors, and surveys. The plans must identify protocols and best practices to be followed upon discovery or disturbance of TCR's during project implementation. Consistent with Public Resources Code section 21084.3, subdivision (a) and as specified in section 8.3.2 of Appendix L to the Definite Plan, avoidance and preservation in place will be the preferred treatment method for historic properties and TCR's.

The parameters summarized above support the conclusion that TCR-1, TCR-2, and TCR-3 do not improperly defer the formulation of mitigation measures, and would reduce or avoid potential impacts to many TCR's, although the potential for some significant impacts would remain, for the reasons explained in Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources*. Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources*.

Comment LA9-79

The impacts analysis considers impacts to tribal cultural resources, built environment historical resources, and historic-period archaeological resources. There is no discussion relevant to prehistoric archaeological sites which may be CRHR eligible (and therefore historical resources under CEQA) but which may not qualify as tribal cultural resources. The DEIR should be revised to include this discussion. Not all prehistoric sites are Tribal Cultural Resources (TCRs).

Response to Comment LA9-79

The introductory text of Section 3.12 *Historical Resources and Tribal Cultural Resources* and Section 3.12.4 *Historical Resources and Tribal Cultural Resources – Impact Analysis Approach* has been revised to clarify that with the exception of isolated occurrences of cultural material, all known and unknown prehistoric archaeological sites within the Project area are considered to be tribal cultural resources for purposes of the EIR analysis. Please refer to Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources* and Section 3.12.4 *Historical Resources and Tribal Cultural Resources – Impact Analysis Approach* for the revisions.

Potential impacts to Tribal Cultural Resources (TCRs) are analyzed in Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources*. Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources.*

Comment LA9-80

There is no mitigation measure that outlines what the HPMP will include. It is referenced somewhat under MM TCR-1, but it should be described in greater detail in an MM of its own and should be referenced under Potential Impacts 3.12-13, 3.12-14, 3.12-15, and 3.12-16 (as well as others). For example, it is not clear whether pre-construction data recovery would be implemented for eligible historic archaeological sites that cannot be avoided by the project. Under CEQA, avoidance and preservation in place are the preferred forms of mitigation for archaeological sites. When avoidance is infeasible, a data recovery plan should be prepared to provide for the systematic recovery of scientifically consequential information from the site (CEQA Guidelines, Section 15126.4). There is no mention of data recovery in the entire DEIR document.

Response to Comment LA9-80

As described in Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources*, Mitigation Measure TCR-1 requires Klamath River Renewal Corporation (KRRC) to develop a Historic Properties Management Plan (HPMP); KRRC would also propose the HPMP for Federal Energy Regulatory Commission's (FERC's) approval as a term of the license surrender order. Per Mitigation Measure TCR-1, the HPMP must contain a Tribal Cultural Resources

Management Program (TCRMP) that addresses how the Project will avoid, minimize, or mitigate adverse impacts to Tribal Cultural Resources (TCRs), consistent with California Public Resources Code section 21084.3(a). The mitigation measure specifies that in developing the HPMP, the KRRC will consider measures listed in California Public Resources Code Section 21084.3(b) that, if feasible, may be appropriate to avoid, minimize, or mitigate adverse impacts. The required content of the HPMP is also specified in Volume II Section 8.3 of Appendix L – *Cultural Resources Plan* to Appendix B of the Definite Plan, including mitigation measures. In regards to data recovery Volume II Appendix L Section 8.3.2; page 62 of the *Cultural Resources Plan* identifies data recovery as a potential mitigation measure when impacts cannot be avoided, as follows: *For effects to archaeological sites that will be mitigated through data recovery, mitigation protocols will include but not be limited to a research design that articulates research questions; data needed to address research questions; methods to be employed to collect data; laboratory methods employed to examine collected materials; and proposed disposition and curation of collected materials and records*.

Comment LA9-81

Under Potential Impact 3.12-11, the DEIR discusses impacts to Copco No. 1 Dam, Copco No. 2 Dam, Iron Gate Dam, and their associated hydroelectric facilities, as well as the Klamath River Hydroelectric Project District as a whole. No mitigation measures are listed relative to this impact in Section 3.12.5.2 or in Table ES-1. The text of the impact discussion mentions that restoration, adaptive re-use, and relocation are all not feasible. It references "inclusion of documentation measures in conformance with the Secretary of the Interior's guidance" but does not specify what this would entail. The text references "KRRC's proposed mitigation measure" but no MM for this impact is included. Typical mitigation for demolition of an eligible resource includes documentation according to Historic American Buildings Survey (HABS) or Historic American Engineering Record (HAER) standards. While such documentation typically does not reduce impacts to less than significant, additional MM can also be crafted. In fact, CEQA requires that all feasible mitigation be undertaken even if it does not mitigate below a level of significance. Such measures might include preparation of interpretive signage, development of public school curriculum related to the historic themes specific to the resource in question, preparation of a historic context document for the county or region in question or related to historic themes specific to the resource, preparation or funding of museum exhibits, or other appropriate strategies.

Response to Comment LA9-81

Please refer to Master Response CEQ-2 for a discussion of federal preemption. Please note that the referenced section discusses measures including documentation that the KRRC has proposed, including documentation. Please refer to Volume III Attachment I for the final version of Section 3.12.5.2 –

Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to the Build Environment Potential Impact 3.12-11.

Comment LA9-82

Potential Impact 3.8-2 in the Water Supply/Water Rights section describes the potential for less water to be available to users (including for irrigation of agricultural lands) as a result of the Proposed Project, as some Klamath Irrigation Project deliveries are made to California users. These same users turn to groundwater pumping when there are surface water shortages; however, there are ground water management plans that must be implemented by 2022 and may adjust sustainable pumping levels. Some farms may not be able to afford, or have the ability, to pump groundwater during dry years, which could result in the indirect conversion of Farmland to a non-agricultural use.

Response to Comment LA9-82

As explained in Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-1 (pages 3-676 to 3-679) and Potential Impact 3.8-2 (pages 3-679 to 3-680), water deliveries to farmers that rely upon the United States Bureau of Reclamation's (USBR's) Klamath Irrigation Project are not sourced from the Lower Klamath Project reservoirs. The USBR is required to release water from the Klamath Irrigation Project into the Klamath River upstream of Keno Dam to comply with the flow requirements in the applicable National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) biological opinion(s). The Proposed Project does not include any changes to the amount of flow released by the Klamath Irrigation Project and the applicable biological opinion(s). Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* summarizes how the applicable biological opinion(s) have changed separately and independently of the Proposed Project from the NMFS and United States Geological Survey (USGS) Joint 2013 Biological Opinion (2013 BiOp) that was the applicable biological opinion at the time of the Notice of Preparation (NOP) for the Lower Klamath Project (i.e., December 22, 2016) to the biological opinions issued by NMFS and USFWS in March 2019 (2019 BiOps) after the Lower Klamath Project Draft EIR had been issued on December 28, 2018. Please refer to Volume III Attachment 1 for the final Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*.

As discussed in Volume I Section 3.8.5 –*Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-2 (pages 3-679 to 3-680), twice in recent years, PacifiCorp has agreed to operate its hydropower projects in a manner that supported increased irrigation deliveries to the Klamath Irrigation Project and assist USBR in meeting requirements of the 2013 BiOp (i.e., the applicable biological opinion at that time). This water was subsequently replaced by the Klamath Irrigation Project. The agreement by PacifiCorp to adjust its operations was not a legal requirement. If PacifiCorp had not released the flows from Iron Gate and Copco No. 1 reservoirs in those years, then USBR would have released flows at Keno Dam and the water would have traveled downstream, regardless.

The Proposed Project would preclude the potential option (not requirement) of utilizing the Lower Klamath Project reservoir water supply to help the USBR meet the applicable biological opinion(s) flow requirements and thereby extend the available water supply to the USBR Klamath Irrigation Project. However, there would be no legal injury to the Klamath Irrigation Project users because the Lower Klamath Project operators are not required to temporarily supplement water deliveries, per the 2013 BiOp that was the applicable biological opinion when the Notice of Preparation for the Lower Klamath Project was issued on December 22, 2016, or per the currently applicable 2019 BiOp. USBR is still required to release water from the Klamath Irrigation Project into the Klamath River upstream of Keno Dam to comply with the flow requirements in the currently applicable biological opinion(s) (i.e., 2019 BiOp). Additionally, there is no indication that water would not be available for public health purposes, absent supplementation of Klamath Irrigation Project available water.

As discussed in Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-2 (pages 3-679 to 3-680), the Tulelake Basin is designated a medium priority basin under the Sustainable Groundwater Management Act (SGMA), in part because of declining groundwater levels and high-volume groundwater extractions, which have been occurring despite the Lower Klamath Project being operational. It can be expected that there will be some adjustment by basin farmers as they comply with future sustainable groundwater extraction requirements, which they would need to do regardless of whether the Lower Klamath Project was in place. The need to comply with future sustainable groundwater extraction requirements may result in indirect conversion of farmland to a non-agricultural use, similar to what could be experienced in other groundwater basins throughout the State. However, this is not a consequence of the Lower Klamath Project. As stated above, there is no legal requirement for the Lower Klamath Project operators to temporarily supplement water deliveries to Klamath Irrigation Project farmers and the USBR. There is no indication that such an optional supply is or should be used as a future planning tool by the USBR or farmers.

Comment LA9-83

As provided in Section 3.11.5 on page 3-762 of the Geology, Soils, and Mineral Resources section of the DEIR and described in Appendix B: Definite Plan, the geologic assessment and slope stability analysis conducted by KRRC indicated that certain segments along the Copco No. 1 Reservoir rim have a potential for slope failure that could impact existing roads and/or private property. These areas include approximately 3,700 linear feet of slopes along Copco Road and approximately 2,800 linear feet of slope adjacent to private property. Up to eight parcels in these areas have existing habitable structures that could potentially be *impacted. The Population and Housing section of the DEIR neglects to consider potential impacts to these residences.*

Response to Comment LA9-83
Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3, including Mitigation Measure GEO-1, has been revised following review of public comments and revisions to Volume II Appendix B: *Definite Plan* – Appendix E. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 for the revisions. Note that Section 3.11.3 *Geology, Soils, and Mineral Resources – Significance Criteria*, as modified in Volume III Attachment 1, includes the exposure of people or structures to adverse effects resulting from slope instability as a relevant consideration; therefore, Mitigation Measure GEO-1 mitigates for significant impacts to people and structures associated with potential slope failures during and immediately following drawdown on potentially unstable slopes. Section 3.16.1 *Population and Housing – Area of Analysis* and Section 3.16.2 *Population and Housing – Environmental Setting* has been revised to clarify that the slope failure impacts on habitable structures are addressed in Section 3.11.5 *Geology, Soils, and Mineral Resources*, and that the combined consideration of potential impacts from slope failure and floodplain changes does not require further consideration for effects on population and housing. Please refer to Volume III Attachment 1 Section 3.16.1 *Population and Housing – Area of Analysis* and Section 3.16.2 *Population and Housing – Environmental Setting* for the revisions.

Comment LA9-84
MMs need to be included when this impact analysis is remedied.

Response to Comment LA9-84
Please refer to response to comment LA9-83. The clarifications discussed in LA9-83 did not result in a need for mitigation.

Comment LA9-85
Section 3.16.2 of the Population and Housing section of the DEIR note that 36 residences would be affected by changes in the FEMA 100-year flood elevations resulting from the removal of Iron Gate Dam. As described on page 3-632 in Section 3.6.5.2 of the Flood Hydrology section of the DEIR, the change to the 100-year floodplain inundation area would pose significant flood risk to these 36 residences, resulting in the possibility that these structures would be relocated. The Population and Housing Section should consider the Proposed Project's effect on these 36 structures together with the 8 residences vulnerable to landslide as a result of reservoir drawdown.

Response to Comment LA9-85
The potential for impacts on 36 residences due to flooding as a result of the Proposed Project is referenced in Volume I Section 3.16.1 *Population and*

Housing – Area of Analysis (page 3-903), which states that the effects of flood elevations upon these residences are analyzed in more detail in Volume I Section 3.6 *Flood Hydrology*. The analysis in the EIR determines that the loss of structures that are not feasible to move or elevate would be a significant impact. In addition, Volume I Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain* (page 3-631) notes that a total of 34 legally-established habitable structures are already located within the existing 100-year floodplain and an estimated 2 additional legally-established habitable structures would be within the altered 100-year floodplain in the same reach following dam removal, for a total of 36 legally established habitable structures within the altered 100-year floodplain following dam removal (Appendix B: *Definite Plan*).

Please also refer to response to comment LA9-83.

Comment LA9-86

MMs need to be included when this impact analysis is remedied.

Response to Comment LA9-86

Please refer to response to comment LA9-85.

Comment LA9-87

Property owners with residences in locations that have views and/or recreational access to the reservoirs could feel discontented by the change from a flatwater aquatic environment to a riverine environment. As a result, the Proposed Project could cause population in the area to decrease, as property owners could conceivably decide to relocate to another location that supports a more favorable perceived aquatic environment. Additionally, the loss of dam operating revenue that would result from the removal of the dams, and loss of tax revenue, could impact the quality of education in the long run. A decline in the quality of education could cause current households to relocate outside the County in search of better educational opportunities. The Population and Housing section of the DEIR should discuss the potential fiscal effects associated with a declining population and loss of tax revenue and the implications this may have for public school enrollment and the quality of education. In addition, the DEIR should consider the relocation of these households, and the need for replacement housing elsewhere, which may be associated with indirect displacement as a result of discontent.

Response to Comment LA9-87

Please note that CEQA documents analyze significant effects on the physical environment; CEQA does not address potential social or economic effects from implementing a project. (CEQA Guidelines, section 15131(a).) However, to inform the public and decisionmakers regarding the potential economic consequences of the proposed project, the EIR includes Section 5.4.1 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Consideration of Economic Information for Resources Potentially Affected by*

Dam Removal (pages 5-4 to 5-11) which summarizes the results of prior economic studies conducted by the U.S. Department of the Interior (DOI) to characterize potential effects on property value. An evaluation of potential population changes as described in the comment would be speculative.

Comment LA9-88

This analysis should be revised to include a discussion of impacts to emergency services due to an increased work force.

Response to Comment LA9-88

Emergency services, which includes a discussion of impacts to services due to an increased work force, is discussed in Volume I Section 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17.5 (starting on page 3-913) and Potential Impact 3.22-4 (pages 3-1075 to 3-1076). Please also refer to response to comment ORG47-56.

Comment LA9-89

The Proposed Project would result in the removal of three readily available water sources, not one as is stated. This should be corrected.

It states, "The removal of the reservoirs could increase the turn-around time for helicopters or ground crews refilling with water for fire abatement purposes." Yet, the next two sentences conflict with this statement saying that it would not be changed, because the river will still be there, and other reservoirs are available. These sentences need to be made consistent with each other.

In addition, the impact analysis fails to quantify the increase in turnaround time for helicopters due to the loss of reservoirs (e.g., two minutes is very different than 30 minutes). Furthermore, although the impacts is determined to be significant and unavoidable, given the potential devastating wildfire implications of implementing the Proposed Project, some quantification of the impacts should be made for the public and wildfire fighting agencies.

Response to Comment LA9-89

The Klamath River, as a whole, represents a single source of water although it contains numerous pools from which water could be drawn to fight fires. The Lower Klamath Project reservoirs represent a portion of this water source, although there are three individual reservoirs in California that are proposed for removal. The EIR project description and impact discussion are clear that three individual reservoirs would be impacted by the Proposed Project. No correction is necessary.

With respect to the comment regarding helicopter turn-around time, please refer to Master Response HAZ-2.

<u>Comment LA9-90</u>

The Definite Plan, Appendix C-01, Fire Management Plan should identify additional permanent water sources that emergency services (specifically, helicopter water tankers) could use for wildland fire fighting, readiness, and prevention. Stating the Klamath River, where it flows freely within the former reservoir footprints could be used for as source of water to fight wildland fire is far too speculative. Topography and river flow patterns/fluctuations will prevent many locations of the River from ever being used by helicopter. The Fire Management Plan should identify areas where man-made structures are located in areas that are safe and reliable for helicopter water tankers to extract water. Man-made structures such as dip tanks provide a reliable, safe and permanent water source, and could be installed/designed integrated with the proposed dry hydrants.

Response to Comment LA9-90

The issue raised in the comment is considered in Appendix O-1 Fire Management Plan. Please also refer to Master Response HAZ-2.

<u>Comment LA9-91</u>

The impact discussion should analyze the potential for the loss of school-aged children due to residential relocation as a result of lower quality of life for areas around the reservoirs. Also, the loss of dam operating revenue that would result from the removal of the dams could impact the quality of education in the long run. A decline in the quality of education could cause current households to relocate outside the County in search of better educational opportunities for their children.

Response to Comment LA9-91

Please note that CEQA documents analyze significant effects on the physical environment; CEQA does not address potential social or economic effects from implementing a project (CEQA Guidelines, section 15131(a). Please also refer to Volume I Section 5.4 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA*.

However, to inform the public and decisionmakers regarding the potential consequences of the proposed project, Volume I Section 3.17.5 *Public Services – Potential Impacts and Mitigation* Potential Impact 3.17-3 (page 3-922) addresses the potential long-term physical impacts of the project on school facilities and services. The additional concern raised in the comment regarding changing demographics as a result of reservoir removal is too speculative for evaluation in the EIR.

<u>Comment LA9-92</u>

Data used to estimate facility and reservoir use was collected in 2001 and 2002 by PacifiCorp (PacifiCorp 2004) and is approximately 18 years old. It is likely that use levels of these facilities and reservoirs have changed since 2002, as *shifts in participation in outdoor recreation has occurred. For example, freshwater fishing across the United States has declined from 43.1 million participants in 2006 to 38.3 million participants in 2017 (RBFF and OF 2018) while boat ownership increased from 20.5 million in 2009 to 21.2 million in 2012 (RBFF and OF 2013) and overall outdoor participation increased from 41.9% of all Americans in 2006 to 49.0% in 2017 (OF 2018). The State Board should address these shifts in the DEIR; otherwise, it is possible that any impact analysis that relies on this information may not be accurate.*

Response to Comment LA9-92

Section 3.20.2 *Recreation – Environmental Setting* has been revised to incorporate more recent recreational data, where possible. Please refer to Volume III Attachment 1 Section 3.20.2 *Recreation – Environmental Setting* for the revisions.

Comment LA9-93

The Significance Criteria for Recreation (Section 3.20.3) include "Changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people" and "Significant increase in the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facilities would occur or be accelerated" (page 3-1002). Because the data used to establish baseline use of the facilities and reservoirs associated with the Proposed Project is approximately 18 years old and outdoor recreation participation has changed in the meantime, meaningful analysis of a "substantial number of people" and/or the current and projected levels of use of regional facilities is unlikely.

For example, the impact analysis for Potential Impact 3.20-1 states, "Overall, the impacts of construction and restoration activities are limited in temporal and geographic scope and so would not result in changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people. Nor would they result in a significant temporary increase in the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facilities would occur or be accelerated. Tables 3.20-2, 3.20-3, and 3.20-4 show that there are numerous alternative recreational facilities and access outside the area of effect, but within the vicinity. Most of these facilities experience low to moderate use levels and they can accommodate additional users. Recreational users who are temporarily displaced would be able to use these other areas, but they are unlikely to overload the other areas because those areas have sufficient capacity to accept them. Therefore, impacts will be less than significant" (page 3-1006). Without updated facility and reservoir use data, the degree to which displaced reservoir recreationists would affect facilities and reservoirs in the region cannot be accurately estimated.

Response to Comment LA9-93

Section 3.20.2 *Recreation – Environmental Setting* has been revised to incorporate more recent recreational data, where possible. The significance criteria noted have also been changed. Please refer to Volume III Attachment 1 Section 3.20.2 *Recreation – Environmental Setting* and Section 3.20.3 *Recreation – Significance Criteria* for the revisions.

<u>Comment LA9-94</u>

Citing from the 2004 PacifiCorp report, the DEIR states "When surveyed on their perception of crowding at the reservoirs, the mean score of respondents was 3.2 (on a 9-point scale from 1—not crowded to 9—extremely crowded), indicating that visitors did not feel overly crowded while participating in recreation activities. Further, approximately 39 percent of respondents had changed their visits to the Lower Klamath Project reservoirs from other lakes in the area to avoid crowding" (page 3-994). The impact analysis for Potential Impact 3.20-2 states "As indicated in the responses to visitor use surveys conducted by PacifiCorp (2004), the reservoirs are popular recreation areas in part because they are uncrowded relative to other lakes in the area and do not require user fees"(page 3-1007), and "…Given that a number of other lakes and reservoirs in the vicinity of the Lower Klamath Project provide similar opportunities for reservoir-based recreation in an uncrowded setting, KRRC's proposal to retain and enhance most existing river access facilities within the Area of Analysis for recreation, and Parcel B land transfer under the Proposed Project that would potentially allow for additional future river-based recreation opportunities, the Proposed Project would be highly unlikely to result in a loss of rare or unique recreational facilities affecting a large area or substantial number of people. In addition, the KRRC has prepared a Draft Recreation Plan (Appendix B: Definite Plan – Appendix Q) that includes stakeholder outreach, identification of potentially new or modified recreational facilities as well as evaluation and screening criteria, which will further reduce any potential impacts" (page 2-1009).

As described in Comment 1, "Changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people" is one of the criteria for the determination of significance. Because visitor surveys have identified the Iron Gate and Copco No. 1 Reservoirs as uncrowded relative to other lakes in the region, these reservoirs could be interpreted as rare within the region for their low use and uncrowded setting. The analysis focuses on the redistribution of these users to other existing lakes in the region, yet the data and analysis explicitly states that conditions at these lakes were unsatisfactory due to perceived overcrowding under current conditions. It can be anticipated that the loss of reservoir-based recreation on Iron Gate and Copco No. 1 Reservoirs would result in the perception of increased levels of overcrowding at other lakes in the region, despite the reported use of these other lakes being low or moderate. Additionally, as there are few reservoirs within Siskiyou County, California that are of similar size and setting, the Iron Gate and Copco 1 reservoirs could be considered rare within the California region.

Response to Comment LA9-94

Section 3.20.3 *Recreation – Significance Criteria* Potential Impact 3.20-1, Potential Impact 3.20-2, and Potential Impact 3.20-6 have been revised to clarify that the analysis considers the potential for adverse changes to recreational facilities, regardless of whether the facilities may be considered rare or unique. Please refer to Volume III Attachment 1 Section 3.20.3 *Recreation – Significance Criteria* and Section 3.20.5 *Recreation – Potential Impacts and Mitigation* for the revisions.

Comment LA9-95

The Draft Recreation Plan is included in the impact analysis as contributing to the "no significant impact" determination for reservoir-based recreation. The impact analysis for Potential Impact 3.20-2 states "The Proposed Project includes a Recreation Plan (see Appendix B: Definite Plan – Appendix Q for the Draft Recreation Plan) that would be used to identify new recreation opportunities that offset the proposed removal of reservoir recreation sites as well as the reduction in whitewater boating days resulting from the Proposed Project. KRRC has started an ongoing stakeholder outreach process seeking input from potentially impacted recreation users, operators, managers and administrators, including tribes, state and federal agencies, county agencies and chambers of commerce, local residents, recreation businesses, and public interest groups. The stakeholder outreach process would continue through the development of the Final Recreation Plan, which is scheduled for completion by KRRC in June 2019. The Draft Recreation Plan includes potential recreation opportunities identified in the USBR (2012) Detailed Plan as well as those identified through recent stakeholder outreach efforts. The Draft Recreation Plan also outlines preliminary criteria for screening opportunities, including whether each recreation opportunity would: "directly address the recreation impacts generated by the KHSA;" and "directly address or offset changes in the localized reservoir recreation or Hells Corner boating near where the impacts are occurring." In addition, the Proposed Project includes the transfer of approximately 8,000 acres of real property (Parcel B lands; see also Section 2.7.10 Land Disposition and Transfer) located in Klamath County, Oregon, and Siskiyou County, California, to the respective states (or a designated third party) for public interest purposes, including river-based recreation, open space, active wetland and riverine restoration, and public education (Page 3-1008)" and "Given that a number of other lakes and reservoirs in the vicinity of the Lower Klamath Project provide similar opportunities for reservoir-based recreation in an uncrowded setting, KRRC's proposal to retain and enhance most existing river access facilities within the Area of Analysis for recreation, and Parcel B land transfer under the Proposed Project that would potentially allow for additional future river-based recreation opportunities, the Proposed Project would be highly unlikely to result in a loss of rare or unique recreational facilities affecting a large area or substantial number of people." The Recreation Plan Update webinar (hosted by KRRC on January 30, 2019) presented an updated Recreation Plan, which consists of eight new or upgraded *river access points (four in Oregon and four in California) including (Americans with Disabilities Act (ADA)-accessible facilities where feasible, and recreational access to existing sites during construction where feasible. As stated in the screening criteria, the opportunities presented in the Recreation Plan will "directly address or offset changes in the localized reservoir recreation…near where impacts are occurring." Restricting the Recreation Plan to eight new or upgraded river access points fail to directly address the loss of flatwater recreation, particularly as reservoir-based recreation opportunities could be considered rare within Siskiyou County, California. For this reason, it is inappropriate to assume that the Recreation Plan would address or offset any impacts to reservoir-based recreation.*

Additionally, the impact analysis for Potential Impact 3.20-4 states As described previously, the Proposed Project involves the development and implementation of a plan to construct new recreational facilities and river access points along the restored river channel between the California-Oregon border and Iron Gate Dam following dam removal activities. Replacement of recreation facilities would not necessarily be "like for like", but rather would be designed to accommodate similar levels, if different types of use. This would require the creation of new gravel roads and other improvements for vehicle and visitor access to and use of the new river-based recreation sites, which could result in construction-related impacts to the environment, including potential impacts to water quality and historical and/or tribal cultural resources. While new recreation facilities are part of the Proposed Project, the final location, size, and design of the facilities are still under development and will be the subject of subsequent approvals. It is thus too soon to conduct a meaningful environmental analysis of the replacement facilities. However, construction and operation of new recreational facilities would undergo any environmental review necessary for the subsequent approvals, and any impacts of the construction and operation of the facilities would be mitigated, if feasible, to levels that comply with all applicable laws, regulations, and environmental standards. Because this component of the Proposed Project would not be approved until a later date, for the purposes of this EIR the impacts of this component are not significant." (page 3-1010).

Specific mitigation measures regarding recreation would be determined by FERC through a separate project permitting process. Therefore, it is inappropriate to assume that impacts to recreation would be less than significant without determining what the mitigation measures would consist of.

Response to Comment LA9-95

With respect to the comment's assertion regarding rare or unique recreational facilities, please refer to response to comment LA9-94.

The State Water Board does not agree that it is inappropriate for the EIR analysis to consider the potential for new recreation opportunities designed to offset the proposed removal of reservoir recreation sites and the reduction in whitewater boating days resulting from the Proposed Project. As stated in Section 3.20.5 *Recreation – Potential Impacts and Mitigation* Potential Impact 3.20-2, the Klamath River Renewal Corporation's (KRRC's) Draft Recreation Plan involves identifying these new recreation opportunities as well as retaining and enhancing most existing river access facilities within the Area of Analysis for recreation. The analysis goes on to acknowledge that a number of other lakes and reservoirs in the vicinity of the Lower Klamath Project provide similar opportunities for reservoir-based recreation in an uncrowded setting and states that Parcel B land transfer under the Proposed Project would potentially allow for additional future river-based recreation opportunities. The analysis considers each of these contributing factors and determines that the Proposed Project would not result in a long-term loss in regional lake-based recreational activities that would affect a large area or a substantial number of people. Please refer to Volume III Attachment 1 for the final Section 3.20.5 *Recreation.* For additional discussion of how the EIR considers the level of detail in KRRC's Draft Recreation Plan, please refer to Master Response REC-2.

Comment LA9-96

The government records database searches, consistent with American Society for Testing and Materials (ASTM) E1527 – 13 or ASTM E2247 – 08 should be conducted.

Additionally, review of available sediment quality data (Bureau of Reclamation Klamath Sediment Chemistry Report [BOR 2011]) suggests that additional assessment may be warranted to include additional deep-sediment samples, additional Total polychlorinated biphenyls (PCB) analyses (especially from deeper sediments), and additional Polycyclic Aromatic Hydrocarbons (PAH) analyses so that the detection level, at a minimum, falls between the threshold effect concentration (TEC) and probable effect concentration (PEC) values, instead of greater than the PEC levels.

Response to Comment LA9-96

The Phase I Environmental Assessment for the Lower Klamath Project was performed by the Klamath River Renewal Corporation (KRRC) in 2018, in general accordance with the American Society for Testing and Materials (ASTM) Practice E-1527-13 for conducting Phase I ESAs (KRRC 2019f,g,h). The assessment was conducted at the J.C. Boyle Development, Copco No. 1 Development, Copco No. 2 Development, Iron Gate Development, and the Iron Gate Fish Hatchery. Phase II investigations were performed by KRRC in 2018 and 2019 (KRRC 2019i,j,k,l,m,n,o). For additional information regarding the Phase I and Phase II Environmental Assessments, please refer to Master Response HAZ-1.

Please refer to Section 3.2.2.8 *Water Quality – Inorganic and Organic Contaminants, Sediment Contaminants* for a discussion of how on-site geologists verified that reservoir sediment cores collected during 2009 and 2010 reached the reservoir-deposited/pre-reservoir sediment boundary to characterize the inorganic and organic contaminants throughout the entire depth of the existing reservoir sediments. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Additional total polychlorinated biphenyls (total PCBs) measurements in reservoir sediments are not necessary to assess the potential adverse effects from short-term and long-term exposure to reservoir sediments since the method reporting limit (MRL) for total PCBs in reservoir sediment was greater than the most stringent screening level for total PCBs. The MRL for total PCBs in reservoir sediment samples was 33,500 picogram per gram (pg/g), but the most stringent screening level for total PCBs was 89,000 pg/g for human health (i.e., California Environmental Protection Agency [CalEPA] California Human Health Screening Level [CHHSL], Residential), 60,000 pg/g for freshwater (i.e., 2009 Pacific Northwest Sediment Evaluation Framework [SEF] Screening Level 1 [SL1]; total PCBs was replaced in the 2018 Pacific Northwest SEF with total Aroclors), and 38,000 pg/g for marine (i.e., Puget Sound Dredged Material Management Program [DMMP]). Furthermore, there are no freshwater threshold effect concentration (TEC) or probable effect concentration (PEC) or the approximately equivalent marine threshold effect level (TEL) or probable effect level (PEL) for total PCBs included in the National Oceanic and Atmospheric Administration (NOAA) screening quick reference tables (SQuiRTs).

As discussed in Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-13 and Potential Impact 3.2-14, some analytes, including six Aroclor PCB compounds, had laboratory MRLs that were greater than the applicable screening levels, so it is not possible to directly confirm that these analytes were above or below the applicable screening levels. However, any undetected analytes would be unlikely to result in substantial adverse impacts on human health since the potential exposure in the short and long-term to these compounds would be limited (e.g., less than the long-term residential levels of exposure considered in the human health screening levels).

Additionally, as discussed in Potential Impact 3.2-13, total PCBs were detected in elutriate reservoir sediment samples above Basin Plan, national priority water quality criteria, so previous measurements sufficiently characterize the total PCBs in elutriate reservoir sediment samples. While the detected elutriate total PCBs concentrations would be less than the most stringent human health drinking water standards upstream of Copco No. 1 once the dilution expected during reservoir drawdown was considered, total PCBs concentrations would be greater than the most stringent human health drinking water standards downstream of Iron Gate Dam even with dilution considered and this would be a significant impact. As explained in Potential Impact 3.2-13, implementation of Mitigation Measure WQ-2 would reduce this impact to a less than significant level. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Seventeen polycyclic aromatic hydrocarbons (PAHs) had laboratory MRLs that were greater than the applicable screening levels, so it is not possible to directly confirm that these analytes were above or below the applicable screening levels in reservoir sediments, as discussed in Potential Impact 3.2-13 and Potential Impact 3.2-14. However, any of these PAHs would be unlikely to result in substantial adverse impacts on human health since the potential exposure in the short and long-term to these compounds would be limited (e.g., less than the long-term residential levels of exposure considered in the human health screening levels). If it was assumed the reservoir sediment concentrations of those seventeen PAHs with MRLs less than the most stringent screening levels were equal to the maximum MRL (i.e., 1,200 micrograms per kilogram [ug/kg]), all seventeen PAHs would be less than the applicable PEC or PEL throughout the Klamath River and fourteen of the seventeen PAHs would meet the most stringent sediment screening level including consideration of dilution during reservoir drawdown. The remaining three of those seventeen PAHs (i.e., acenaphthene, dibenz(a,h)anthracene, fluorene) would meet the most stringent reservoir sediment screening level upstream of Copco No. 1 Reservoir considering dilution during drawdown, but those three PAHs would not meet the most stringent sediment screening level in the Klamath River downstream of Iron Gate Dam until additional tributary inflows sufficiently increased dilution (i.e., approximately Klamath River at Orleans for all three based on modeled decreases in suspended sediment concentration [SSCs]). While the seventeen PAHs with MRLs greater than the most stringent sediment screening levels would be unlikely to result in substantial adverse impacts on human health due to limited opportunities for exposure, implementation of Mitigation Measure WQ-2 for other inorganic and organic contaminants also would further reduce potential exposure and result in these PAHs having a less than significant impact.

Additionally, if it was assumed the elutriate sediment concentrations of PAHs with MRLs less than the most stringent water quality standards were equal to the maximum MRL (i.e., 0.02 to 0.1 micrograms per liter [ug/L] depending on the PAH compound), all PAHs, including acenaphthene, dibenz(a,h)anthracene, and fluorene, would be less than the most stringent human health drinking water standards throughout the Klamath River once the expected dilution during reservoir drawdown was considered. Thus, additional PAHs analyses are not necessary to assess the potential adverse effects from short-term and long-term exposure to reservoir sediments.

Comment LA9-97

Recommended Measure TR-1 (Section 3.22) should be implemented as an MM, as mentioned previous comments. TR-1 should assess:

The use of selective transportation scheduling to identify the least-traveled times on Copco Road for materials transportation;

The use of guide vehicles for transporting hazardous materials/wastes;
The use of busses to transport construction personnel to and from a central location to the construction sites; and,

Development of construction crew housing at a location nearer to the construction sites to reduce traffic volume on Copco Road.

Response to Comment LA9-97
Please refer to Master Response CEQ-2 and note that Recommended Measure TR-1 has been changed to be Mitigation Measure TR-1. Please note that the suite of measures described in the comment are the type of management measures that can be assessed with others for feasibility and effectiveness in the development of a Traffic Management Plan (TMP), as described in Mitigation Measure TR-1. The mitigation measure specifically contemplates consultation with local agencies.

Comment LA9-98
Similarly, Recommended Measure PS-1 – Fire Management Plan should be implemented as an MM, and should appropriately assess the feasibility of identifying, improving, constructing, and maintaining an adequate number of pools in the river and restoration areas for use as helicopter water tank filling locations and water sources for ground crews in order to fully mitigate the impact of wildland fire.

Response to Comment LA9-98
Please refer to Master Response HAZ-2. For a discussion of preemption under the Federal Power Act, please refer to Master Response CEQ-2.

Comment LA9-99
Section 3.22.5 of the Transportation and Traffic section of the DEIR states that the Proposed Project would include the import and export of construction equipment. Section 3.22.2.2 states that the Proposed Project would include the provision of off-road construction equipment such as cranes, excavators, loaders, and large capacity dump trucks, which would be delivered by tractor trailer vehicles. However, Table 3.22-6 and the analysis of proposed construction-related traffic do not consider vehicle trips associated with equipment delivery. Therefore, the analysis of construction-related vehicle traffic is incomplete and should be revised to consider vehicles trips associated with equipment delivery.

Response to Comment LA9-99
Please refer to Volume I Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* (starting on page 3-1069) for a discussion of transportation-related impacts. Equipment hauling is discussed in this section

(e.g., pages 3-1063, 3-1070, and 3-1074) and is part of the analysis. Potential Impacts 3.22-1 and 3.22-2 (starting on page 3-1069) determined that the level of proposed traffic would be less than the Level of Service (LOS) design of the roadways. Volume II Appendix B: *Definite Plan – Appendix O2 Traffic Management Plan* (TMP) (page 9 to page 12), which is part of the Proposed Project, provides a framework for addressing equipment hauling. Please refer to Master Response CEQ-2 for a discussion of why the text of the Final EIR has been revised to reflect that Recommended Measure TR-1 is now Mitigation Measure TR-1. Please also refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* Potential Impacts 3.22-1 through 3.22-5 for the revisions.

Comment LA9-100

Section 3.22-5 states that non-reservoir-based recreation within the Area of Analysis would still occur but would be dispersed away from the immediate vicinity of Copco No. 1 and Iron Gate and therefore would not overlap with construction traffic. Page 3-986 of the Recreation section of the DEIR indicates that two privately-owned recreation facilities are located within 2.5 miles downstream of the Iron Gate Dam along Copco Road: The R Ranch Klamath River Campground and the Klamath Ranch Resort Blue Heron RV Park. It is reasonable to assume that non-reservoir-based recreation activities associated with these facilities would still occur during Proposed Project construction and would peak during summer months, thereby overlapping with peak construction traffic, contrary to statements in the DEIR. The DEIR should be revised to reflect the fact that these recreational facilities attract large recreational vehicles (RVs) and other recreational motorists that would share Copco Road with construction vehicles hauling exported demolition materials and oversized equipment during peak construction season.

Response to Comment LA9-100

Traffic from the two referenced facilities in the comment was included as part of the existing conditions average daily traffic (ADT) and the LOS (Level of Service) considered in the EIR. Potential conflicts with recreational uses within the traffic and transportation Area of Analysis are indicated in both Volume II Appendix B: *Definite Plan – Appendix O2 Traffic Management Plan* (TMP), which is part of the Proposed Project, and in Volume I Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation*. Please refer to Master Response CEQ-2 for a discussion of why the text of the Final EIR has been revised to reflect that Recommended Measure TR-1 is now Mitigation Measure TR-1. Please also refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* Potential Impacts 3.22-1 through 3.22-5 for the revisions.

Section 3.22.5 *Traffic and Transportation – Potential Impacts and Mitigation* Potential Impact 3.22-1 has been revised to clarify that non-reservoir-related traffic could still occur within the Area of Analysis. Please refer to Volume III

Attachment 1 Section 3.22.5 *Traffic and Transportation – Potential Impacts and Mitigation* for the revisions.

Comment LA9-101

The Traffic Management Plan lacks a strategy to address potential conflicts arising from encounters between construction vehicles hauling oversized equipment, RVs, and vehicles pulling trailers. Recommended Measure TR-1 A-1 also neglects consideration of potential oversized construction vehicle/equipment conflicts. While the DEIR states that construction vehicles hauling oversized equipment would operate under wide load restrictions, no detail was provided about what such restrictions would entail. Accordingly, the final version of the Traffic Management Plan and/or mitigation measures should include a strategy for minimizing potential oversize equipment hazards to recreational motorists. Additionally, the DEIR should clarify what the wide load restrictions entail and elaborate on how these restrictions would reduce safety concerns.

Response to Comment LA9-101

Please refer to responses to comments LA9-99, LA9-100, and LA9-102. In addition, the California Vehicle Code, starting with Section 35780 (State of California 1993) and California Department of Transportation (Caltrans) Transportation Permits Manual (e.g., Section 1003.5 Construction Equipment [Caltrans 1990]) are examples of existing regulations that apply to oversized equipment hauling and would inform Klamath River Renewal Corporation (KRRC's) Final Traffic Management Plan (TMP), which it has committed to in its most recent water quality certification application (KRRC 2019a).

Please also refer to Master Response CEQ-2.

Comment LA9-102

Section 3.23.5 of the Noise Section of the DEIR states that construction activities associated with dam deconstruction would occur during daytime and nighttime hours. The DEIR does not discuss potential hazards from construction related traffic operating during nighttime hours. Further, Recommended Measure TR-1 A-1 and the Traffic Management Plan do not include any traffic control devices and safety features to mitigate potential traffic safety hazards from truck hauling during nighttime hours. The DEIR should discuss potential safety hazards resulting from construction vehicle travel during nighttime hours. In addition, Recommended Measure TR-1 A-1 and/or the Traffic Management Plan should incorporate nighttime traffic control devices and safety features such as warning lights and markings on construction vehicles.

Response to Comment LA9-102

Please note that Klamath River Renewal Corporation (KRRC) has clarified that there will be no off-site nighttime hauling (Pers. comm. Seth Gentzler, AECOM on behalf of KRRC, to Parker Thaler, State Water Resources Control Board, 07/26/2019). Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic*

– *Potential Impacts and Mitigation* Mitigation Measure TR-1 provides for traffic control and safety implementation details consistent with all applicable regulatory requirements including the latest version of the Caltrans California Manual on Uniform Traffic Control Devices (Caltrans 2019a) and coordination with the noted agencies (Caltrans, Siskiyou County Public Works and Sheriff's Departments, California Highway Patrol, California Department of Forestry and Fire Protection (CALFIRE), and other emergency response agencies) as part of the detailed design phase and prior to start of construction. These requirements address the concerns expressed in the comment related to construction-related traffic during nighttime hours. For instance, the Caltrans California Manual on Uniform Traffic Control Devices references standards for both daytime and nighttime illumination and traffic control (Caltrans 2019a). Construction is usually accomplished at night because conditions are safer (i.e., less traffic and more noticeable activity); however, regardless of when construction occurs, Caltrans requires that standard traffic control measures are implemented to result in a safe transportation environment. Please refer to Master Response CEQ-2 for a discussion of why the text of the Final EIR has been revised to reflect that Recommended Measure TR-1 is now Mitigation Measure TR-1. Please also refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* Potential Impacts 3.22-1 through 3.22-5 for the revisions.

Section 3.1.5 *Aesthetics – Potential Impacts and Mitigation* Potential Impact 3.19-7 states that the Proposed Project's construction lighting could result in new sources of substantial light or glare that would adversely affect nighttime views in the area. This potential impact was determined to be significant and unavoidable. Please refer to Volume III Attachment 1 for the final Section 3.1 *Aesthetics*.

Comment LA9-103

The Traffic Management Plan is a series of "Recommended Measures" as it was deemed unenforceable by the SWRCB; therefore, the Proposed Project will result in significant and unavoidable impacts. As the lead CEQA agency, the SWRCB can require the preparation of a Traffic Management Plan as a condition of approval of the Proposed Project, in order to mitigate significant effects. The SWRCB should use its authority to require, and ensure, the preparation of the Traffic Management Plan in order to reduce the known significant impacts on the transportation system.

Response to Comment LA9-103

Please refer to Master Response CEQ-2.

Comment LA9-104

Section 3.23.5 of the Noise section of the DEIR states that construction activities associated with the removal of the dams would involve two shifts: a daytime shift and nighttime shift. Presumably, construction vehicles would be required during both shifts for transporting waste to off-site landfills and worker commutes.

However, construction related peak traffic noise was only evaluated against existing noise levels estimated for the daytime, as provided in Table 3.23-2. Because construction activities are scheduled to occur during nighttime, the DEIR should also evaluate peak construction related traffic noise against existing nighttime noise levels.

Response to Comment LA9-104

The Yreka Transfer Station (also known as the Pelletier Transfer Station), where offsite waste disposal would be hauled, is a daytime facility (i.e., it is open from 8 a.m. to 4 p.m.). Driving time between the Yreka Transfer Station, Copco No. 1, Copco No. 2, and Iron Gate dams would be approximately 1 hour or less based on the distances between these locations (Google Maps 2019). Including driving time, offsite waste hauling trips would be limited to the daytime, defined as 7 a.m. to 10 p.m. (USEPA 1974) and considered in the EIR. It is unnecessary to assess levels of peak construction-related traffic noise due to offsite hauling during nighttime hours. Additionally, since issuance of the Draft EIR in December 2018, the Klamath River Renewal Corporation (KRRC) has clarified that there will be no off-site nighttime hauling (Pers. Comm. Seth Gentzler, AECOM on behalf of KRRC, to Parker Thaler, State Water Resources Control Board, 7/26/2019). Regarding assessment of peak construction-related traffic noise due to worker commutes during nighttime hours, Volume I Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* (page 3-1070) states the following: "Because recreational facilities at the reservoirs would be closed during the construction period, this analysis assumes that traffic associated with recreational use of the reservoirs would cease during the construction period. When the additional traffic flow from the short-term concurrent activities associated with dam removal is compared to the current traffic flow for recreational use of the reservoirs, the workforce traffic is similar to the current recreational use traffic." Therefore, it is unnecessary to assess levels of peak construction-related traffic noise due to worker commutes during nighttime hours.

Comment LA9-105

As described in the Transportation and Traffic section of the DEIR, the Proposed Project involves road, bridge, and culvert improvements. As provided in Appendix K of the 2018 Definite Plan, some of these improvement projects would occur within the vicinity of sensitive receptors. For example, construction access improvements consisting of the installation of a temporary bridge would be established adjacent to the Klamath Ranch Resort Blue Heron RV Park and within 3,400 feet of residences along Tarpon Drive. Construction access improvements consisting of the replacement of the Lakeview Road bridge would be established within 2,600 feet of residences along Tarpon road. Other construction access improvements such as pavement rehabilitation that would occur prior to and/or following dam removal activities would also occur in locations near sensitive receptors. The DEIR should evaluate whether construction noise associated with road, bridge, and culvert improvements would result in short-term increases in noise levels affecting nearby residences.

Response to Comment LA9-105

Section 3.23.4 *Noise – Impact Analysis Approach* and Section 3.23.5 *Noise – Potential Impacts and Mitigation* have been revised to clarify the nature and timing of certain project elements and reference particular aspects of the Proposed Project that would be likely to use construction equipment that would exceed Siskiyou County General Plan noise thresholds.

Del Norte County Board of Supervisors, Taylor Carsley, Lori L. Cowan

Comment LA6-1

The Del Norte County Board of Supervisors (Board) wishes to provide comment on the Lower Klamath Project License Surrender (Project) and the Draft EIR released by the State Water Resources Control Board (SWRCB).

Response to Comment LA6-1

Thank you for your comment.

Comment LA6-2

The Klamath River is a key part of the economy, culture, and natural environment of Del Norte County; where the river meets the Pacific Ocean. The Board is responsible for ensuring projects affecting the County contribute to the health and welfare of the community and the local economy.

Response to Comment LA6-2

Thank you for your comment. Please refer to Master Response GEN-2. Please note that CEQA documents analyze significant effects on the physical environment; CEQA does not address potential social or economic effects from implementing a project (CEQA Guidelines, section 15131(a). Please also refer to Volume I Section 5.4 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA*.

Comment LA6-3

While the Board supports the recovery of Klamath River and Pacific Ocean commercial and recreational fisheries, we do have significant concerns with regard to how the Project may exacerbate the issue of siltation and sedimentation at the Crescent City Harbor, located 15 miles north of the river mouth. Also concerning are the known unavoidable and significant impacts to oceanic and riverine fisheries resources that are so essential to our local commercial and sport-fishing industries.

Response to Comment LA6-3

Section 3.3.5.1 *Aquatic Resources – Potential Impacts and Mitigation – Suspended Sediment* provides a summary of the detailed analysis of anticipated suspended sediment effects on aquatic resources that is presented in Potential Impact 3.2-3 and Appendix E. Section 3.3.5.2 *Aquatic Resources – Potential Impacts and Mitigation – Bed Elevation and Grain Size Distribution* provides a summary of the detailed analysis of anticipated bedload sediment effects on aquatic resources that is presented in Appendix F. Appendix E and F, and Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* include detailed assessments of the anticipated effects of sediment on focal aquatic species under the Proposed Project. As reflected in Section 3.3.5.9, the EIR finds no unavoidable and significant impacts to riverine or ocean fisheries resources. In addition, Section 3.3.5.9 describes aquatic resource measures proposed by Klamath River Renewal Corporation (KRRC) (i.e., AR-1, AR-2) and mitigation measures included in the EIR (i.e., AQR-1, AQR-2). As explained in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation*, those aquatic resource measures and mitigation measures would ensure no significant impacts to riverine or oceans fisheries resources. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment LA6-4

The Draft EIR (DEIR) is clear that the proposed project will increase suspended materials to a high degree following the drawdown and dam removal phases. For example, suspended sediment concentrations (SSCs} would potentially increase 220 times the threshold of significance downstream of Copco No. 1 Dam upon drawdown with similar numbers projected for the drawdown of the other dams in California. The Board is concerned with the fact that the quantity of sediment delivered to the Pacific Ocean is still not known with certainty, and more importantly, how the material will react once delivered to the ocean. Conservative estimates place the amount of sediment discharge to the ocean as a result of drawdown and dam removal at about 5.8 million tons (4 million tons of fine sediment and 1.8 million tons of sand and larger sediment). While the DEIR estimates that the quantity released would be similar to that transported by the river to the ocean in a year with average flow, this quantity would be in addition to what is transported naturally by the river, whether it be a dry, average, or wet year. On the year of dam removal and drawdown, a significant amount of sediment will be delivered to the ocean, relative to any year without the project. Recognizing the uncertainty on where the material will settle in the ocean, it is known that normal ocean currents transport material north and there is certainty that our Harbor already has issues with dredging and dredge spoils management.

The Crescent City Harbor District is designated a "harbor of safe refuge" by the California Harbors and Navigation Code. The Harbor supports a U.S. Coast Guard cutter, commercial and sport fishing, waterfront industry, and recreational activities. A study titled "Coastal Geomorphology of the Smith River Plain" (Roberts and Dolan, 1968) found that the littoral current pattern south of Crescent City transports sediment northwestward and contributes to a continued seaward growth of sand south of the breakwater at the mouth of the Harbor. Sediment accumulating at the entrance of the Harbor travels inward and requires regular dredging to maintain a safe navigation depth of recreational and commercial vessels in the federal channels and inner boat *basins. Fine sediment accumulation is particularly problematic because is typically unsuitable for use as beach replenishment and thus more difficult to dispose of. The Harbor District's dredge materials holding site is currently at capacity and a feasible replacement site has not yet been established; complicated by the permitting hurdles between the U.S. Army Corps of Engineers and the California Coastal Commission which are less than amenable toward achieving maintenance dredging in the first place. The Harbor faces incredible challenges with managing the current amount of siltation experienced in and around its facilities, let alone potentially more as a result of the Project. Even if a very small percentage of project sedimentation impacts the Harbor, the issue could be compounded in a way that severely hampers the essential marine operations of the County. It follows that the Board needs the guarantee from the Project coalition that we will be actively supported in our efforts to acquire the necessary permits to dredge our Harbor, as these are probable future projects whose impacts must be considered cumulatively. (14 C.C.R. 15064(g).) Only by assisting the County in our ability to dredge the Harbor will the potential for impacts as a result of the Project be mitigated.*

Response to Comment LA6-4

As specified in Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance*, the significance threshold for short-term suspended sediment concentration (SSC) impacts to salmonids is 100 milligrams per liter (mg/L) over a continuous two-week exposure period. SSCs are modeled to reach maximums (i.e., peaks at one point in time) of up to 2,000-3,000 mg/L downstream of J.C. Boyle Reservoir, 7,000-8,000 mg/L downstream of Copco No. 1 Reservoir, and 7,000-14,000 mg/L downstream of Iron Gate Dam, with potential for SSCs in excess of 1,000 mg/L downstream of Iron Gate Dam on a timescale of weeks to months. Components of the Proposed Project, including increasing the drawdown rate and sediment jetting, would preferentially reduce the duration of the modeled suspended sediment impacts, although these components could also increase the modeled SSC maximums, and suspended sediments are still expected to exceed 100 mg/L for durations of over two weeks at all locations, resulting in a significant and unavoidable short-term impact (see Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Sedimentation and River Hydraulics sediment transport model (SRH-1D) model simulations (USBR 2012a) estimate that between 5.4 and 8.6 million yd^3 [1.2 to 2.3 million tons], or 36 to 57 percent of the total reservoir sediment volume, is expected to be eroded and transported downstream during the drawdown period (see Table 3.11-7 in Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [pages 3-765 to 3-775]). For a discussion of how this amount compares to background annual sediment loads, please refer to the response to comment ORG46-31.

As described throughout the EIR and in Master Response GEO-1, the majority of eroded reservoir sediments are predicted to be transported to the Pacific Ocean as particles that remain suspended in the water during drawdown and in the short-term following drawdown. Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-769 to 3-770 and 3-775) describes that there would be no significant impact to the Pacific Ocean Nearshore Environment in the short- or long-term, given the relatively small amount of total sediment input from reservoir sediment release in comparison to the total annual naturally occurring sediment inputs to the nearshore environment, and because any sedimentation of the nearshore seafloor resulting from the Proposed Project would likely be transported farther offshore to the mid-shelf and into deeper water off-shelf. Furthermore, no cumulatively considerable sediment impacts have been identified (see Volume I Section 3.24.11 *Cumulative Effects – Geology, Soils, and Mineral Resources* [pages 3-1191 to 3-1194]). As discussed in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, while the direction of suspended sediment transport would be generally northward from the mouth of the Klamath River, the plume carrying reservoir sediments would likely be influenced by a range of meteorological and ocean conditions (e.g., storm and non-storm periods, differing storm directions) during the weeks to months of elevated suspended sediment concentrations. Some of the time the plume would likely be constrained to shallower nearshore waters, while at other times it would likely extend further offshore and spread more widely, before depositing along the continental shelf seaward of the mouth of the Klamath River. Overall, the total sediment input from reservoir sediment release would be well within the range of natural sediment release conditions from the Klamath River, such that any associated sediment transport and deposition in the Pacific Nearshore Ocean Environment would also be within the range of natural conditions.

Given that the sediment input will be within the natural existing range, there is no evidence to suggest that dam removal would increase the need for dredging of Crescent City Harbor. Note that the existing shoaling and dredging rate for the Entrance, Inner Harbor Basin, and Marina Access Channels is approximately 20,000 cubic yards per year, or approximately 100,000 cubic yards every 5 years [HydroPlan and Anchor QEA 2015 cited in USACE 2019]. Additionally, Crescent City Harbor is located approximately 15 miles north of the Klamath River Estuary. Due to this distance, and the fact that most of the sediment released from the reservoirs is anticipated to be fine sediment (not coarse sediments such as sand), which is easily transported, it is unlikely that significant sediment deposition will occur in the Crescent City Harbor as a result of the Project.

The comment does not provide an explanation for how the process for obtaining future permits from responsible agencies for ongoing dredging operations at the Crescent City Harbor would be affected by sediment deposition that occurs in the Pacific Ocean Nearshore Environment due to the Proposed Project. Based on the above paragraphs, there is no evidence that the Proposed Project would impinge future permits for Crescent City Harbor.

Comment LA6-5

Recreational and commercial fishing is an economic lifeline for many members of Del Norte County, where the per capita median income is below state average. Guided recreational fishing and the tourism dollars that this fishery supports make meaningful and significant impacts to our local economy. For example, we estimate that the spring-run fishery, most likely to be affected by the Project, generates close to $521,000 in revenue to our communities.

Losses in revenue of our local hospitality, restaurant, hotel, and service sector industries, not to mention licensed river guides as a result of impacts from the Project is unacceptable. The DEIR paints an optimistic picture of limited short-term impacts to anadromous fisheries as a result of the Project, and predicts significant long-term beneficial economic impacts on the coastal commercial fishing industry. But the DEIR fails to consider the short-term economic impacts that a lost year will have on the county's half-million dollar industry. Indeed, the DEIR acknowledges the short term impact that increased turbidity will have on recreators-and dismisses these impacts as temporary-but fails to consider the associated economic impacts that decreased recreation will have on tourism. (14 C.C.R. §15131.) Those impacts, even if temporary, should be considered significant to Del Norte County's economy, and specific funding mechanisms to mitigate those impacts should be included in the project. (14C.C.R §15123.4.) It is understood that substantial funding is available for the offset of unavoidable impacts to spring- and fall-run fisheries. The Board requests that a portion of funding be set aside and made available to our community that relies on these dwindling fisheries, already under pressure for special status listing from resource agencies. We simply cannot afford to mitigate the impacts associated with increased pressure on commercial and sport fisheries without financial assistance from the Project's coalition.

Response to Comment LA6-5

Please refer to Section 5.4.1 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA – Consideration of Economic Information for Resources Potentially Affected by Dam Removal* (pages 5-4 to 5-11), which summarizes the results of prior economic studies conducted by the U.S. Department of the Interior (DOI) to characterize potential commercial fishing effects due to dam removal. The results of DOI's prior economic analysis of ocean sport fishing are also summarized in the EIR to provide broader context for possible increased recreational fishing opportunities given dam removal.

Comment LA6-6

While this Board can recognize certain long-term benefits of the Project, and a recent meeting with representatives from both the Klamath River Renewal Corporation (KRRC) and the Pacific Coast Federation of Fishermen's Associations (PCFFA) was reassuring, the potential impacts of siltation and sedimentation still exist and could have real impacts on the economy and livelihood of the County. Impact assessment for sedimentation on the nearshore ocean environment is lacking in the DEIR, and the results of the modelling lead to much uncertainty. The Board would be much more at ease should the project contain a plan that provides for the potential negative contingencies. If assurances could be made that impacts to our County would be directly mitigated, a more thorough level of support would be provided. One solution could be provided in the form of a fund established for monitoring and remediation of short and long-term impacts resulting from Project implementation. It has been acknowledged that KRRC has ample resources assist with these necessary contingencies through PacifiCorp customer surcharges and California Proposition 1 water bonds. Funding for the mitigation of impacts is worth very little, however, if they are not made readily available as needed. An efficient mechanism to distribute resources that alleviate the adverse effects of the project needs to be included in the DEIR. This would ensure that the SWRCB truly has a worst case scenario in mind and is willing to address the impacts of this scenario if it does indeed affect our local community in the short or long-term.

Response to Comment LA6-6

Contrary to the comment's assertion, an impact assessment for sedimentation in the Pacific Ocean Nearshore Environment is provided in Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3 and Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5, which are revised in Volume III Attachment 1. Please also refer to the response to comment LA6-5 above. Given that the EIR does not identify significant individual or cumulative sedimentation impacts from the Proposed Project on the Pacific Ocean Nearshore Environment in the vicinity of the Klamath River mouth and Crescent City Harbor, other than potential *significant and unavoidable* short-term elevated suspended sediment concentrations (SSCs), mitigation is not required for short- or long-term sediment deposition.

Please also refer to response to comment ORG47-51.1.

Comment LA6-7

We hope that our Board's concerns are considered seriously in the evaluation of and response to DEIR comments. Further, we press that in the *process of preparing findings on the feasibility of reducing and limiting potential significant environmental impacts, appropriate mitigation and monitoring is examined that addresses the issues that have been raised. It is with enthusiasm that we would support this Project if the proper mitigation funding, resources, and access to them were made available in the event that future impacts to the Crescent City Harbor and our commercial and sport-fishing industries are more severe than the DEIR makes them out to be. Thank you for the consideration of our comments.*

Response to Comment LA6-7
Thank you for your comment.

Humboldt County Board of Supervisors, Rex Bohn, Hank Seemann

Comment LA4-1
The draft Environmental Impact Report ("Draft EIR") released by the State Water Resources Control Board on December 27, 2018, for the proposed Section 401 water quality certification concludes that dam removal is the best option for improving fisheries and water quality. The Draft EIR concludes that removal of the lower four dams is superior to six alternatives and will result in many significant, long- term benefits. The data and analysis presented in the Draft EIR demonstrate that removal of the lower four Klamath River dams will improve water quality and increase runs of anadromous fish in the Klamath River. In particular, the Draft EIR concludes that dam removal will curtail blue green algae blooms and fish disease problems below the dams. This issue is critically important for Humboldt County residents who fish and recreate in the Klamath River.

Response to Comment LA4-1
Thank you for your comment. Please refer to Master Response GEN-1.

Comment LA4-2
Most negative impacts are short-term and/or can be avoided or reduced through mitigation measures. The Draft EIR concludes that sediment impacts will be temporary. Humboldt County understands that for an initial period of time the river will experience weeks and potentially months with heavy loads of suspended sediment, and we agree that these temporary impacts are worth the long-term gains in water quality and fish production.

Response to Comment LA4-2
Please refer to Master Response GEN-1.

Comment LA4-3
The Draft EIR describes loss of reservoirs for wildland fire fighting as a significant and unavoidable impact. We encourage continued discussions with the Klamath River Renewal Corporation and other parties to better define this impact and identify alternative water supply and preparedness measures.

Response to Comment LA4-3
Please refer to Master Response HAZ-2.

Comment LA4-4
Humboldt County continues to support decommissioning the lower four Klamath River dams through implementation of the Amended KHSA. Humboldt County looks forward to continuing our participation in the Clean Water Action section 401 certification process and seeing the Amended KHSA fully implemented. We appreciate the State Water Resources Control Board's consideration of our comments.

Response to Comment LA4-4
Please also refer to Master Response GEN-1.

Humboldt County Department of Health, John H. Moseman IV

Comment LA10-1
I am writing to express my full support of removal all of the dams on the Klamath River Hydroelectric Project and to have my opinion counted as part of the comment period. After I graduated HSU with a degree in Natural Resource Planning and Recreation, I worked for a planning agency (EDAW) on the Klamath River to assess Pacific Corps relicensing project at the time. I had the ability to survey folks about their opinions about the hydro-electric project there and learned a lot from the locals and users of this portion of the river.

It is my assessment that one of the greatest salmon rivers of our country is currently in an unhealthy state due to the dams on the Klamath River. Removal of the dams will benefit the people that live there as well as the ecosystems that depend on a healthy river. It took millions of years for it to evolve to its healthy state and needs the ability to return to an undammed state.

Response to Comment LA10-1
Thank you for your comment. Please refer to Master Response GEN-1.

2.3.3 Native American Tribes

This section presents written comments received on the Draft EIR from Native American Tribes and the State Water Board’s responses to those comments. Written comments and responses in this section are organized alphabetically by tribe name. To determine whether your comment is associated with an affiliation type other than Native American Tribes, please refer to Table 2-1 or Table 2-2.

Table of Written Native American Tribes Comments and Responses

Hoopa Valley Tribe, Tom Schlosser

Comment TR17-1

Technical staff of the Hoopa Valley Tribal Fisheries Department have reviewed the subject document produced by staff of the State Water Resources Control Board (Board), and provide the comments below. The Hoopa Valley Tribe (Tribe) is strongly supportive of dam removal by Klamath River Renewal Corporation, as the impacts are expected to include substantial improvements to water quality in areas downstream of the Oregon-California border, while affording anadromous fish access to habitat in both California and Oregon long blocked by hydropower facilities.

Response to Comment TR17-1

Thank you for your comment. Please refer to Master Response GEN-2.

Comment TR17-2

Members of the Tribe exercise fishing rights in Trinity River and Klamath River portions of the Reservation. Terms of the Water Quality Certification include some with far-reaching implications for salmon and other fishes in both rivers, and therefore we are concerned that the states of California and Oregon as well as the federal government discharge throughout the certification process their respective responsibilities for restoration and protection of anadromous fish.

Response to Comment TR17-2

The State Water Board notes the Hoopa Valley Tribe's concern that the water quality certification should protect salmon. Comments related to Oregon and federal permit terms and conditions should be submitted to the respective agencies. For information on Proposed Project impacts to Aquatic Resources (including coho and Chinook salmon), please refer to Section 3.3 *Aquatic Resources*.

Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*. Hoopa Valley Tribe's fishing rights are noted in the EIR – for example, please see Volume I Section 3.8.2.2 *Water Supply/Water Rights* –

Environmental Setting – Mid and Lower Klamath Basins – Federal Reserved Rights for Native American Tribes – Hoopa Valley Tribe and Yurok Tribe (pages 3-673 to 3-674) and Section 5.4.1.1 *Social and Economic Factors Under CEQA – Consideration of Economic Information for Resource Potentially Affected by Dam Removal – Commercial Fishing* (pages 5-5 to 5-7).

Comment TR17-3

The Tribe has established "treatment-as-a-state" under the Clean Water Act, is recognized by the federal government as having fully-vetted property rights to annual harvest of salmon and other fishes, and views its authorities as extending to active participation with the State of California as a co-manager alongside the various federal and tribal resource agencies involved. The Tribe is to be consulted with in regards to plans, investigations and reports dealing with dam removal and impacts of recovery efforts. We are committed to a collaborative effort leading to successful restoration.

Response to Comment TR17-3

This comment relates to Hoopa Valley Tribe's commitment to successful restoration and desired role in developing dam removal and restoration plans. Comment noted.

Comment TR17-4

The current document contemplates that Iron Gate Hatchery (IGH) will be transferred to the State of California and funded by Pacific Corp for eight years after 4 lower dams are removed on Klamath River. We have concerns with regard to CDFW's Technical Staff Recommendations for hatchery operations in the post-dam era which were provided to the State Board. First, establishing a sunset of eight years post dam removal for operations is arbitrary and appears to be based upon the assumption that recolonization and robust production will occur within two brood cycles of Chinook or three brood cycles of Coho. Instead, the term of operation of the hatchery should extend until verification of successful recolonization and robust production. Second, the scale of mitigation programs at the facility should not be dictated by the availability of a water source, rather clear mitigation goals need to be developed and then the facility tailored to meet the need. Third, experimental lots of fish should be trucked to just above the Trinity River confluence to evaluate improved survival and potential for straying. Finally, the significant reduction in fall Chinook yearling production presented in the technical recommendation will have immediate consequences for dependent Tribal fisheries.

With regard to an arbitrary eight-year period for post dam mitigation, we are concerned that the modified KHSA failed to define metrics which would evaluate the implied hypothesis that both fall Chinook and Coho populations would rebound in the post-dam removal era to a level equal to or exceeding contemporary mitigation at IGH (900,000 yearling, 5,100,000 smolt fall Chinook and 75,000 Coho salmon). Full IGH mitigation should instead continue until such *time that it can be demonstrated that natural production, as measured at the present location of Irongate Dam, has on average matched or exceeded an approximate 6,000,000 outmigrant fall Chinook and 75,000 Coho outmigrants. Dam removal, while implemented by the KRRC, will still be pursuant to authority of the federal government and by extension would itself be a federal action. Current levels of mitigation result in significant contributions to dependent Tribal fisheries and we do not agree that this harvest opportunity should be compromised by limited action within an arbitrary set of years (8) and should rather be supported by data showing that naturally produced fish populations have increased to levels approximating the mitigation targets today. According to the CDFW's technical recommendation, it appears that hatchery production will be scaled to availability of water. We instead would advise that production not waiver from contemporary mitigation levels, and that instead of scaling production to water availability, recirculating systems be developed to sustain contemporary mitigation. The intention would be to use as much available cold-water inflow as may be gathered from Bogus Creek or other sources and extending its usefulness through repurposing and filtration of effluent. To address concerns of the role hatchery fish may play in disease transmission to natural juvenile salmonids, we would advocate that an experimental group of marked IGH fingerlings (400,000 individuals), be trucked to immediately above the Trinity River confluence and released. Future recovery of these fish would enable scientists to evaluate the risks and benefits of off-site releases of fingerlings. The State Technical Recommendations advise that yearling fall Chinook production be reduced to just 13% of current mitigation levels during the post-dam era. Given that IGH yearlings historically outperformed fingerlings three- to six-fold, this dramatic reduction is likely to have an immediate and profound impact to Tribal fisheries. Again, our requirement would be that mitigation remain at current levels for both fall Chinook and Coho Salmon until there is compelling evidence that natural fish production would provide comparable benefits to fisheries.*

Response to Comment TR17-4

The Hoopa Valley Tribe's comment expresses concerns with the proposed eight-year term operation of hatcheries under the Proposed Project. The Hoopa Valley Tribe's comment recommends that hatchery operations should extend until verification that natural salmonid production has on average matched or exceeded 6,000,000 outmigrant fall Chinook and 75,000 coho salmon (the current hatchery production goal). Further, the Hoopa Valley Tribe suggests that the scale of mitigation programs should be tailored to meet specific production goals rather than setting hatchery targets based on available water supply, and expresses concern for potential fisheries impacts due to the reduction of the yearling production. Finally, the comment recommends a test-release of hatchery smolts just above the Trinity River, to evaluate the impacts of such an operational change on straying, disease, and escapement.

The Klamath River Renewal Corporation's (KRRC's) Proposed Project includes hatchery modifications and operations for up to eight years following dam removal. The EIR evaluates the potential environmental impacts associated with implementation of the KRRC's Proposed Project and project alternatives (including a No Hatchery Alternative).

The EIR finds that the Proposed Project would not result in a significant impact on salmonid populations, or on the tribal or commercial fisheries (see specific sections referenced below).

Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* discusses the likely effects of eight years of hatchery production following dam removal, including an analysis of the sources of hatchery and natural production likely to occur each year of dam removal and post-dam removal through post-dam removal year 10. The potential for natural production of salmon smolts upstream of the current location of Iron Gate Dam is discussed for each species in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 (fall-run Chinook salmon), Potential Impact 3.3-8 (spring-run Chinook salmon), and Potential Impact 3.3-9 (coho salmon). The analysis is based on scientific literature, and in the case of fall-run Chinook salmon (Potential Impact 3.3-7), a quantitative life-cycle model (Hendrix 2011). This analysis concludes that successful fall-run Chinook salmon recolonization and robust production following dam removal and eight years of hatchery operations is likely to occur under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.3. *Aquatic Resources*. Please also refer to Master Response AQF-2 regarding the suggestion to increase and/or extend hatchery production.

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, analyzes the anticipated effects of a reduction in hatchery production on the escapement of fall-run Chinook salmon, and Potential Impact 3.12-9 analyzes the potential impacts of reduced hatchery production on tribal fisheries. Please refer to Volume III Attachment 1 for the final Section 3.3. *Aquatic Resources*. Please also refer to Master Response AQF-3 regarding the concern regarding salmon abundance available for harvest.

Additionally, the Hoopa Tribe noted that under the Proposed Project the reduction in yearling production is far greater than the reduction in smolt production. Based on coded wire tagging between 1990 and 2015, adult hatchery returns of smolts has averaged 0.178 percent, and returns of hatchery yearlings has averaged 0.352 percent (Giudice and Knechtle 2018). Despite higher survival of yearling releases, the substantially higher number of smolt releases results in most hatchery adult returns being fish released as age-0 smolts. Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 has been revised to include this information.

Karuk Tribe, Alex Watts-Tobin

Comment TR22-1

As the Karuk THPO, I appreciate the opportunity to comment on the State Water Board's draft EIR for the Water Quality 401 Certification of the Lower Klamath Hydroelectric Project. The project was discussed at the February 5th, 2019 Karuk Resources Advisory Board Meeting. The THPO attended the Public Meeting on this issue in Yreka in the evening of February 5th, together with one staff member. Both of these staff members and Karuk Vice-Chair Robert Super made comments on the project at that meeting. Other staff members attended the meeting in Orleans on February 7th.

Response to Comment TR22-1

Thank you for your comment. Oral comments provided during public scoping meeting are also considered in this Final EIR. Please refer to Volume III Section 2.4.1 *Yreka Public Meeting—February 5, 2019* and 2.4.3 *Orleans Public Meeting—February 7, 2019* for comment responses to oral comments provided during the Yreka and Orleans public meetings.

Comment TR22-2

The Karuk THPO office concurs with the comments of Karuk Chairman Attebery filed February 26, 2019.

Response to Comment TR22-2

Please refer to responses to comments TR18-1 through TR18-67.

Comment TR22-3

Overall, the Karuk Tribe and the THPO office strongly support the Board's findings and conclusions – namely that that the proposed project (removal of lower four dams) is superior to the six alternatives analyzed.

Response to Comment TR22-3

Please also refer to Master Response GEN-1.

Comment TR22-4

I would like to make some detailed comments on the dEIR, especially with respect to section 3.12, the Cultural Resources section.

The Ethnography section for Karuk draws substantially on the section on Karuk by William Bright in Heizer's Handbook of North American Indians, vol 8. This is, by common consent, not Bright's best work. The work by John Salter and Craig Tucker, which is referenced by Chair Attebery in his comment letter, is a much more up-to-date and accurate account of Tribal practices,, river conditions, and environment. Likewise, Thomas King's work on the Klamath Riverscape is also superior to Bright's summary. Both of these works draw directly on considerable anthropological research and ethnographic testimony from Karuk Tribal members.

Response to Comment TR22-4
Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography – Northwest California Culture Area – Ethnography – Karuk* has been updated based on the comment provided by Chair Attebery. Please refer to Volume III Attachment 1 Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography – Northwest California Culture Area – Ethnography – Karuk* for the revisions. Please also refer to response to comment TR18-19.

Please note that the Bright (1978) citations referenced in this comment are carried over from the Karuk ethnography sections of the 2012 KHSA EIS/EIR. Additionally, the State Water Board appreciates that the Karuk Tribe has provided the Salter and Tucker (2010) summary of history and ethnography, thus including the associated information in the record for the Lower Klamath Project EIR.

Comment TR22-5
The THPO concurs with the other comments provided by Chair Attebery on Section 3.12 of the Draft EIR.

Response to Comment TR22-5
Comment noted. Please refer to responses to comments TR18-1 through TR18-67.

Karuk Tribe, Chairman Attebery

Comment TR18-1
Please accept the attached comment letter and associated document from Karuk Tribe as our comments on the dEIR on the Lower Klamath Project.

Response to Comment TR18-1
Thank you for your comment.

Comment TR18-2
On September 23, 2016, PacifiCorp and the Klamath River Renewal Corporation (KRRC) filed a joint license transfer application with the Federal Energy Regulatory Commission (FERC). Pursuant to the amended KHSA, PacifiCorp and the KRRC seek to transfer the lower four dams (J.C. Boyle; Copco No. 1; Copco No. 2; and Iron Gate) to the KRRC for the purpose of decommissioning and removal. Before FERC can accept a license surrender application, PacifiCorp and the Klamath River Renewal Corporation must obtain water quality certification under Section 401 of the Clean Water Act (33 U.S.C. § 1341) from the State Water Board. Under Section 401 conditions of a water quality certification become conditions of any federal license or permit for the project. The State Water Board is the agency authorized to issue certification of any

potential discharge from an activity that requires a FERC license or amendment. The State Water Board adopted the Water Quality Control Plan for the North Coast Region (Basin Plan). The Basin Plan includes the Beneficial Uses and Water Quality Objectives necessary to protect the Beneficial Uses. Together these constitute the Water Quality Standards that must be met before the State Water Board can issue Water Quality Certification. Issuance of a water quality certification is a discretionary action subject to CEQA compliance. The State Water Board has correctly chosen to prepare an Environmental Impact Report (EIR) because there are potentially significant impacts associated with dam transfer and removal. On December 27, 2018 the California State Water Resources Control Board issued a draft Environmental Impact Report for the surrender of the Lower Klamath Hydroelectric Project (LKHP). Under the California Environmental Quality Act (CEQA) a Lead Agency is required to solicit comments from interested parties and the public. The Karuk Tribe is submitting comments as a long-term participant in the Klamath Hydroelectric Project decommissioning process and a signatory to the amended Klamath Hydroelectric Settlement Agreement (KHSA). Our participation in this process is driven by the unequivocal fact that reduced fish populations and poor water quality are a direct result of the operation of the Klamath Hydroelectric Project. Furthermore, operation of the Klamath Hydroelectric Project has had profound negative impacts on the traditional cultural practices and the health of Karuk Tribal members.

Response to Comment TR18-2

Thank you for your comment. In addition to the potential impact analyses presented in Section 3.2 *Water Quality* and Section 3.3 *Aquatic Resources*, the potential for impacts to tribal cultural resources due to the Proposed Project is analyzed in Section 3.12 *Historical Resources and Tribal Cultural Resources*, including Potential Impact 3.12-10, which discusses the ability of tribes to use the Middle and Lower Klamath River for ceremonial and other purposes given seasonal adverse water quality and nuisance and/or noxious blue-green algae blooms. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, Section 3.3 *Aquatic Resources*, and Section 3.12 *Historical Resources and Tribal Cultural Resources*.

Comment TR18-3

CEQA requires a lead agency to analyze the impacts of a project as defined in the CEQA Guidelines. In the case of an existing hydroelectric project that has been in operation before the adoption of the Clean Water Act and Endangered Species Act the ongoing impacts of the project will not register as significant. While CEQA considers the existing conditions as the baseline for analysis of project impacts, the State Water Board must analyze the existing operations to determine compliance with the Clean Water Act. We assert that the LKHP has been operating in violation of the Clean Water Act, and potentially other State and Federal Laws, for decades and this must be disclosed in a discussion of the baseline conditions. We assert that the LKHP cannot be brought into *compliance with State and Federal Laws without being removed. Clearly, dam removal and the expected discharge of sediments will have an immediate negative impact on water quality downstream of the LKHP. However, the expected long-term benefits are enormous and have been thoroughly researched and described in the 2012 EIR/EIS on Klamath Facilities Removal and further expanded on in the Klamath Dam Removal Overview Report for the Secretary of Interior (October 2012). We are pleased that in their own analysis the Board correctly concludes that the proposed project (removal of lower four dams) is superior to the six alternatives analyzed.*

Response to Comment TR18-3
Comment noted. Please refer to Master Response GEN-1. For the Proposed Project, the CEQA document analyzes the impacts of the Proposed Project to existing conditions and this evaluation does not take into consideration ongoing impacts of continued operations of the Lower Klamath Project. The water quality certification process analyzes the Proposed Project impacts from the context of water quality standards which is different from the existing conditions (baseline) evaluated in CEQA. Please note, the No Project Alternative (Volume I Section 4.2) does acknowledge that it is not clear that if the Lower Klamath Project dams and reservoirs remained in place, if they would be able to comply with California water quality standards. Additionally, the Continued Operations with Fish Passage Alternative (Volume I Section 4.4) also acknowledges that in 2007 FERC's EIS found that PacifiCorp's proposal for relicensing of the Klamath Hydroelectric Project (KHP) failed to address the project's water quality impairments within and downstream of the Hydroelectric Reach (FERC 2007), and since 2007, PacifiCorp has developed several iterations of a Reservoir Management Plan to address water quality impairments associated with operations of Lower Klamath Project facilities. While study results indicate the actions listed its Reservoir Management Plan can improve some of the project's impacts to water quality, it has not demonstrated compliance with all water quality impacts associated with the project.

Please also note that the EIR uses the phrase "existing adverse conditions" instead of "existing conditions" in situations where the environmental resource under consideration is impaired or can result in adverse impacts on an environmental receptor(s). Use of this phrase is intended to provide appropriate and helpful context for the general reader to understand the nature of the existing condition in light of the CEQA requirement to consider the baseline condition as existing conditions (CEQA Guidelines Section 15125(a)).

Comment TR18-4
We appreciate the hard work of the California Water Board, Board staff, and consultants on developing this document.

Response to Comment TR18-4
Comment noted.

Comment TR18-5

In general, we find that fisheries and aquatic resources were adequately addressed and therefore we have very few comments. There is very good coverage of fisheries issues and impacts to fish to the point where there is almost too much information and redundancy.

Response to Comment TR18-5

Comment noted.

Comment TR18-6

General Comment on Sediment Concentrations--The largest threat to fish described under the proposed action is suspended sediment concentrations (SSC) downstream of the dams. The document does a good job in laying out the time frames of the treat (year 1 and year 2) and scenarios base on water year types ranging from dry to wet years and the longitudinal effects from upstream reaches to downstream reaches. Given the project is located below upper Klamath Lake where water is stored and could be released to increase the flushing rate of sediments, we suggest that this could be included as an alternative. Could some volume of water be stored in UKL to be later used as a flushing flow during reservoir drawdown to increase the rate of flushing and lessen the impact to fish and decrease the duration of fish exposures to high SSC?

Response to Comment TR18-6

Upper Klamath Lake is operated by the United State Bureau of Reclamation (USBR) as part of the Klamath Irrigation Project and is not part of either the Klamath Hydroelectric Project (KHP) or the Lower Klamath Project.

Lake level elevations and flow releases from Upper Klamath Lake are currently dictated by a 2019 Biological Opinion for the protection of listed lost river sucker, shortnose sucker, and coho salmon. Any flow changes in the Klamath River would be from the Biological Opinion revision process, rather than implementation of the Proposed Project. As such, use of Upper Klamath Lake for additional flushing flows during drawdown of Lower Klamath Project reservoirs is not a feasible alternative to consider in CEQA.

Please note, four sediment transport modeling scenarios were analyzed by Stillwater Sciences (2008) to examine the potential for using Upper Klamath Lake or an upstream reservoir to alter inflows to downstream reservoirs in order to reduce downstream suspended sediment concentration's (SSCs) during drawdown.

The exact flow conditions in the four modeled scenarios are slightly different from flow conditions proposed by the comment (i.e., typical Klamath River inflow for the water year type plus an additional flushing flow release from Upper Klamath

Lake), but model results from the four scenarios quantify the relative change in the magnitude and duration of SSCs resulting from an increase in Klamath River flow into the reservoirs during drawdown.

In the four modeled scenarios, an increase in the flow to the reservoirs during drawdown did not result in an overall decrease in the potential impacts from SSCs. In one modeled scenario, SSCs initially decreased during the increase in flow to the reservoirs, but a second spike in SSCs followed the flow increase and resulted in SSCs exceeding the threshold of significance (i.e., 100 milligrams per liter [mg/L]) during a period that otherwise would not have occurred under typical Klamath River flow conditions. Additionally, the flow increase produced minimal to no benefit in reducing SSCs during subsequent flow increases (e.g., spring storm events) and the duration SSCs exceeded the threshold of significance (i.e., 100 mg/L) slightly increased in the spring. In the other three modeled scenarios, the increase in Klamath River flow also had minimal to no benefit in reducing SSCs (Stillwater Sciences 2008). As such, a flushing flow during reservoir drawdown using water from Upper Klamath Lake would potentially increase the amount of reservoir sediments transported during drawdown, but it was not evaluated as an alternative or adopted as a potential mitigation measure to reduce the potential impacts to SSCs and fish exposure to high SSCs due to the infeasibility of such action, and to the potential for flushing flows to increase the duration SSCs exceed the threshold of significance (i.e., 100 mg/L) or to generate a minimal to negligible decrease in SSCs. Therefore, even if adjustments to flow releases from Upper Klamath Lake were feasible, modeling evidence does not indicate that this would reduce the potential impacts of the Proposed Project.

The issue raised in the comment does not introduce a feasible project alternative or mitigation measure considerably different from others previously analyzed that would clearly lessen the environmental impacts of the project (CEQA Guidelines Section 15088.5(a)(3)).

Comment TR18-7

The document does a good job in describing fish species and utilization under current and proposed conditions and impacts. We found a few minor inaccuracies in descriptions of the Pacific Lamprey life cycle where there was no mention of the “transformer” stage or metamorphosis from ammocoetes to adults. There an assumption that lamprey juvenile out migration occurs in the spring (like salmon smolts) when SSC would be high following reservoir drawdown. This may not be accurate because outmigration trapping in the Klamath during the fall months shows that seaward migration of juvenile “transformers” occurs during the late summer and fall months. Thus, the impact to lamprey may be over stated.

Response to Comment TR18-7
Volume I Section 3.3.2.1 *Aquatic Species – Environmental Setting – Aquatic Species – Fish – Anadromous Fish Species – Pacific Lamprey* has been modified to clarify the "transformer" stage; please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Species – Environmental Setting – Aquatic Species – Fish – Anadromous Fish Species – Pacific Lamprey* for the revision.

Please refer to revised Section 3.3 in Volume III Attachment 1, specifically, Table 3.3-8 for a summary of available data on outmigration timing of Pacific lamprey in the Klamath River Basin. Table 3.3-8 illustrates that juvenile outmigration does occur during late summer and fall months as explained by the commenter.

Comment TR18-8
Section 2.6.1 Water Conflicts Timeline Page 2-21. Despite being the topic of at least 3 feature films and receiving extensive national and international media coverage, there is no mention of the coalition of Tribes, fishermen, and conservationists that protested 3 Scottish Power Shareholder meetings in Scotland (2004-2006) follow by the disruption and protest of 3 Berkshire Hathaway Meetings in Omaha NE (2008-2010). These events were clearly more influential and significant than many of the other items included in the timeline. Additionally, despite being extensively covered by national and international media and being led in part by California Governors Schwarzenegger and Brown, there is no mention of the Klamath Hydroelectric Settlement Agreement and the Klamath Basin Restoration Agreement signed by over 40 parties in 2010. The Agreements were unprecedented in scale, scope, and bipartisan support for a Western water conflict resolution and although the agreements were not ratified by congress, they clearly led the current project under consideration.

Response to Comment TR18-8
The events described in the comment are noted and included in the record for consideration. The introduction to the timeline in Volume I Section 2.6.1 *Project Background – Water Conflicts in the Klamath River Basin* has been modified to further clarify that it is not intended to be a comprehensive history. Additionally, the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III. Please refer to Volume III Attachment 1 Section 2.6.1 *Project Background – Water History* for this revision.

Please note that Volume I Section 2.6.3 *Proposed Project – Project Background – Klamath Settlement Agreements* (pages 2-23 to 2-24) discusses the Klamath Hydroelectric Settlement Agreement (KHSA) and the Klamath Basin Restoration Agreement (KBRA).

Comment TR18-9
Timeline should also include dates of dam construction and FERC license expiration.

Response to Comment TR18-9

The events described in the comment are noted and included in the record for consideration. The introduction to the timeline in Volume I Section 2.6.1 *Project Background – Water Conflicts in the Klamath River Basin* has been modified to further clarify that it is not intended to be a comprehensive history. Please also note that the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III. Please refer to Volume III Attachment 1 Section 2.6.1 *Project Background – Water History in the Klamath River Basin* for the revisions.

Please note that the term of the Federal Energy Regulatory Commission (FERC) annual license is included in Volume I Section 2.6.2 *Proposed Project – Project Background – Relationship with Klamath Hydroelectric Project* (page 2-22). The dam construction dates are provided at the beginning of each of the facility-specific sections: Volume I Section 2.3.1 *Proposed Project – Existing Lower Klamath Project Features – J.C. Boyle Dam and Associated Facilities* (page 2-8), Volume I Section 2.3.2 *Proposed Project – Existing Lower Klamath Project Features – Copco No. 1 Dam and Associated Facilities* (page 2-11), Volume I Section 2.3.3 *Proposed Project – Existing Lower Klamath Project Features – Copco No. 2 Dam and Associated Facilities* (page 2-13), and Volume I Section 2.3.4 *Proposed Project – Existing Lower Klamath Project Features – Iron Gate Dam and Associated Facilities* (page 2-13).

Comment TR18-10

The "Major fish die-off" of 2002 should be referred to directly as a "fish kill." The fish did not die of old age – they were killed by anthropogenic factors including operation of the Lower Klamath Project. The CDFG report referenced here is not included in the references at end of section. Although initial reports put the body count at 33,000, later reports included the one referenced here suggest the actual total was twice that amount.

Response to Comment TR18-10

The phrases "fish kill" and "fish die-off" are both used to describe the 2002 event in reports authored by responsible agencies referenced in this EIR, and both phrases are likewise used in this EIR. The primary reference for the 2002 fish kill (CDFG 2004) is included as a full reference in Section 3.3.6 *Aquatic Resources – References*.

Section 3.3.2.3 *Aquatic Resources – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* has been revised to clarify that the California Department of Fish and Game (CDFG) analysis indicates the total fish kill may have been twice the conservative estimate of 34,056. Please refer to Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* for the revisions.

<u>Comment TR18-11</u>

Timeline should include that in 2006, in the first proceeding of its kind under recent amendments to the Federal Power Act, an Administrative Law Judge ruled that there was indeed suitable habitat upstream of Iron Gate Dam for anadromous fishes.

Response to Comment TR18-11

The events described in the comment are noted and included in the record for consideration. The introduction to the timeline in Volume I Section 2.6.1 *Proposed Project – Project Background – Water Conflicts in the Klamath River Basin* has been modified to further clarify that it is not intended to be a comprehensive history. Please also note that the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III. Please refer to Volume III Attachment 1 Section 2.6.1 *Project Background – Water History in the Klamath River Basin* for the revisions.

Please note that the determinations of the dispute resolution proceeding are used as a reference in the EIR.

<u>Comment TR18-12</u>

2.6.4 Prior/Related Environmental Reviews Page 2-24. This section should note that the 2007 FERC EIS recommended relicensing with trap and haul; however, the fish agencies later filed mandatory terms and conditions pursuant to section 4e of the Federal Power Act mandating volitional fish passage. This mandate by the agencies was challenged in court by PacifiCorp who alleged there was no viable fish habitat upstream of the dams. In 2006, the Administrative Law Judge overseeing PacifiCorp's appeal of agency terms and conditions ruled that fish habitat does indeed exist above the dams and affirmed the agency mandates.

Response to Comment TR18-12

Volume I Section 2.6.4 *Proposed Project – Project Background – Prior/Related Environmental Reviews* is a summary of the environmental reviews conducted in relation to the Proposed Project, and it does not include details regarding the determinations of the 2006 Administrative Law Judge. Please refer to Section 4.1.1.1 *Alternatives – Alternatives Selection/Overview – Alternatives Selection – Alternatives Carried Forward for More Detailed Analysis – Continued Operation with Fish Passage Alternative* (pages 4-3 to 4-4). For information on the Continued Operations with Fish Passage Alternative that discusses its incorporation of the 2007 FERC staff Alternative along with the mandatory fish passage conditions required agencies. Additionally, please refer to the Volume I Section 4.4 *Continued Operations with Fish Passage Alternative* for evaluation of various fish passage options if the Lower Klamath Project continued to operation which includes trap and haul as well as volitional fish passage as required by mandatory conditions during relicensing of the Klamath Hydroelectric Project KHP).

Comment TR18-13

3.2.3 Significance Criteria Page 3-43 – The Significance Criteria includes water quality control plans for the Hoopa Valley Tribe and Yurok Tribe but not that of the Karuk Tribe. This exclusion of the Karuk Tribe continues throughout the section. The Karuk Tribe water quality control plan and our pending 'Treatment as a State' application to EPA are attached for inclusion.

Response to Comment TR18-13

The State Water Board notes the receipt of the Karuk Tribe's water quality control plan and has included it in the record.

Comment TR18-14

Section 3.3.2.1 Aquatic Species Page 3-194 The Karuk Tribe and the Salmon River Restoration Council recently submitted a petition to list Upper Klamath Trinity River Spring Chinook salmon the California Endangered Species List. (petition attached). On February 6, 2019 the California Fish and Game Commission voted unanimously to make Upper Klamath Trinity River Spring Chinook a candidate for listing while the petition undergoes a 12-month review. Table 3.3-1 should break out Upper Klamath Trinity River Spring Chinook from the more generic Chinook salmon category.

Response to Comment TR18-14

The Upper Klamath-Trinity River Spring-run Chinook salmon has been added to Section 3.3.1 *Aquatic Resources – Environmental Setting – Aquatic Species* Table 3.3-1. Please refer to Volume III Attachment 1 Section 3.3.1 *Aquatic Resources – Environmental Setting – Aquatic Species* for the revisions.

Comment TR18-15

Table 3.3-2 Misrepresents the population of wild Upper Klamath-Trinity Spring Chinook by including Trinity River spawners that are of hatchery origin. Wild Upper Klamath-Trinity Spring Chinook spawn almost exclusively in the Salmon River and South Fork Trinity Rivers and have averaged 786 individuals since 1981. See CDFW staff presentation on the petition to list Spring Chinook to the CA Fish and Game Commission on February 6, 2019 (https://videobookcase.com/california/fish-game-commission/february-6-2019-2/).

Response to Comment TR18-15

Section 3.3.1 *Aquatic Resources – Environmental Setting – Aquatic Species* Table 3.3-2 has been revised to clarify that California Department of Fish and Wildlife (CDFW) reports do not distinguish wild and hatchery origin for spring-run Chinook spawners, and that values are based on fish that returned to the hatchery. Please refer to Volume III Attachment 1 Section 3.3.1 *Aquatic Resources – Environmental Setting – Aquatic Species* for the revisions.

Comment TR18-16

Page 3-202 Refers to Salmon River Watershed Council – should be Salmon River Restoration Council.

Response to Comment TR18-16

Section 3.3.2.1 Aquatic Resources – Environmental Setting – Aquatic Species – Chinook Salmon has been revised to clarify the change from the Salmon River Watershed Council to the Salmon River Restoration Council. Please refer to Volume III Attachment Section 3.3.2.1 Aquatic Resources – Environmental Setting – Aquatic Species –Chinook Salmon for the revisions.

Comment TR18-17

Page 3-204 Should refer to Prince et al. 2017 and Thompson et al. 2018 for a more robust discussion of the status of Upper Klamath-Trinity River Spring Chinook population (attached). Thompson et al. 2018 includes physical evidence of the presence of Upper Klamath-Trinity River Spring Chinook above the dams.

Response to Comment TR18-17

Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Resources – Spring-Run Chinook Salmon* has been revised to clarify genetic information as requested. Please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Resources – Spring-Run Chinook Salmon* for the revisions.

Comment TR18-18

Section 3.12.2.1 Tribal Cultural Chronology and Ethnology P3-794 The Karuk Tribe opposes mention of Ruffey Rancheria as representing the Shasta People. The founder and namesake of the Ruffey Rancheria, Old Man Ruffey, as well as the final distributees of the Rancheria, were all Karuk Indians. The present-day descendants of Old Man Ruffey and the final distributees who qualify by blood quantum are enrolled with the Karuk Tribe. A subgroup of Shasta People recently tried to use the terminated Ruffey Rancheria to congressionally establish their own Tribe. The Karuk Tribe's challenge to this group's claim to the Ruffey Rancheria effectively killed this effort. This EIR is an inappropriate venue to re-litigate the issue therefore mention of Ruffey Rancheria should be dismissed from the document or else Karuk's communications to congress should be included herein (attached).

Response to Comment TR18-18

Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People* has been clarified to remove the phrase referencing the Ruffey Rancheria. Please refer to Volume III Attachment 1 Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including*

Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People for the revisions.

Comment TR18-19

P3-797 1979 was not the date when the Karuk Tribe became federally recognized. In that year, the Karuk Tribe re-established a government to government relationship with the United States.

The Karuk Tribe does not view Bright (1978) as a particularly good source to describe our ethnography. Attached is an ethnographic report we developed with a detailed bibliography. We also refer you to consider the ethnographic section of the 2012 Klamath Facilities Removal EIS/EIR as a reasonable attempt to describe Karuk Ethnography. See https://klamathrestoration.gov/sites/klamathrestoration.gov/files/Additonal%20Files%20/1/Chapter%203 %20-%20Affected%20Environment_Environmental%20Consequences.pdf

Response to Comment TR18-19

Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography – Northwest California Culture Area – Ethnography – Karuk* has been revised to clarify that in 1979 the Karuk Tribe re-established a government to government relationship with the United States. Please refer to Volume III Attachment 1 Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography – Northwest California Culture Area – Ethnography – Karuk* for the revisions.

Please note that the 2012 KHSA EIS/EIR was used as a source of information for developing Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods)*. The Bright (1978) citations referenced in this comment are carried over from the Karuk ethnography sections of the 2012 KHSA EIS/EIR. Additionally, the State Water Board appreciates that the Karuk Tribe has provided the Salter and Tucker (2010) summary of history and ethnography, thus including the associated information in the record for the Lower Klamath Project EIR.

Comment TR18-20

Section 3.12.2.2 Historic Period P3-803 The description of the 'Historic Period' is highly sanitized and offensive. Although there is reference to the growth of Euro American settlers, the document fails to mention the magnitude of the genocide waged against Indian People by those settlers. We refer you to Madley's An American Genocide: The United States and the California Indian Catastrophe, 1846-1873, or Lindsay's Murder State: California's Native American Genocide, 1846-1873.

The description of the Klamath Hydroelectric Project and the "significant role" it played in the area's economic development should also include the role it played in destroying the area's robust eco-tourism. Similarly, it should describe the preferential power rate that the California/Oregon Power Company was required to provide the Klamath Irrigation Project with was terminated in 2006.

Response to Comment TR18-20
Section 3.12.2.2 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods)* has revised to clarify that the development of the Klamath Hydroelectric Project (KHP) played a significant role that was both positive and negative in the area's development. Please refer to Volume III Attachment I Section 3.12.2.2 *Historical Resources and Tribal Cultural Resources – Environmental Setting* – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) for the revision.

Comment TR18-21
P3-812 Klamath Cultural Riverscape The Board correctly includes a discussion of the Klamath Cultural Riverscape which provides important context for the document.

Response to Comment TR18-21
Comment noted.

Comment TR18-22
Section 3.12.5.1 Potential Impacts to Tribal Cultural Resources

Page 3-818 Mitigation Measure TCR-1 Develop and Implement a Tribal Cultural Resources Management Plan

The Karuk Tribe strongly supports this measure.

Response to Comment TR18-22
Comment noted.

Comment TR18-23
Mitigation Measure TCR-2 − Develop and Implement a Looting and Vandalism Prevention Program. The Karuk Tribe strongly supports this measure.

Response to Comment TR18-23
Comment noted.

Comment TR18-24
Mitigation Measure TCR-3 − Develop and Implement Inadvertent Discovery Plan (IDP) The Karuk Tribe strongly supports this measure.

Response to Comment TR18-24
Comment noted.

Comment TR18-25
Mitigation Measure TCR-4 − Endowment for Post-Project Implementation The Karuk Tribe asserts that the construction and operation of the Klamath Hydroelectric Project has had devastating impacts on Traditional Cultural Resources (TCRs) of every Tribe in the Klamath Basin. An endowment to protect and enhance TCRs should not be limited to the TCR's in the project area, but to all TCRs impacted by the construction and/or operation and/or removal of the dams.

Response to Comment TR18-25
CEQA requires that the lead agency analyze a proposed project's impacts to California environmental resources. Impacts of the proposed project are determined by comparing the actions of the proposed project to the existing environmental conditions which are usually established at the time CEQA was initiated. If there is a potentially significant impact compared to the baseline condition, then the EIR evaluates mitigation measures.
Mitigating for legacy impacts associated with prior project approvals and existing conditions (that together constitute the baseline) is not appropriate for this CEQA process.

Comment TR18-26
Mitigation Measure TCR-6 − Land Transfer Page 3-841 The Karuk Tribe tentatively agrees with the Board's interpretation of the KHSA Section 7.6.4. However, given the Board's acknowledgement that "The process for determining future land uses under KHSA Section 7.6.4 has not advanced to the point at which competing uses, financial limitations, parcel access requirements, or other constraints have become clear," and "it is too early in the process to determine the feasibility of such [a land] transfer" we see TCR-6 as overly specific and inappropriate to include as a mitigation measure.

Response to Comment TR18-26
During development of the Draft EIR, the State Water Board conducted formal Assembly Bill 52 (AB 52) consultation with the Shasta Nation, Shasta Indian Nation, and Yurok Tribe. In consultation with the Shasta Indian Nation and the Klamath River Renewal Corporation (KRRC), it was agreed upon by all three parties, that an appropriate mitigation measure to reduce impacts to Native American Tribal Cultural Resources (TCRs) associated with implementation of the Proposed Project would include the potential for land transfer of Project lands to Native American Tribal entities, which is consistent with Section 7.6.4 of the Klamath Hydroelectric Settlement Agreement (KHSA).

Mitigation Measure TCR-7 is similarly consistent with Section 7.6.4 of the KHSA, and provides for consideration of a range of potential real property instruments in the process for disposition of Parcel B Lands. Neither it nor any other measure in this section of the EIR commits the KRRC to transfer specific portions of lands to specific Native American entities, or to adopt conservation easements or other real property protections for any particular parcel. The process outlined in Section 7.6.5 of the KHSA provides for input from KHSA signatories and other potentially affected tribes on the ultimate disposition of Parcel B lands.

CEQA provides that real property mitigation measures should be considered and are available for mitigation for tribal cultural resources impacts (Public Resources Code section 21084.3). Further, CEQA provides for identification of mitigation measures in tribal consultation, and for inclusion of such measures in the EIR (Public Resources Code sections 21080.3.2, 21082.3).

Comment TR18-27

Potential Impact 3.12-9 Klamath Cultural Riverscape Contributing Aspect – Combined effects on the Klamath River fishery of dam removal, changes in hatchery production, and increased habitat for salmonids and 3.3.2.3Habitat Attributes Expected to be Affected by the Proposed Project Page 3-247 Fish Hatcheries

These sections presume that the impact of hatcheries on Klamath basin fisheries is positive. The Karuk Tribe urges the Board to broaden the discussion and consider peer reviewed evidence to the contrary. Quinones et al. makes a compelling argument that Iron Gate Hatchery has served to reduce native wild Chinook salmon in the Klamath Basin. Furthermore, recent studies suggest that hatchery reared salmon suffer impaired survival rates due to epigenetic factors.

Response to Comment TR18-27

Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries* includes an analysis of the effects of the Iron Gate Hatchery, including referencing research articles and studies specific to the Klamath River Basin. The analysis in the EIR includes consideration of research indicating potential positive and negative effects of hatcheries, including consideration of research consistent with Quinones et al. (2013) and the epigenetic study by Le Luyer et al. (2017), which have been included in the record. Consideration of the additional research referenced by commenter does not alter the analysis or conclusions reached by the EIR. Please also refer to responses to comments ORG34-14 and ORG42-9.

Comment TR18-28

Potential Impact 3.20-5 Changes to or loss of river conditions that support whitewater boating While it is true that dam removal will impact the current business model associated with commercial rafting the Hell's Corner reach, changes in river conditions and the restoration of the river channel will create new runs that may be commercially viable year-round. These new runs may *require a change in the business model (e.g. inflatable kayaks as opposed to guided 14-foot rafts or multi-day wilderness trips). In addition, the discussion here fails to highlight or mention how many of these 'user days' are marred by water quality impairments. This reach is commonly posted for blooms toxic blue green algae. This should be included in the discussion. The Karuk Tribe asserts that impacts to Hell's Corner are avoidable if the mitigation included assistance in re-writing existing business plans and you consider water quality improvements associated with dam removal.*

Response to Comment TR18-28

State Water Board does not anticipate that consideration of the number of whitewater boating user days lost in the Hell's Corner Reach due to existing conditions water quality impairments would change the determination that the Proposed Project would result in the total loss of opportunity to raft Class IV+ rapids for three months during the late summer and early fall and this would be a significant and unavoidable impact. It is certainly possible that other recreational boating opportunities would become available under the Proposed Project; however, the degree to which this may happen is speculative and thus cannot be relied upon under CEQA for a significance determination.

Comment TR18-29

The only mitigation measure that we have questions about is the arsenic testing and remediation (WQ-3 - Monitoring and potential remediation of reservoir sediments deposited along the Middle and Lower Klamath River floodplain) (see specific comment below in 3.2.5.7)

The proposed water quality monitoring plan is inadequate. Our main concerns with the water quality monitoring plan here:

1) Add a site at Walker Bridge. There is a 60 mile gap in monitoring stations between Iron Gate Dam and Seiad Valley, and that reach of river will experience both the greatest short-term impacts and long-term changes following dam removal. A site should be added at Walker Bridge to address this concern. While it notes in the Definite Plan (Appendix B-Definite Plan Appendix M) that Walker Bridge site was dropped due to access issues, USGS staff have been working on securing a location for a Walker Bridge monitoring location.

Response to Comment TR18-29

Please refer to response to comment TR18-56 regarding Mitigation Measure WQ-3.

The commenter is expressing concerns that the Klamath River Renewal Corporation's (KRRC's) water quality monitoring plan, put forth in the Definite Plan, is inadequate. Additionally, the commenter asserts that the June 7, 2018, water quality monitoring and adaptive management plan required by the State Water Resources Control Board's draft water quality certification is also inadequate. The commenter notes that it has provided comments on the State Water Resources Control Board's draft water quality certification.

The EIR analyzes the potential for environmental impacts due to implementation of the KRRC's Proposed Project and alternatives to the Proposed Project. The requests regarding monitoring and data collection are not raised in connection with concerns regarding the EIR's evaluation of potential environmental impacts of the Proposed Project, or mitigation for such impacts. The comment expresses general support for the EIR's impact analysis of fisheries impacts (please refer to comment TR18-5), and raises concerns regarding the EIR's water quality analysis with respect to only one mitigation measure regarding remediation for sediment deposits that is not a part of the water quality monitoring and data collection concerns.

Please note that the State Water Resources Control Board has made several revisions to its water quality monitoring and adaptive management plan that will be included in its final water quality certification, including in response to comments by the Karuk Tribe.

Please refer to Volume I Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* (pages 2-97 to 2-99) for a general summary of the water quality monitoring included in the Definite Plan. Volume I Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* provides a general discussion of the water quality monitoring with regards to the individual water quality parameters (see Potential Impact 3.2-1 for water temperature; Potential Impact 3.2-3 for suspended sediments; Potential Impact 3.2-7 for nutrients; Potential Impact 3.2-9 for dissolved oxygen; Potential Impact 3.2-11 for pH; Potential Impact 3.2-12 for chlorophyll-a and algal toxins; and, Potential Impact 3.2-14 for inorganic and organic contaminants). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR18-30

Increase/adjust parameters collected for water quality monitoring. There is a substantial reduction in the number of stations and water quality parameters in the proposed water quality monitoring plan relative to the Klamath Hydroelectric Settlement Agreement (KHSA) Interim Measure 15 (IM15) monitoring program which has been collecting baseline data since 2009. Aside from the sonde and suspended sediment monitoring, the current monitoring plan only calls for total nitrogen, total phosphorous, and blue green algae speciation monthly. Monthly nutrient sampling should also include the other forms of nitrogen and phosphorous as well as dissolved carbon that are currently being collected as part of IM15. Total nitrogen and total phosphorous alone are not adequate in analyzing changes in nutrient loads from the proposed project. Phytoplankton speciation should be focused more in the seasonal growing period (May to October) rather than monthly throughout the year and should include not only *speciation of microcystin-producing algae but also concentrations of microcystin. Adding sites at state line (Shovel Creek) and Walker Bridge will allow for a more comprehensive analysis of water quality impacts by the project.*

Response to Comment TR18-30
Please refer to response to comment TR18-29.

Comment TR18-31
Work with USGS and KRRC to ensure that enough event-based suspended sediment concentrations (SSC) samples will be collected. An adequate number of samples need to be collected to be able to combine with continuous turbidity and flow data to construct the sediment budgets that are necessary to understand the ultimate fate of reservoir sediments. Consider adding tributary sites as well (Shasta, Scott, Salmon, Trinity), particularly to aid in the development of the sediment budget.

Response to Comment TR18-31
Please refer to response to comment TR18-29.

Comment TR18-32
We would also suggest that monitoring should continue for at least five years post-drawdown. The massive scale of the proposed dam removal project merits a monitoring plan sufficiently detailed that it will adequately assess the results of the project. It is our understanding that the water quality monitoring plan is still in development, and that the SWRCB will have the final word on what needs to be included. Please ensure that the monitoring plan will provide enough information to determine if the actual effects of the dam removal matched the predictions, with the ancillary benefit of using this once-in-a-lifetime opportunity to provide crucial information needed to guide long-term river management.

Response to Comment TR18-32
Please refer to response to comment TR18- 29.

Comment TR18-33
The Comments on Specific Details section below is organized by section and page number. It provides suggested edits to improve the EIR's technical accuracy.

Response to Comment TR18-33

Similar text is often repeated on multiple pages within the DEIR. In general, our comments here specifically reference only one page (or section) but are intended to apply to multiple pages/sections if the text we reference also appears elsewhere in the DEIR.

Response to Comment TR18-34
Comment noted.

<u>Comment TR18-35</u>
2.7.8.7 Water Quality Monitoring and Construction BMPs

USGS did not collect sediment samples in 2017 from the reservoirs. We suggest contacting Ben Swann of CDM Smith to see which consultants to KRRC collected the samples.

Response to Comment TR18-35
Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* has been updated to clarify that the Klamath River Renewal Corporation (KRRC) collected reservoir sediment core samples from November 28, 2017 to December 1, 2017. Please refer to Volume III Attachment 1 Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* for the revisions.

<u>Comment TR18-36</u>
Please improve the water quality monitoring plan with suggestions listed above.

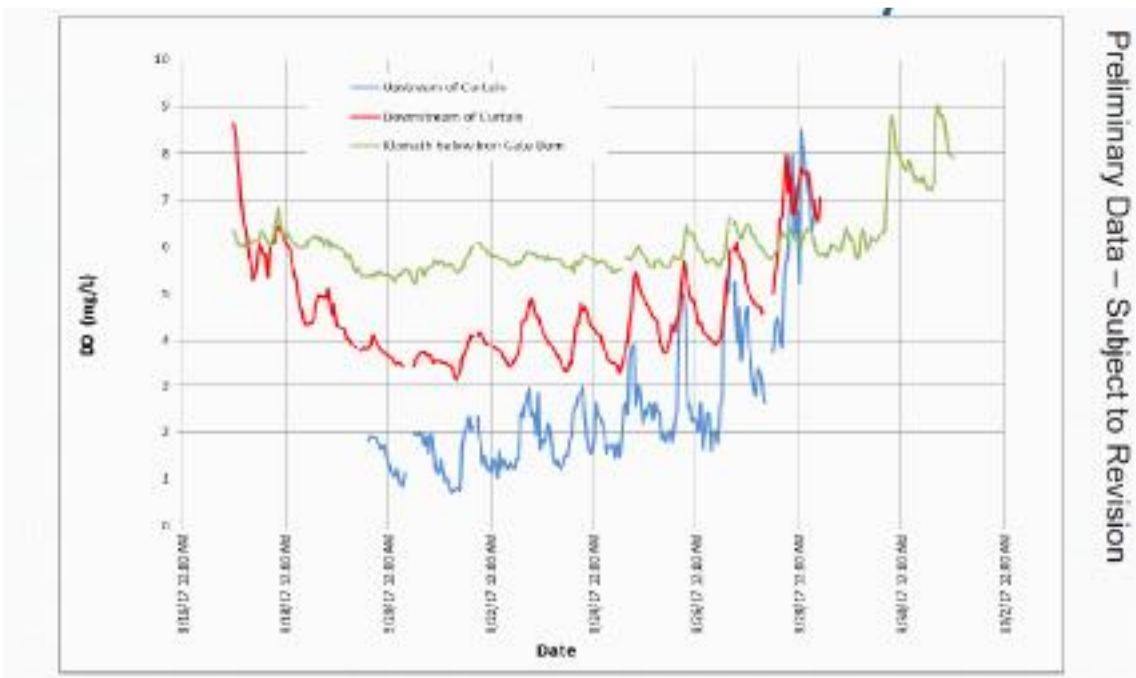
Response to Comment TR18-36
Please refer to response to comment TR18-29.

<u>Comment TR18-37</u>
Page 3-22: "The relatively shallow depth and short hydraulic residence times do not support thermal stratification in J.C. Boyle Reservoir (FERC 2007; Raymond 2008a, 2009a, 2010a) and thus this reservoir does not directly alter summertime water temperatures in further downstream reaches (NRC 2004)." We recommend adding ", other than reducing the magnitude of diel (i.e., 24-hour cycle) fluctuations" to the end of the sentence.

Response to Comment TR18-37
J.C. Boyle Reservoir itself does not alter the magnitude of the diel water temperature fluctuations in the J.C. Boyle Bypass Reach downstream of the dam. The magnitude of diel water temperatures is reduced due to bypass operations from J.C. Boyle Dam that reduce the relative proportion of flow in the river from upstream and increase the relative proportion of flow from groundwater springs in the J.C. Boyle Bypass Reach. Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify the influence of bypass operations on water temperatures in the J.C. Boyle Bypass Reach based on the comment recommendation. Please refer to Volume III Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* for these revisions.

Comment TR18-38

Page 3-23 (and also applicable to many other section of the DEIR): We recommend that any text discussing the effects of the Iron Gate Reservoir curtain should also note that during intense algae blooms the curtain has the detrimental side-effect of reducing dissolved oxygen concentrations in water released downstream. Operationally, this means that the curtain must be raised during intense blooms to avoid reducing dissolved oxygen downstream, which limits the curtain's usefulness for reducing algae. The preliminary data in the following slide from PacifiCorp's October 16, 2017 presentation to the Interim Measures Implementation Committee (there is not yet a draft report that includes these data) shows low dissolved oxygen values in late September 2017 downstream of the curtain (red line) and below Iron Gate Dam (green line):



Response to Comment TR18-38

The preliminary dissolved oxygen data from PacifiCorp's October 16, 2017 presentation to the Interim Measures (IMs) Implementation Committee that is provided in the comment is too limited to draw broad conclusions about the influence of the Iron Gate Reservoir powerhouse intake curtain on dissolved oxygen conditions downstream of Iron Gate Dam. However, in its 2018 report, PacifiCorp acknowledges that it had to raise the curtain several times after the curtain was deployed to access water with higher dissolved oxygen concentrations and comply with water quality standards, potentially limiting the effectiveness of the curtain to reduce transport of cyanobacteria into the Klamath River downstream of Iron Gate Dam (PacifiCorp 2018a). Section 3.2.2.2 *Water Quality – Existing Conditions – Water Temperature* and other water quality sections discussing the powerhouse intake curtain have been clarified to acknowledge that the potential beneficial effects of the intake curtain on algae and water temperature in the Klamath River downstream of Iron Gate Dam may be reduced when the curtain is raised in response to low dissolved oxygen concentrations. Please refer to Volume III Attachment 1 Section 3.2.2.2 *Water Quality – Existing Conditions – Water Temperature*, Section 3.2.2.7 *Water Quality – Existing Conditions – Chlorophyll-a and Algal Toxins*, Section 4.2.2 *No Project Alternative – Water Quality – Water Temperature*, Section 4.2.2 *No Project Alternative – Water Quality – Chlorophyll-a and Algal Toxins,* Section 4.4.2.1 *Continued Operations with Fish Passage Alternative – Water Quality – Water Temperature*, Section 4.4.2.2 *Continued Operations with Fish Passage Alternative – Water Quality – Suspended Sediments*, Section 4.4.2.4 *Continued Operations with Fish Passage Alternative – Water Quality – Dissolved Oxygen, and Section 4.4.2.6 Continued Operations with Fish Passage Alternative – Water Quality – Chlorophyll-a and Algal Toxins* these revisions.

Comment TR18-39

Page 3-24 "Species present in the Klamath River capable of producing microcystin include Microcystis aeruginosa and Anabaena flos-aquae, while species present in the Klamath River in the genus Anabaena can produce anatoxin-a and saxitoxin." Other species capable of producing microcystin have been detected in the Klamath River as well (even though they never dominate). These are Gloeotrichia and Planktothrix/Oscillatoria (Genzoli and Kann 2017, E&S Environmental Chemistry, Inc. 2018, Asarian and Kann 2006). Additional potentially toxin producing genera found in the Klamath River and/or reservoirs include Limnothrix (E&S Environmental Chemistry, Inc. 2018) and Pseudanabaena (Genzoli and Kann 2017).

Response to Comment TR18-39

Please note that the sentence quoted in the comment and attributed to page 3-24 is actually found on page 3-34.

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify using language similar to that requested in the comment. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-40

Page 3-26 "However, in the summer months, organic suspended materials can increase in the Klamath River between Iron Gate Dam and Seiad Valley (RM 132.7) due to the transport of in-reservoir algal blooms to downstream reaches of Klamath River as well as resuspension of previously settled organic materials (YTEP 2005; Sinnott 2008; Armstrong and Ward 2008; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016). Further downstream, near the confluence with the Scott River (RM 145.1) concentrations of organic suspended materials tend to decrease with distance as phytoplankton gradually settle out of the water column farther downstream or are diluted by *tributary inputs (see Appendix C for more detail)." The Scott River is downstream of Seiad Valley, so it is potentially confusing to use the term "further downstream" here.*

Response to Comment TR18-40

Section 3.2.2.3 Water Quality – Environmental Setting – Suspended Sediments has been revised to clarify the location near the Scott River confluence. Please refer to Volume III Attachment 1 Section 3.2.2.3 Water Quality – Environmental Setting – Suspended Sediments for the revision.

<u>Comment TR18-41</u>

Page 3-28: The sentence "TP and TN concentrations in the Klamath River vary with flow, with the highest concentrations tending to occur during low flow years (e.g., 2001-2004) and the lowest concentrations tending to occur during high flow years (e.g., 2006, 2010, 2011) (Asarian and Kann 2013)" should be revised to note that it pertains only to the low-flow season (summer and early fall). TP can be very high during peak winter and spring flows due to suspended sediment.

Response to Comment TR18-41

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify that the statement pertains to summer through early fall. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions.

<u>Comment TR18-42</u>

Page 3-34: The sentence previous to this one "Diatoms (i.e., unicellular, photosynthetic microalgae) typically dominate in spring then decrease due to zooplankton grazing and the onset of water column stratification, which results in the diatoms settling out of the water column below the lake or reservoir surface layer (epilimnion)." refers to longitudinal trends including those for the riverine reaches, but this quoted sentence focuses on lentic (i.e., non-flowing) waters only- it should be revised to note that, since the dynamics do not apply to free-flowing river reaches.

Response to Comment TR18-42

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify when the results being discussed are related to river or lake/reservoir conditions. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

<u>Comment TR18-43</u>

Page 3-36: "Phycocyanin, a pigment produced by blue-green algae, has been collected between May and November at some monitoring sites in the Klamath River downstream of Iron Gate Dam since 2007. At Seiad Valley (RM 132.7), phycocyanin is typically low from May through early August, increases to a peak *in early September, and decreases until reaching low levels again by the end of October (Asarian and Kann 2013). Phycocyanin concentrations generally coincide with chlorophyll-a concentrations for the portion of the Klamath River at Seiad Valley." We recommend that these sentences should be revised/replaced. Genzoli and Kann (2016) has a much more comprehensive analysis of Klamath River phycocyanin data than Asarian and Kann (2013). In addition, phycocyanin is measured by continuous probes, so it would be more accurate to say "measured" rather than "collected".*

Response to Comment TR18-43

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify phycocyanin data in the Klamath River according to the comment. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-44

Page 3-37 The text citing the Otten et al. (2015) study should also be revised to briefly mention the genetic evidence for Iron Gate Reservoir being the source for Microcystis in the lower Klamath River. This genetic evidence is mentioned in section 3.4 Phytoplankton and Periphyton. Otten et al. (2015) document with genetic analysis that algal production in Iron Gate Reservoir is the principal source of Microcystis aeruginosa responsible for the observed public health exceedances occurring in the Klamath River downstream from Iron Gate Dam.

Response to Comment TR18-44

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* been revised to clarify that the genetic analysis of *Microcystis aeruginosa* populations included Copco No. 1, Iron Gate Reservoir, and Klamath River sites and *Microcystis aeruginosa* populations in Iron Gate Reservoir likely contribute to *Microcystis aeruginosa* public health exceedances in the Klamath River below Iron Gate Reservoir. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-45

Page 3-37: Genzoli and Kann (2017) serves as a recent compilation of Microcystis and microcystin trends in the middle Klamath River, including diel, seasonal and longitudinal trends. Although this document is covered elsewhere (e.g., page 3-403; 3-414; 3-417, 3-431) it would be useful to cite here as well.

Response to Comment TR18-45

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been clarified as requested. Please refer to EIR Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-46

Page 3-38 contains the following paragraph regarding anatoxin-a:

"Anatoxin-a produced by the genus Anabaena of blue-green algae species was detected in Iron Gate Reservoir on September 3, 2005, in testing by the California Department of Health Services (Kann 2007a; Kann 2008b). In additional, monitoring conducted for the Karuk Tribe during 2005, 2006, 2007, 2008 in Copco No. 1 or Iron Gate reservoirs found no anatoxin-a detected (Kann and Corum 2006, 2007, 2009; Kann 2007b). At Lower Klamath River monitoring sites, anatoxin-a was not detected above the reporting limit in water samples collected during 2008 and 2009 (Fetcho 2009, 2011). In recent years, anatoxin-a has been measured in the Klamath River downstream of Iron Gate Reservoir on several occasions, typically in the lower reaches including at monitoring sites near Weitchpec and Orleans (Otten 2017). While concentrations of Anabaena flos-aquae cells have continued to be monitored, anatoxin-a concentrations are not available for Lower Klamath Project reservoir and Klamath River sites in recent years."

We recommend that this paragraph be updated to reflect more recent Klamath River data, the uncertainty in the sources of anatoxin, and the potential contribution of benthic sources (i.e. periphyton) in anatoxin-a production. The issue of potential benthic contributions to anatoxin-a production also applies to several other places within the DEIR. In our opinion, potential benthic production of anatoxin would not change any of the effects determinations in DEIR but should probably be included for the sake of completeness. Here is a replacement paragraph to consider using in place of the paragraph quoted above:

"Anatoxin-a has been detected in the Klamath River system, although the timing, distribution, and sources of anatoxin-a production in the Klamath is not well understood. Cyanobacterial species from a number of genera are capable of producing anatoxin-a, including Dolichospermum (planktonic species previously considered part of the genus Anabaena are now called Dolichospermum), Anabaena (previously included planktonic and benthic species whereas it is now only benthic species), Aphanizomenon, Cylindrospermopsis, Planktothrix (Oscillatoria), and Phormidium (Chorus and Bartram 1999, Quiblier et al. 2013, U.S. EPA 2014, Bouma-Gregson et al. 2018). Although toxin-producing phytoplankton are more well studied, periphyton can also produce toxins including anatoxin-a (Heath et al. 2011, Quiblier et al. 2013). In many California rivers and streams not impounded by dams, periphyton are assumed to be the primary sources Anatoxin-a (Fetscher et al. 2015), including species in genus Anabaena and Phormidium in tributaries of the Eel River located south of the Klamath River (Asarian and Higgins 2018, Bouma-Gregson et al. 2018). Anatoxin-a was detected in Iron Gate Reservoir on September 3, 2005, in testing by the California Department of Health Services (Kann 2007a; Kann 2008b),

while monitoring conducted for the Karuk Tribe during 2005-2008 in Copco No. 1 and Iron Gate reservoirs did not detect anatoxin-a (Kann and Corum 2006, 2007, 2009; Kann 2007b). At Lower Klamath River monitoring sites, anatoxin-a was not detected in water samples collected during 2008 and 2009 (Fetcho 2009, 2011). In more recent years (2010, 2015, 2016), anatoxin-a was detected in the Klamath River from sites directly below Iron Gate Dam to the Klamath River Estuary (unpublished data from the Yurok and Karuk Tribes). Genetic tools that detect the presence of an anatoxin-a synthase gene came back positive for 19.5% of 123 samples from throughout the Klamath River system, although how the presence of the synthase gene relates to toxin concentrations is still unknown (Otten 2017). The detection of anatoxin-a over many years suggest that anatoxin-a poses a persistent public health threat for the Klamath River, yet the timing, spatial scale, and sources of the toxin are poorly understood due to limited monitoring for anatoxin-a."

Response to Comment TR18-46

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the discussion of uncertainty for anatoxin-a distribution and sources and which cyanobacteria species are capable of producing anatoxin-a. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-47

Page 3-54: Table 3.2-7 lists the Hoopa Valley Tribe's water quality objectives that are to be used (along with the applicable objectives from the NCRWQCB and Yurok Tribe) to evaluate thresholds of significance for water quality impacts. The table has a footnote that:

'HVTEPA (2008) includes a natural conditions clause which states, "If dissolved oxygen standards are not achievable due to natural conditions, then the COLD and SPAWN standard shall instead be dissolved oxygen concentrations equivalent to 90% saturation under natural receiving water temperatures." USEPA has approved the Hoopa Valley Tribe definition of natural conditions; the provision that site-specific criteria can be set equal to natural conditions and the procedure for defining natural conditions have not been finalized as of December 2018.'

There is also a second similar footnote regarding total nitrogen and total phosphorus. While not strictly wrong, those footnotes are incomplete because they do not mention that until the Tribe establishes the procedure for defining natural conditions, and EPA approves that procedure, the natural conditions do not have any legal weight. The exact wording in EPA's Feb 14, 2008 approval letter was: "with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing Natural Condition reference conditions, the stated numerical criteria... will constitute the operative criteria for all purposes."

Therefore, we recommend that "USEPA has approved the Hoopa Valley Tribe definition of natural conditions; the provision that site-specific criteria can be set equal to natural conditions and the procedure for defining natural conditions have not been finalized as of December 2018" be replaced with "USEPA has approved the Hoopa Valley Tribe definition of natural conditions with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing Natural Condition reference conditions, the stated numerical criteria will constitute the operative criteria for all purposes."

Response to Comment TR18-47
Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance* Table 3.2-7 has been revised to include reference that United States Environmental Protection Agency (USEPA) has approved the Hoopa Valley Tribe definition of natural condition with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing the "natural conditions" reference condition, the stated numerical criteria will constitute the operative criteria for all purposes. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance* Table 3.2-7 for the revisions.

Comment TR18-48
Page 3-59 and page 3-60: The overall approach for assessing the significant of impacts for nutrients makes sense, but we are unclear on why this section mentions the TMDL targets for Total Nitrogen (TN) and Total Phosphorus (TP) but not the Hoopa Valley Tribe's objectives for TN and TP?

Response to Comment TR18-48
Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Nutrients* has been revised to clarify a refence to Hoopa Valley Tribe Total Phosphorus (TP) and Total Nitrogen (TN) numeric targets. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Nutrients* for the revisions.

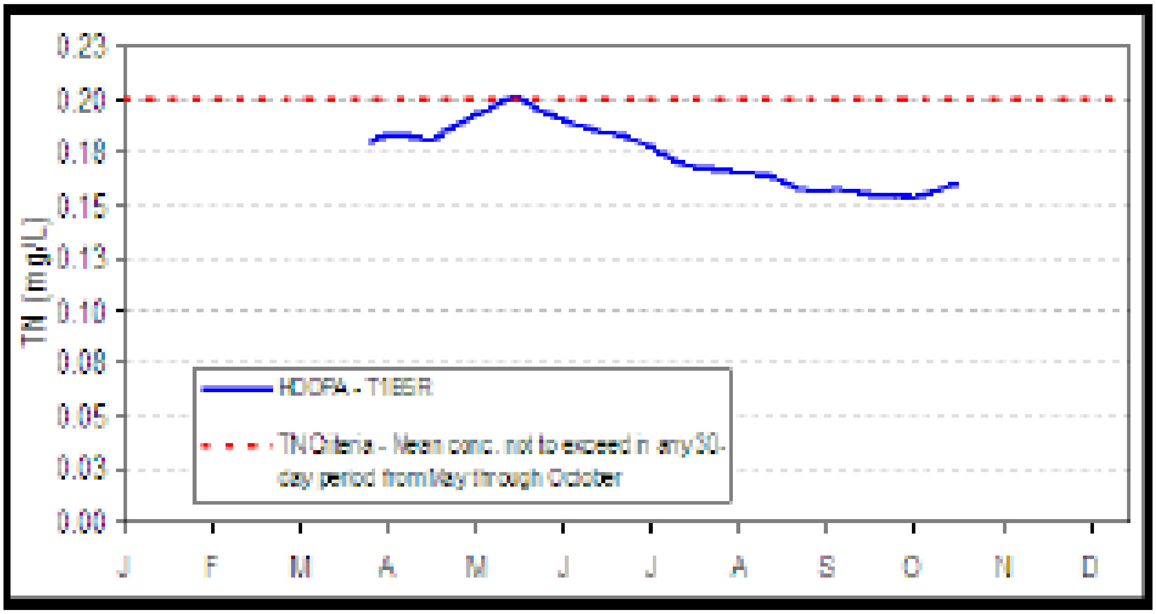
Please note, the minor clarifications raised by the comment do not change an environmental impact or mitigation measure analyzed in the EIR because the Hoopa Valley Tribe numeric TP and TN surface-water quality objectives already had been used in the Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 analysis. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR18-49
Page 3-117 includes the following sentence:

"Klamath River TMDL model results indicate that while resulting TP levels would meet the existing Hoopa Valley Tribe numeric water quality objective (0.035 mg/L TP) in all months at the Hoopa reach (approximately RM 45) of the Klamath

River, TN levels would continue to be in excess of the existing objective (0.2 mg/L TN) in all months, as would TN levels for the modeled 'natural conditions' (T1BSR) and the modeled 'dams-in' scenario (T4BSRN) (for the months of October through June) (North Coast Regional Board 2010)."

The second half of this sentence is incorrect, so we recommend that it be revised. The TN concentrations predicted in the final version of the 'natural conditions' (T1BSR) scenario exceeded the Hoopa Valley Tribe's criteria only for a few days in May, not 'in all months'. In addition, the magnitude of the exceedance is so small that it can reasonably be considered de minimis, as shown in the following figure from the North Coast Regional Board (2010):



The incorrect statement on TN exceedances may be a result of outdated information. Initial versions of the 'natural conditions' (T1BSR) scenario did indicate substantive exceedances of the Hoopa Valley Tribe's TN objective; however, these exceedances were caused by unrealistically high TN concentrations assigned to tributaries. Once these tributary concentrations were corrected to more closely represent available data, the exceedances essentially disappeared in the final official version of the model (i.e., see figure above).

Response to Comment TR18-49

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been revised to clarify the Hoopa Valley Tribe numeric water quality Total Nitrogen (TN) objective exceedance information for Total Maximum Daily Load (TMDL) model results. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

Comment TR18-50

Page 3-117 "While there would be a slight increase in absolute nutrient concentrations entering the Middle Klamath River under the Proposed Project, phytoplankton, especially blue-green algae, would be limited in their ability to use those nutrients for growth and reproduction without calm reservoir habitat (Potential Impact 3.4-2)." We recognize that word choices are subjective, but "slight" is probably not the most accurate word to describe the expected increase, unless it is specifically in reference to annual time scales, not seasonal time scales. As noted on page 3-116, the increases in TN for the July through September period are expected to be in the range of 48-55%. We suggest replacing "a slight increase" with "an increase".

Response to Comment TR18-50

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

Comment TR18-51

Page 3-118: "In general, although dam removal would result in a slight long-term increase in TP and TN away from the numeric targets, such an increase would not support the growth of nuisance and/or noxious phytoplankton or nuisance periphyton." Similar to our previous comment above regarding page 3-117, it would be more accurate to replace "a slight long-term increase in TP and TN" with "a long-term increase in TP and TN" or "a slight long-term increase in annual TP and TN".

Response to Comment TR18-51

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

Comment TR18-52

Page 3-135: "…monitoring data at multiple locations further downstream in the Middle and Lower Klamath River indicate that pH patterns over a 24-hour period are driven primarily by photosynthesis and respiration of periphyton (Ward and Armstrong 2010; Asarian et al. 2015; see Section 3.4.2.2 Periphyton) rather than phytoplankton." A direct quantification of the relative contributions to primary production in the Middle Klamath River is provided by Genzoli and Hall (2016). Even though Genzoli and Hall's (2016) analysis did not specifically evaluate pH, we recommend that it should still be cited here.

Response to Comment TR18-52

The reference provided in the comment (i.e., Genzoli and Hall 2016) supports the premise of Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH*

Potential Impact 3.2-11 discussion and analysis, which is that, in the absence of a reservoir phytoplankton bloom that is subsequently transported into the Middle and Lower Klamath River, periphyton are relatively more important for influencing diel fluctuations in water quality conditions (e.g., dissolved oxygen and pH) compared to phytoplankton. As the EIR analysis is focused on pH changes in the river, while the reference provided in the comment focuses on primary productivity in grams oxygen per square meter per day (g $O_2/m^2/d$) rather than pH, the reference provided in the comment has not been added to the pH analysis. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR18-53

Page 3-136: "Since N-fixing species dominate the periphyton communities in the lower portions of the Middle Klamath River as well as the Lower Klamath River where inorganic nitrogen concentrations are low (Asarian et al. 2010, 2014, 2015), changes in nutrients due to dam removal are not expected to alter the periphyton community in these reaches (see Potential Impact 3.4-5)." The species composition of the periphyton community may well shift, but the biomass is not expected to increase substantially. We suggest that this end of this sentence be revised to "…are not expected to substantially alter total periphyton biomass in these reaches (see Potential Impact 3.4-5)."

Response to Comment TR18-53

Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 has been revised to clarify that changes in the periphyton species composition under the Proposed Project would not significantly alter the total periphyton biomass in the Middle and Lower Klamath River. Please refer to Volume III Attachment 1 Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 for the revisions.

Comment TR18-54

Page 3-137. While reservoir phytoplankton are by far the dominant source of algal toxins in the Klamath River, Section 3.2.5.6 Chlorophyll-a and Algal Toxins should probably also mention that river periphyton are capable of producing cyanotoxins including anatoxin-a. This would not change the effects determinations but should be mentioned for the sake of completeness. See comments regarding page 3-38 above for details.

Response to Comment TR18-54

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been updated to note that cyanotoxins (including anatoxin-a) can be produced by riverine periphyton in addition to phytoplankton. Please refer to Volume III Attachment I Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for these revisions.

Please note, while some periphyton species are capable of producing algal toxins, including microcystin and anatoxin-a (Heath et al. 2011; Quiblier et al. 2013; see Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins*), all available data indicate that algal toxin presence (i.e., microcystin and anatoxin-a) in the Klamath River corresponds to high concentrations of phytoplankton blue-green algae cells (i.e., algae blooms of *Microcystis aeruginosa* for microcystin or *Anabaena flos-aquae* for anatoxin-a) (Kann and Corum 2006, 2007, 2009; Kann 2006, 2007a,b,c,d, 2008b; Jacoby and Kann 2007; CH2M Hill 2008; Kann et al. 2010a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Otten et al. 2015). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Clarifications based on this comment do not change effects determinations in Section 3.2 *Water Quality*.

Comment TR18-55

"While algal toxins and chlorophyll-a produced in Upper Klamath Lake may still be transported downstream after dam removal, existing data indicate that microcystin concentrations in the Klamath River decrease to below California water quality objectives (see Section 3.2.3.1 Thresholds of Significance) by the upstream end of J.C. Boyle Reservoir, regardless of the microcystin concentration measured leaving the Upper Klamath Lake (Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016)."

There have been high microcystin levels on occasion in JC Boyle at Topsy Campground. It is more correct to say that microcystin concentrations in the Klamath River decrease to below California water quality objectives downstream of JC Boyle. (e.g., E&S Environmental Chemistry, Inc. 2018). Then the following sentence is still correct: "Thus, algal toxins and chlorophyll-a production upstream of J.C. Boyle Dam would not be expected to be transported into California and result in algal toxin or chlorophyll-a concentrations in a manner that would cause or substantially exacerbate an exceedance of water quality standards or would result in a failure to maintain existing beneficial uses currently supported."

Response to Comment TR18-55

Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* Potential Impact 3.2-12 (pages 3-137 to 3-139) has been revised to clarify that high microcystin levels have been detected in J.C. Boyle Reservoir at Topsy Campground and the potential for localized *Microcystis aeruginosa* growth and high microcystin concentrations in J.C. Boyle would be reduced under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR18-56

Page 3-150: Mitigation Measure WQ-3 (Monitoring and potential remediation of reservoir sediments deposited along the Middle and Lower Klamath River floodplain) proposes that following dam removal, floodplain deposits in areas with agricultural and residential land use should be tested for arsenic and then remediated (removal or soil capping) if arsenic levels exceed background levels found in adjacent soils and USEPA or CalEPA human health residential screening levels. According to information presented on page 3-142 of the DEIR, soils in the Klamath Basin have naturally high arsenic levels, and arsenic levels in samples from reservoir sediments were within those natural ranges. Remediating arsenic-rich soils along the river corridor could be quite expensive and is not a decision to be taken lightly. Floodplains are naturally dynamic environments and healthy floodplains experience both sediment deposition and erosion. Floodplain soils are heterogeneous with deposits of varying ages and source compositions. Basing the decision about whether to remediate a particular reservoir-derived sediment deposit on a comparison to arsenic levels in adjacent soils seems subject to a high degree of uncertainty and luck of the draw (e.g. what particular portion of reservoir sediment ended up settling on top of what particular floodplain deposit). How will decisions be made about the definition "exceed" (e.g., does that mean that the average has to be 0.1% higher, or some greater threshold? What if any statistical tests will be used?) And how many samples will need to be collected and over what geographic area? There is definitely value in remediating truly contaminated soils that have arsenic concentrations substantially higher than ambient conditions, but is how will such thresholds be determined?

Response to Comment TR18-56

Comment noted. As described in Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-15, remediation is required only in instances where (1) there are visibly obvious sediment deposits that are consistent with physical sediment properties associated with Lower Klamath Project reservoir sediments (2) these are in agricultural or residential areas (with heightened ingestion potential) and (3) when these sediments have arsenic levels that are both higher than local background levels and exceed health residential screening levels. Please note that the State Water Board has revised Mitigation Measure WQ-3 to add additional reporting on and oversight of test methods and remediation in order to allow for appropriate tailoring of testing and remediation to the individual circumstance that arises.

Please refer to Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Mitigation Measure WQ-3 for the revisions.

Comment TR18-57

Page 3-397: Need to distinguish planktonic "Anabaena" which is now called Dolichospermum, from benthic forms still referred to as Anabaena.

Response to Comment TR18-57

Section 3.4.2.1 *Phytoplankton and Periphyton – Environmental Setting – Phytoplankton – Anabaena flos-aquae* has been revised to clarify that the EIR continues to use the *Anabaena* name for both planktonic and benthic species since *Anabaena* was more frequently used in the literature cited and it is still commonly used in descriptions of this species. Please refer to Volume III Attachment 1 Section 3.4.2.1 *Phytoplankton and Periphyton – Environmental Setting –Phytoplankton – Anabaena flos-aquae* for the revisions.

Comment TR18-58

Page 3-403: "Monitoring at multiple locations along the Middle and Lower Klamath River indicates that dissolved oxygen and pH patterns over a 24-hour period are driven primarily by photosynthesis and respiration of periphyton (Ward and Armstrong 2010, Asarian et al. 2015)." A citation of Genzoli and Hall (2016) should be added here (see comment above regarding page 3-135 for justification).

Response to Comment TR18-58

Section 3.4.2.2 *Phytoplankton and Periphyton – Environmental Setting – Periphyton* has been revised to clarify the relative influence of phytoplankton and periphyton on dissolved oxygen and pH in the Middle and Lower Klamath River. Please refer to Volume III Attachment 1 Section 3.4.2.2 *Phytoplankton and Periphyton – Environmental Setting – Periphyton* for the revisions.

Comment TR18-59

Page 3-413: "Nuisance blooms of periphyton have not been documented in the riverine portions of the Hydroelectric Reach. In the J.C. Boyle Peaking Reach, it has been noted that periphyton tends to be absent from the margins of the river that are alternately dried and wetted during peaking operations (E. Asarian, pers. comm., 2011)." We recommend that the end of this sentence be re-structured with different references, so that it ends with "periphyton tends to be absent from the margins of the river that are alternately dried and wetted during peaking operations (Karuk Tribe 2006), due to reasons described by PacifiCorp (2005)". Note that the PacifiCorp (2005) report is unavailable online but we have it in our files; please contact us if you need a copy.

Response to Comment TR18-59

Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Periphyton* has been revised to clarify that the lack of periphyton along the margins of the J.C. Boyle Peaking Reach is due to turbid conditions that limit light availability for photosynthesis, high water velocities that limit establishment and growth of periphyton, and the variable flow regime that causes cycles of drying and rewetting. Please refer to Volume III Attachment 1 Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Periphyton* for the revisions.

Comment TR18-60

Page 3-431: This sentence suggests that river growth of BGA is causing exceedances:

"Some phytoplankton growth may still occur after dam removal in calm, slow-moving habitats along shorelines and protected coves and backwaters during low-flow periods in the Middle and Lower Klamath River, but these habitats already support growth of blue-green algae, including Microcystis aeruginosa, that results in occasional exceedances of 2016 CCHAB secondary thresholds and WHO guidelines (Falconer et al. 1999; Kann et al. 2010; State Water Board et al. 2010, updated 2016; Genzoli and Kann 2016, 2017)."

It is not likely that these slow-moving and backwater areas support growth of blue-green algae, but rather are sites where upstream sources accumulate as slowed velocity allows them to settle or become trapped in vegetation. Thus the exceedances currently detected in such areas would decrease with dam removal. There is no evidence that we are aware of for actual growth of planktonic cyanobacteria in the Middle and Lower Klamath.

Response to Comment TR18-60

Section 3.4.5.1 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Phytoplankton* Potential Impact 3.4-2 has been revised to clarify blue-green algae and microcystin entrapment and accumulation in backwater areas of the Klamath River from upstream sources. Please refer to Volume III Attachment 1 Section 3.4.5.1 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Phytoplankton* Potential Impact 3.4-2 for the revisions

Comment TR18-61

Page 3-717. This section mentions that the DEIR's method for estimating methane emissions from Klamath Hydroelectric Project reservoirs was adapted from Karuk Tribe's (2006) comments which multiplyied the reservoirs' area by areal emissions rates from reservoirs around the world with similar water quality characteristics. The Karuk Tribe's estimates were best the information available at that time, but there is now new information available including a global synthesis (Deemer et al. 2016) and field measurements of methane emissions available from J.C. Boyle Reservoir and Keno Reservoir (Harrison et al 2017) using methods from Deemer et al. (2011). We also encourage SWRCB to consider incorporating these recent studies into the EIR.

Response to Comment TR18-61
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment TR18-62
During our review of the DEIR we noticed a few minor/insignificant errors, which we present in this separate list to avoid cluttering our other comments.

Response to Comment TR18-62
Comment noted. This comment indicates that a few minor/insignificant errors were noticed, and are provided in comments below.

Comment TR18-63
Page 2-98: "Microcystin [-Producing Blue-green Algae] Cell Count" is odd phrasing that doesn't match the conventions used in the rest of the DEIR. Should be "Microcystin-Producing Blue-green Algae Cell Count"?

Response to Comment TR18-63
Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* summarizes the Klamath River Renewal Corporation (KRRC) Proposed Water Quality Monitoring Plan included in the Proposed Project (see Volume II Appendix B: *Definite Plan – Appendix M*). In the Proposed Project Water Quality Monitoring Plan, one parameter to monitor is called "Microcystin Cell Count", but this is likely a typo because microcystin is only chemical compound that does not have a cellular structure that can be counted. It is assumed that the "Microcystin Cell Count" parameter is meant to refer to microcystin-producing blue-green algae cell counts, a commonly measured blue-green algae parameter. Thus, Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* Table 2.7-18 (page 2-98) lists the parameter name as specified in the Proposed Project Water Quality Monitoring Plan, but it uses brackets [ ] to clarify what the parameter name actually means (i.e., microcystin-producing blue-green algae cell counts).

Comment TR18-64
Page 3-35: The last sentence on this page references the wrong figure regarding chlorophyll-a (should be Figure 3.2-5, not Figure 3.2-25).

Response to Comment TR18-64
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the refence to Figure 3.2-5, which originally incorrectly referred to Figure 3.2-25. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revision.

Comment TR18-65

page 3-58: "the clarity or murkiness of the water causes by small particles" should be "the clarity or murkiness of the water caused by small particles"

Response to Comment TR18-65

Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* for the revision.

Comment TR18-66

Page 3-137: "Microcystis aeruginosa" should be italicized at line bottom of the page

Response to Comment TR18-66

Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* Potential Impact 3.2-12 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* for the revision.

Comment TR18-67

Page 3-717: This page cites Appendix N for greenhouse gas emissions but it should actually be Appendix O instead?

Response to Comment TR18-67

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Quartz Valley Indian Reservation, Crystal Robinson

Comment TR20-1

Attached is a scientific review, from the Quartz Valley Tribal Environmental Program, of the Draft Environmental Impact Report for the Lower Klamath Project License Surrender, State Clearinghouse No. 2016122047.

If there are any questions, please contact me.

Response to Comment TR20-1

Thank you for your comment. Comment noted.

Comment TR20-2

We have reviewed, with the help of our consultants Kier Associates, portions of the California State Water Resources Control Board's (SWRCB) draft Environmental Impact Report for the lower Klamath Project License Surrender, State Clearinghouse No. 201612204v(DEIR) that was circulated for public comment in December of 2018. We focused our review almost exclusively on *the portions of the following sections most relevant to water quality: Executive Summary, 3.2 Water Quality, and 3.4 Phytoplankton and Periphyton. We did not review Appendix C - Water Quality Supporting Technical Information or Appendix D - Water Quality Environmental Effects Determination Methodology Supplemental Information, but some of our comments on other sections are likely applicable to those appendices.*

We recognize the long-term benefits of removal of the four Klamath River dams far outweigh the short-term impacts. Overall, the sections of the DEIR that we reviewed do a good job of characterizing the impacts and benefits of the proposed dam removal project, and the proposed mitigation measures seem reasonable. The only mitigation measure that we have questions about is the arsenic testing and remediation (WQ-3 - Monitoring and potential remediation of reservoir sediments deposited along the Middle and Lower Klamath River floodplain).

Response to Comment TR20-2

This comment expresses general support for the analysis in the sections the commenter reviewed, and notes a concern with Mitigation Measures WQ-3. Comment noted. With respect to Mitigation Measure WQ-3, please refer to response to comment TR20-25.

Comment TR20-3

Our biggest concern is the proposed water quality monitoring plan. The plan proposed by the Klamath River Renewal Corporation (KRRC) is inadequate , as are the proposed monitoring requirements in the SWRCB's June 2018 draft Water Quality Certification for the Lower Klamath Project. During the June 2018 public comment period for the draft Water Quality Certification, we provided detailed comments regarding the draft monitoring plan that we will not repeat here given that the current public comment opportunity is focused on the DEIR's proposed mitigation measures and descriptions of environmental impacts. However, we are compelled to reiterate our main concerns with the water quality monitoring plan here: 1) the 60 mile gap in monitoring stations between Iron Gate Dam and Seiad Valley, the reach of river that will experience both the greatest short-term impacts and long-term changes following dam removal, 2) the substantial reduction in the number of stations in the proposed water quality monitoring plan relative to the Klamath Hydroelectric Settlement Agreement (KHSA) Interim Measure 15 (IM15) monitoring program which has been collecting baseline data since 2009, 3) lack of enough event-based suspended sediment concentrations (SSC) sampling to be able to combine with continuous turbidity and flow data to construct the sediment budgets that are necessary to understand the ultimate fate of reservoir sediments, and 4) given the Klamath River's high interannual hydrologic variability, monitoring should continue for at least five years post-drawdown. The massive scale of the proposed dam removal project merits a monitoring plan sufficiently detailed that it will adequately assess the results of the project. It is our understanding that the *water quality monitoring plan is still in development, and that the SWRCB will have the final word on what needs to be included. Please ensure that the monitoring plan will provide enough information to determine if the actual effects of the dam removal matched the predictions, with the ancillary benefit of using this once-in-a-lifetime opportunity to provide crucial information needed to guide long-term river management.*

Response to Comment TR20-3

The commenter is expressing concerns that the Klamath River Renewal Corporation's (KRRC's) water quality monitoring plan, put forth in the Definite Plan, is inadequate. Additionally, the commenter asserts that the June 7, 2018, water quality monitoring and adaptive management plan required by the State Water Resources Control Board's draft water quality certification is also inadequate. The commenter notes that it has provided comments on the State Water Resources Control Board's draft water quality certification.

The EIR analyzes the potential for environmental impacts due to implementation of the KRRC's Proposed Project and alternatives to the Proposed Project. The requests regarding monitoring and data collection are not raised in connection with concerns regarding the EIR's evaluation of potential environmental impacts of the Proposed Project, or mitigation for such impacts. The comment expresses general support for the EIR's impact analysis and raises concerns as to only one mitigation measure that is not a part of the water quality monitoring and data collection concerns. See response to comment TR20-2.

Please note that the State Water Resources Control Board has made several revisions to its water quality monitoring and adaptive management plan that will be included in its final water quality certification, including in response to comments by the Quartz Valley Indian Reservation.

Please refer to Volume I Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* (pages 2-97 to 2-99) for a general summary of the water quality monitoring included in the Definite Plan. Volume 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* provides a general discussion of the water quality monitoring with regards to the individual water quality parameters (Potential Impact 3.2-1 for water temperature; Potential Impact 3.2-3 for suspended sediments; Potential Impact 3.2-7 for nutrients; Potential Impact 3.2-9 for dissolved oxygen; Potential Impact 3.2-11 for pH; Potential Impact 3.2-12 for chlorophyll-a and algal toxins; and, Potential Impact 3.2-14 for inorganic and organic contaminants). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR20-4

The Comments on Specific Details section below is organized by section and page number. It provides suggested edits to improve the EIR's technical accuracy.

COMMENTS ON SPECIFIC DETAILS

Similar text is often repeated on multiple pages within the DEIR. In general, our comments here specifically reference only one page (or section) but are intended to apply to multiple pages/sections if the text we reference also appears elsewhere in the DEIR.

Response to Comment TR20-4
Comment noted.

Comment TR20-5
As described in the summary at the beginning of our comments above, and in our previous comments on the June 2018 draft Water Quality Certification for the Lower Klamath Project, the water quality monitoring plan proposed by KRRC is inadequate and needs to be substantially improved.

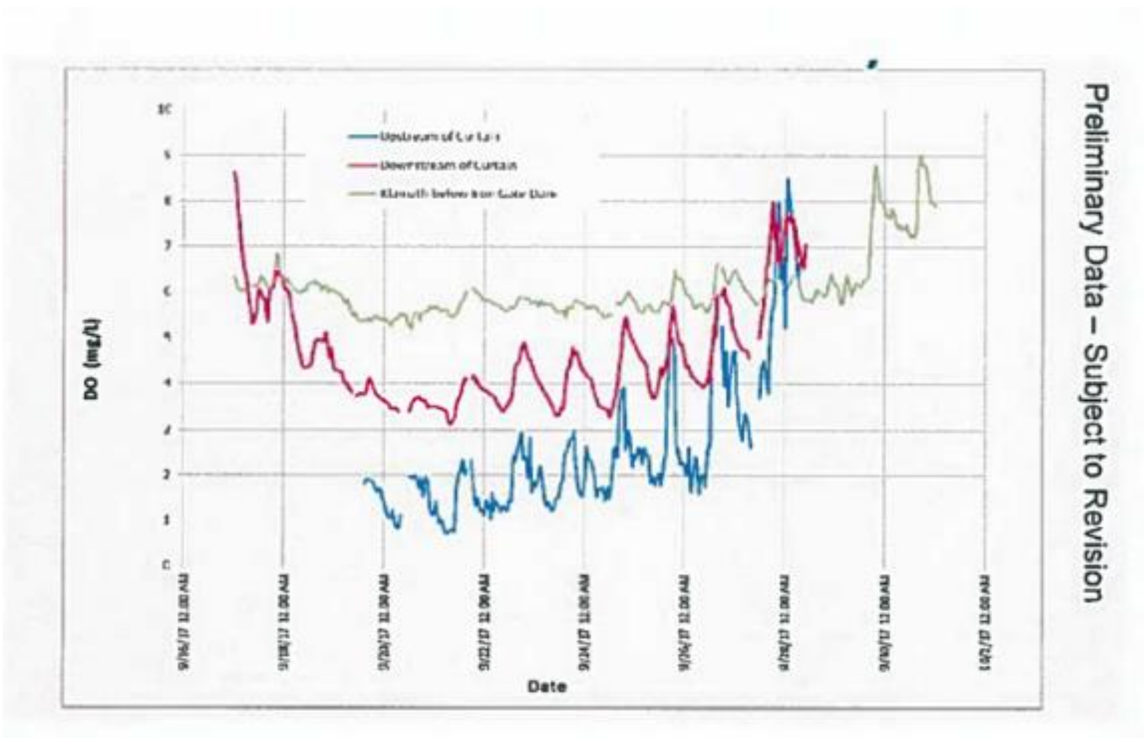
Response to Comment TR20-5
Please see response to comment TR20-3.

Comment TR20-6
Page 3-22: "The relatively shallow depth and short hydraulic residence times do not support thermal stratification in J.C. Boyle Reservoir (FERC 2007; Raymond 2008a, 2009a, 2010a) and thus this reservoir does not directly alter summertime water temperatures in further downstream reaches (NRC 2004). "We recommend adding", other than reducing the magnitude of diel (i.e., 24-hour cycle) fluctuations" to the end of the sentence.

Response to Comment TR20-6
J.C. Boyle Reservoir itself does not alter the magnitude of the diel water temperature fluctuations in the J.C. Boyle Bypass Reach downstream of the dam. The magnitude of diel water temperatures is reduced due to bypass operations from J.C. Boyle Dam that reduce the relative proportion of flow in the river from upstream and increase the relative proportion of flow from groundwater springs in the J.C. Boyle Bypass Reach. Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify the influence of bypass operations on water temperatures in the J.C. Boyle Bypass Reach based on the comment recommendation. Please refer to Volume III Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* for these revisions.

Comment TR20-7
Page 3-23 (and also applicable to many other section of the DEIR): We recommend that any text discussing the effects of the Iron Gate Reservoir curtain should also note that during intense algae blooms the curtain has the detrimental side-effect of reducing dissolved oxygen concentrations in water released

downstream. Operationally, this means that the curtain must be raised during intense blooms to avoid reducing dissolved oxygen downstream, which limits the curtain's usefulness for reducing algae. The preliminary data in the following slide from PacifiCorp's October 16, 2017 presentation to the Interim Measures Implementation Committee (there is not yet a draft report that includes these data) shows low dissolved oxygen values in late September 2017 downstream of the curtain (red line) and below Iron Gate Dam (green line):



Response to Comment TR20-7

The preliminary dissolved oxygen data from PacifiCorp's October 16, 2017 presentation to the Interim Measures Implementation Committee (IMIC) that is provided in the comment is too limited to draw broad conclusions about the influence of the Iron Gate Reservoir powerhouse intake curtain on dissolved oxygen conditions downstream of Iron Gate Dam. However, in its 2018 report, PacifiCorp acknowledges that it had to raise the curtain several times after the curtain was deployed to access water with higher dissolved oxygen concentrations and comply with water quality standards, potentially limiting the effectiveness of the curtain to reduce transport of cyanobacteria into the Klamath River downstream of Iron Gate Dam (PacifiCorp 2018a). Section 3.2.2.2 *Water Quality – Existing Conditions – Water Temperature* and other water quality sections discussing the powerhouse intake curtain have been clarified to acknowledge that the potential beneficial effects of the intake curtain on algae and water temperature in the Klamath River downstream of Iron Gate Dam may be reduced when the curtain is raised in response to low dissolved oxygen concentrations. Please refer to Volume III Attachment 1 Section 3.2.2.2 *Water*

Quality – Existing Conditions – Water Temperature, Section 3.2.2.7 *Water Quality – Existing Conditions – Chlorophyll-a and Algal Toxins*, Section 4.2.2 *No Project Alternative – Water Quality – Water Temperature*, Section 4.2.2 *No Project Alternative – Water Quality – Chlorophyll-a and Algal Toxins,* Section 4.4.2.1 *Continued Operations with Fish Passage Alternative – Water Quality – Water Temperature*, Section 4.4.2.2 *Continued Operations with Fish Passage Alternative – Water Quality – Suspended Sediments*, Section 4.4.2.4 *Continued Operations with Fish Passage Alternative – Water Quality – Dissolved Oxygen, and Section 4.4.2.6 Continued Operations with Fish Passage Alternative – Water Quality – Chlorophyll-a and Algal Toxins* these revisions.

Comment TR20-8

Page 3-24 "Species present in the Klamath River capable of producing microcystin include Microcystis aeruginosa and Anabaena flos-aquae, while species present in the Klamath River in the genus Anabaena can produce anatoxin-a and saxitoxin." Other species capable of producing microcystin have been detected in the Klamath River as well (even though they never dominate). These are Gloeotrichia and Planktothrix/Oscillatoria (Genzoli and Kann 2017, E&S Environmental Chemistry, Inc. 2018, Asarian and Kann 2006). Additional potentially toxin producing genera found in the Klamath River and/or reservoirs include Limnothrix (E&S Environmental Chemistry, Inc. 2018) and Pseudanabaena (Genzoli and Kann 2017).

Response to Comment TR20-8

Please note that the sentence quoted in the comment and attributed to page 3-24 is actually found on page 3-34.

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify using language similar to that requested in the comment. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-9

Page 3-26 "However, in the summer months, organic suspended materials can increase in the Klamath River between Iron Gate Dam and Seiad Valley (RM 132.7) due to the transport of in-reservoir algal blooms to downstream reaches of Klamath River as well as resuspension of previously settled organic materials (YTEP 2005; Sinnott 2008; Armstrong and Ward 2008; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016). Further downstream, near the confluence with the Scott River (RM 145.1) concentrations of organic suspended materials tend to decrease with distance as phytoplankton gradually settle out of the water column farther downstream or are diluted by tributary inputs (see Appendix C for more detail)." The Scott River is downstream of Seiad Valley, so it is potentially confusing to use the term "further downstream" here.

Response to Comment TR20-9
Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* has been revised to clarify the location near the Scott River confluence. Please refer to Volume III Attachment 1 Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* for the revision.

Comment TR20-10
Page 3-28: The sentence "TP and TN concentrations in the Klamath River vary with flow, with the highest concentrations tending to occur during low flow years (e.g., 2001-2004) and the lowest concentrations tending to occur during high flow years (e.g., 2006, 2010, 2011) (Asarian and Kann 2013)" should be revised to note that it pertains only to the low-flow season (summer and early fall). TP can be very high during peak winter and spring flows due to suspended sediment.

Response to Comment TR20-10
Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify that the statement pertains to summer through early fall. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions.

Comment TR20-11
Page 3-34: The sentence previous to this one "Diatoms (i.e., unicellular, photosynthetic microalgae) typically dominate in spring then decrease due to zooplankton grazing and the onset of water column stratification, which results in the diatoms settling out of the water column below the lake or reservoir surface layer (epilimnion)." refers to longitudinal trends including those for the riverine reaches, but this quoted sentence focuses on lentic (i.e., non-flowing) waters only- it should be revised to note that, since the dynamics do not apply to free-flowing river reaches.

Response to Comment TR20-11
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify when the results being discussed are related to river or lake/reservoir conditions. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-12
Page 3-36: "Phycocyanin, a pigment produced by blue-green algae, has been collected between May and November at some monitoring sites in the Klamath River downstream of Iron Gate Dam since 2007. At Seiad Valley (RM 132.7), phycocyanin is typically low from May through early August, increases to a peak in early September, and decreases until reaching low levels again by the end of October (Asarian and Kann 2013). Phycocyanin concentrations generally coincide with chlorophyll-a concentrations for the portion of the Klamath River at Seiad Valley." We recommend that these sentences should be revised/replaced.

Genzoli and Kann (2016) has a much more comprehensive analysis of Klamath River phycocyanin data than Asarian and Kann (2013). In addition, phycocyanin is measured by continuous probes, so it would be more accurate to say "measured" rather than "collected".

Response to Comment TR20-12
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify phycocyanin data in the Klamath River according to the comment. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-13
Page 3-37 The text citing the Otten et al. (2015) study should also be revised to briefly mention the genetic evidence for Iron Gate Reservoir being the source for Microcyslis in the lower Klamath River. This genetic evidence is mentioned in section 3.4 Phytoplankton and Periphyton. Otten et al. (2015) document with genetic analysis that algal production in Iron Gate Reservoir is the principal source of Microcystis aeruginosa responsible for the observed public health exceedances occurring in the Klamath River downstream from Iron Gate Darn.

Response to Comment TR20-13
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* been revised to clarify that the genetic analysis of *Microcystis aeruginosa* populations included Copco No. 1, Iron Gate Reservoir, and Klamath River sites and *Microcystis aeruginosa* populations in Iron Gate Reservoir likely contribute to *Microcystis aeruginosa* public health exceedances in the Klamath River below Iron Gate Reservoir. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-14
Page 3-37: Genzoli and Kann (2017) serves as a recent compilation of Microcystis and microcystin trends in the middle Klamath River, including diel, seasonal and longitudinal trends. Although this document is covered elsewhere (e.g., page 3-403; 3-414; 3-417, 3-431) it would be useful to cite here as well.

Response to Comment TR20-14
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been clarified as requested. Please refer to EIR Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-15
Page 3-38 contains the following paragraph regarding anatoxin-a:

"Anatoxin-a produced by the genus Anabaena of blue-green algae species was detected in Iron Gate Reservoir on September 3, 2005, in testing by the California Department of Health Services (Kann 2007a; Kann 2008b). In addition, monitoring conducted for the Karuk Tribe during 2005, 2006, 2007, 2008 in Copco No. 1 or Iron Gate reservoirs found no anatoxin-a detected (Kann and Corum 2006, 2007, 2009; Kann 2007b). At Lower Klamath River monitoring sites, anatoxin-a was not detected above the reporting limit in water samples collected during 2008 and 2009 (Fetcho 2009, 2011). In recent years, anatoxin-a has been measured in the Klamath River downstream of Iron Gate Reservoir on several occasions, typically in the lower reaches including at monitoring sites near Weitchpec and Orleans (Otten 2017). While concentrations of Anabaena flos-aquae cells have continued to be monitored, anatoxin-a concentrations are not available for Lower Klamath Project reservoir and Klamath River sites in recent years."

We recommend that this paragraph be updated to reflect more recent Klamath River data, the uncertainty in the sources of anatoxin, and the potential contribution of benthic sources (i.e. periphyton) in anatoxin-a production. The issue of potential benthic contributions to anatoxin-a production also applies to several other places within the DEIR. In our opinion, potential benthic production of anatoxin would not change any of the effects determinations in DEIR but should probably be included for the sake of completeness. Here is a replacement paragraph to consider using in place of the paragraph quoted above:

"Anatoxin-a has been detected in the Klamath River system, although the timing, distribution, and sources of anatoxin-a production in the Klamath is not well understood. Cyanobacterial species from a number of genera are capable of producing anatoxin-a, including Dolichospermum (planktonic species previously considered part of the genus Anabaena are now called Dolichmpermum), Anabaena (previously included planktonic and benthic species whereas it is now only benthic species), Aphanizome11011, Cylindrmpermopsis, Planktothrix (Oscillatoria), and Phormidium (Chorus and Bartram 1999, Quiblier et al. 2013, U.S. EPA 2014, Bouma-Gregson et al. 2018). Although toxin- producing phytoplankton are more well studied, periphyton can also produce toxins including anatoxin-a (Heath et al. 2011, Quiblier et al. 2013). In many California rivers and streams not impounded by dams, periphyton are assumed to be the primary sources Anatoxin-a (Fetscher et al. 2015), including species in genus Anabaena and Phormidium in tributaries of the Eel River located south of the Klamath River (Asarian and Higgins 2018, Bouma-Gregson et al. 2018). Anatoxin-a was detected in Iron Gate Reservoir on September 3, 2005, in testing by the California Department of Health Services (Kann 2007a; Kann 2008b), while monitoring conducted for the Karuk Tribe during 2005-2008 in Copco No. I and Iron Gate reservoirs did not detect anatoxin-a (Kann and Corum 2006, 2007, 2009; Kann 2007b). At Lower Klamath River monitoring sites, anatoxin-a was not detected in water samples collected during 2008 and 2009 (Fetcho 2009,

2011). In more recent years (2010, 20 I 5, 2016), anatoxin-a was detected in the Klamath River from sites directly below Iron Gate Dam to the Klamath River Estuary (unpublished data from the Yurok and Karuk Tribes). Genetic tools that detect the presence of an anatoxin-a synthase gene came back positive for I 9.5% of 123 samples from throughout the Klamath River system, although how the presence of the synthase gene relates to toxin concentrations is still unknown (Otten 2017). The detection of anatoxin-a over many years suggest that anatoxin-a poses a persistent public health threat for the Klamath River, yet the timing, spatial scale, and sources of the toxin are poorly understood due to limited monitoring for anatoxin-a."

Response to Comment TR20-15

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the discussion of uncertainty for anatoxin-a distribution and sources and which cyanobacteria species are capable of producing anatoxin-a. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-16

Page 3-54: Table 3.2-7 lists the Hoopa Valley Tribe's water quality objectives that are to be used (along with the applicable objectives from the NCRWQCB and Yurok Tribe) to evaluate thresholds of significance for water quality impacts. The table has a footnote that:

'HVTEPA (2008) includes a natural conditions clause which states, "If dissolved oxygen standards are not achievable due to natural conditions, then the COLD and SPAWN standard shall instead be dissolved oxygen concentrations equivalent to 90% saturation under natural receiving water temperatures." USEPA has approved the Hoopa Valley Tribe definition of natural conditions; the provision that site-specific criteria can be set equal to natural conditions and the procedure for defining natural conditions have not been finalized as of December 2018.'

There is also a second similar footnote regarding total nitrogen and total phosphorus. While not strictly wrong, those footnotes are incomplete because they do not mention that until the Tribe establishes the procedure for defining natural conditions, and EPA approves that procedure, the natural conditions do not have any legal weight. The exact wording in EPA's Feb 14, 2008 approval letter was: "with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing Natural Condition reference conditions, the stated numerical criteria... will constitute the operative criteria for all purposes." Therefore, we recommend that "USEPA has approved the Hoopa Valley Tribe definition of natural conditions; the provision that site-specific criteria can be set equal to natural conditions and the procedure for defining natural conditions have not been finalized as of December 2018" be replaced with "'USEPA has *approved the Hoopa Valley Tribe definition of natural conditions with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing Natural Condition reference conditions, the stated numerical criteria will constitute the operative criteria for all purposes."*

Response to Comment TR20-16
Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance* Table 3.2-7 has been revised to include reference that United States Environmental Protection Agency (USEPA) has approved the Hoopa Valley Tribe definition of natural condition with the understanding that unless and until the Hoopa Valley Tribe completes the process of establishing the "natural conditions" reference condition, the stated numerical criteria will constitute the operative criteria for all purposes . Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance* Table 3.2-7 for the revisions.

Comment TR20-17
Page 3-59 and page 3-60: The overall approach for assessing the significant of impacts for nutrients makes sense, but we are unclear on why this section mentions the TMDL targets for Total Nitrogen (TN) and Total Phosphorus (TP) but not the Hoopa Valley Tribe's objectives for TN and TP?

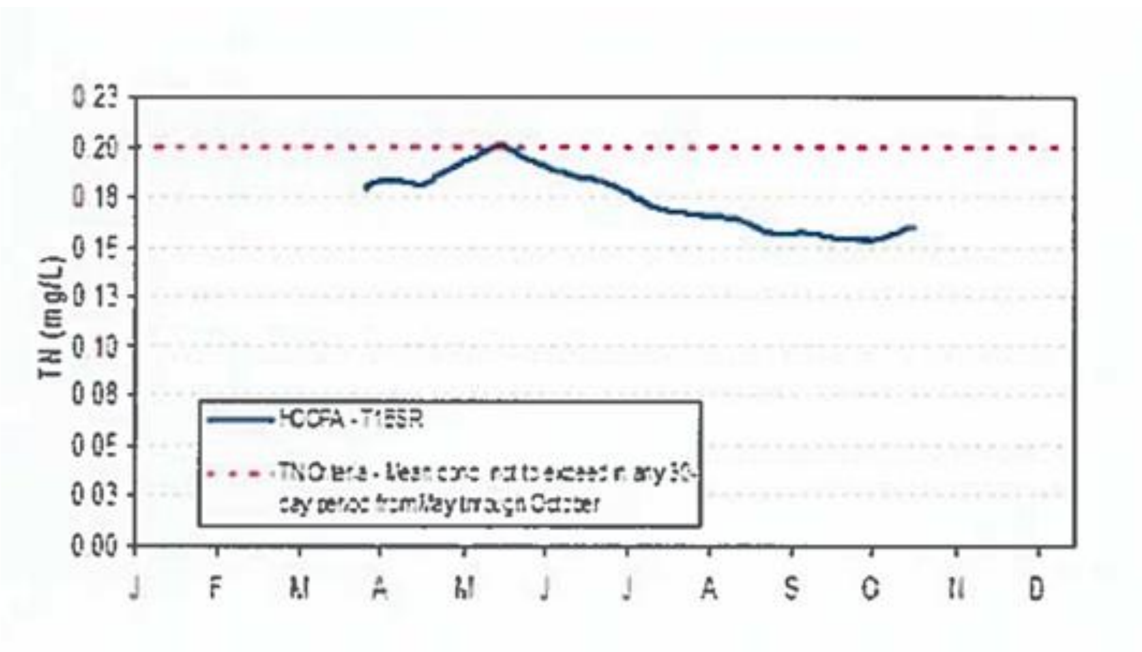
Response to Comment TR20-17
Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Nutrients* has been revised to clarify a refence to Hoopa Valley Tribe Total Phosphorus (TP) and Total Nitrogen (TN) numeric targets. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Nutrients* for the revisions.

Please note, the minor clarifications raised by the comment do not change an environmental impact or mitigation measure analyzed in the EIR because the Hoopa Valley Tribe numeric TP and TN surface-water quality objectives already had been used in the Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 analysis. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR20-18
Page 3-117 includes the following sentence:

'"Klamath River TMDL model results indicate that while resulting TP levels would meet the existing Hoopa Valley Tribe numeric water quality objective (0.035 mg/L TP) in all months at the Hoopa reach (approximately RM 45) of the Klamath River, TN levels would continue to be in excess of the existing objective (0.2 mg/L TN) in all months, as would TN levels for the modeled 'natural conditions' (Tl BSR) and the modeled 'dams- in' scenario (T4BSRN) (for the months of October through June) (North Coast Regional Board 2010)."

The second half of this sentence is incorrect, so we recommend that it be revised. The TN concentrations predicted in the final version of the 'natural conditions' (TI BSR) scenario exceeded the Hoopa Valley Tribe's criteria only for a few days in May, not 'in all months'. In addition, the magnitude of the exceedance is so small that it can reasonably be considered de minimis, as shown in the following figure from the North Coast Regional Board (2010):



The incorrect statement on TN exceedances may be a result of outdated information. Initial versions of the •natural conditions' (Tl BSR) scenario did indicate substantive exceedances of the Hoopa Valley Tribe's TN objective; however, these exceedances were caused by unrealistically high TN concentrations assigned to tributaries. Once these tributary concentrations were corrected to more closely represent available data, the exceedances essentially disappeared in the final official version of the model (i.e., see figure above).

Response to Comment TR20-18

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been revised to clarify the Hoopa Valley Tribe numeric water quality Total Nitrogen (TN) objective exceedance information for Total Maximum Daily Load (TMDL) model results. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

<u>Comment TR20-19</u>

Page 3-117 "While there would be a slight increase in absolute nutrient concentrations entering the Middle Klamath River under the Proposed Project, phytoplankton, especially blue-green algae, would be limited in their ability to use *those nutrients for growth and reproduction without calm reservoir habitat (Potential Impact 3.4-2)." We recognize that word choices are subjective, but "slight" is probably not the most accurate word to describe the expected increase, unless it is specifically in reference to annual time scales, not seasonal time scales. As noted on page 3-116, the increases in TN for the July through September period are expected to be in the range of 48- 55%. We suggest replacing "a slight increase" with "an increase".*

Response to Comment TR20-19

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

Comment TR20-20

Page 3-118: "In general, although dam removal would result in a slight long-term increase in TP and TN away from the numeric targets, such an increase would not support the growth of nuisance and/or noxious phytoplankton or nuisance periphyton." Similar to our previous comment above regarding page 3-117, it would be more accurate to replace "a slight long-term increase in TP and TN" with "a long-term increase in TP and TN" or "a slight long-term increase in annual TP and TN".

Response to Comment TR20-20

Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for the revisions.

Comment TR20-21

Page 3-135: "....monitoring data at multiple locations further downstream in the Middle and Lower Klamath River indicate that pH patterns over a 24-hour period are driven primarily by photosynthesis and respiration of periphyton (Ward and Armstrong 2010; Asarian et al. 2015; see Section 3.4.2.2 Periphyton) rather than phytoplankton." A direct quantification of the relative contributions to primary production in the Middle Klamath River is provided by Genzoli and Hall (2016). Even though Genzoli and Hall's (2016) analysis did not specifically evaluate pH, we recommend that it should still be cited here.

Response to Comment TR20-21

The reference provided in the comment (i.e., Genzoli and Hall 2016) supports the premise of Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 discussion and analysis, which is that, in the absence of a reservoir phytoplankton bloom that is subsequently transported into the Middle and Lower Klamath River, periphyton are relatively more important for influencing diel fluctuations in water quality conditions (e.g., dissolved oxygen and pH) compared to phytoplankton. As the EIR analysis is focused on pH changes in the river, while the reference provided in the comment focuses on primary productivity in grams oxygen per square meter per day (g $O_2/m^2/d$) rather than pH, the reference provided in the comment has not been added to the pH analysis. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment TR20-22

Page 3-136: "Since N-fixing species dominate the periphyton communities in the lower portions of the Middle Klamath River as well as the Lower Klamath River where inorganic nitrogen concentrations are low (Asarian et al. 2010, 2014, 2015), changes in nutrients due to dam removal are not expected to alter the periphyton community in these reaches (see Potential Impact 3.4-5)." The species composition of the periphyton community may well shift, but the biomass is not expected to increase substantially. We suggest that this end of this sentence be revised to "...are not expected to substantially alter total periphyton biomass in these reaches (see Potential Impact 3.4-5)."

Response to Comment TR20-22

Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 has been revised to clarify that changes in the periphyton species composition under the Proposed Project would not significantly alter the total periphyton biomass in the Middle and Lower Klamath River. Please refer to Volume III Attachment 1 Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 for the revisions.

Comment TR20-23

Page 3-137. While reservoir phytoplankton are by far the dominant source of algal toxins in the Klamath River, Section 3.2.5.6 Chlorophyll-a and Algal Toxins should probably also mention that river periphyton are capable of producing cyanotoxins including anatoxin-a. This would not change the effects determinations but should be mentioned for the sake of completeness. See comments regarding page 3-38 above for details.

Response to Comment TR20-23

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been updated to note that cyanotoxins (including anatoxin-a) can be produced by riverine periphyton in addition to phytoplankton. Please refer to Volume III Attachment I Section 3.2.2.6 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for these revisions.

Please note, while some periphyton species are capable of producing algal toxins, including microcystin and anatoxin-a (Heath et al. 2011; Quiblier et al. 2013; see Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins*), all available data indicate that algal toxin presence (i.e., microcystin and anatoxin-a) in the Klamath River corresponds to high concentrations of phytoplankton blue-green algae cells (i.e., algae blooms of *Microcystis aeruginosa* for microcystin or *Anabaena flos-aquae* for anatoxin-a) (Kann and Corum 2006, 2007, 2009; Kann 2006, 2007a,b,c,d, 2008b; Jacoby and Kann 2007; CH2M Hill 2008; Kann et al. 2010a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Otten et al. 2015). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Clarifications based on this comment do not change effects determinations in Section 3.2 *Water Quality*.

Comment TR20-24

Page 3-138. This statement merits correction:

"While algal toxins and chlorophyll-a produced in Upper Klamath Lake may still be transported downstream after dam removal, existing data indicate that microcystin concentrations in the Klamath River decrease to below California water quality objectives (see Section 3.2.3.1 Thresholds of Significance) by the upstream end of J.C. Boyle Reservoir, regardless of the microcystin concentration measured leaving the Upper Klamath Lake (Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016)."

There have been high microcystin levels on occasion in JC Boyle at Topsy Campground. It is more correct to say that microcystin concentrations in the Klamath River decrease to below California water quality objectives downstream of JC Boyle. (e.g., E&S Environmental Chemistry, Inc. 2018). T hen the following sentence is still correct: "Thus, algal toxins and chlorophyll-a production upstream of J.C. Boyle Dam would not be expected to be transported into California and result in algal toxin or chlorophyll-a concentrations in a manner that would cause or substantially exacerbate an exceedance of water quality standards or would result in a failure to maintain existing beneficial uses currently supported."

Response to Comment TR20-24

Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* Potential Impact 3.2-12 (pages 3-137 to 3-139) has been revised to clarify that high microcystin levels have been detected in J.C. Boyle Reservoir at Topsy Campground and the potential for localized *Microcystis aeruginosa* growth and high microcystin concentrations in J.C. Boyle would be reduced under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* for the revisions.

Comment TR20-25

Page 3-150: Mitigation Measure WQ-3 (Monitoring and potential remediation of reservoir sediments deposited along the Middle and Lower Klamath River *floodplain) proposes that following dam removal, floodplain deposits in areas with agricultural and residential land use should be tested for arsenic and then remediated (removal or soil capping) if arsenic levels exceed background levels found in adjacent soils and USEPA or CalEPA human health residential screening levels. According to information presented on page 3-142 of the DEIR, soils in the Klamath Basin have naturally high arsenic levels, and arsenic levels in samples from reservoir sediments were within those natural ranges. Remediating arsenic-rich soils along the river corridor could be quite expensive and is not a decision to be taken lightly. Floodplains are naturally dynamic environments and healthy floodplains experience both sediment deposition and erosion. Floodplain soils are heterogeneous with deposits of varying ages and source compositions. Basing the decision about whether to remediate a particular reservoir-derived sediment deposit on a comparison to arsenic levels in adjacent soils seems subject to a high degree of uncertainty and luck of the draw (e.g. what particular portion of reservoir sediment ended up settling on top of what particular floodplain deposit). How will decisions be made about the definition "exceed" (e.g., does that mean that the average has to be 0.1% higher, or some greater threshold? What if any statistical tests will be used?) And how many samples will need to be collected and over what geographic area? There is definitely value in remediating truly contaminated soils that have arsenic concentrations substantially higher than ambient conditions, but is how will such thresholds be determined?*

Response to Comment TR20-25

Comment noted. As described in Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-15, remediation is required only in instances where (1) there are visibly obvious sediment deposits that are consistent with physical sediment properties associated with Lower Klamath Project reservoir sediments (2) these are in agricultural or residential areas (with heightened ingestion potential) and (3) when these sediments have arsenic levels that are both higher than local background levels and exceed health residential screening levels. Please note that the State Water Board has revised Mitigation Measure WQ-3 to add additional reporting on and oversight of test methods and remediation in order to allow for appropriate tailoring of testing and remediation to the individual circumstance that arises.

Please refer to Volume III Attachment 1 Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Mitigation Measure WQ-3 for the revisions.

Comment TR20-26

Page 3-397: Need to distinguish planktonic "Anabaena" which is now called Dolichospermum, from benthic forms still referred to as Anabaena.

Response to Comment TR20-26

Section 3.4.2.1 *Phytoplankton and Periphyton – Environmental Setting – Phytoplankton – Anabaena flos-aquae* has been revised to clarify that the EIR continues to use the *Anabaena* name for both planktonic and benthic species since *Anabaena* was more frequently used in the literature cited and it is still commonly used in descriptions of this species. Please refer to Volume III Attachment 1 Section 3.4.2.1 *Phytoplankton and Periphyton – Environmental Setting –Phytoplankton – Anabaena flos-aquae* for the revisions.

Comment TR20-27

Page 3-403: “Monitoring at multiple locations along the Middle and Lower Klamath River indicates that dissolved oxygen and pH patterns over a 24-hour period are driven primarily by photosynthesis and respiration of periphyton (Ward and Armstrong 2010, Asarian et al. 2015)." A citation of Genzoli and Hall (2016) should be added here (see comment above regarding page 3- I 35 for justification).

Response to Comment TR20-27

Section 3.4.2.2 *Phytoplankton and Periphyton – Environmental Setting – Periphyton* has been revised to clarify the relative influence of phytoplankton and periphyton on dissolved oxygen and pH in the Middle and Lower Klamath River. Please refer to Volume III Attachment 1 Section 3.4.2.2 *Phytoplankton and Periphyton – Environmental Setting – Periphyton* for the revisions.

Comment TR20-28

Page 3-413: "Nuisance blooms ofperiphyton have not been documented in the riverine portions of the Hydroelectric Reach. In the J.C. Boyle Peaking Reach, it has been noted that periphyton tends to be absent from the margins of the river that are alternately dried and wetted during peaking operations (E. Asarian, pers. comm., 2011)." We recommend that the end of this sentence be re-structured with different references, so that it ends with "periphyton tends to be absent from the margins of the river that are alternately dried and wetted during peaking operations (Karuk Tribe 2006), due to reasons described by PacifiCorp (2005)". Note that the PacifiCorp (2005) report is unavailable online but we have it in our files; please contact us if you need a copy.

Response to Comment TR20-28

Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Periphyton* has been revised to clarify that the lack of periphyton along the margins of the J.C. Boyle Peaking Reach is due to turbid conditions that limit light availability for photosynthesis, high water velocities that limit establishment and growth of periphyton, and the variable flow regime that causes cycles of drying and rewetting. Please refer to Volume III Attachment 1 Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Periphyton* for the revisions.

Comment TR20-29

Page 3-431: This sentence suggests that river growth of BOA is causing exceedances:

"Some phytoplankton growth may still occur after dam removal in calm, slow-moving habitats along shorelines and protected coves and backwaters during low-flow periods in the Middle and Lower Klamath River, but these habitats already support growth of blue- green algae, including Microcystis aeruginosa, that results in occasional exceedances of 2016 CCI-IAB secondary thresholds and WHO guidelines (Falconer et al. 1999; Kann et al. 2010; State Water Board et al. 2010, updated 2016; Genzoli and Kann 2016, 2017)."

It is not likely that these slow-moving and backwater areas support growth of blue-green algae, but rather are sites where upstream sources accumulate as slowed velocity allows them to settle or become trapped in vegetation. Thus, the exceedances currently detected in such areas would decrease with dam removal. There is no evidence that we are aware of for actual growth of planktonic cyanobacteria in the Middle and Lower Klamath.

Response to Comment TR20-29

Section 3.4.5.1 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Phytoplankton* Potential Impact 3.4-2 has been revised to clarify blue-green algae and microcystin entrapment and accumulation in backwater areas of the Klamath River from upstream sources. Please refer to Volume III Attachment 1 Section 3.4.5.1 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Phytoplankton* Potential Impact 3.4-2 for the revisions

Comment TR20-30

Page 3-717. This section mentions that the DEIR's method for estimating methane emissions from Klamath Hydroelectric Project reservoirs was adapted from Karuk Tribe's (2006) comments which multiplied the reservoirs' area by areal emissions rates from reservoirs around the world with similar water quality characteristics. The Karuk Tribe's estimates were the best information available at that time, but there is now new information available including a global synthesis (Deemer et al. 2016) and field measurements of methane emissions available from J.C. Boyle Reservoir and Keno Reservoir (Harrison et al 2017) using methods from Deemer et al. (2011). We also encourage SWRCB to consider incorporating these recent studies into the EIR.

Response to Comment TR20-30

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment TR20-31
During our review of the DEIR we noticed a few minor/insignificant errors, which we present in this separate list to avoid cluttering our other comments.

Response to Comment TR20-31
Comment noted. This comment indicates that a few minor/insignificant errors were noticed, and are provided in comments below.

Comment TR20-32
Page 2-98: "Microcystin [-Producing Blue-green Algae] Cell Count" is odd phrasing that doesn't match the conventions used in the rest of the DEIR. Should be '"Microcystin-Producing Blue- green Algae Cell Count"?

Response to Comment TR20-32
Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* summarizes the Klamath River Renewal Corporation (KRRC) Proposed Water Quality Monitoring Plan included in the Proposed Project (see Volume II Appendix B: *Definite Plan – Appendix M*). In the Proposed Project Water Quality Monitoring Plan, one parameter to monitor is called "Microcystin Cell Count", but this is likely a typo because microcystin is only chemical compound that does not have a cellular structure that can be counted. It is assumed that the "Microcystin Cell Count" parameter is meant to refer to microcystin-producing blue-green algae cell counts, a commonly measured blue-green algae parameter. Thus, Section 2.7.8.7 *Proposed Project – Proposed Project – Other Project Components – Water Quality Monitoring and Construction BMPs* Table 2.7-18 (page 2-98) lists the parameter name as specified in the Proposed Project Water Quality Monitoring Plan, but it uses brackets [ ] to clarify what the parameter name actually means (i.e., microcystin-producing blue-green algae cell counts).

Comment TR20-33
Page 3-35: The last sentence on this page references the wrong figure regarding chlorophyll-a (should be Figure 3.2-5, not Figure 3.2-25).

Response to Comment TR20-33
Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the refence to Figure 3.2-5, which originally incorrectly referred to Figure 3.2-25. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revision.

Comment TR20-34
page 3-58: "the clarity or murkiness of the water causes by small particles" should be "the clarity or murkiness of the water caused by small particles"

Response to Comment TR20-34

Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* for the revision.

Comment TR20-35

Page 3-137: "Microcystis aeruginosa" should be italicized at line bottom of the page

Response to Comment TR20-35

Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* Potential Impact 3.2-12 has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* for the revision.

Comment TR20-36

Page 3-717: This page cites Appendix N for greenhouse gas emissions, but it should actually be Appendix O instead?

Response to Comment TR20-36

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Shasta Indian Nation, Chair Janice Crowe, Sami Jo Difuntorum

Comment TR23-1

Thank you for the opportunity to comment on the California State Water Resource Control Board's Draft Environmental Impact Report (DEIR) for the Lower Klamath Project License Surrender (Project). Our comments will focus on Tribal Cultural Resources and other Project activities under consideration as they pertain to Tribal Cultural Resources.

The Shasta Indian Nation's membership is comprised principally of the Shasta Indian descendants who were impacted by the construction of the Copco No. 1 Dam. Our ancestors owned property that was taken by eminent domain for its construction. Although the Federal government arranged for our Tribe to live on land nearby, this dam's construction disrupted our community in significant ways. Some of our traditional villages, burial grounds, and fishing sites were inundated by rising waters and remain submerged today. Ongoing dam operations have impacted our Tribe's ability to access sacred places for prayers and ceremonies. One of our most sacred places known as K'uč'ux·warax in our language and which we sing about in our prayer songs, is oil limits to us.

Our ancestors cried when the Copco No. 1 Dam was constructed. They knew how devastating it would be to the lives of our people and to our Tribe. One of our elders died as she was removed from her home. There is no way to turn back time and to mitigate these impacts.

The Project now proposes the decommissioning and removal of four dams (J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate) and associated facilities, to re-establish a free-flowing Klamath River. The dam's removal will also result in significant impacts to our now inundated villages, burial grounds, fishing sites, and sacred places, as well as to non-inundated Tribal Cultural Resources located within the Project area.

Response to Comment TR23-1
The potential for impacts to tribal cultural resources due to the Proposed Project is analyzed in Section 3.12 *Historical Resources and Tribal Cultural Resources*. As noted in this section, the Shasta Indian Nation requested consultation under AB 52 and met with the State Water Board and the Klamath River Renewal Corporation (KRRC) in a series of confidential consultation meetings within the timeframe of February 2017 through October 2018. The consultations with the Yurok Tribe and the Shasta Indian Nation resulted in identification of potentially-impacted resources, articulation of potential impacts, and development of, and agreement on, specific mitigation measures (see Section 3.12.5.1 *Potential Impacts to Tribal Cultural Resources*, TCR-1 through TCR-8). Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources.*

State Water Board staff have valued the information and perspectives shared by the Shasta Indian Nation during consultation. Information shared by the Shasta Indian Nation has assisted the State Water Board in understanding the scope, scale, and significance of Shasta Indian Nation tribal cultural resources located in the Proposed Project area. Details on our consultation process have been included in Volume I Confidential Appendix Q and distributed to the Shasta Indian Nation.

Comment TR23-2
The California State Water Resource Control Board's DEIR finds that this Project will result in significant and unavoidable impacts to Tribal Cultural Resources. We support this finding. The Shasta Indian Nation also concurs with the proposed DEIR that these impacts include:

1) Pre-dam-removal activities that involve disturbance of the landscape, including construction or improvement of associated roads, bridges, water supply lines, staging areas, disposal sites, hatchery modifications, recreation site removal and/or development, and culvert construction and improvements that could result in potential exposure of or damage to known Tribal Cultural Resources through ground-disturbing construction and disposal activity and increased access to sensitive areas;

2) The drawdown of Iron Gate, Copco No. 1, and Copco No. 2 reservoirs that could result in shifting, erosion, and exposure of known or unknown, previously submerged Tribal Cultural Resources;

3) The removal of Iron Gate, Copco No. 1, and Copco No. 2 Dams that could result in physical disturbance to known Tribal Cultural Resources from blasting or other removal techniques;

4) Ground disturbance associated with reservoir restoration, recreation site removal and/or development, and disposal site restoration could physically disturb known Tribal Cultural Resources;

5) Increased potential for looting of Tribal Cultural Resources during Project activities;

6) Exposure of or disturbance to Tribal Cultural Resources following reservoir drawdown and prior to vegetation establishment/full stabilization of sediment deposits; and

7) Increased looting opportunities and surface and subsurface erosion of Tribal Cultural Resources over the long-term.

To address these impacts, a comprehensive mitigation plan has been proposed in the DEIR. These measures have been developed in consultation with affected Tribes including the Shasta Indian Nation. These measures include:

1. The development and implementation of a Tribal Cultural Resources management plan

2. The development and implementation of a looting and vandalism prevention program.

3. The development and implementation of inadvertent discovery program.

4. Acknowledgement that the transfer of Parcel B and other lands, the ultimate disposition of which is determined through KHSA Section 7.6.4., to tribal ownership and control will foster tribal cultural conservation practices, promote tribal identity and begin to address the impacts of the past disturbances of Tribal Cultural Resources caused during construction of Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam and the associated reservoirs, and to mitigate the impacts to Tribal Cultural Resources during and following Project implementation.

5. To create an endowment for post-project activities related to Tribal Cultural Resources protection.

The Shasta Indian Nation supports and endorses these mitigation measures strongly, which were developed in consultation. Should the Klamath River Renewal Corporation implement the mitigation measures as they are currently written, the significant impacts to Tribal Cultural Resources caused by decommissioning and removing the dams and associated facilities will be mitigated successfully.

Response to Comment TR23-2

Thank you for your comment concurring with Shasta Indian Nation tribal cultural resource impacts and mitigation measures listed in Volume I Section 3.12 *Historical Resources and Tribal Cultural Resources*.

Comment TR23-3

Additionally, the California State Water Resource Control Board's DEIR identified a final recreation plan as a requirement for the proposed Project. The Shasta Indian Nation has ongoing concerns about post-dam removal recreation plans that have been developed for the Project without tribal consultation. The Shasta Indian Nation opposes the proposed "Copco Valley" Recreation Site (#5) because it will result in new negative impacts to Tribal Cultural Resources caused by earthwork and grading as well as increased access to the immediate area. The proposed DEIR mitigation measures are inadequate to address new adverse impacts that will result from the siting and construction of this proposed recreation site. There may also be negative impacts to Tribal Cultural Resources at the proposed "Fall Creek Boat Launch" Recreation Site (#6). We understand that a recent proposal moves the launch 1/3 mile downstream from the original site. Moving the launch site downstream past the confluence of Fall Creek will lessen the possibility of impact.

Response to Comment TR23-3

Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* Potential Impact 3.12-5 includes consideration of ground disturbance associated with recreation site removal and/or development that could physically disturb known Tribal Cultural Resources. Neither the Klamath River Renewal Corporation's (KRRC) Definite Plan nor the most recent water quality certification application, received December 2, 2019, identify the specific sites referenced in the comment; however, regardless of whether these sites or different sites were to be developed as new recreation sites under the Proposed Project, the KRRC would be required to implement Mitigation Measures TCR-1 (Tribal Cultural Resources Management Program [TCRMP]), TCR-2 (Looting and Vandalism Prevention Program [LVPP]), TCR-3 (Inadvertent Discovery Program [IDP]), and TCR-4 (Endowment) to reduce these impacts considerably, and, for most resources to avoid impacts completely. Further, as stated in Potential

Impact 3.12-5, the impact would remain significant and unavoidable. Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources.*

As listed in Mitigation Measure TCR-1, the KRRC shall develop, in consultation with Affected Tribes, a Historic Properties Management Plan (HPMP), which would include the development of a TCRMP. In part, the TCRMP shall include site-specific mitigation measures for potentially affected Tribal Cultural Resources (TCR). The TCRMP shall provide for ongoing consultation or site-specific mitigation refinement with the relevant Affected Tribe(s) with a traditional and cultural affiliation to an impacted TCR, as appropriate and feasible consistent with the schedule for Project implementation.

Though no Recreation Plan has been provided to the State Water Board, the above site-specific mitigation and consultation requirements of the TCRMP would be required for TCRs potentially affected by any new proposed recreation site.

<u>Comment TR23-4</u>

We welcome opportunities to engage in ongoing consultation and dialogue with the California State Water Resource Control Board and with the Klamath River Renewal Corporation about the Project. We gratefully acknowledge the California State Water Resource Control Board's good faith interest in the protection of the Shasta Indian Nation's Tribal Cultural Resources throughout this process consistent with the requirements under the California Environmental Quality Act. Please feel free to contact either me or Sami Jo Difuntorum, Tribal Cultural Resources Coordinator, for any questions or additional matters.

Response to Comment TR23-4

Thank you for your comment. State Water Board staff has valued the time and efforts invested by the Shasta Indian Nation during the consultation process.

Shasta Nation, Chairman Roy Hall

<u>Comment TR24-1</u>

I will be quoting some of the materials that have been submitted and commenting on each.

The next statements in Quotes are misleading and/or False and should be looked at carefully or removed from the Draft EIR.

Response to Comment TR24-1

Thank you for your comments. The structure of comment letter noted.

<u>Comment TR24-2</u>
Regarding: "Volume 1, 3. 12-15 December 2012. Establishment of the Klamath Tribes Interim Fishing Site could result in impacts/effects of Trust Resources and other Traditional used resources."

Comment 1

The fishing site in question located between Iron Gate and Federal Interstate highway 5 (I-5).

The area designated is wholly within the aboriginal lands of the Shasta Nation and its establishment is unacceptable. If the Klamath tribe believe that taking the dams out will 'make the fish return' to their lands then why would they ask for fishing sites below the dams?

In Pre-contact times the Klamath tribe asked permission to come onto Shasta lands to fish. They did so because the fish were met with natural barriers and hotsprings and NEVER traveled up the Klamath River into the Klamath Tribes lands.

The Klamath Tribes did not protest the dams. They were offered fish ladders but refused because the fish would still not be able to get up the river past the hot springs to their lands. Trucking fish up stream was also declined because the river is a hostile environment for spawning and immature fish.

Response to Comment TR24-2
Please see Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People* for the EIR's description of Shasta aboriginal lands, informed by consultation with the Shasta Nation under AB 52. Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources*. Please note that the material referenced by the commenter is from the USBR's 2012 document that analyzed dam removal in combination with other actions. The Proposed Project does not include establishment of a Klamath Tribes fishery below Iron Gate Dam, which was part of the now-expired Klamath Basin Restoration Agreement (KBRA). Additionally, regarding historic salmonid abundance, please refer to AQF-4.

<u>Comment TR24-3</u>
Regarding: "Appendix V KHSA 2012 EIS/EIR Section 3.12 Tribal Trust December 218 Volume II (Page:Vol, 3.12-16 December 2012)

3.12.3.2 Quartz Valley Community

3.12.3.2.1 Quartz valley Community History.

Quartz Valley Community History. Most of the Quartz valley Community's Tribal Members are descendants of people of Karuk Ancestry, although a few tribal members are also of Shasta Ancestry."

"(Therefore, their cultural traditions are similar to those described in the Karuk section of this report.)"

Comment 2

The two tribes do not have the same customs or cultures. Shasta's had rules and structure. The Karuk tribe lived a life without structure or laws. Prior to contact time, the Shasta did not interact with the Karuk unless absolutely necessary.

Response to Comment TR24-3

Please note that the appendix referenced in this comment is reprinted from the USBR's 2012 document. The following text changes have been made to clarify the history of the Quartz Valley Indian Community (Volume I page 3-799).

"Quartz Valley Indian Community

The Quartz Valley Community is a federally recognized tribe mainly representing people of Karuk and Shasta ancestry, with 174 acres of reservation lands in the Scott Valley, near Fort Jones, California. Karuk cultural history is described in Section 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northwest California Culture Area – Ethnography –* Karuk (pages 3-798 to 3-799), and Shasta cultural history is described in Section 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People* (pages 3-794 to 3-797). ~~Their cultural history is similar to that described for the Karuk, as most members are of Karuk ancestry (Appendix V – 2012 KHSA EIS/EIR *Section 3.12 Tribal Trust*).~~ The Quartz Valley Indian Community's reservation lands are located near the community of Fort Jones. The Quartz Valley Indian Community initially filed their constitution and bylaws with the Office of Indian Affairs in 1939 (DOI 1939)."

Please also refer to Master Response GEN-2.

Comment TR24-4

"The Quartz valley Community is a federally recognized tribe representing people of middle Klamath (Karuk) and Shasta Indian ancestry."

Comment 3

Quartz Valley is a Reservation that was created by the sole efforts of Fred Wicks, a Shasta Indian.

The reservation was established for the Shasta Indians who lived in Scott and Shasta Valleys and for the Shasta Indians on the upper Klamath. (Upper Klamath refers to the Shasta Indian on the mid river. It does not mean 'upriver' as the Karuks call themselves). Karuks were allowed to become members of Quartz Valley because they were homeless and there were allotments available. That does not make them aboriginal to Scott Valley.

Response to Comment TR24-4
Please refer to Master Response GEN-2.

Comment TR24-5
"Some tribal members are descendants of the same tribal leaders that signed the unratified 1851 Treaty 'R' negotiated between Indian agent Redick McKee and Indian inhabitants of Scott valley and the upper Trinity and Klamath Rivers."

Comment 4

Very misleading and incorrect. Only Shasta Indians signed Treaty "R" in Scott Valley. The Karuk tribe signed their own treaty down the River near the mouth of Salmon River. (The Karuk's treaty is Treaty Q/Supplement to 'the aforementioned treaty' signed by the Hoopa and Yurok)

Response to Comment TR24-5
Please note that the appendix referenced in this comment is reprinted from the USBR's 2012 document. Please refer to Master Response GEN-2.

Comment TR24-6
Comment 5

Everything in this EIR re: Quartz Valley Shasta Reservation IS FALSE AND MUST BE DELETED.

'Refer to the Karuk History to learn about the Shasta Indians' is an insult to the separate customs, cultures and heritage the tribes fight hard to preserve.

You have an excellent document in your possession to explain/ reveal the Shasta Nation history. The History of the Shasta by Brian Daniels. Use it.

Response to Comment TR24-6
Please refer to Master Response GEN-2. Section 3.12.2 *Historical Resources and Tribal Cultural Resources – Environmental Setting –Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People* provides a description of the Shasta People, which includes information obtained from Daniels (2006). Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources.* Additional information

on the Shasta People was also included in Volume II Confidential Appendices P and Q, which also incorporate information obtained from Daniels (2006).

The following text changes have been made to clarify the history of the Quartz Valley Indian Community (Volume I page 3-799).

"Quartz Valley Indian Community
The Quartz Valley Community is a federally recognized tribe mainly representing people of Karuk and Shasta ancestry, with 174 acres of reservation lands in the Scott Valley, near Fort Jones, California. Karuk cultural history is described in Section 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northwest California Culture Area – Ethnography – Karuk* (pages 3-798 to 3-799), and Shasta cultural history is described in Section 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northern Interior California Culture Area – Ethnography – Shasta People* (pages 3-794 to 3-797). ~~Their cultural history is similar to that described for the Karuk, as most members are of Karuk ancestry (Appendix V – 2012 KHSA EIS/EIR *Section 3.12 Tribal Trust*).~~ The Quartz Valley Indian Community's reservation lands are located near the community of Fort Jones. Comment TR24-7
Comment 6

The Shasta Nation has worked with and submitted information and relevant laws and California statutes directly related to the issues of dam removal, The Shasta Nation has been met either silence on all issues with no responses, resulting in default and dishonor. The dishonorable practice of KRRC inviting and involving any and all alien tribes to get a favorable consensus to move forward without Shasta Nation consent is biased and racist. Any and all tactics are acceptable as the Shasta Nation's Constitutional rights, Customs, Culture and Tribal Sovereignty is not recognized or respected.

To address these biases, and racist attitudes and actions, we must revisit these issues to comply with working with the appropriate Native American Indian Tribe, Tribes.

Response to Comment TR24-7
The State Water Board appreciates the consultation with the Shasta Nation that has informed the EIR. The comment raises concerns with consultation, with the legality of the dam removal proceedings and with the Klamath River Renewal Corporation's (KRRC's) tribal outreach and involvement. These comments are noted. Please note that CEQA documents analyze significant effects on the physical environment. (CEQA Guidelines, § 15131(a).)

Comment TR24-8
Comment 7

The Shasta Nation is in support of clean, renewable, hydro power, rule of law, protecting property rights, and affordable power rates.

The Shasta Nation supports Siskiyou County Supervisors, Siskiyou water users, and other local agencies and organizations who support re-licensing and keeping the dams on the Klamath River.

Response to Comment TR24-8
Please refer to Master Response GEN-1. Please also refer to Master Response ENR-1 for a discussion of power rates. With respect to renewable hydropower, please note that this comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

In relation to the comment's reference to the rule of law and property rights please refer to Volume I Section 1.1 *Introduction – Authorization, Purpose and Use of EIR* (page 1-1) and to Volume I Section 2.8 *Proposed Project – Intended Uses of the EIR* (pages 2-110 to 2-111).

Comment TR24-9
Comment 8

The Shasta Nation would like to see curtailing excessive off shore salmon fishing and unsupervised salmon take by tribes down river. Those two activities have a great impact on the returning salmon count. They deplete our returning salmon population and decimates the ability of the few returning fish to spawn and increase the amount of salmon produced by the river.

Tribal tradition on the Klamath River is constantly being pushed in the comments. It was necessary, if all the Indians were to have plenty of salmon for food and spawning, and was strictly adhered to by ALL the tribes.

Each tribe (Yurok, Karok, Shasta) had people watch the salmon come up the river. When enough fish had gone by for the villages and tribes up the river, and for spawning, then, and only then, did the tribes start to take their share of the salmon run.

Response to Comment TR24-9
Commercial and tribal ocean and in-river fisheries are regulated by the Pacific States Marine Fisheries Commission (PSMFC). The PSMFC is an interstate compact agency that helps resource agencies and the fishing industry sustainably manage Pacific Ocean resources. Managing, or curtailing, harvest of salmonids does not address water quality concerns related to the Lower Klamath

Project facilities, or address the migration barriers these facilities present. As described in Volume I, Section 4.1 Alternatives – *Alternatives Selection Overview* (page 4-1) an alternative that does not address the underlying purpose of the proposed project is not a feasible alternative. Further, fisheries management is not under the purview of the Klamath River Renewal Corporation, is not a part of the Proposed Project, nor is it part of the Klamath Hydroelectric Project (KHP). Therefore, such management was not evaluated as a feasible alternative in the EIR.

Yurok Tribe, Vice Chairman Franklin Joseph Myers, Michael Belchik

Comment TR19-1

The Yurok Tribe hereby provides comments on the December 2018 Public Review Draft of the Environmental Impact Report for the Lower Klamath Project License Surrender (DEIR). As you know, the Klamath River is the axis around which Yurok cultural and spiritual beliefs and practices are centered. The Yurok Tribe is the largest California Tribe. The Yurok Reservation straddles the lower 45 miles of the Klamath River, for a mile on each side providing the Yurok Tribe with regulatory authority over the lands and river within the Reservation. The Tribe maintains senior water and fishing rights on the River. For the Yurok Tribe, there is no other river; no alternatives exist with regard to the restoration of the Klamath River. We have long believed that restoring the river is necessary and for true restoration to take place, landscape-scale actions must be implemented, including removal of the four dams along the mainstem river. We appreciate the Board's insights and creative thinking on how to mitigate the short-term impacts to the river so that the long-term benefits of dam removal and river restoration can be realized.

Response to Comment TR19-1

Thank you for your comments regarding river restoration and its importance to the Yurok Tribe.

Comment TR19-2

The Yurok Tribe fully supports the full removal alternative as described in the DEIR as well as the partial removal alternative as long as the river itself is restored to a free-flowing condition and any serious environmental impacts by remaining structures are adequately addressed. Years of study have led to a comprehensive understanding of the potential impacts of this project and we are past the time for additional studies—it is now time for action.

Response to Comment TR19-2

Please refer to Master Response GEN-1.

Comment TR19-3

In general, we support the impacts analyses and believe that sufficient study and analysis has happened to support moving forward with dam removal on an aggressive time schedule.

Response to Comment TR19-3
Comment noted. The comment refers to the sufficiency of the EIR analysis.

Comment TR19-4
We offer the following comments with regard to these specific areas:

- *Tribal Cultural Resources and the Fate of the Parcel B Lands*
- *Water Quality*
- *Restoration and Construction Activities*
- *Fisheries and Aquatic Resources*
- *Emergency Response*

Response to Comment TR19-4
The specific concerns raised are addressed below in responses to comments TR19-EMAIL-5 through TR19-EMAIL-16.

Comment TR19-5
One of the Yurok Tribe's most serious concerns has to do with the ultimate fate of the Parcel B lands as they become exposed when the reservoirs are drained.

The Yurok Tribe does not support mitigation measure seven regarding land transfer and recommends the mitigation measure be stricken from the document. The measure regards lands referred to as "parcel B" in the Klamath Hydroelectric Settlement Agreement ("KHSA"), Section 7.6.4 and identifies that the Shasta Indian Nation has proposed to transfer the lands to the Kikaceki Land Conservancy. The proposal is included in the mitigation measure for analysis in the Environmental Impact Report. The mitigation measure does not disclose details of the Shasta Indian Nation's proposal such as location of the lands or amount of acreage.

As the Yurok Tribe has previously expressed, it is inappropriate for the State Water Board to include this proposal in the Environmental Impact Report as: 1) doing so potentially circumvents the process in KHSA Section 7.6.4, 2) the record before the State Water Board is incomplete with respect to other tribal entities that may have traditional or cultural ties to the lands, and 3) the details of the proposal are confidential which prohibits other entities from determining whether the proposal has negative impacts on their legal rights. While Yurok acknowledges the mitigation measure does not undue the process in KHSA Section 7.6.4, it does give the proposal preferential treatment and an unfair advantage over other proposals by completing environmental work required for transfer. The Yurok Tribe recommends the reference to the proposal be stricken from the document.

Instead, the State Water Board should defer mitigation and any predetermination of the fate of these lands to a future time as prescribed in the KHSA 7.6.4. If *proposals come forward in the future regarding the fate of these lands, a separate environmental analysis could then be conducted.*

Response to Comment TR19-5

Thank you for your comment. The State Water Board notes that the Yurok Tribe has concerns regarding the land transfer mitigation measure, and that land transfer presents a sensitive issue.

The EIR's analysis of the disposition and transfer of Parcel B lands is at a general level since the specific impacts associated with the transfers and any future land uses remain uncertain, and subject to the process described in the Klamath Hydroelectric Settlement Agreement (KHSA 2010) Section 7.6.4..Please note that ultimate disposition of Parcel B lands, and specific environmental impacts from future land uses, are speculative at this point. The EIR provides a general analysis of broadly applicable construction-related impacts to water quality and terrestrial resources and assesses the availability of generally accepted best management practices as mitigation measures (e.g., Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-18 and Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* Potential Impact 3.5-28; please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*). Any specific proposal to alter Parcel B lands would require further assessment. Please note that CEQA guidelines provide for a categorical exemption from CEQA for land transfers for purposes of protecting natural, historical and archaeological resources.

During development of the Draft EIR, the State Water Board conducted formal AB 52 consultation with the Shasta Nation, Shasta Indian Nation, and Yurok Tribe. In consultation with the Shasta Indian Nation and the Klamath River Renewal Corporation (KRRC), it was agreed upon by all three parties that an appropriate mitigation to reduce impacts to Native American Tribal Cultural Resources associated with implementation of the Proposed Project could include the potential transfer of Project lands to Native American Tribal entities, and particular resources were identified for which land transfer might be appropriate as a mitigation measure. As with other confidential information regarding the location of tribal cultural resources, this information is not disclosed in the public portions of the EIR. Any decision regarding whether transfer of these lands is ultimately feasible in light of other land use needs – and to whom the land would be transferred – would be made through the process established in Section 7.6.4 of the Klamath Hydroelectric Settlement Agreement (KHSA 2010).

Mitigation Measure TCR-7 is similarly consistent with Section 7.6.4 of the KHSA (2010), and it provides for consideration of a range of potential real property instruments in the process for disposition of Parcel B properties. Neither it nor any other measure in this section of the EIR commits the KRRC to transfer specific portions of lands to specific Native American entities, or to adopt conservation easements or other real property protections for any particular parcel. The process outlined in Section 7.6.5 of the KHSA (2010) provides for input from KHSA signatories and other potentially affected tribes on the ultimate disposition of Parcel B lands.

CEQA provides that real property mitigation measures should be considered and are available for mitigation for tribal cultural resources impacts. (Public Resources Code section 21084.3.) Further, CEQA provides for identification of mitigation measures in tribal consultation, and for inclusion of such measures in the EIR. (Public Resources Code sections 21080.3.2, 21082.3.).

Comment TR19-6

*Additionally, the Yurok Tribe does have specific concerns with some of the language in the Tribal Cultural Resources section of the document, and we herein provide alternative language below that addresses these concerns. (See page 3-799). Language requested for deletion is in ~~strikeout type~~, language for addition is underlined, and comments notes for consideration are in **Bold**. Plain text language is quoted from the DEIR.*

Yurok

*Pilling (1978) summarizes ethnographic information regarding Yurok collected by Waterman (1920), Waterman and Kroeber (1934), and others. Sloan (2003, 2011) also presents a summary of the ethnography of the Yurok and the relationship to the tribe to the Klamath River. Yurok are members of the Algonquian language family. ~~Yurok ancestral territory extends along the Pacific coast of California from Crescent City in the north to Trinidad in the south and along the Klamath River from the coast to a point near the confluence of the Klamath andTrinity Rivers and the town of Weitchpec (Pilling 1978).~~ The Ancestral Lands of the Yurok Tribe extend unbroken along the Pacific Ocean coast (including usual and customary off-shore fishing areas) from Damnation Creek, its northern boundary, to the southern boundary of the Little River drainage basin, and unbroken along the Klamath River, including both sides and its bed, from its mouth upstream to and including the Bluff Creek drainage basin. Included within these lands are the drainage basin of Wilson Creek, the drainage basins of all streams entering the Klamath River from its mouth upstream to and including the Bluff Creek and Slate Creek drainage basins, including the village site at Big Bar (except for the drainage basin upstream from the junction of Pine Creek and Snow Camp Creek), and the Canyon Creek (also known as Tank Creek) drainage basin of the Trinity River, the drainage basins of streams entering the ocean or lagoons between the Klamath River and Little River (except for the portion of the Redwood Creek drainage basin beyond the McArthur Creek drainage basin and except for the portions of the Little River drainage basin which lies six miles up from the ocean). **[NOTE: Cite the Yurok Constitution for consistency as the existing reference isn't correct.]** The Yurok Tribe's reservation currently consists of a strip of land beginning at the*

Pacific Ocean and extending upstream a mile along each side of the Klamath River for approximately 45 miles.

The Yurok life, language, ceremonies, society, and economy are linked with the Klamath River. There are Yurok stories that reinforce the Yurok belief that the River was created in a distinct way in order to provide Yurok people with the best of worlds (Sloan 2003, 2011). Yurok refer to the river as HeL kik a wroi or "watercourse coming from way back in the mountains." Contemporary Yurok often refer to the Klamath River as the "Yurok Highway" emphasizing its comparison to a blood vessel that provides the main flow of sustenance. Karuk, Yurok, and Hupa share similar cultural traits and traditional stories state that the Klamath River was created to facilitate their interaction with each other and with salmon

*The Yurok had permanent settlements with substantial architectural features including houses, smokehouses, and storage facilities (Kroeber and Barrett 1910, Pilling 1978). ~~Pilling (1978) cites 44 villages, 97 fishing spots, 82 significant cultural places (e.g., places used for ceremonies, gathering, and hunting), and 41 places of cultural significance along the Klamath River in Yurok~~ **~~territory~~ [NOTE: Not an accurate count. Can keep sentence if numbers are removed or add a sentence that says a minimum of…The Tribe has documented over 70 villages in our ancestral territory]***

The Yurok represent a socially complex hunter-gatherer population in California (Fredrickson 1984, Kroeber 1925) that used marine and salmon resources. Organizing labor to capture the short-duration salmon runs, preserving fish by smoking, then packing and storing the fish suggests a high degree of sociopolitical differentiation.

There is also evidence of a maritime expression to Yurok culture involving marine mammal hunting more than 10 miles offshore. The most telling argument for an open- ocean maritime adaptation comes from the presence of the large amount of northern fur seal fauna in the Stone Lagoon midden. Jones and Hildebrandt (1995) argued that pinnipeds were extirpated early on shore by Native Americans, who then developed watercraft to hunt offshore.

The material culture of the Yurok people includes, to this day, dugout redwood canoes, split-plank houses, storage boxes, sweathouse pillows and stools, many fishing devices, baskets and leather, shell, straw and feather garments and ceremonial regalia.

Transportation along the rivers and streams is essential to Yurok ceremonial activity. One of the most important aspects of Yurok technology was the river- and ocean-going canoe or yoch, which were carved from selected redwood trees (Sloan 2003, 2011).

There are historic accounts of expeditions traveling up to 180 miles along the coast (Sloan 2003, 2011). A typical river canoe measured 16 to 20 feet in length and 3 to 4 feet in width. River canoes were customarily paddled and/or pushed with a long pole. Yurok technology and facilities do not only serve utilitarian functions, but also include ceremonial aspects of Yurok culture. For example, facilities, such as fishing weirs, were created specifically to signify the time of sacred ceremonies (e.g., the White Deerskin and Jump ceremonies).

Fishing places along the Klamath River are owned by individuals, families, or groups of individuals. Fishing places can be borrowed, leased, inherited, or bought and sold (Sloan 2003, 2011). Some ownership rights at fishing places depended on species of fish caught at the site, while others depended on the water level (i.e., individuals owned the right to fish at a place if the river was below or above a certain level). Yurok still recognize this traditional form of resource management and use of the river. Families and individuals continue to use and own rights to fishing places on the Klamath River.

Like the Karuk, the religious and ceremonial practices highlight the Yurok relationship to the Klamath River and its associated resources. Of particular importance were the Jump, White Deerskin, Boat, and Brush Dance ceremonies. The Jump and White Deerskin ceremonies were held in late fall to give thanks for food resources abundance collected during the year and to insure a continued abundance of food resources for the next year (Sloan 2003, 2011). Affluent individuals and religious leaders conduct most ceremonies, and wealthy individuals were expected to feed salmon to everyone attending the ceremonies.

The Boat Ceremony is part of the White Deerskin Ceremony. In this ceremony, several boats filled with participants travel down the Klamath River. The participants thank the river for continuing to flow and provide resources. The Brush Dance Ceremony unfolds over a ten day period and is for the healing of a sick child or individual. This ceremony highlights the importance of Klamath River resources to Yurok. For example, baskets made of plant materials collected at the water's edge are used to hold food and ceremonial medicine; acorns are cooked in the baskets using cooking stones gathered at specific river bars; ceremonial regalia is made from various plant and animals that live along the river; ceremonial bathing is performed; and participants listen to the sounds made by the Klamath River (King 2004).

The social and ceremonial significance of the Klamath River is evident in and reinforced by Yurok traditions. For example, there are at least 77 Yurok stories that make direct reference to the Klamath River (Sloan 2003, 2011). These Yurok stories reinforce the belief that the Klamath River was created to provide Yurok with a very good place to live.

Spanish explorers and vessels traveling from the Philippines interacted with Yurok along the coast in the late 1700s. ***[NOTE: Bodega visited the Village of***

Tsuri and the Vancouver expedition followed shortly after.] *Other explorers such as Peter Skene Odgen and Jedediah Smith certainly encountered Yurok along the Klamath River in the early 1800s. Regardless, Euro American settlement and use of Yurok territory did not begin until after the discovery of gold in California in early 1850. With strikes along the Klamath and Trinity rivers, gold prospectors inundated the region affecting Yurok traditional culture (Pilling 1978). In 1851 a "Treaty of Peace and Friendship" was signed between the United States Government and the Klamath River Indians, but the United States Congress did not ratify this treaty. Subsequently, on November 16, 1855, the Klamath River Reserve, also known as the Klamath Indian Reservation, was established by Executive Order. The Order designated the reservation lands from the mouth of the Klamath River, one mile on each side extending approximately 20 miles upriver to Tectah Creek (Sloan 2003, 2011).*

Escalating conflict between Yurok and Euro Americans during the 1860s and 1870s over encroachment onto the Klamath Indian Reservation resulted in the ~~gradual~~ attempted displacement of Lower Klamath Indians further upriver (Sloan 2003, 2011). Euro Americans on the reserve resisted attempts to remove them, including eviction in 1879 by the United States Army (Sloan 2003, 2011). After decades of struggle to keep their traditional homelands, the Yurok Tribe was re-organized and was granted its own reservation in 1988. As a result of the 1988 Hoopa-Yurok Settlement Act (PL-100-580), the Yurok Indian Reservation was established.

The ancestral lands of the Yurok Tribe extend unbroken along the Pacific Ocean coast (including usual and customary off-shore fishing areas) from Damnation Creek, its northern boundary, to the southern boundary of the Little River drainage basin, and unbroken along the Klamath River, including both sides to the associated tributary watershed boundaries from the mouth upstream to the Bluff Creek drainage basin. The Yurok Tribe considers cultural resources sites along and associated with the Klamath River to be part of a larger ethnographic riverscape (King 2004, Yurok Tribe 2012).

Sites include fishing areas; a fish dam (weir) site; many different types of resource gathering sites, complex trail systems that connect villages, camps, the river, ceremonial sites, gathering areas, and other Tribes; and 47 villages with graves/cemeteries.

The Yurok Tribe is the largest tribe in California, with over 6,200 enrolled tribal members and over 300 tribal government employees. The Yurok Tribe is actively pursuing economic development and management of fisheries, forestry, and cultural programs, both on the reservation and Yurok ancestral lands.

Resighini Rancheria: *The Resighini Rancheria is located on the southern banks of the Klamath River Estuary, surrounded by the Yurok Reservation. The Rancheria is composed of Indians <u>relocated through the Homeless Indian Act</u>*

which include some individuals with Yurok ancestry, ~~and has~~ other homeless Indians from central California.

NOTE: Major shifts in federal Indian policy at the national level during the late 19th century exacerbated the Indian problems in California. Passage of the General Allotment Act in 1887 opened part of the limited lands in California to non-Indian settlement. In 1905 the public was finally advised of the 18 unratified treaties. Citizens sympathetic to the economic and physical distress of California Indians encouraged Congress to pass legislation to acquire isolated parcels of land for homeless California Indians. Between 1906 and 1910 a series of appropriations were passed that provided funds to purchase small tracts of land in central and northern California for landless Indians of those areas. The land acquisitions resulted in what has been referred to as the Rancheria System in California.

Land known as the Resighini Rancheria was designated by Secretarial Order and was officially declared a reservation in 1939. In 1975, a group of Indians stood together and formally created a non-traditional form of government with a constitution and bylaws which was approved and ratified by the last Indian Commissioner Bruce Thompson from the Department of Interior of the United States. However, the disastrous flooding of 1964 (see also Figure 3.6-14) led to the temporary evacuation of Resighini Rancheria.

Today, the tribal government consists of a General Council with an elected Tribal Council to operate our governmental and private tribal affairs as well as represent the tribal needs of our small membership. The Tribal Council consists of five tribal members who are elected annually by staggered two-year terms of Chairman, Vice Chairman, Secretary, Treasurer and Councilperson. Their general membership serves on boards, committees, commission and corporations to assist the Tribal Council.

Response to Comment TR19-6

Section 3.12.2.1 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northwest California Culture Area – Ethnography – Yurok* has been clarified to include additional information that did not result in changes to the impact analysis, including clarification based on the comments provided . Please refer to Volume III Attachment 1 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods) – Northwest California Culture Area –Ethnography – Yurok* for the revisions.

Comment TR19-7

The Yurok Tribe's Environmental Program (YTEP) has reviewed the document and does not have substantive comments except to say that they support the conclusions of the DEIR and the methods used. Most, if not all of our previous *concerns with regard issues related to water quality appear to have been resolved to the best of our knowledge.*

Response to Comment TR19-7
Comment noted. The comment regards agreement with the conclusions and methods in the EIR's water quality analysis.

Comment TR19-8
With regard to proposed restoration activities and construction, the Yurok Tribe fully supports the Proposed Project as described in the Draft EIR document distributed on December 2018. The tribe specifically supports the following proposed actions listed in the DEIR and the Definite Plan Appendix H including:

- *Overall Project Implementation Schedule*
- *Reservoir Drawdown Schedule*
- *Road Access and Bridge Improvements*
- *Spoils and Staging Area Development*
- *Deconstruction Activities*
- *Sediment management during reservoir drawdown including Sediment Jetting*
- *All Restoration Actions within and outside the Reservoir Footprints including: Revegetation Seeding and Planting, Habitat Restoration and Enhancement Actions, Tributary and Floodplain Connectivity Actions, and Upland Restoration components.*

Response to Comment TR19-8
Comment noted. The comment relates to Volume II Appendix B: *Definite Plan – Appendix H*.

Comment TR19-9
Page 2-8: the storage volumes given for the various project facilities are misleading because much of it is dead storage which cannot be released under normal operations. Please revise table with available storage and dead storage.

Response to Comment TR19-9
Table 2.3-1 provides built storage capacity. Section 2.3 *Proposed Project – Existing Lower Klamath Project Features* Table 2.3-1 has been revised to include a footnote on "Reservoir storage volume" which clarifies that volumes reflect the total storage volume following dam construction, not just active storage. Please refer to Volume III Attachment 1 Section 2.3 *Proposed Project – Existing Lower Klamath Project Features* for the revisions.

Additionally, please refer to Volume I Section 3.8 *Water Supply/Water Rights* (pages 3-667–3-684), where the cumulative total active storage volume of the Upper Klamath Lake is discussed, which provides 98 percent of the active water storage in the Klamath watershed.

Comment TR19-10

Page 2-20: It should be noted that Article X (10) of the Klamath River Compact states that "To deprive any individual Indian, tribe, band or community of Indians of any rights, privileges, or immunities afforded under federal treaty, agreement or statute."

Response to Comment TR19-10

Comment noted. The timeline referenced presents examples of major events associated with water-related disputes in the Klamath Basin, and the short summaries are not intended to be comprehensive. Please also see Master Response CEQ-4, which provides additional information on the Klamath River Basin Compact.

Comment TR19-11

Not sure what purpose 2.6.1 serves, given that dam removal is only peripherally related to water management. Certainly the Yurok Tribe would add 1994 to the list of water conflicts where the Klamath River flows were taken down to less than 400 cfs at Iron Gate Dam. Recommend deleting entire section as needlessly controversial and not entirely relevant. A better approach might be to sum up from a 20,000 ft level "Water management in the Klamath Basin has been controversial in the past few decades with farm shortages, commercial salmon fishery failures and uncertainty and other effects all occurring frequently." Or something similar.

Response to Comment TR19-11

Volume I Section 2.6.1 *Proposed Project – Project Background – Water Conflicts in the Klamath River Basin* presents examples of major events associated with water-related disputes in the Klamath Basin and is not intended to be a comprehensive history of water use and/or management in the basin. The section provides relevant points of context for the Proposed Project and its objectives. Text has been added prior to introducing the timeline to further explain the reason for its inclusion. Please also note that the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III. Please refer to Volume III Attachment 1 Section 2.6.1 *Proposed Project – Project Background – Water History in the Klamath River Basin* for the revisions.

Comment TR19-12

Page 2-67: even if coarser sediment is only 0.5% of the total of over 12,000,000 cu. yd. that's still over 60,000 yards of coarse sediment. This is an immensely important amount of sediment for macroinvertebrates and can be more easily mobilized than the current armored condition of the bed. Furthermore, fine sediment that does settle near the removal location is important to lamprey ammocoetes and other species.

Response to Comment TR19-12

Consistent with the comment, the potential effects of increased bedload supply and transport on channel bed elevations and grain size under the Proposed Project are described in Volume II Appendix F and summarized in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775). Effects of more natural sediment transport process on macroinvertebrates are specifically discussed in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-20, and effects on Pacific lamprey are discussed in Potential Impact 3.3-11. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment TR19-13

Section 2.7.6.1 (page 2-78) currently reads: "percent of Bogus Creek flow during part of each year, especially during October, November, April, and May. In spring/early summer of 2014, Bogus Creek flows were insufficient to meet the proposed full water needs of the hatchery. These results may be due to the short duration of the dataset or drought conditions between 2013 and 2017 that may not represent long-term conditions. The KRRC proposes that if Bogus Creek flows are insufficient to meet minimum operational needs while balancing flow requirements in the creek, water reuse (recirculation) from the rearing raceways could be utilized. In addition to recirculation, early release of smolts (i.e., prior to April 1) may occur to reduce water use requirements in the hatchery. The effectiveness of recirculation and early smolt release would be studied to determine whether they could be used to meet minimum operational flow and water temperature needs in the hatchery given annual variations in Bogus Creek flow and water temperature during the early release period." Comment: The above statement should more clearly state what recirculation capacity will exist at the hatchery. It should also clearly state that the "early smolt release" option will only be used after exhausting Bogus Creek diversion and recirculation options. Due to competition with natural rearing fish in the Klamath River, release of smolts early should only be done as a last resort. The above text leaves too much latitude to use recirculation OR early release of smolts.

Response to Comment TR19-13

Volume I Section 2.7 *Proposed Project – Proposed Project* summarizes information provided in the KRRC's Fish Hathery Plan, found in Section 7.8 of the Klamath River Renewal Corporation's (KRRC's) Definite Plan (see Volume II Appendix B pages 273 to 294). The Fish Hatchery Plan provides additional detail on the potential need for early hatchery releases and constraints for using recirculation. It states: "CDFW and NMFS would establish numeric trigger thresholds to determine whether CDFW would release some or all fish early (e.g., Bogus Creek 24-hour average water temperature exceeds 18 to 19 degrees C; see Figure 7.8-3)." California Department of Fish and Wildlife (CDFW) would also utilize water reuse/recirculation to extend release dates when Bogus Creek flow is low, but water temperature is sufficient to recirculate in the raceways without exceeding trigger thresholds. With regard to the potential for early hatchery releases, please refer to response to comment ORG46-68.

Comments on the KRRC's Hatchery Plan included in their Proposed Project should be directed to the KRRC.

Comment TR19-14

Page 4-17: Suggest inserting the following language. "In 2018 and continuing into 2019 , the Bureau of Reclamation has initiated formal consultation under the ESA for the operation of the Klamath Project. The resulting BiOp is expected to govern water operations for the next 10 years from implementation. Although the Bureau of Reclamation released its Biological Assessment in late December 2018 and has stated its intention to finish consultation by April 1, 2019, it is speculative to forecast what hydrology may result from implementation of the proposed action. NMFS and USFWS may either or both require modification of the proposed action in ways that are not foreseeable at this time. Therefore, this DEIR uses current hydrology as described in the previous few paragraphs.

Response to Comment TR19-14

In March 2019, the National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) issued a final biological opinion (2019 BiOp) for the Klamath Irrigation Project that sets the current operational flow requirements for the Klamath River. Section 4.2.1.1 *No Project Alternative – Alternative Description* has been revised to clarify how the 2019 BiOp is considered in the EIR. Please also refer to Master Response HYD-1.

Comment TR19-15

Page 4-68: The Yurok Tribe does not agree that the probability of dam removal is low for the KHP. Iron Gate Dam, for example, has no emergency spillway, has recently been raised due to an increase in the maximum probable flood estimate, and the emergency drain tunnel has never actually been used. Because the tunnel and penstock have relatively low capacities, the bulk of large flood flows must pass over the spillway, which is located immediately adjacent to the face of the dam. If the spillway should fail (as happened on Oroville Dam) there is no emergency action that can save the dam from catastrophic failure. In fact, spillway failure nearly brought the dam down in the 1964 flood, after which the spillway was lined with concrete. This concrete lining, while it is presumably inspected, is vulnerable to failure as was seen in Oroville.

Response to Comment TR19-15

Volume I Section 4.2 *No Project Alternative* (pages 4-15 to 4-74) analyzes the No Project Alternative and describes the environment should the Klamath River Renewal Corporation's (KRRC's) Proposed Project to decommission the Lower Klamath Project not proceed. The EIR does not assess the probability of dam removal absent the Proposed Project.

Volume I Section 3.6.5.3 *Flood Hydrology – Potential Impacts and Mitigation – Risks of Dam Failure* Potential Impact 3.6-6 has been revised to clarify the discussion of risks of dam failure under existing conditions, during reservoir drawdown, and dam deconstruction; as well as the most recent (2019) Division of Safety of Dams ratings and hazard classifications for the three California dams. Please refer to Volume III Attachment 1 Section 3.6.5.3 *Flood Hydrology – Potential Impacts and Mitigation – Risks of Dam Failure* Potential Impact 3.6-6 for the revisions.

Comment TR19-16

The Tribe urges the State Water Board to reconsider its finding that the restoration of the free-flowing Klamath River will permanently decrease response ability for catastrophic fire. Although reservoirs provide more options for emergency aerial water tanker response, this is a very small portion of the overall response to fire danger. Safe evacuation routes (which will be left in an improved state due to necessary upgrades for demolition activities), fuels management, and a host of other factors go into this determination. We believe that other activities (a renewed focus on fuels management, for example) can offset the loss of flatwater areas for refilling aerial tankers. It is also possible for restoration projects to deliberately include off-channel areas suitable for filling water buckets via helicopter

Response to Comment TR19-16

Volume I Section 3.21.5 *Hazards and Hazardous Materials – Potential Impacts and Mitigation* Potential Impact 3.21-8 (pages 3-1051 to 3-1054) acknowledges that water for fighting wildfires could be obtained from the Klamath River, Lake Ewauna, and Upper Klamath Lake, and that there is the potential to ameliorate the impact by, for example, providing replacement water sources.

Wildfire risk is complex, multifaceted and highly unpredictable. The State Water Board acknowledges that to the extent Project-related road improvements improve area roads, this improvement has the potential to improve ground fire response and evacuation in some situations. Any such improvement would depend on the particularities of the wildfire, the road improvements and the response, and cannot be quantified. The EIR's conservative assessment errs on the side of disclosure: "where suitable replacement water sources cannot be identified in close proximity to a fire in a location for which the reservoirs would otherwise have been the nearest water source, long-term impacts to the public's risk of loss from wildfires remain significant and unavoidable." Such a conservative approach remains appropriate in light of the number of houses abutting Very High Fire Hazard Severity Zones surrounding the currently existing reservoirs.

Improved fuel management in the basin post-dam removal, as suggested in the response, is not a feasible mitigation measure as there is no articulated path for developing, funding and implementing such a plan, and in light of federal preemption.

Please note, on December 3, 2019, the Klamath River Renewal Corporation (KRRC) filed an updated water quality certification application with the State Water Board that identifies that the KRRC will develop an updated Fire Management Plan with the intent to avoid a material net increase of fire risk as compared to baseline conditions in the Project area, and to enhance both short and long-term fire prevention, detection, and suppression in the Klamath River Basin. These commitments improve the likelihood that the risk conservatively identified in the EIR will be eliminated. However, due to the ongoing nature of the analysis to support the ultimate fire risk maintenance and reduction goals of the Fire Management Plan, in combination with federal preemption, the State Water Board does not rely on this commitment to change the significance determination.

Please also refer to Master Response HAZ-2 and CEQ-2.

Comment TR19-17

The Yurok Tribe has reviewed the DEIR and has found it to be a thorough and sound document, above comments notwithstanding. The DEIR appropriately uses the voluminous material generated in previous environmental analysis efforts for the FERC relicensing itself as well as the Secretarial Determination EIS that was a product of the first version of the KHSA.

The full dam removal project, as well as the partial removal alternative, would be the largest fisheries restoration project in the history of the United States, and would represent a major boost to the economy of the west coast. It is also a very important step toward protecting the Yurok Tribe's federally reserved fishing rights. Additionally, this type of landscape-scale restoration effort is essential for providing for diverse Tribal, farming, and environmental interests to peacefully coexist in the Klamath Basin. We urge the timely implementation of this project as soon as possible.

Response to Comment TR19-17

Comment noted. The comment references the overall quality of the EIR and describes potential benefits of dam removal.

2.3.4 Organizations

This section presents written comments received on the Draft EIR from organizations and the State Water Board's responses to those comments. Written comments and responses in this section are organized alphabetically by organization name. To determine whether your comment is associated with an affiliation type other than organizations, please refer to Table 2-1 or Table 2-2.

Table of Written Comments and Responses from Organizations

American Rivers, Mark Busto

Comment ORG48-1

I write in support of the conclusions of the draft EIR. The Klamath is an historic, iconic river that used to support large runs of steelhead and salmon that cannot recover without removal of the dams. Here in the State of Washington, we know first-band the tremendous impact that dam removal can have on the health of a river with the removal of the two dams on the Elwha River. I urge you to adopt the Draft EIS and keep the project on track.

Response to Comment ORG48-1

Thank you for your comment. Please also refer to Master Response GEN-1.

American Rivers, California Trout Incorporated, Trout Unlimited, Sustainable Northwest, Steve Rothert, Curtis Knight, Brian Johnson, Greg Block

Comment ORG27-1

American Rivers, California Trout, and Trout Unlimited [SNW?] submit these comments on the Draft Environmental Impact Report (DEIR) for the Lower Klamath Project License Surrender (FERC Project No. 14803).

American Rivers is a national river conservation organization founded in 1973 to restore and protect our rivers for the benefit of people, fish and wildlife. We have 15 offices around the country including Oregon and California, with 110,000 supporters including more than 10,000 in California and Oregon. Our members use and enjoy the Klamath River, which has been one of our highest national priorities for two decades.

California Trout is a statewide conservation organization whose mission is to ensure resilient wild fish in healthy waters for a better California. California Trout was founded in 1971 and has over 7,500 members statewide. California Trout operates offices in San Francisco, San Diego, Ventura, Mammoth Lakes, Arcata, Davis and Mt. Shasta. California Trout's Mt. Shasta office is located in Siskiyou County where three of the four Klamath dams, providing a local presence in the community. California Trout members use and enjoy the Klamath River in the areas surrounding the Project for recreational, aesthetic, and educational purposes, including sport-fishing for trout, steelhead and salmon.

Trout Unlimited (TU) is the largest and oldest sportsmen's organization dedicated to the conservation of trout and salmon and their habitats in North America. TU has some 14,000 members in California and Oregon who rely on the Klamath River for sportfishing opportunities and as vital habitat for salmon and steelhead. We have offices in Mt. Shasta, Klamath Falls, Emeryville, Ft. Bragg, Truckee, and Carmel Valley. Our members use and enjoy the Klamath River, which, historically, was the third most productive watershed for salmon and steelhead on the West Coast.

Sustainable Northwest is a conservation non-profit working at the intersection of economy, environment, and community, pioneering natural resource solutions that work for people and nature. For well over a decade, Sustainable Northwest has been working with stakeholders to form agreements over the Basin's long-standing water resource challenges. We believe dam removal is a key step to resolving longstanding disputes in the Klamath Basin and is critical to improving the long-term water quality issues facing the health of the river and the community it supports.

American Rivers, California Trout, Trout Unlimited, and Sustainable Northwest are active participants in finding durable solutions for the Klamath River fisheries and communities. AR, CalTrout, and TU have actively participated in PacifiCorp's dam relicensing proceeding beginning in 2000 and with tribes and agencies coordinated our efforts during the Energy Policy Act proceeding in 2006 that up held the federal government prescriptions for volitional fish passage, and Sustainable Northwest has been active in various collaborative projects for water and fish for the same period of time. Our groups have been actively involved in settlement negotiations and the four groups are signatories to the Klamath Hydroelectric Settlement Agreement (KHSA). Our groups are also represented on the Board of the Klamath River Renewal Corporation.

The KHSA is a remarkable multi-party agreement between stakeholders with divergent interests in the Klamath Basin to resolve decades of litigation and other controversies in the region over the future of the Klamath River. Under the agreement, the parties agreed to facilitate the physical removal of all or part of each of the Lower Klamath Project dams to achieve a free-flowing condition and volitional fish passage along the Klamath River below the Keno Dam. Critically, the agreement provides that the proposed removal of the Lower Klamath Project facilities would be completed in a manner that achieves site remediation and restoration and with the implementation of measures to avoid or minimize downstream impacts.

The undersigned strongly support the proposed project to remove four dams (J. C Boyle, Copco No. 1; Copco No. 2, and Iron Gate) and associated facilities that comprise the Lower Klamath Project pursuant to the terms of the KHSA. The purpose of the proposed project is to restore free-flowing river conditions and volitional fish passage for salmon and steelhead along more than 400 stream-miles of historic spawning habitat upstream of the dams on the Klamath River. Our support for other measures in the Klamath Basin to improve water quality and security for both people and fish – including collaborative water supply, economic redevelopment and habitat restoration projects in the upper basin – is just as strong.

The DEIR confirms that implementation of the proposed project will meet water quality objectives. It is the only alternative that does this and achieves the *project purpose. The DEIR further confirms that the project will contribute to the restoration of native anadromous and other fish species; and benefit the local economy by providing commercial and fishing job opportunities. As the Oregon and California Public Utility Commissions have found, the project will also benefit PacifiCorp's ratepayers, as the costs of removal of the dams would be less than the upgrades that would otherwise be necessary to relicense the dams.*

The environmental analysis of this project required under the California Environmental Quality Act (CEQA) underscores the scientific rationale for removing the dams. Numerous fish species—some of which are listed under federal or state Endangered Species Acts—use the Klamath Basin during all or phases of their life histories. The dams harm river ecosystems and aquatic life and provide little no benefit power generation and no benefit for water supply. They block passage to upstream tributaries and mainstem habitat that salmon, steelhead and other native fishes require for population recovery and for sustaining now at-risk recreational, commercial and tribal fisheries.

We support the DEIR conclusion that the environmentally superior alternative is the proposed project. As the Draft EIR finds, the removal of the Lower Klamath Project's dams would provide a wide range of beneficial impacts, including: short- and long-term improvements in water quality that would promote substantial progress towards achievement of water quality objectives; long-term benefits to aquatic species listed under the Endangered Species Act; long-term beneficial effects on riparian habitat and listed species that rely on such riparian habitat; and long-term benefits for Native American tribes that depend on the Lower Klamath River for fisheries and ceremonial purposes. Removing the Klamath dams will improve spawning opportunities and reduce the incidence of fish disease that has resulted in massive fish die-offs in some years. Moreover, per the DEIR, impacts related to release or migration of sediment will be temporary while the benefits long-term for improved water quality are considerable.

Restoring the Klamath River and its fisheries could help facilitate resolution of long-term water conflicts in the Klamath Basin, watershed-scale environmental and habitat restoration, and a beneficial ripple effect for fisheries in both the river and marine environments. Recovering the Klamath's legendary runs of salmon and steelhead is key to revitalizing fishing-based communities and cultures in this region and to bolstering the regional economy more broadly.

KRRC appreciates the State Water Board's detailed examination of a number of other alternatives that potentially would meet some, but not necessarily all, of the proposed project's objectives. Restoration of free-flowing river conditions per the proposed project will provide the maximum benefits to the Klamath River's water quality and ecosystem.

In summary, we concur with the key findings of the DEIR that the proposed project is the environmentally superior alternative. It is the only option that fully *meets the project purpose and meet the water quality objectives. We urge the Water Board to certify the EIR and issue the water quality certification required under Sec. 401 of the Clean Water Act for the proposed project.*

Response to Comment ORG27-1
Thank you for your comment. The State Water Board is not a signatory to the Klamath Hydroelectric Settlement Agreement (KHSA) or the Amended Klamath Hydroelectric Settlement Agreement.

Please also refer to Master Response GEN-1.

Endangered Habitat League, Dan Silver

Comment ORG35-1
Endangered Habitats League (EHL) appreciates the opportunity to comment. For your reference, EHL is a Southern California regional conservation group.

We support for the full removal of the lower four Klamath River dams.

The DEIR supports dam removal as the best option for water quality. Removal is also best for fisheries, yet removal will not affect agriculture. The dams are also not needed for flood control.

All evidence points to removal of all four dams.

Response to Comment ORG35-1
Thank you for your comment. Please also refer to Master Response GEN-1.

Friends of Del Norte, Eileen Cooper

Comment ORG36-1
Thank you for the opportunity to express our full support for the alternative that will removal all four dams on the Klamath River. The benefits to the vitality of our fishery and local economy cannot be overstated:

The removal would "…advance the long-term restoration of natural fish populations in the Klamath Basin, including having a significant beneficial effect on commercial fisheries and associated significant beneficial economic impact on the coastal commercial fishing industry." (Environmental Impact Report)

The EIR report brings more good news for the Crescent City Harbor. Although dam removal will unlock some sediment trapped in the reservoirs, Crescent City Harbor should not be affected, with the DEIR stating:

"…it is expected that the amount of sediment released during the year of drawdown and dam removal would be similar to that transported by the Klamath

River to the Pacific Ocean in a year with average flow, much less than that transported by the Klamath River in a wet year…."

We appreciate all the hardwork and persistence by our community to make this dream come true.

Response to Comment ORG36-1
Thank you for your comment. Please also refer to Master Response GEN-1.

Institute for Trade, Standards and Sustainable Development, Inc., Lawrence Kogan

Comment ORG44-1
I write out of conscience, as the former counsel retained during 2016 by two local Oregon and California state instrumentalities, the Klamath Irrigation District, Klamath Falls, Oregon, and the Siskiyou County Board of Supervisors, Yreka, California, and as the former counsel retained during 2016-2017, by a private citizens-operated nonprofit organization, the Siskiyou County Water Users Association. Each of these entities, during my tenure as retained counsel, was integrally involved in the public debate surrounding the removal of the above-referenced dams and decidedly against their removal.

The ITSSD and I thank the California State Water Resources Control Board for the opportunity to participate in this open stakeholder process, and hereby submit the attached comments for the Board's review.

Please don't hesitate to contact us should you have any questions.

Response to Comment ORG44-1
Thank you for your comment. Please refer to Master Response GEN-1.

Comment ORG44-2
There is no genuine material difference between the substance of the discussion about dam reservoir sediments in the December 2018 "Draft Environmental Impact Report for the Lower Klamath Project License Surrender" prepared by Stillwater Sciences, and the September 2011 CDM report which Stillwater Sciences helped prepare, entitled, "Screening-Level Evaluation of Contaminants in Sediments from Three Reservoirs and the Estuary of the Klamath River, 2009-2011." In both reports, the authors omit material information about the toxicity of the reservoir sediments at each of the four PacifiCorp owned and operated Klamath River dams slated for removal (John C. Boyle, Copco 1, Copco 2 and Iron Gate).

More specifically, there is little to no information about the hazards such sediments would pose to human health and welfare when they are released upon dam removal, and there are no bona fide human health risk assessment-related data of the potential exposure from dam reservoir sediments at each of the four

Klamath River dams. This strongly suggests that USEPA has performed no human health risk assessments at all which the California State Water Resources Control Board ("SWRCB") or the California Environmental Protection Agency ("EPA") has publicly disclosed. Rather there are only perfunctory data of screened contaminants in dam reservoir sediments which were gathered and publicly disclosed by the U.S. Department of Interior's Fish and Wildlife Service.

Response to Comment ORG44-2

Please refer to Master Response WQ-6.

Comment ORG44-3

Indeed, the legal pathway the former Obama administration had used to initiate this process – i.e., the Clean Water Act § 401 certification process – had intentionally been chosen because the U.S. Department of Energy's Federal Energy Regulatory Commission ("FERC") would retain jurisdiction over this process to assure a favorable dam removal outcome. This was and remains a pure case of 'the ends justifying the means,' no matter the projected wildlife losses dam sediment release upon removal would engender, and completely without regard to the potential risks to human health and welfare that dam sediment releases would pose.

Had the proper legal pathway been selected – the Clean Water Act §§ 303(d) process – EPA would have retained jurisdiction over the calculation by California of the total maximum daily load for the lower Klamath River, including the dam reservoirs, and EPA would have been required to conduct human health risk assessments to evaluate the potential human exposure to sediments released at each of the four dam reservoirs. This would have especially been the case if EPA had determined that any one or more of the dam reservoirs constituted a Superfund site under the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA").

It is quite remarkable that the State of California EPA has not yet admitted to the members of the public how USEPA had previously conditioned its prior approval of the North Coast Regional Water Quality Control Board's December 2010 TMDLs for the Klamath River on the State's quiet agreement to treat the incremental impairments it had calculated from the dams as something other than a TMDL load allocation.

In sum, the California EPA, rather than the SWRCB should be the primary agency involved in evaluating the pros and cons of dam removal, and the process should be one of addressing each dam's contribution to the total maximum daily load of the impaired lower Klamath River, rather than one of water quality certification relating to FERC dam license transfer and termination and hydroelectric decommissioning. The State of California has unnecessarily continued to deceive the public in favor of its political agenda of dam removal, and to deny it the material facts concerning the potential hazards to human *health and welfare the release of toxic sediments from the four Klamath River dam impoundments would trigger upon removal.*

Response to Comment ORG44-3
Please refer to Master Response CEQ-2 and WQ-5.

Comment ORG44-4
Historic and Recent Sources of Toxic Contamination in the Upper Klamath Basin

During the 2004, the National Research Council issued a report describing the historic human activities that shaped the Klamath River Basin and ultimately endangered and threatened fish in the Basin. These activities included significant cattle ranching and pasturing in Klamath County, Oregon during the 1950's and 1960's with only slight declines in the 1990's and increased cattle production intensity by 2002. "In 1998, the Environmental Protection Agency's Index of Watershed Indicators estimated that at least 110,000 acres of the watershed had been converted to irrigated pasture or other agricultural activities." "The effects of grazing in the watershed were probably profound but are impossible to quantify. […] Grazing can mobilize nutrients and sediments, both of which are of concern in the upper Klamath basin."[1]

These activities also included substantial commercial logging over more than two-thirds (e.g., 73%) of the upper Klamath Basin which subjected the forest land to severe erosion.[2] Logging had accelerated during the late 1910's because of national demand for ponderosa pine, and by 1918, "large amounts of reservation timber were being sold to private parties." "[B]y 1920, annual harvest rates had increased to 120 million board ft.[,…and p]eak lumber production occurred in 1941, when 22 lumber mills processed a total of 808.6 million board ft within the upper basin. Harvest has dropped to about 400 million board ft in recent year."[3]

During 2012, the U.S. Geological Survey issued a report documenting the historical contamination of the Klamath River. It stated that "[d]ocumented contaminant impacts within the Klamath Basin date back to at least the 1960's when wildlife deaths were linked to organochlorine pesticides (such as dichlorodiphenyltrichloroethane [DDT]) that were commonly applied to the National Wildlife Refuges and surrounding agricultural land."[4] "Organochlorines (OCs) are a class of pesticide introduced in the 1940s that experienced widespread and heavy use through the subsequent 20 to 30 years. DDT, aldrin, dieldren, toxaphene, chlordane, and heptachlor were among the most commonly used compounds, and their popularity was due, in part, to their high insect toxicity, relatively low acute mammalian toxicity, and their persistence in the environment."[5]

Subsequent research on the environmental effects of these compounds, however, revealed that many were highly bioaccumulative and non-degrading. As the result, "they caused significant impacts to upper trophic level fish, birds, *and mammals."[6] "Organochlorine use in the Upper Basin was widespread from the 1940s to the 1960s, with some applications of a few compounds continuing into the 1970s."[7] "The last applications of DDT, toxaphene, and dieldrin reported in the Klamath basin (California side) were in 1971, 1982, and 1976, respectively. […] However, dicofol (which commonly contained DDT and DDE as contaminants) was used until 1981."[8] "[T]wo major pesticide classes, organophosphate and carbamate insecticides, emerged as major constituents of post-1960s pest management in agricultural lands of the Klamath Basin." Although there was increased use of "a suite of herbicides, fungicides, and fumigants" for pest control during this period, "there is[, however,] limited information on their distribution and pathways through the Klamath basin ecosystem."[9]*

The USGS report further documented how, in 1988, mercury (Hg) distribution had been quantified "in abiotic and biotic matrices in the Upper Klamath Basin. Although aqueous concentrations were less than reporting limits, sediment concentrations of total [mercury] Hg (THg; inorganic + [methylmercury] MeHg) were similar to geometric mean values for soils in the Western United States, with the exception of sediments downstream of the Link River Dam, which had concentrations that exceeded the rest of the basin by at least 4-fold."[10] Moreover, the USGS report documented anthropogenic sources of arsenic in the upper Klamath basin including industrial processes and wood preservatives. "The environmental toxicity of arsenic strongly depends on its speciation. The most common inorganic forms are arsenite (As (III)) and arsenate (As (V)), with arsenite being substantially more toxic. […] The inorganic speciation (and thus environmental risk) of arsenic is reliant on pH and redox conditions, with As (V) being reduced to As (III) under anoxia."[11] Since "the measured arsenic was not speciated," the environmental risks of their findings were unclear."[12] Nevertheless, "arsenic in water was highest (62 μg/L) at Lower Klamath Lake unit 12C (range <1–62 μg/L, median = 7 μg/L, N=18) and arsenic in bottom sediment was highest at Klamath Straits Drain at pumping plant FF (range 0.6–16 μg/g, median = 6.3 μg/g, N=13)."[13]

Additionally, the report expressed uncertainty regarding the extent of major lead sources in the Klamath basin. "It is currently unclear if there are any major lead sources in the Klamath Basin, but some evidence exists for substantial lead exposure in wildlife in the area."[14]

The USGS report also documented more recent sources of contamination in the Klamath basin. For example, it states that "use of numerous pesticides, combined with the active management of irrigation and drain water present the possibility of pesticide exposure in fish and wildlife species through overspray, runoff, and dissolution and transport." (emphasis added).[15] "Pesticide use on the lease lands averages approximately 52,125 kg of active ingredient per year across more than 30.8 km2 of agricultural land."[16] "Annual pesticide use patterns likely reflect a combination of changes in (1) use requirements or restrictions, (2) *type of crops grown, (3) pest outbreaks, and (4) water availability. Herbicide and fungicide applications have seen steady decreases since the late 1990s, from 7,000 to 8,000 kg of active ingredient per year to just more than approximately 4,000 kg of active ingredient per year in 2009 (fig. 6). Conversely, fumigant use has increased sharply over that time period from less than 10,000 to more than 90,000 kg of active ingredient per year."*[17] *"Some chemical classes, such as chloronitrile (fungicide), organophosphates (insecticides), phenoxycarboxylic acid (herbicide), and triazinone (herbicide) have seen relatively consistent annual use between 1998 and 2009. […A] handful of classes, such as arylphenoxypropionate (herbicide/fungicide), biopesticide bacterium (insecticide), carbamates (insecticide), carboximide (fungicide), chloroacetamide (herbicide), cyclohexidione derivitives (fungicide), dithiocarbamates (fumigant), halocarbons (fumigant), and strobilurin (fungicide) have seen a steady or recent increase in their use ."*[18]

"Importantly, the leased lands within the Refuge boundaries represent only a very small proportion of total agricultural activity in the Basin. Within the Upper Basin alone, agriculture accounts for nearly 2,000 km2 of land area of which 68 km2 are the lease lands. Moreover, 80 percent of the agriculture in Klamath and Siskiyou Counties and 27 percent of the agriculture in Modoc County occurs within the boundaries of the Klamath Basin." (emphasis added).[19]
"Additionally, much of the irrigated cropland surrounding the refuge is hydrologically connected to the refuge via canals that are part of the Klamath Project (National Research Council, 2004). Farmers within those adjacent and nearby agricultural properties are not restricted in their pesticide use in the same ways as those that use the leased lands. Thus, there exists the possibility for wildlife and fish within the Refuge boundaries to be exposed to chemicals that are not approved for refuge use. In fact, in 2008 and 2009 there were a total of 189 different chemicals reportedly used as pesticide in those three counties, and only 41 of them (22 percent) were approved for refuge use (table 6). […] Moreover, some of those compounds were either used at exceptionally high rates (for example, methyl bromide), or are particularly toxic (for example, acrolein, diazinon, ethoprop, etc.). Thus, it is important to consider ecological exposure potential for these compounds as well."[20]

"Elemental analysis of recent sediment cores taken from the three major upstream reservoirs, and the Klamath Estuary, show relatively low concentrations of chromium and nickel within the reservoir sediments, and substantially more elevated concentrations in the sediments from the Estuary (fig. 20). Conversely, arsenic and lead data in reservoir sediments were substantially more elevated than in the estuary." (emphasis added).[21]

The report, moreover, reveals that "based on EPA databases, there are at least 2 superfund sites, 8 brownfields, 3 pesticide producers, 3 major NPDES dischargers, and 21 minor NPDES dischargers that are identified within the Basin (fig. 21). These sites are associated with a broad range of contaminants, *including: petroleum products, asbestos, volatile organic compounds (VOCs), lead and other heavy metals, dioxins, polyaromatic hydrocarbons (PAHs), and other organic contaminants (fig. 22). The extent to which contaminants from these potential sources reach the surrounding environment is unclear, but there is a possibility that at least some of these sites result in exposure of the Basin's biological resources. Further, human population centers are often situated adjacent to water resources and are frequently associated with various contaminants they may enter the environment, but the specific compounds are not readily documented and potential effects of exposure to biota are not well understood." (emphasis added).* [22]

Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-13 (pages 3-139 through 3-151) includes analysis of inorganic and organic contaminants relevant to the Proposed Project and includes the following EIR citations; Eagles-Smith and Johnson (2012), CDM (2011), USEPA (2010), and Shannon & Wilson, Inc. (2006). Please refer to Volume III Attachment 1 Section 3.2.5.7 Potential Impact 3.2-13 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-13 for the revisions.

Section 3.2.4.7 *Water Quality – Impact Analysis Approach – Inorganic and Organic Contaminants* (pages 3-73 through 3-74) includes a determination of potential toxicity and bioaccumulation with respect to aquatic species and humans under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.2.4.7 *Water Quality – Impact Analysis Approach – Inorganic and Organic Contaminants* for the revisions.

Comment ORG44-5

Looking upstream from the mouth of the Klamath River at the Pacific Coast, the Iron Gate Dam, completed in 1962, is located between river mile (RM) 190.1 and RM 196.9 (encompassing a total of approximately 7 RM). The Iron Gate hydroelectric dam reservoir "impounds a reservoir of 944 surface acres," "contains about 50,941 acre-feet of total storage capacity (at elevation 2,328.0 feet) and 3,790 acre-feet of active storage capacity."[23] *It has "a maximum depth of 162 feet."*[24] *The Iron Gate dam has been operational for approximately 56 years, and thus its large reservoir/impoundment, contains 56 years' worth of accumulated sediment.*

Copco 2 Dam, completed in 1925, is located between RM 198.3 and RM 198.6 (encompassing a total of approximately 1/3 RM). The Copco 2 hydroelectric dam reservoir "is about 0.25 miles long and has a relatively small storage capacity of 73 acre-feet."[25] *The Copco 2 dam has been operational for approximately 93 years, and thus, its reservoir/impoundment contains 93 years' worth of accumulated sediment.*

Copco 1 Dam, completed in 1918, is located between RM 198.6 and RM 203.1 (encompassing a total of approximately 4.5 RM). The Copco 1 hydroelectric dam reservoir "impounds a reservoir of 1,000 surface acres," "contains approximately 33,724 acre-feet (40,000 acre-feet26) of total storage capacity at elevation 2,607.5 feet and approximately 6,235 acre-feet of active storage capacity. The normal maximum and minimum operating levels of the reservoir are at elevations 2,607.5 and 2,601.0 feet, respectively."27 It has a maximum depth of 115 feet.28 The Copco 1 Dam has been operational for approximately 100 years, and thus, its large reservoir/impound contains 100 years' worth of accumulated sediment.

John C. Boyle Dam, completed in 1958, is located between RM 220.4 and RM 228.3 (encompassing a total of approximately 8 RM).[29] The John C. Boyle hydroelectric dam reservoir impounds "420 surface acres of water," "contains approximately 3,495 acre-feet of total storage capacity and 1,724 acre-feet of active storage capacity."[30] It's "maximum depth is about 40 feet."[31] The John C. Boyle dam has been operational for approximately 61 years, and thus, its reservoir/impoundment contains 61 years' worth of accumulated sediment.

PacifiCorp has not frequently or recently reported about the composition of the sediment at the bottom of the four dam reservoirs/impoundments; it has reported, however, about the reservoir water quality. During 2004, PacifiCorp reported that both Copco and Iron Gate reservoirs are dominated by thermal stratification, where water temperature, pH, and chlorophyll are lower at lower reservoir surface levels in both reservoirs.[32] The 2004 report notes that, "[h]owever, Copco reservoir has a much higher concentration of ammonia, orthophosphate, total phosphorous and TKN [Kjeldahl nitrogen]" in the upper reservoir surface water levels. In "Iron Gate reservoir those constituents are the same concentration in both" the upper and lower reservoir surface water levels.[33]

And, in 2012, PacifiCorp similarly reported about the variations in water temperature in the John C. Boyle reservoir's upper and lower surface water levels,[34] and about the nutrients load in the upstream and downstream ends of said reservoir. According to the 2012 report, "J.C. Boyle is not appreciably retaining (reducing) nutrient [nitrogen and phosphorous] levels under typical conditions. This is in contrast to the larger downstream Copco and Iron Gate reservoirs which retain (reduce) significant amounts of the annual load of nutrients that flow into those reservoirs."[35] The report also notes that the John C. Boyle reservoir experiences low dissolved oxygen levels at the deeper portions near the bottom, and receives organic matter input that reduces dissolved oxygen levels primarily from upstream sources.[36] "J.C. Boyle reservoir is eutrophic because of the large nutrient load from upstream sources and seasonally warm temperatures."[37]

The 2012 report also relays that the Copco reservoir complex experiences seasonal water temperature stratification, "acts as an annual net sink for both total nitrogen and total phosphorous," and produce "[n]uisance bloom-forming *blue-green algae […] in the summer." "Sustained Microsystis blooms in Copco reservoirs are consistent with the potentially elevated levels of inorganic nitrogen (ammonia) and organic matter in influent waters."[38] The report admits that the Copco reservoir "bears the burden of accepting and processing the water quality that is ultimately borne out of Upper Klamath Lake and any agricultural and municipal/industrial return flows."[39]*

Moreover, the 2012 report concedes that Iron Gate reservoir "is eutrophic largely due to nutrient inputs (organic and inorganic) from upstream sources."[40] It also admits that, "[a]t times, the upstream conditions from Upper Klamath Lake and Keno reservoir may produce large quantities of organic matter and can increase the nutrient fluxes into both Copco and Iron Gate reservoirs substantially."[41] "[M]eteorological conditions, hydrology, and upstream water quality conditions playing important roles in the species timing, and magnitude, persistence, and duration of algal standing crop."[42] According to the report, "Iron Gate reservoir is the second relatively large mainstem reservoir on the Klamath River below Upper Klamath Lake. Iron Gate reservoir receives large hydraulic and nutrient loads from the inflowing Klamath River. The result of these substantial upstream loads is a eutrophic reservoir."[43]

Only the U.S. Environmental Protection Agency, ("EPA"), and neither the U.S. Department of Interior Fish and Wildlife Service, nor the Federal Energy Regulatory Commission, is responsible for enforcing the provisions of the U.S. Clean Water Act ("CWA") in waters of the United States ("WOTUS") within the State of California. If California State water quality standards are inadequate to protect a WOTUS (e.g., the Klamath River that flows from southern Oregon through northern California on its way to the Pacific Ocean) via imposition of point source (i.e., discrete conveyance (pipe or tunnel)) pollution effluent limitations or permitting adjustments, then California must identify and list the Klamath River as "impaired," pursuant to CWA§ 303(d). California would then be required, pursuant to CWA § 303(d)(1)(A), to identify the Klamath River and, pursuant to CWA § 303(d)(1)(C), to determine the "total daily maximum load" ("TMDL") for each problematic pollutant in said river. The TMDL, generally is the calculation of the maximum amount of each such pollutant that can occur in the waterbody (i.e., the Klamath River) without causing it not to meet State water quality standards.[44]

Pursuant to USEPA rules, the California's TMDL for the Klamath River must allocate the necessary reductions to one or more pollution sources, including nonpoint sources, in order to implement the State's applicable water quality standards.[45] See Pronsolinoz v. Nastri, 291 F.3d 1123, 1139 (9th Cir. 2002). Nonpoint sources of pollution are non-discrete sources, including, for example, sediment run-off from timber harvesting or agriculture. 291 F.3d at 1126. They must be part of the TMDL calculation. 291 F.3d at 1139, citing Alaska Center for the Environment v. Browner, 20 F. 3d 981, 985 (9th Circ. 1994) (holding that "Congress and the EPA have already determined that establishing TMDLs is an *effective tool for achieving water quality standards in waters impacted by non-point source pollution.").*

Furthermore, California is authorized to determine TMDLs also with respect to waterbodies that are affected mostly, if not, entirely by nonpoint source pollution. Pronsolinoz v. Nastri, 291 F.3d at 1139. In fact, USEPA has directed states, including California, to calculate TMDLs for waterbodies and watersheds where nonpoint source pollution arises from different land use activities upstream from a dam.[46] "Soil erosion has been determined to be the major source of suspended solids, nutrients, organic wastes, pesticides, and sediment that combined form the most problematic form of NPS pollution."[47]

It is well-known that upstream agricultural and urban land use can "contribute to contaminant and sediment loads [of dam] reservoirs," and that dam operations "can determine the fate of" pollutants accumulated in reservoir sediment, and "potentially downstream as water is released from the dam." (emphasis added).[48] And, techniques, such as "selective withdrawal, can enable near-surface and below-surface withdrawals of warmer and cooler reservoir waters, respectively, to accommodate the temperature and water quality needs of fish populations in the summer and winter months."[49] However, these techniques offer no guarantee against downstream discharges of contaminated and polluted reservoir sediments potentially threatening human health and welfare.

USEPA has emphasized, for example, how dams act as barriers to the flow of water and to the materials the water transports, which can impact water quality both in the dam's impoundment/reservoir and downstream from the dam.[50] The longer the period of time waters and materials are retained in a dam reservoir and are prevented from flowing freely downstream, the more significantly the chemical and physical qualities of that retained water will change.[51] "Water held in a small basin behind a run-of-river dam may undergo minimal alteration," while "water stored for months or even years behind a large storage dam can undergo drastic changes that impact the downstream environment " (emphasis added) and population centers when released. [52]

According to USEPA, "[a] storage dam that impounds a large reservoir of water for an extended time period will cause more extensive impacts to the physical and chemical characteristics of the water than a smaller dam with little storage capacity."[53] "The nature and severity of impacts will depend on the location in the river or stream, in relation to the upstream or downstream side of the dam, the storage time of the impounded water, and the operational practices at the dam." (emphasis added).[54] Physical changes include changes in instream water velocities, timing and duration of flows, flow rates, sediment transport capacities, turbidity, temperature and dissolved gases. Chemical changes include changes in nutrients, alkalinity and pH, metals and other toxic pollutants, and organic matter. And, physical and chemical changes can be interrelated. "For example, changes in temperature may result in changes in dissolved oxygen levels or *changes to pH may result in changes to nutrient dynamics and the solubility of metals."[55]*

As USEPA has found, "[w]hen the stream flow behind a dam slows, the sediment carrying capacity of the water decreases and the suspend sediment settles onto the reservoir bottom. Any organic compounds, nutrients, and metals that are absorbed to the sediment also settle and can accumulate in the reservoir bottom."[56] The longer the holding time in the reservoir, and the more planktonic algal growth in a reservoir, the more likely periodic episodes of turbidity from upstream storm events carrying sediment rich stormwater will result, especially "if the sediment is predominantly very fine clay particles."[57] In addition, the greater the depth of a reservoir, the lower the volume of water that will be exposed to solar radiation and ambient temperatures, and the greater the likelihood of thermal stratification, with reservoir surface water layers bearing different temperatures, different water quality and biological processes, and different water density gradients.[58] Furthermore, the impoundment of accumulated upstream nutrients can cause a dam reservoir to become eutrophic and trigger algal and aquatic plant growth that consumes oxygen and eventually dies, leaving microbially decomposed material that depletes bottom waters of dissolved oxygen and produces potentially toxic concentrations of gases such as hydrogen sulfide.[59] Studies show that microbial decomposition can result in increased levels ammonia and hydrogen sulfide concentrations that affect the pH of reservoir waters. "Highly acidic (or highly alkaline) waters tend to convert insoluble metal sulfides to soluble forms, which can increase the concentration of toxic metals in reservoir waters."[60]

The key question, therefore, that must be answered for CWA purposes, is whether the pollutants and contaminants attributable to upriver nonpoint sources that have long flowed into and accumulated, aggregated and synergized in the reservoir sediments and/or water columns of the John C. Boyle, Copco 1, Copco 2 and Iron Gate Dams have incrementally impaired the water quality of the Klamath River. If the answer to this question is Yes, as it should be, then the States of Oregon and California should have properly characterized and included these dam-related impairments as a load allocation under CWA § 303(d)/40 CFR Part 130 in calculating the TMDL of the Klamath River, for purposes of ensuring that the release of pollutant-laden sediments from each dam's reservoir pursuant to the amended Klamath Hydropower Settlement Agreement ("KHSA") implementation would not adversely impact public health and welfare.

Oregon's integrated 2010 Total Maximum Daily Load (TMDL) and Water Quality Management Plan (WPMP) for the Upper Klamath and Lost River Subbasins reveals, consistent with CWA § 303(d) requirements, that the state had identified inter alia point sources and nonpoint sources and developed load allocations for nonpoint sources where the four PacifiCorp dams scheduled for removal are located.[61] In addition, the integrated plan reveals that ODEQ and California's North Coast Regional Water Quality Control Board ("NCRWQCB") had *cooperatively developed a TMDL that "adopt[ed] the Upper Klamath Lake phosphorus TMDL total phosphorus as a boundary condition for developing the Klamath River and lost River TMDLs."[62] ODEQ had intended for this TMDL to cover the Lost River and the Klamath Straits Drain, as well as, the Klamath River from Link River to the Pacific Ocean.[63]*

In March 2010, California submitted to USEPA its 2010 Action Plan for the Klamath River64 as a CWA § 303(d) amendment to the NCRWQCB's Water Quality Control Plan ("WQCP"). The Action Plan, which had aimed to establish the Klamath River Total Maximum Daily Loads (TMDLs) addressing temperature, dissolved oxygen,[65] nutrients,[66] and microcystin[67] impairments in the Klamath River, also referenced the Lower Lost River TMDLs that USEPA had previously established.[68] The 2010 Action Plan reflected USEPA's 2008 decision, in the face of litigation,[69] to reconsider its prior approval of California's omission of microcystin toxins as an additional cause of impairment of the Klamath River segment known as "Klamath River [hydrologic unit] HU, Middle [hydrologic area] HA, Oregon to Iron Gate" from the state's 2006 CWA § 303(d) list submission.[70]

The NCRWQCB's 2010 integrated TMDL/WQMP plan, furthermore, indicated that Oregon and California had worked cooperatively and aligned with "USEPA and its contractor Tetra Tech, Inc. to develop a uniform water quality model of the basin and conduct joint analyses to ensure compatible TMDLs," with each state "establish[ing] independently the TMDLs for those portions of the basin within their respective jurisdiction."[71] This information appears to have been consistent with the Memoranda of Agreements that ODEQ and NCRWQCB had signed with USEPA Regions 9 and 10 in 2008 and 2010, respectively, to develop[72] and implement[73] the Klamath River/Lost River TMDL.

In November 2010, USEPA subsequently approved the NCRWQCB's amended WQCP, in part,[74] and clarified the scope of two Klamath River segments properly included in California's CWA § 303(d) (TMDL) list because of impairments due to sediments – the segments spanning from Scott River to Trinity River, and from Iron Gate Dam to Scott River.[75] USEPA, however, did not fully agree with how California had calculated the TMDLs for the Klamath River to address the temperature, dissolved oxygen, nutrients, and microcystin impairments identified. Principally, it disagreed with the state's categorization of these impairments as a TMDL load allocation.[76]

According to USEPA, "'the incremental impairment from a dam' occurs because river waters containing pollutants (usually nutrients) are impounded, and the resulting change in physical conditions (velocity, depth, etc.) can create conditions in the reservoir that lead to violations or increased violation of water quality standards in the reservoir."[77] USEPA also admitted that "States around the country have taken different approaches to characterizing these incremental impairments from dams" which the agency had approved. As an example, USEPA cited how the State of Washington's Spokane River Dissolved Oxygen

(DO) TMDL, which USEPA had approved, "first identified the incremental impairment from a dam and then assigned that incremental impairment to the dam operator as a 'responsibility' that would be implemented under the CWA 401 certification process."[78] USEPA then noted the complexity of calculating the extent of the Washington dam's impairment of the Spokane River's water quality.

The State first simulated the —natural DO condition of the river by leaving the dam in place and assuming no other sources of pollution; this approach was used to represent the current critical condition (i.e., the dam is there, and there are no plans to remove it). Then the incremental impairment from the dam was calculated as the difference between the current critical condition DO conditions in the reservoir and the impairments that would occur in the reservoir when phosphorus concentrations entering the lake are at minimal levels of human impact, as represented by EPA's ecoregional criterion.[79]

USEPA expressed its disagreement with California's taking of a different approach in calculating its TMDL, asserting that California incorrectly "included the incremental impairments from the Klamath River dams in its load allocation to the dam owner" - PacifiCorp.

USEPA's disagreement with California's approach, however, is based on its thinly veiled belief that the scope of a State's list of "impaired" or "threatened" waterbodies need not be the same as its obligation to do TMDLs. USEPA's position boils down to a previously withdrawn 1999 proposed regulation wherein it disingenuously reasons how it "sees great value in listing waterbodies impaired or threatened by both pollutants and pollution" (emphasis added) pursuant to CWA § 303(d)(1)(A), while requiring states to address only waterbodies "impaired" or "threatened" by pollutants under CWA § 303(d)(1)(C).[80] USEPA's logic, however, is laid bare in its explanation of why the upstream nonpoint source pollutants that have deposited themselves in the reservoirs of each of the four PacifiCorp dams for decades should not be considered a 'load' or 'wasteload' for TMDL purposes.

EPA believes that the incremental impairments from a dam, as discussed above, are not properly characterized as a 'load allocation' under CWA Section 303(d) or its implementing regulations at 40 CFR Part 130. Under CWA Section 303(d)(1)(C), a state is to develop TMDLs for 'pollutants.' EPA does not believe it is appropriate to categorize the incremental impairments from a dam of the kind described in the Final TMDL Report for the Klamath River as a 'load' or 'wasteload' allocation because the dam is not contributing impairment-causing 'pollutants' as defined in CWA Section 502(6).[81]

The slyness of USEPA's position becomes quite apparent when this explanation is compared to how Washington State's TMDL calculation had been reached. Clearly, Washington State had calculated the incremental impairment of the Spokane River attributable to nonpoint source pollutants settling in the dam *reservoir "by leaving the dam in place" (emphasis added).[82] USEPA also had ceded federal jurisdiction to FERC under the auspices of the CWA §401 water quality certification process (i.e., hydroelectric generation-related environmental matters) incident to the dam owner's application for relicensure. Furthermore, USEPA left to the State of Washington the decision regarding whether to act on the FERC-licensed dam owner's application for a water quality certificate within a reasonable time period in order to address the nonpoint source pollution issue, or to waive that right and thereby cede jurisdiction to FERC.[83]*

By analogy, in the case of the Klamath River Dams, USEPA had taken the position that, there can be no load-contributing pollutants at dam reservoirs that will be/have been removed as "the anticipated endpoint" of the KHSA/Amended KHSA process.[84] Therefore, it had decided it should cede jurisdiction to FERC under the auspices of the CWA §401 water quality certification process (i.e., hydroelectric generation-related environmental matters) incident to PacifiCorp's application for license transfer to the Klamath River Renewal Corporation KRRC. USEPA also had decided to leave to the State of California the decision regarding whether to act on KRRC's prospective water quality certificate application to address water quality protection upon removal. Presumably, California recognizes that if it and KRRC were to engage in repeated withdrawal and refiling of applications for water quality certifications, as PacifiCorp had previously done, and thereby failed to provide an expeditious state decision, FERC could interpret those actions as being contrary to the public interest and to the spirit of the Clean Water Act, and thus, as a "waiver" by the State of its CWA §401 authority to require such a certificate.[85] This would result in FERC reasserting its authority to authorize the proposed activity upon license transfer.

In both cases, USEPA conveniently stepped aside and ceded jurisdiction to FERC and the State, when arguably it should have retained federal jurisdiction under CWA § 303(d) to ensure the protection of the public and the environment. The problem is that, in the present case, Klamath River dam removal will pose a genuine threat to human health and welfare which USEPA cannot ignore.

Consequently, USEPA conditioned its December 2010 approval of California's proposed TMDLs upon the NCRWQCB's agreement to characterize and treat the incremental impairments from the four Klamath River dams "as something other than a TMDL load allocation."[86] "Conditioned on this clarification of the characterization of the incremental impairments from dams, EPA concludes that the State Board's submittal meets the requirements of CWA Section 303 and the underlying regulations at 40 CFR Part 130."[87]

In light of USEPA's refusal to treat nonpoint source pollutants and contaminants accumulated, aggregated and synergized in the four Klamath River dam reservoir sediments and water columns as a separate point source of pollution, it also is likely that the agency had not considered any discharge from the four Klamath River dams as a "stormwater" discharge into navigable waters requiring *a National Pollutant Discharge Elimination System (NPDES) permit under CWA § 311 and accompanying regulations.*[88]

In conclusion, without proper notice and comment required by the Administrative Procedure Act, USEPA effectively reinterpreted/changed the CWA § 303(d)/40 CFR Part 130 rules for calculating TMDLs as applied to nonpoint source dam-related impairments to water quality. It also compelled California and Oregon to calculate their jointly developed Klamath River basin TMDLs for temperature, dissolved oxygen, nutrients, and microcystin impairments consistent with that interpretation to ensure they did not reflect the incremental nonpoint source impairments arising from the John C. Boyle, Copco 1, Copco 2 and Iron Gate Dams upon planned dam removal. USEPA compelled this behavior, by otherwise refusing to approve these states' CWA § 303(d) submissions. USEPA, thereafter, in its comments approving the Interior Department Bureau of Reclamation's Draft[89] *and Final*[90] *Environmental Impact Statements/Reports for Dam Removal, expressed biased support for dam removal, without regard to the public health and welfare impacts the release of NPS pollutants and contaminants accumulated in dam reservoir sediments and water columns to the Klamath River would engender upon dam removal. USEPA also granted Interior such approval notwithstanding its "concerns regarding potential impacts to wetlands and the short-term effects on fisheries and water quality from dam deconstruction," because it "believe[d] that those concerns [could] be addressed through the implementation of mitigation measures."*[91] *USEPA, furthermore, supported the Department of Interior's assessment of the environmental benefits to be realized from the KHSA [and Amended KHSA] process*[92] *following dam removal even though those results were uncertain at best.*[93]

Response to Comment ORG44-5

Please refer to Volume I Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* (pages 2-60 to 2-69) for a discussion of the reservoir sediment deposits, including an estimate of annual sediment deposition rates for years following the United States Bureau of Reclamation's (USBR) original sediment core sampling and sediment volume estimates and a discussion of uncertainty in the estimates.

Section 3.2.2 *Water Quality – Environmental Setting* and Appendix C *Water Quality Support Technical Information* discuss the water quality in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean Nearshore Environment under existing conditions, including the water temperature, suspended sediment, nutrient (i.e., nitrogen and phosphorus), dissolved oxygen, pH, chlorophyll-a and algal toxins, and inorganic and organic contaminant conditions measured from 2000 through 2017. Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* specifically discusses the inorganic and organic contaminants measured in the reservoir sediments. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C

Water Quality Support Technical Information. Please also refer to Master Response WQ-1 for further discussion of the role of the Lower Klamath Project Dams/Reservoirs with respect to overall water quality in the Klamath River and Master Response WQ-6 for further discussion of the potential contaminants in reservoir sediments. The environmental setting information in this comment is added to the record, but does not result in changes to the EIR's description of the environmental setting, which includes a broader set of sources, including more recent sources.

Portions of this comment make assertions regarding the Environmental Protection Agency's role in Clean Water Act 303(d) listing and total maximum daily loads (TMDLs), including the Klamath River TMDL process. With respect to the comment's assertion that the existing TMDLs for the Klamath River are improperly framed with respect to non-point source pollution originating from upstream of the Lower Klamath Project, this issue relates to basin planning efforts that are not part of the Proposed Project.

Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* analyzes the potential water quality impacts under the Proposed Project, including potential impacts to water bodies on the 303(d) List within the water quality Area of Analysis (see Table 3.2-3). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Please also refer to Master Response CEQ-2 regarding the role of FERC and the State Water Board.

Comment ORG44-6

USEPA Failed to Exercise its Primary CERCLA Jurisdiction Over the Presence of the Virtually Unexamined and Unreported Decades-Old Contaminants in the Sediments of the Four Klamath River Dam Reservoir Bottoms

Since at least 2006,[94] PacifiCorp, the current owner of the four FERC-licensed Klamath River dams the former Interior Secretary had designated for removal pursuant to the Klamath Hydroelectric Settlement Agreement process, has known about the presence of nonpoint source ("NPS") hazardous substances and pollutants and contaminants attributable to various decades-long upstream Oregon-based industrial activities, which have settled, accumulated and become stored in the sediments at the reservoir bottoms and water columns of each said dam over many decades. However, PacifiCorp has apparently failed to submit the required CERCLA notification to the former and current EPA Administrators to apprise them of such substances at these sites, even though a number of these substances, including heavy metals (such as arsenic and nickel, as well as, chromium, mercury and zinc[95] and inorganic chemicals (such as dieldrin, dioxin, DDT and pentachlorophenol) appeared on the Clean Water Act and CERCLA lists of hazardous substances and would have required further EPA study.[96]

The facts reveal that samples of reservoir bottom sediments had been taken from these locations/sites during 2004-2005 and, again, during 2009-2011, as the 2011 DOI Draft and 2012 Final Environmental Impact Statements' ("DEIS" and "FEIS") discussion of sediment contaminants disclosed.[97] PacifiCorp, therefore, knew or should have known, or should have at least suspected that some of these substances had been released when it discharged reservoir waters from the gates of its facilities. Arguably, EPA became aware of these toxic sediments only because it had participated in Interior Department Klamath Technical Management Team preliminary efforts to evaluate reservoir bottom sediments samples taken from each of the four dams, and had found that there were then "no current public health concerns from direct human exposure to reservoir sediments."[98]

In other words, it is arguable that PacifiCorp knowingly failed to notify the USEPA Administrator of the possibility (probability) of decades of hazardous substances stored (accumulated/aggregated) in the reservoir bottoms of John C. Boyle, Copco 1, Copco 2 and Iron Gate dams.[99] And at least one PacifiCorp consultant had previously identified the potential for CERCLA liability in connection with dam removal, and the need to consider the use of a CERLA § 122 administrative order as a possible risk mitigation tool.[100] It is unknown whether USEPA had ever quietly pursued the negotiation of a settlement agreement to address remedial actions PacifiCorp would need to take that also could be entered as an enforceable consent judgment.[101] CERCLA likely applies in this case, even though there is no record that USEPA has yet added these four PacifiCorp-owned and operated Klamath River dams to the National Priorities List (NPL), commonly known as "Superfund."[102]

The Obama administration USEPA Administrator had been well aware that removal of the four PacifiCorp-owned and operated Klamath River dams pursuant to the Klamath Hydroelectric Agreement (Amended KHSA) process, and consequent release of nonpoint source pollutants, contaminants and hazardous substances which have accumulated and become stored in the bottom sediments of the reservoirs of these dams would pose a substantial threat to human health and welfare. CERCLA requires the USEPA Administrator to ensure that U.S. Department of Health and Human Services' Agency for Toxic Substances and Disease Registry (ATSDR")[103] performed assessments of the health risks associated with such NPS pollutants, contaminants and hazardous substances, taking into account the potential migration of any hazardous substance or pollutant or contaminant through such surface water to downstream sources of drinking water. However, the administrative record does not reflect that USEPA or ATSDR has yet conducted any such health-related risk assessment. In fact, the draft and final versions of the Interior Secretary's environmental impact statements ("DEIS" and "FEIS"), which were intended to satisfy only the requirements of the National Environmental Policy Act ("NEPA"), clearly indicated otherwise.

Although "[a]s part of the Klamath Dam Removal Secretarial Determination studies, a sediment evaluation [had been] undertaken during 2009–2011 to evaluate potential environmental and human health impacts of the downstream release of sediment deposits currently stored behind the dams under the Proposed Action [dam removal],"[104] "[…] special evaluations […] such as risk assessments [had…] not [been] utilized for this [the Secretarial Determination sediment] evaluation." (emphasis added).[105]

When samples were found to exceed human health screening levels, the DOI response was to rely upon Stillwater and Gathard studies claiming the risk would be minimized once the dams were removed because the chemicals were highly volatile and would evaporate or otherwise dissipate rapidly upon exposure to the air.[106]

The Obama administration's former USEPA Administrator also had failed, like the current administration's former USEPA Administrator, to conduct assessments of the indirect risks to human health posed by those hazardous substances known to have "accumulated in invertebrate tissues (i.e., acenaphthene, arsenic, benzo(a)pyrene, DDT/DDE, endosulfan I, endosulfan II, endosulfan sulfate, fluoranthene, hexachlorobenzene, lead, mercury, phenanthrene, pyrene, total PBDEs, total PCBs)" (e.g., crustaceans) that humans could potentially consume.[107] The DEIS and FEIS also clearly stated that, "fish tissue samples […] collected in Copco 1 and Iron Gate Reservoirs and analyzed for total mercury […]" exceeded federal and state criteria and guidelines.[108]

USEPA likely did not conduct assessments of human health risks directly and indirectly tied to the chemicals of concern ("COCs"), hazardous substances, pollutants and/or contaminants contained in the dam reservoir bottom sediments because the methodologies, protocols and processes USEPA had previously utilized in its Integrated Risk Information System ("IRIS") to conduct risk assessments on hazardous substances such as dichlorodiphenyltrichloroethane ("DDT"), dieldrin and pentachlorophenol[109] were then considered questionable, at best. Indeed, in 2011, the National Academy of Sciences had determined EPA's IRIS human and ecological toxicological risk assessment process had been seriously flawed and in need of substantial revision.[110]

In addition, that bore samples taken had been few in number for the total reservoirs' surface acreage and generally taken at relatively shallow depths, would seem to indicate the federal agencies intended to downplay the toxicity of the sediments containing chemicals included on the CWA and CERCLA hazardous substance lists. For example, as the Bureau of Reclamation explained, the 2009 Gathard Engineering Consulting study methods used to analyze the physical and chemical properties of the sediments [were] adequate and the number of samples collected seem[ed] reasonable for an appraisal-level analysis. Appraisal-level designs and cost estimates represent an early stage of *project development based on available data, and are used to determine whether more detailed investigations of a potential project are justified. Reclamation does not use appraisal-level cost estimates to seek Congressional authorization. Approximately 26 samples were collected in the reservoirs and none of these samples contained hazardous material based upon criteria established under the Puget Sound Dredged Disposal Analysis program. The samples were spaced throughout the reservoirs in a reasonable manner, but only one sample was collected at a depth greater than 10 feet of the sediment stored in the reservoir. Considering the size of the impoundments and the costs of removal, the Team recommends collecting additional samples for feasibility design. There would be three reasons for collecting additional samples: 1) to verify the absence of hazardous material at all sediment depths, 2) to obtain physical sediment properties at all sediment depths, and 3) to improve the estimate of the stored sediment volume. The Team believes that it is highly unlikely that hazardous materials exist in the reservoir sediment because with 26 samples collected there would have been at least some indication of contamination. However, this needs to be verified at all sediment depths and for more locations within the reservoir.*[111]

It is rather unfathomable that only 26 bore samples had been taken from the reservoir bottoms of the four dams three of which cover approximately 2,400 surface acres. And although the under-detection of COCs from the few reservoir composite samples was thereafter reported as possibly giving rise to biased results,[112] *DOI (USGS)*[113] *and USEPA, nevertheless, found from the limited data on sediment quality behind the dams that the risk-based and effects-based values for dioxins did not exceed estimated regional background concentrations.*[114] *When samples were found to exceed human health screening levels, as in the case of microcystin growth in dam reservoirs, the DOI response was to claim the risk would be minimized once the dams were removed despite the presence of such toxic substances throughout the Klamath River.*

The record does not reflect, furthermore, that the USEPA Administrator had conducted, as had been required, an assessment of permanent solutions and alternative treatment technologies, or resource recovery technologies that would result in a permanent and significant decrease in the toxicity, mobility, or volume of such hazardous substances, pollutants, and contaminants.[115] *Moreover, the record does not reflect that the EPA Administrator had addressed the long-term effectiveness of various alternatives, taking specific account inter alia of the short- and long-term potential for adverse health effects from human exposure, and the potential threat to human health and the environment associated with excavation, transportation, and redisposal, or containment. Furthermore, the EPA Administrator failed to select a remedial action that is protective of human health as well as the environment.*[116]

Lastly, the record does not reflect that the USEPA Administrator had assessed the human health risks associated with the contamination or potential contamination resulting from the release upon dam removal of the nonpoint *source runoff of upstream-derived hazardous substances, pollutants and contaminants that had settled in the water columns of the four dam reservoirs, and consequently, in the reservoir's surface waters used for recreation. In addition, the Obama administration USEPA Administrator had failed to assess the potentially severe human health risks associated with the release upon dam removal of toxic microcystin[117] occurring in these reservoirs which greatly exceeded recommended federal and state thresholds,[118] and which are acknowledged as also being currently present downriver of the dams[119] and as likely to be present following the dams' removal.[120]*

Response to Comment ORG44-6

Please refer to Master Responses WQ-7 and CEQ-2. Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants* and Appendix C Section C.7 *Inorganic and Organic Contaminants* specifically discuss the inorganic and organic contaminants under existing conditions, including a summary of the inorganic and organic contaminants detected in 25 sediment cores collected during 2006 (Shannon & Wilson, Inc. 2006), the inorganic and organic contaminants detected in 37 sediment cores collected during 2009 to 2010 (USBR 2011), and the subsequent analysis of those sediment cores to evaluate potential impacts from the downstream release of reservoir sediment deposits (CDM 2011). No sediment cores were collected from the reservoirs during 2004 to 2005. Sediment cores collected by Shannon & Wilson, Inc. (2006) occurred in 2006 and the 2012 Klamath Facilities Removal Final Environmental Impact Statement/Environmental Impact Report misstated these sediment cores were collected during 2004 to 2005. While 26 locations were listed for reservoir sediment coring by Shannon & Wilson, Inc. (2006), only 25 locations had reservoir sediment samples collected and no reservoir sediment samples were collected at one location. Overall, the inorganic and organic contaminants were measured at 62 locations on and off the center of the historical river channel with on-site geologists verifying that the 37 sediment cores collected during 2009 and 2010 reached the reservoir-deposited/pre-reservoir sediment boundary to characterize the inorganic and organic contaminants throughout the entire depth of the existing reservoir sediments. The discussion in the comment of only 26 sediment cores collected from the Lower Klamath Project reservoirs neglects to consider the additional 37 sediment cores taken during 2009 to 2010 (USBR 2011). The subsequent analysis by CDM (2011) concluded from multiple lines of evidence, including the inorganic and organic contaminants detected in reservoir sediment cores, that the sediment quality of reservoirs does not appear to be notably contaminated based on the detected chemicals of potential concern in reservoir sediments and comparisons to ecological freshwater and marine Pacific Northwest Sediment Evaluation Framework (SEF), U.S. Army Corp of Engineers Dredge Material Management Program, National Oceanic and Atmospheric Administration Screening Quick Reference Tables (SQuiRT), and Oregon Department of Environmental Quality (ODEQ) bioaccumulative screening levels (SLs) along with comparisons to human health SLs, including U.S. Environmental Protection

Agency residential (total carcinogenic and total non-carcinogenic) regional screening levels (RSLs), California Environmental Protection Agency (CalEPA) Office of Environmental Health Hazard Assessment (OEHHA) California Human Health Screening Levels (CHHSLs), or ODEQ bioaccumulation (human subsistence and human general) SLs. Microcystin concentrations and growth of *Microcystis aeruginosa* in the Klamath River under existing conditions are discussed separately in Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins*, Appendix C Section C.6 *Algal Toxins and Chlorophyll-a*, and Volume I Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* (pages 3-392 to 3-422). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Support Technical Information*. Please also refer to Volume III Attachment 1 Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* for revisions to this section.

Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* specifically analyzes the human (i.e., Potential Impact 3.2-13) and freshwater and marine aquatic species (i.e., Potential Impact 3.2-14) exposure to inorganic and organic contaminants under the Proposed Project due to releases of reservoir sediments during drawdown and interactions with sediment deposits remaining within the reservoir footprints after reservoir drawdown is completed. Additionally, Mitigation Measures WQ-2 and WQ-3 are specified to reduce the short-term significant impact of human exposure to inorganic and organic contaminants in the Middle and Lower Klamath River and the Klamath River Estuary to less than significant. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment ORG44-7

FERC Should Not Have Federal Jurisdiction Over Klamath River Dam Removal

USEPA Retained Primary Jurisdiction Over Dam Removal Under CWA and CERCLA:

The Obama administration USEPA likely recognized that the Federal Energy Regulatory Commission ("FERC") has exclusive authority, under the Federal Power Act ("FPA") (16 U.S.C. §§ 791-828c), to license all nonfederal hydropower projects located on navigable waters. "The hydropower dam relicensing process offers an opportunity to assess the balance between natural resources and the generation of electricity and to address some areas that are determined to be problematic. […] In conjunction with FPA licensing requirements, states and authorized tribes certify that discharges (including those that originate from dams) meet water quality standards under section 401 of the Clean Water Act (CWA)."[121]

On June 16, 2016, the FERC granted "PacifiCorp's May 6, 2016 motion to hold in abeyance the processing of the relicense application for the Klamath

Hydroelectric Project No. 2082,"[122] consistent with the amended Klamath Hydroelectric Settlement Agreement ("KHSA") process.[123] In its ruling, FERC noted that, consistent with the amended KHSA process, "PacifiCorp and a new entity, the Klamath River Renewal Corporation (Renewal Corporation), will jointly file on or around July 1, 2016, an application to transfer the four developments to the Renewal Corporation."[124] In addition, the agency noted that "on or around July 1, 2016, the Renewal Corporation will file an application with the Commission to surrender and remove the four dams, and applications for water quality certifications under section 401 of the Clean Water Act for dam removal with the California State Water Resource Control Board (California Water Board) and Oregon Department of Environmental Quality (Oregon DEQ)."[125]

On June 24, 2016, "with the relicensing proceeding in abeyance,[126] and consistent with Section 6.5.2 of the amended KHSA," PacifiCorp filed with FERC a request to withdraw the prior November 10, 2015 applications for water quality certification it had filed with the California State Water Resources Control Board Oregon Department of Environmental Quality to ensure the California and Oregon portions of Project No. P-2082 were in compliance with CWA § 401 and the respective state requirements.[127] Tongue-in-cheek, PacifiCorp reserved the right to reactivate these applications if the circumstances changed, apparently emboldened that FERC had previously ruled that it would not conclude that repeated withdrawal and refiling of license applications violated the letter of the Clean Water Act.[128] As previously discussed, FERC would, even under these circumstances, retain jurisdiction over the transfer of the four PacifiCorp dam licenses to KRRC, and over KRRC's eventual dam license terminations and decommissions. However, as previously discussed, it is because of USEPA's shrewd maneuver during the last presidential administration that FERC has since retained jurisdiction over the dams.

On January 29, 2019, however, the U.S. Court of Appeals for the District of Columbia Circuit ruled the repeated withdrawal and resubmission of water quality certification requests pursuant to the CWA § 401 process that had been agreed upon between PacifiCorp and the States of California and Oregon did not toll each state's one-year waiver period, and thus, did not trigger new statutory periods of review. Thus, the Court found that FERC had acted arbitrarily and capriciously when it treated each PacifiCorp resubmission of an application over the course of a decade as an independent request subject to a new period of review. "Such an arrangement does not exploit a statutory loophole; it serves to circumvent a congressionally granted authority over the licensing, conditioning, and developing of a hydropower project." Hoopa Valley Tribe v. Federal Energy Regulatory Commission, No. 14-1271 (D.C. Cir. Jan. 25, 2019), slip op. at 11.[129] According to the Court, "Congress intended [CWA] Section 401 to curb a state's dalliance or unreasonable delay." Slip op at 12 citing 115 Cong. Rec. 9264 (1969). The Circuit Court's decision directs FERC "to proceed with its review of, and licensing determination for, the Klamath Hydroelectric Project" (slip op. at 14) (i.e., with the license transfers from PacifiCorp to KRRC), and ultimately, to

KRRC's decommissioning of each dam's hydroelectric transmission, without regard for the risk to human health and welfare that the release of the accumulated toxins in the dam reservoir bottoms would create.

Notwithstanding this recent ruling, USEPA arguably should have jurisdiction over the dam removal process because of the four dam's demonstrated contribution to the impairment of the Klamath River. As the result of the decades-old aggregation of nonpoint source pollutants in each dam's reservoir bottom, the release of those accumulated toxic sediments upon dam removal seriously threatens public health and welfare, within the meaning of CWA § 303(d).

In Clark Fork and Blackfoot, LLC,[130] the FERC ruled that it no longer had jurisdiction over the 120-mile Milltown Project (dam) site located along the Clark Fork River in southwestern Montana where USEPA had designated it as a Superfund site within the meaning of CERCLA,[131] made its remedy selection upon adopting a final three-stage Record of Decision ("ROD"),[132] and the only actions to be undertaken under the proposed license amendment/USEPA ROD concerned the cessation of generation and the dismantling and complete removal of the project.[133] FERC explained that, under these circumstances, it was reasonable to conclude, consistent with CERCLA § 121(e)(1), that no license amendment tantamount to a "permit" would be necessary,[134] since all remedial and restorative actions to be undertaken pursuant to the ROD which USEPA would direct and implement, effectively "transferred […] complete regulatory control […] from the Commission to EPA."[135] According to FERC, There is therefore nothing remarkable about the constraint on our jurisdiction embodied in CERCLA section 121(e)(1). […] The cessation of generation and complete removal of the project by EPA under CERCLA transfers effective regulatory control over the entire project to EPA and leaves the Commission with nothing to regulate. The only authority we can exercise in these unique circumstances is the authority, pursuant to FPA section 6, to accept surrender of the project license. License surrender is not subject to the comprehensive development standard of section 10(a)(1), but to a broad 'public interest' standard, which is not the same thing. [fn] We continue to believe that the public interest is best served if all matters pertaining to decommissioning of the project and removal of the dam pursuant to EPA's remedy selection are addressed by EPA itself.[136]

In the present case, the amended KHSA process calls for the planned decommissioning and removal of the four Klamath River dams. In addition, PacifiCorp arguably should have, but failed, in violation of CERCLA, to notify USEPA of the presence of hazardous substances and chemicals of concern contained in the sediments and water columns of the dam reservoir bottoms that appear in the CERCLA "list of lists," in violation of CERCLA § 103(c). Furthermore, USEPA, knowing of the presence of such substances by virtue of its participation in the amended KHSA process, failed to undertake the type of thorough human health risk assessments of those substances that would have *enabled it to determine whether to properly list the dam sites as falling under the Superfund law (CERCLA), in violation of CERCLA § 105(c)(2).*

Arguably, neither the Interior Department nor FERC should have exercised or had active control and influence over the dismantling and complete removal of the Klamath River dams given the potentially adverse impacts on human health and welfare the removal of the four dams will have, considering the decades-old aggregation of nonpoint source pollutants and toxic contaminants now present in the four dams' reservoir bottoms. Consequently, based on the FERC's prior ruling in Clark Fork and Blackfoot, LLC, FERC's jurisdiction over the Klamath Hydroelectric Project should terminate once it orders the transfers of the four PacifiCorp licenses to KRRC. Thereafter, USEPA should properly retain jurisdiction over all subsequent activities involving the dams which the amended KHSA process anticipates will result in their decommissioning and removal. However, since the removal plan for these dams fail to include the development of an adequate plan of remediation and restoration as prescribed by CERCLA § 121(a) and § 121 (b)(1), since USEPA had failed to previously conduct a robust human health risk assessment consistent with the Clean Water Act and the Safe Drinking Water Act,137 and since USEPA also had failed to ensure that the U.S. Interior Department had conducted a robust evaluation of the composition of the sediment bottoms of each dam's reservoir/impoundment bottom, USEPA must first conduct each such assessments before it can decide that dam removal is in the best interests of the public.

Response to Comment ORG44-7

The commenter asserts that United States Environmental Protection Agency (USEPA), rather than Federal Energy Regulatory Commission (FERC) should have jurisdiction over the proposed dam removal. The comment cites *Clark Fork and Blackfoot, LLC* 110 FERC 61160, which holds that FERC loses jurisdiction when a hydropower facility is being removed under a USEPA Comprehensive Environmental Response, Compensation, and Liability Act *(*CERCLA) remediation plan. However, the Proposed Project is not a removal proposed under a CERCLA remediation plan. *Clark Fork and Blackfoot, LLC* 110 FERC 61160 does not stand for the proposition that FERC does not maintain jurisdiction over license surrender proceedings.

The issue raised by the commenter relates to the actions of federal agencies. Comment noted. Please also refer to Master Response CEQ-2.

Comment ORG44-8

Congress Must Consent to and Ratify the Klamath Basin Agreements Before the Four Klamath River Hydroelectric Power Dams Can be Removed:

The authorization by the States of California and Oregon to remove the four Klamath River dams and their reservoirs, pursuant to the Klamath Basin agreements (i.e., the Amended KHSA process), violates Congress' authority *under Article I, Section 8 (the Commerce Clause) and Article I, Section 10, Clause 3 (the Compact Clause) of the United States Constitution, and under relevant and applicable United States Supreme Court jurisprudence.*

The federal government holds at least seven (7) paramount federal interests in the Klamath River that trump, subordinate and subjugate the rights of the States of California and Oregon to effectively reallocate Klamath River water and use rights among its citizens and the adjacent Indian nations by removing these dams and reservoir-impoundments, especially, in the interest of the privately-owned PacifiCorp, a Federal Energy Regulatory Commission licensee. These paramount federal interests include: 1) the federal navigation servitude; 2) the federal assurance of affordable power; 3) federal flood control; 4) the federal irrigation project operation and management; 5) the federal regulation of environmental protection and pollution control; 6) the federal protection of fish and wildlife; and 7) the federal trust obligation to protect tribal rights.

Furthermore, Congress' and the President's prior legally valid enactment of the Klamath River Basin Compact into federal law in 1957 reaffirmed these paramount federal interests, and further established Congress' primary jurisdiction over the disposition of the four (4) Klamath River hydroelectric power dams in question, pursuant to Article VI, Clause 2 (the Supremacy Clause) of the United States Constitution.

The Klamath Basin Restoration Agreement ("KBRA"), Klamath Hydroelectric Settlement Agreement ("KHSA"), Upper Klamath Basin Comprehensive Agreement ("UKBCA"), the Amended Klamath Hydroelectric Settlement Agreement ("Amended KHSA"), Klamath Power Facility Agreement ("KPFA"), and the prior Wyden-Merkley legislation (SA 3288) collectively address the same federal interests the Klamath River Basin Compact ("KBRC"), which Congress and the President enacted into law in 1957, addressed. Since these agreements would collectively amend the 1957 KRBC, either directly through changes to the KRBC text, or indirectly, through supplements to (protocols implementing) the KRBC text, such agreements and their effective changes to the KRBC, a federal-interstate compact, require the consent and ratification of Congress and the signature of the President to enact such changes into federal law.

The memorandum of law accompanying this submission, which was dispatched recently to various members of Congress explains in detail why Congress has primary interest in and primary jurisdiction over the disposition of the four Klamath River dams in question.

Response to Comment ORG44-8

The issue raised by the commenter relates to the actions of Congress and federal agencies and does not focus on the sufficiency of the EIR in identifying and analyzing the possible impacts of the Proposed Project on the environment and ways in which the significant effects of the project might be avoided or mitigated (CEQA Guidelines section 15204(a)). Please also refer to Master Response CEQ-4.

Klamath River Renewal Corporation, Laura Zagar, Mark Bransom

<u>Comment ORG47-1</u>
GENERAL COMMENTS

General Comment 1. The Proposed Project will provide more environmental benefits to the Klamath River as compared to the other action alternatives considered in the Draft EIR.

We support the Draft EIR's conclusion that the environmentally superior alternative is the Proposed Project, under which the four dams in the Lower Klamath Project would be removed to create free-flowing river conditions. See p. ES-24. As the Draft EIR finds, the removal of the Lower Klamath Project's dams will comply with applicable water quality requirements and provide a wide range of beneficial impacts, including: benefits to aquatic species listed under the Endangered Species Act; long-term beneficial effects on riparian habitat and listed species that rely on such riparian habitat; and benefits for Native American tribes that depend on the Lower Klamath River for fisheries and ceremonial purposes (Draft EIR, Executive Summary, pp. ES-9 to ES-10; ES-24 [finding that the Proposed Project as the environmentally superior alternative]).

KRRC appreciates the State Water Board's detailed examination of a number of other alternatives that potentially would meet some, but not all, of the Proposed Project's objectives. Restoration of free-flowing river conditions per the Proposed Project will provide the maximum benefits to the Klamath River's water quality and ecosystem.

Response to Comment ORG47-1
Thank you for your comments and comment noted.

<u>Comment ORG47-2</u>
General Comment 2. As conditions of license surrender, KRRC will implement comprehensive measures to avoid and minimize the Proposed Project's adverse environmental impacts.

While the Proposed Project will have substantial environmental benefits, we recognize that it will have adverse effects on environmental quality, absent the implementation of appropriate mitigation measures. The scope of state and local authority to require such mitigation measures is limited, because the Proposed Project is under the licensing jurisdiction of the Federal Energy Regulatory Commission (FERC) under the Federal Power Act (California v. Federal Regulatory Commission et al., 495 U.S. 490 (1990)). While regulating the Proposed Project under the non-preempted authority of Clean Water Act Section 401, the State Water Board has authority to require mitigation measures as *necessary to assure compliance with water quality objectives and related water quality requirements (Draft EIR, p. ES-11). However, it does not have jurisdiction to require mitigation of other potentially adverse impacts. Where the Draft EIR identifies potentially adverse impacts that fall outside of the State Water Board's water quality certification authority, the State Water Board has chosen to identify these impacts as significant and unavoidable impacts since they cannot ensure implementation of mitigation measures to reduce the impacts (Draft EIR, Page ES-24).*

The Draft EIR does not reflect, however, that FERC and other agencies considering KRRC's applications for regulatory approvals can and should implement measures to reduce the Proposed Project's adverse effects. Such approvals include the license surrender order, the Biological Opinion under the Endangered Species Act, dredge-and-fill permit under Clean Water Act section 404, and other applicable regulatory authorizations. Before such approvals can be issued, the Proposed Project will also be subject to additional environmental review under the National Environmental Policy Act (NEPA). In addition, the Federal Power Act requires FERC to include terms and conditions in the surrender order that are determined by FERC to be necessary to protect environmental resources and public safety during project decommissioning activities and will serve the public interest.

KRRC has proposed a comprehensive set of mitigation measures for the purpose of license surrender. These measures are described in the Draft EIR as well as in KRRC's Definite Plan, attached to the Draft EIR as Appendix B. The KRRC proposes to implement these measures through the following plans or project components:

- *Risk Management Plan*
- *Draft Recreation Plan*
- *Reservoir Area Management Plan*
- *Cultural Resources Plan*
- *Water Quality Monitoring Plan*
- *Groundwater Well Management Plan*
- *Fire Management Plan*
- *Traffic Management Plan*
- *Downstream Flood Control Improvements*
- *Hazards Material Management Plan*
- *Emergency Response Plan*
- *Noise and Vibration Control Plan*
- *Aquatic Resource Measures*
- *Terrestrial Resource Measures*
- *Road Improvements*

- *Yreka Water Supply Improvements*
- *Recreation Facilities Removal and Development Plan*

We derived many of these mitigation measures from the recommendations in the Final Environmental Impact Statement/Environmental Impact Report completed by the Department of Interior and the California Department of Fish and Wildlife in 2012 (2012 EIS/EIR). KRRC then worked closely with a number of federal and state resource agencies and impacted tribes to carefully review the 2012 EIS/EIR's measures to evaluate the efficacy of those measures and to update the measures where appropriate based on additional data gained from recent dam removal projects in the Western United States.

KRRC has also committed to implement additional measures to reduce the Proposed Project's impacts. For example, we are committed to implement mitigation measures to avoid or minimize any impacts to historical and tribal cultural resources. We developed these measures with Native American tribes that requested consultation under Assembly Bill (AB) 52 (Draft EIR, Chapter 3.12). KRRC will continue to work with these and other tribes in the Klamath Basin as we complete both the National Historic Preservation Act Section 106 consultation process associated with the ongoing FERC surrender proceeding and the Tribal Cultural Resources Management Program as part of a comprehensive Historic Properties Management Plan.

Finally, KRRC is working with state and local agencies participating in the FERC process to develop agreements, referred to in the Draft EIR as "good neighbor agreements," to provide FERC with joint recommendations related to mitigation of the Proposed Project's potential impacts to the extent such impacts are not adequately addressed through KRRC's commitments or the State Water Board's required mitigation measures outlined in the Draft EIR (Draft EIR, ES-11). KRRC is working diligently to reach agreements with key state and local stakeholders in an effort to ensure that their concerns are sufficiently addressed prior to the Proposed Project's implementation.

Response to Comment ORG47-2

This comment concerns the Klamath River Renewal Corporation's (KRRC's) commitment to implement mitigation measures. Comment noted. Please also refer to Master Response CEQ-2.

Comment ORG47-3

General Comment 3. As a condition of license surrender, KRRC will address any potential increased response time and associated wildland fire risk due to implementation of the Proposed Project.

The Draft EIR finds that implementation of the Proposed Project may increase risk associated with wildland fire during the Proposed Project's construction activities and after construction is complete due to the loss of reservoirs as a *potential source of water for fire suppression crews. KRRC is committed to addressing this impact and to reduce any increase in wildland fire risk for the Klamath Basin due to the implementation of the Proposed Project. To that end, KRRC is working closely with CAL FIRE to develop effective ways that KRRC can reduce any increased wildland fire risk during the Proposed Project's construction activities, and to identify ways that KRRC can assist improving emergency response in the Klamath Basin after the Proposed Project is implemented.*

KRRC has prepared a draft Fire Management Plan, which sets forth the initial framework by which KRRC will work with local emergency responders to reduce response time and any associated additional risk attributable to the Proposed Project (Draft EIR, Appendix B [Definite Plan, Appendix 01]). The Fire Management Plan details how KRRC will comply with applicable regulations and requirements set forth by the fire suppression agencies in the Proposed Project vicinity. In the draft Fire Management Plan, KRRC commits to having a designated Safety Officer who will be on-call 24 hours a day, 7 days a week who will be the primary on-site contact for emergency responders and will be responsible for implementing the fire suppression and elimination measures. The Safety Officer will be onsite during the removal of the dam facilities. The Safety Officer and KRRC's contractor will work closely with California and Oregon fire suppression agencies to develop broad scale contingency plans for fire suppression within their respective jurisdictions. During construction, KRRC will take precautionary, pre-suppression and suppression measures to ensure public safety, and will comply with applicable fire season regulations and requirements in California and Oregon (Id., p. 33-35). KRRC will carefully monitor weather patterns that may increase fire hazards during construction and will update operations and fire response plans to address changing environmental conditions while closely communicating with relevant fire suppression agencies (Id, p. 34-35). KRRC will also work closely with emergency responders to ensure that construction operations will not impede emergency vehicles or impede public access to evacuation routes.

The draft Fire Management Plan also includes a preliminary analysis concerning potential sources of replacement water that can be used by fire suppression crews to replace the reservoirs eliminated by the Proposed Project (Id., Chapter 6). KRRC recognizes that fire suppression efforts in the Klamath Basin rely on helicopter crews. As reflected in the draft Fire Management Plan, KRRC has confirmed with CAL FIRE that helicopter fire suppression will be able to draw water from the Klamath River (Id., p. 41; pers. comm., M. Hebrard, February 2019). Because the water must be a certain depth to extract water, KRRC is working with CAL FIRE to identify which specific portions of the Klamath River are suitable for extraction by helicopter crews during wildland fires (Id., p. 41). KRRC appreciates the feedback from the State Water Board that certain potential replacement measures, such as dry hydrants, will not be an effective replacement source of water. However, KRRC continues to work with CAL FIRE *to identify not only replacement sources of water, but ways in which KRRC can facilitate the reduction of overall emergency response times through communications and roadway improvements. KRRC intends to expeditiously finalize the Fire Management Plan in conjunction with our contactor, federal, state, and local fire suppression agencies, and emergency responders.*

Response to Comment ORG47-3
While no text revisions are necessary to the Executive Summary, the additional clarification provided in the comment is noted.

Please also refer to additional information regarding wildfire found in Master Response HAZ-2.

Comment ORG47-4
General Comment 4. The Proposed Project will not result in the procurement of additional fossil fuel generation.

The implementation of the Proposed Project will result in the elimination of a source of hydropower, which PacifiCorp would need to replace in its portfolio. As the Draft EIR correctly concludes, the power that PacifiCorp will procure to replace the Lower Klamath Project's generation will not increase overall greenhouse gas (GHG) emissions (Draft EIR, pp. 2-727 to 730).

As a preliminary matter, PacifiCorp has already accounted for the loss of the generation from the Lower Klamath Project in its Integrated Resource Plan (IRP). Substantial evidence demonstrates that the Lower Klamath Project will not be replaced through the procurement of fossil fuel generation. However, the loss of production attributable to the decommissioning of the Lower Klamath Project loss is many, many times offset by PacifiCorp's acquisition of renewable resources. PacifiCorp's 2017 IRP states that, through the end of 2036, the updated preferred portfolio includes over 2,700 megawatts (MW) of new wind resources, 1,860 MW of new solar resources, 1,877 MW of incremental energy efficiency resources, and approximately 268 MW of direct-load control resources. The 2017 IRP contains no new natural gas resources through the 20-year planning horizon. This is the first time an IRP has not included new fossil-fueled generation as a least-cost, least-risk resource for PacifiCorp. This was reinforced in PacifiCorp's 2017 IRP Update, in which the preferred portfolio continues to assume existing owned coal capacity will be reduced by 3,650 MW through the end of 2036.

The fact that the Lower Klamath Project generation will not be replaced with newly procured fossil fuels is underscored by the energy policies in both California and Oregon. Both states have enacted aggressive renewable energy and carbon reduction goals. In addition to the goals set forth in the Draft EIR, Governor Jerry Brown signed Senate Bill (SB) 100, which accelerates the state's Renewables Portfolio Standard (RPS) to require utilities and other load serving *entities derive 60% of their energy from renewable sources by 2030. SB 100 also requires the state to obtain all of its electricity from carbon-free sources by 2045.*

The State of Oregon also has a state policy to reduce GHG emissions in Oregon to meet certain GHG reduction goals by 2020 and 2050; ORS 468A.205 et seq. In 2016, Governor Kate Brown signed legislation that increased the state's RPS to require utilities to procure at least 50% of its power from renewable resources by 2040. Currently, the Oregon legislature is evaluating a number of bills to further its state policy to reduce GHG emissions. This legislation includes House Bill 2020, which would set new GHG reduction goals for 2035 and 2050 and establish a new "cap and trade" regulatory program administered by a new state agency, the Carbon Policy Office, to address GHG emissions by (1) placing a cap on the total anthropogenic GHG emissions by setting annual allowance budgets for 2021 and 2050; and (2) providing a market-based mechanism for covered entities, which includes certain electric companies, to demonstrate compliance with the program.

In light of aggressive efforts by California and Oregon to increase carbon reduction goals and PacifiCorp's stated intention to replace existing fossil fuel generation with an increasing amount of renewable energy, there is substantial evidence that the loss of the Lower Klamath Project's generation will not result in the procurement of fossil fuel generation.

Response to Comment ORG47-4
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (Greenhouse Gas Emissions and Energy).

<u>Comment ORG47-5</u>
ES-5. Clarify that the timing of the drawdown at Copco No. 2 would be before breaching Copco No. 1 dam, not after.

Suggested revision (second paragraph, second sentence):

"Copco No. 2 Reservoir is substantially smaller than the other three dams and the KRRC proposes to drawdown this reservoir ~~after~~ <u>before</u> Copco No. 1 Dam has been breached to final grade in May of dam removal year 2."

Response to Comment ORG47-5
The Executive Summary has been clarified as requested. Please refer to Volume III Attachment 1 *Executive Summary* for the revision.

Comment ORG47-6
ES-5. To clarify, the capacity of the embankment dam crest is related to the passage of a 1 in 150 probable seasonal flow, which would be a higher standard than the annual rate (i.e., 100-year flood event).

Suggested revision (third paragraph, last sentence):

"During Iron Gate Dam removal, the embankment dam crest would be retained at a level to accommodate the passage of a ~~100-year flood event~~ 1 in 150 probable seasonal flow."

Response to Comment ORG47-6
The Executive Summary has been clarified as requested. Please refer to Volume III Attachment 1 *Executive Summary* for the revision.

Comment ORG47-7
ES-5. Clarify the first sentence to describe the sequencing of the dam removal and reservoir drawdowns.

Suggested revision (second paragraph, first sentence):

"Copco No. 1 Reservoir would be drawn down first (~~November–March of dam removal year 1~~ November of dam removal year 1 to March of dam removal year 2)[1], followed by J.C. Boyle (Oregon) and Iron Gate reservoirs (January–March of dam removal year 2)."

Response to Comment ORG47-7
The Executive Summary has been clarified as requested. Please refer to Volume III Attachment 1 *Executive Summary* for the revision.

Comment ORG47-8
ES-11. Clarify how the State Water Board's limited scope of jurisdiction restricts the scope of mitigation it may require through its water quality certification jurisdiction, resulting in a greater number of determinations of "significant and unavoidable" impacts than would actually happen during the Proposed Project's implementation. Many of these significant impacts will be reduced by the commitments that KRRC has made to fully mitigate adverse impacts of the Proposed Project to the extent feasible. In addition, many of these significant impacts will also be reduced during the additional layers of environmental review and regulatory approvals of FERC, the U.S. Army Corps of Engineers, the U.S. Fish and Wildlife Service, and the National Marine Fisheries Service. Through this extensive regulatory process, these agencies will add additional terms and conditions under which KRRC must comply in the implementation of the Proposed Project that will further reduce significant impacts identified in the EIR.

Suggested revision (last paragraph, "Significant Unavoidable Adverse Impacts")

"Below is a summary, by resource area, of impacts found to be 'significant and unavoidable' with or without mitigation (Table ES-1). Please note, many of these impacts determinations are based on the limitations of the State Water Board's jurisdiction based on the proposed issuance of a water quality certification. This is the first of many agencies' review of the Proposed Project. Before KRRC could implement the Proposed Project, the Proposed Project would undergo additional environmental review and permitting by FERC, the U.S. Army Corps of Engineers, the U.S. Fish and Wildlife Service, and the National Marine Fisheries Service. On balance, this robust federal environmental review and regulatory oversight will result in a reduction of the impacts identified by the State Water Board in this Draft EIR. Because that review has not yet occurred, however, the State Water Board has made significance determinations based only on the scope of mitigation that it can enforce, resulting in a greater number of significant and unavoidable determinations than might actually occur during the Proposed Project's implementation. These impact characterizations are thus conservative from a legal standpoint, and reflect the fact that the State Water Board, by itself, cannot ensure that the significant impacts at issue cannot be mitigated to less than significant levels. For many of these impacts, however, binding mitigation obligations imposed by other regulatory agencies will likely ensure that the impacts will ultimately be mitigated to less than significant levels.

In addition, KRRC has made a wide range of commitments to implement measures to reduce the environmental impacts of this Project. T~~t~~he KRRC proposes to further develop Proposed Project actions relating to certain state and local regulatory requirements for several resource areas that fall outside of State Water Board's water quality certification authority. KRRC anticipates entering into Memoranda of Understanding (MOUs or "good neighbor agreements") with certain state or local agencies, under which KRRC and the relevant agency would provide joint recommendations to FERC to include those terms and conditions in FERC's surrender order.

The State Water Board anticipates implementation of additional measures (e.g., good neighbor agreements between the KRRC and relevant state or local agencies, recommended measures in this EIR, and any modifications developed through the FERC process that provide the same or better level of protection for the resource in question) would reduce impacts. The EIR notes where such protection would eliminate the potential for a significant impact. However, the State Water Board cannot ensure implementation of good neighbor agreements, recommended measures included in this EIR, or modifications anticipated to be developed through the FERC process. Therefore, the State Water Board has identified impacts that rely on implementation of such agreements or recommended measures to reduce impacts to less than significant levels in this EIR as significant and unavoidable in this EIR."

Response to Comment ORG47-8

Please refer to Master Response CEQ-2 regarding the scope of federal preemption and the resulting impact on mitigation measures and findings of significance. The last paragraph of Volume I *Executive Summary – Summary of Proposed Project Effects, Potential Impacts, and Potential Cumulative Impacts – Significant and Unavoidable Impacts* (page ES-11) has been clarified in light of the information in Master Response CEQ-2 and the textual recommendations in the comment.

Comment ORG47-9

ES-14. Clarify under bullet one under Public Service that it is a short-term increase on response times during construction activities. It is also recommended to clarify that the potential increase in response time is unknown at this time. There are a number of factors that contribute to the severity and extent of a wildland fire. It is hard to predict whether any specific factor will contribute to the severity of a fire (pers. comm., M. Hebrard, February 2019). In addition, as conditions of license and surrender, KRRC has committed to implement Recommended Measure PS-1, which will substantially reduce impacts to emergency response time in suppressing wildland fire. KRRC will work closely with fire suppression agencies to finalize the Fire Management Plan consistent with Recommended Measure PS-1.

Suggested revision (top of page, "Public Services")

- *"Short term i~~I~~ncreases in public service response times for emergency fire, police, and medical services due to construction and demolition activities, including construction related traffic; and*
- *~~Substantial~~ Potential increase in response times for suppressing wildland fires where suitable replacement water sources cannot be identified in close proximity to a fire in a location for which the Lower Klamath Project reservoirs would otherwise have been the nearest water source."*

Response to Comment ORG47-9

The *Executive Summary – Summary of Proposed Project Effects, Potential Impacts, and Potential Cumulative Impacts – Significant Unavoidable Adverse Impacts – Public Services – Public Services* first bullet has been revised to clarify that increases in public service response times are related to short-term impacts during construction activities. Please refer to Volume III Attachment 1 *Executive Summary – Summary of Proposed Project Effects, Potential Impacts, and Potential Cumulative Impacts – Significant Unavoidable Adverse Impacts – Public Services* for the revisions. No changes were made to the second bullet because the term "substantial" reflects the standard of significance that is assessed as part of Potential Impact 3.17-2 in Volume I Section 3.17.5 *Public Services – Potential Impacts and Mitigation* (pages 3-915 to 3-919).

Comment ORG47-10

ES-24. Clarify how the State Water Board's limited scope of jurisdiction restricts the scope of mitigation it may require through its water quality certification jurisdiction, resulting in a greater number of determinations of "significant and unavoidable" impacts than would actually happen during the Proposed Project's implementation. Many of these significant impacts will be reduced by the commitments that KRRC has made to fully mitigate adverse impacts of the Proposed Project to the extent feasible. In addition, many of these significant impacts will also be reduced during the additional layers of environmental review and regulatory approvals of FERC, the U.S. Army Corps of Engineers, the U.S. Fish and Wildlife Service, and the National Marine Fisheries Service. Through this extensive regulatory process, these agencies will add additional terms and conditions under which KRRC must comply in the implementation of the Proposed Project that will further reduce significant impacts identified in the EIR.

Suggested revision (last paragraph):

"The KRRC proposes to further develop Proposed Project actions related to certain state and local regulatory requirements that fall outside of the State Water Board's water quality certification authority. The State Water Board anticipates that implementation of additional measures, ~~(e.g.,~~ measures that are ultimately recommended through the good neighbor agreements between the KRRC and relevant state or local agencies, KRRC's commitment to implement certain recommended measures in this EIR, and any modifications developed through the FERC, U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, and/or National Marine Fisheries Service processes that provide the same or better level of protection for the resource in question) would ultimately reduce many of the Proposed Project's impacts to less than significant levels.

In certain instances, the EIR notes where such protection is anticipated to eliminate the potential for a significant impact. However, the State Water Board cannot ensure implementation of good neighbor agreements, recommended measures included in this EIR, or modifications anticipated to be developed through the FERC, U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, the National Marine Fisheries Service processes. Therefore, the State Water Board has conservatively identified impacts that rely on FERC's adoption of measures included in ~~implementation of~~ such agreements, the terms and conditions that may be imposed by FERC, U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, and National Marine Fisheries Service, or recommended mitigation measures in this EIR as significant and unavoidable. As noted above, these impact characterizations are thus conservative from a legal standpoint, and reflect the fact that the State Water Board, by itself, cannot ensure that the significant impacts at issue cannot be mitigated to less than significant levels. For many of these impacts, however, binding mitigation obligations imposed by other regulatory agencies will likely ensure that the impacts will ultimately be mitigated to less than significant levels."

Response to Comment ORG47-10

Please refer to Master Response CEQ-2. Additionally, the *Executive Summary* has revised to clarify how the EIR addresses implementation of measures to reduce potential environmental impacts for resource areas that fall outside of the State Water Board's water quality certification authority. Please refer to Volume III Attachment 1 *Executive Summary* for the revisions.

Comment ORG47-11

ES-26. Table ES-1 currently distinguishes between categories of impacts that are "significant and unavoidable" and categories of impacts that are "significant and unavoidable with mitigation." This is a useful and helpful distinction. KRRC believes that Table ES-1 would be even more informative, however, if the table also identified an additional basis for differentiating amongst these significant unavoidable impacts. KRRC suggests that the table be modified to show a distinction between, on the one hand, impacts that are significant and unavoidable because the State Water Board cannot identify any mitigation measures—including any that might be beyond the State Water Board's regulatory jurisdiction—that would reduce the impacts below applicable significance thresholds; and on the other hand, impacts that the State Water Board considers significant and unavoidable simply because the Board lacks the regulatory authority to impose mitigation on its own. The table is currently misleading insofar as it portrays the Proposed Project as causing a larger number of significant unavoidable impacts than will truly exist once agencies other than the Water Board issue regulatory approvals and the KRRC develops the good neighbor agreements with relevant state and local agencies. As is clear from pages ES-9 through ES-11, the Proposed Project is, on balance, a project that is very beneficial to the environment, and in particular to long-term water quality and the long-term health of fisheries, by reestablishing a free-flowing river condition and volitional fish passage on the Lower Klamath River.

Suggested revision:

Table ES-1 should be modified to include asterisks and other symbols, defined in a key, to indicate whether particular significant unavoidable impacts are labeled as such (i) due to the Water Board's jurisdictional limitations, or (ii) due to the fact that no known mitigation—as imposed by any agency or as imposed by KRRC on itself—is available to reduce the impacts at issue to less than significant levels.

Response to Comment ORG47-11

EIR *Executive Summary* Table ES-1 does distinguish impacts that are significant and unavoidable due to jurisdictional limitations from otherwise significant and unavoidable impacts (i.e., significant impacts for which there is no known mitigation that could be implemented by any agency or Klamath River Renewal Corporation (KRRC) itself, using as asterisk at the end of the impact title. The asterisk is defined at the end of the table as follows: "* Indicates a Significant and Unavoidable Impact that would be reduced to No Significant Impact with Mitigation if one or more Recommended Measures were to be implemented. Due to federal preemption the State Water Board cannot guarantee the implementation of Recommended Measures."

Comment ORG47-12
ES-42. Mitigation Measure TER-5 is applicable to "Potential Impact 3.5-6. Short-term and long-term impacts on culturally significant species in riparian and wetland habitats" in the short-term for the Proposed Project and other alternatives including the Partial Removal Alternative, the Two Dam Removal Alternative, the Three Dam Removal Alternative, and the No Hatchery Alternative.

Suggested revision:

Add TER-5, as revised in later comments, to Potential Impact 3.5-6 in Table ES-1.

Response to Comment ORG47-12
Under the Proposed Project there is no need for Mitigation Measure TER-5 (please refer to Volume I Section 4.4.5.1 *Alternatives – Continued Operations with Fish Passage Alternative – Terrestrial Resources – Vegetation Communities* page 4-165) because the Proposed Project includes a wetland delineation that would be conducted within the Limits of Work at the Lower Klamath Project dams and associated facilities, access and haul roads, and disposal sites, in accordance with the 1987 USACE Wetland Delineation Manual. Mitigation Measure TER-5 is only necessary under alternatives that involve construction of a fish ladder because activities associated with fish ladder construction would not otherwise include a wetland delineation. The State Water Board has modified Mitigation Measure TER-5 in response to ORG47-41. Please refer to Volume III Attachment 1 Section 4.4.5.1 *Alternatives – Continued Operations with Fish Passage Alternative – Terrestrial Resources – Vegetation Communities* for these revisions. The State Water Board has also added Mitigation Measure TER-5 to the alternatives where fish ladder construction would occur (i.e., the Two Dam Removal and Three Dam Removal alternatives). Please refer to Volume III Attachment 1 Section 4.5.5 *Alternatives – Two Dam Removal Alternative – Terrestrial Resources – Vegetation Communities* and Section 4.6.5 *Alternatives – Three Dam Removal Alternative – Terrestrial Resources – Vegetation Communities* for these revisions.

Comment ORG47-13
2-8. Since Table 2.3-1 refers to existing features, the word "modified" should be removed from the description of the diversion tunnels at Copco No. 1. The diversion tunnel at Copco No. 1 would only be modified as part of the Proposed Project.

Suggested revision (Table 2.3-1):

Under column "Copco No. 1": "Overflow spillway with larger control gate and ~~modified~~ diversion tunnel"

Response to Comment ORG47-13
Section 2.3 *Proposed Project – Existing Lower Klamath Project Features* Table 2.3-1 has been clarified as requested. Additionally, based on comment ORG46-44, Table 2.3-1 has been revised to clarify the type of feature that allows water to flow past each of the dams under existing conditions. References to diversion culverts/tunnels are no longer associated with J.C. Boyle and Copco No. 1 dams in Table 2.3-1, since these features are not functional under existing conditions. Please refer to Volume III Attachment 1 Section 2.3 *Proposed Project – Existing Lower Klamath Project Features* Table 2.3-1 for the revisions.

Comment ORG47-14
2-20. Clarify the title of Section 2.6.1 with the following language.

Suggested revision:

"2.6.1 Water ~~Conflicts~~ History in the Klamath River Basin"

Response to Comment ORG47-14
This EIR section focuses on major events associated with water-related disputes in the Klamath Basin and is not intended to be a comprehensive history of water use and/or management in the basin.

The title for Section 2.6.1 of the EIR has been revised for clarity in Volume III.

Comment ORG47-15
2-27. In Table 2.7-1, J.C. Boyle does not require any canal modifications in preparation for drawdown.

Suggested revision:

Under J.C. Boyle tasks:" ~~Modify canal and~~ Prepare for drawdown"

Response to Comment ORG47-15
Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 has been clarified as requested. Please refer to Volume III Attachment 1 Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 for the revisions.

Comment ORG47-16

2-27. In Table 2.7-1, under Copco No. 1 tasks "Modify diversion tunnel, prepare for drawdown" and "Dam modifications" are the same, and one or the other should be removed.

Suggested revision:

Table 2.7-1, under Copco No. 1: ~~Dam modifications~~

Response to Comment ORG47-16

Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 has been clarified as requested by removing references to dam modifications to prevent duplicate references. Please refer to Volume III Attachment 1 Section 2.7 *Proposed Project – Proposed Project Features* Table 2.7-1 for the revision.

Comment ORG47-17

2-27. In Table 2.7-1, revise the schedule under Copco No. 1 for "Power generation facilities demolition" to November 4 to April 14.

Suggested revision:

Under Copco No. 1: "Power generation facilities demolition" to take place November 4 to April 14 (change from October to January).

Response to Comment ORG47-17

Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 date range has been updated to be November 4 to April 14. Please refer to Volume III Attachment 1 Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 for the revision.

Comment ORG47-18

2-32. No improvements to the Access Road from Overlook Point Recreational Facility to Copco Road are envisioned for the project. This bullet point should be removed.

Suggested revision (bottom of page):

- *"Access Road from Long Gulch Recreational Facility to Lakeview Road—some road surface rehabilitation during construction.*
- ~~*Access Road from Overlook Point Recreational Facility to Copco Road—some road surface rehabilitation during construction."*~~

Response to Comment ORG47-18

Section 2.7.1.2 *Proposed Project – Copco No. 1 Dam and Powerhouse – Construction Access and Road Improvements – Road and Bridge Improvements/Replacements* has been revised to remove the reference to the road surface rehabilitation during construction activities on the access road from Overlook Point Recreational Facility to Copco Road. For consistency, Section 3.22.2.3 *Transportation and Traffic – Environmental Setting – Road Conditions– Road and Bridge Improvement/Replacements* has also been revised. Please refer to Volume III Attachment 1 Section 2.7.1.2 *Proposed Project – Copco No. 1 Dam and Powerhouse – Construction Access and Road Improvements – Road and Bridge Improvements/Replacements* and Section 3.22.2.3 *Transportation and Traffic – Environmental Setting – Road Conditions– Road and Bridge Improvement/Replacements* for these revisions.

Comment ORG47-19

2-43. Clarify that KRRC is committed to returning the roads to their "pre-project condition."

Suggested revision (first paragraph, second sentence):

"The KRRC proposes to return roads used for the Proposed Project to an acceptable state <u>(i.e., their pre-project condition)</u>, including mitigating any potential reduction in function attributed to the dam removal work."

Response to Comment ORG47-19

Section 2.7.1.3 *Proposed Project – Dam and Powerhouse Deconstruction – Copco No. 2 Dam and Powerhouse – Construction Access and Road Improvements* has been revised to clarify that the roads would be returned to their pre-project condition. The revision does not change any potential impact assessments, recommended measures, or significance determinations associated with road conditions in the EIR. Please refer to Volume III Attachment 1 Section 2.7.1.3 *Proposed Project – Dam and Powerhouse Deconstruction – Copco No. 2 Dam and Powerhouse – Construction Access and Road Improvements* for these revisions.

Comment ORG47-20

2-46. The first paragraph of this page describes flood release capacity. KRRC's analysis shows that the 1% seasonal flow is about 4,200 cubic feet per second (cfs) for the second half of June and less than 3,000 cfs for July through September, which is different than what is stated in the document. The flow updates should not affect the impact determination. The Proposed Project will maintain flood protection for a 1 in 150 probable flow during dam removal from June 15 to September 30.

Suggested revision (first paragraph):

"The KRRC proposes to remove Iron Gate Dam and its associated facilities following spring runoff of dam removal year 2 (approximately June 1). The embankment dam crest would be retained at a level needed for flood protection, with a minimum flood release capacity of approximately ~~7,000~~ <u>3,000</u> cfs in July (reservoir water surface elevation 2,242.3 feet) and 3,000 cfs in August and

September (reservoir water surface elevation 2,194.3 feet), in order to accommodate the passage of at least a 1 percent probable flood for that time of year. Excavation of the embankment section at Iron Gate Dam would not begin before June 1 of dam removal year 2, and it would be complete by September 30 to minimize the risk of flood overtopping. During excavation, rockfill would be temporarily stockpiled for placement on the downstream slope of a temporary cofferdam. Throughout excavation, access would be provided to the gate control house at the base of the intake tower for flow control."

Response to Comment ORG47-20

The statement has been revised in Section 2.*7.1.4 Proposed Project – Dam and Powerhouse Deconstruction – Iron Gate Dam and Powerhouse – Deconstruction Activities* has been revised to clarify the correct minimum flood release capacity for Iron Gate Dam in July. The revision does not change any potential impact assessments, mitigation measures, or significance determinations in the EIR. Please refer to Volume III Attachment 1 Section 2.*7.1.4 Proposed Project – Dam and Powerhouse Deconstruction – Iron Gate Dam and Powerhouse – Deconstruction Activities* for these revisions.

Comment ORG47-21

2-57. See comment above regarding the flow analysis conducted by KRRC. The flow for Iron Gate in July would be 4,200 cfs, not 7,700 cfs. Text should be clarified with the updated information.

Suggested revision (last paragraph):

"June – approximately ~~7,700~~ 4,200 cfs
July – approximately ~~7,000~~ 3,000 cfs
August/September – approximately 3,000 cfs"

Response to Comment ORG47-21

Section 2.7.2 *Proposed Project – Reservoir Drawdown* has been clarified as requested to indicate the correct minimum flood release capacities for Iron Gate Dam in June and July. The revision does not change any potential impact assessments, mitigation measures, or significance determinations in the EIR. Please refer to Volume III Attachment 1 Section 2.7.2 *Proposed Project – Reservoir Drawdown* for these revisions.

Comment ORG47-22

2-81. An additional location for the settling pond at the existing lower raceways at Fall Creek Hatchery should also be included in the description of the hatchery. This third location is situated within the footprint of existing infrastructure and therefore would have lesser impacts than the other sites being considered.

Suggested revision: (first paragraph, fourth sentence):

"The settling pond would be constructed on one of three ~~two~~ potential nearby sites located on Parcel B lands downstream of the Fall Creek Hatchery, including a location at the existing lower raceways at the hatchery, with a minimally buried or at-grade conveyance pipeline transporting flows from the hatchery to the settling pond."

Response to Comment ORG47-22
Section *2.7.6.2 Proposed Project – Hatchery Operations – Fall Creek Hatchery* has been revised as requested to clarify that the Proposed Project includes constructing the settling pond at one of three potential sites, including a location at the existing lower raceways at the Fall Creek Hatchery (FCH). Please refer to Volume III Attachment Section *2.7.6.2 Proposed Project – Hatchery Operations – Fall Creek Hatchery* for these revisions.

Comment ORG47-23
3-82 Significance Finding for Potential Impact 3.2-1. The Draft EIR finds that the Proposed Project will have beneficial impacts or no significant adverse impacts on water temperature, varying by Project reach, due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-23
Comment noted.

Comment ORG47-24
3-84 Significance Finding for Potential Impact 3.2-2. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on seasonal water temperature, due to morphological changes, due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-24
Comment noted.

Comment ORG47-25
3-106 Significance Finding for Potential Impact 3.2-3. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on water quality in the long term from sediment release due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-25
Comment noted.

<u>Comment ORG47-26</u>
3-109 Significance Finding for Potential Impact 3.2-5. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on water quality in the long term from the alteration in inorganic suspended material, due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-26
Comment noted.

<u>Comment ORG47-27</u>
3-110 Significance Finding for Potential Impact 3.2-6. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on water quality in the long term from the alterations in organic suspended material, due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-27
Comment noted.

<u>Comment ORG47-28</u>
3-111 Significance Finding for Potential Impact 3.2-7. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on water quality in the short term from the release of sediment associated nutrients, due to conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-28
Comment noted.

<u>Comment ORG47-29</u>
3-119 Significance Finding for Potential Impact 3.2-8. The Draft EIR finds that the Proposed Project will have no significant adverse impacts on alterations in nutrients in the long term due to the removal of the dams and will have a beneficial impact on water quality due to the cessation of seasonal releases of total nutrients and the conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-29
Comment noted.

<u>Comment ORG47-30</u>
3-124 Significance Finding for Potential Impact 3.2-9. The Draft EIR finds that the Proposed Project will have no significant adverse impacts to dissolved oxygen due to the short term increases in oxygen demand in the lower reaches, due to the removal of the dams and the conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-30
Comment noted.

<u>Comment ORG47-31</u>
3-131 Significance Finding for Potential Impact 3.2-10. The Draft EIR finds that the Proposed Project will have long term beneficial impacts to the summer and fall variabilities in dissolved oxygen and will have no significant adverse impacts to dissolved oxygen for the daily variability due to the conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-31
Comment noted.

<u>Comment ORG47-32</u>
3-136 Significance Finding for Potential Impact 3.2-11. The Draft EIR finds that the Proposed Project will have no significant adverse impacts to pH levels in the Hydroelectric Reach from the Oregon-California state line and the lower reaches in the short and long term and will have beneficial impacts to pH levels from Copco No.1 to Iron Gate due to the conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Response to Comment ORG47-32
Comment noted.

<u>Comment ORG47-33</u>
3-139 Significance Finding for Potential Impact 3.2-12. The Draft EIR finds that the Proposed Project will have beneficial impacts to levels of chlorophyll-a and algal toxins in the short and long term due to the conversion from reservoir areas to free-flowing conditions.

Suggested revision: None. We concur.

Comment ORG47-35
3-161. In Potential Impact 3.2-15, update the pre-construction activities at Iron Gate by removing "canal" in the description.

Suggested revision (first paragraph, first sentence):

"Under the Proposed Project, pre-construction activities that would potentially affect water quality include ~~canal and~~ diversion tunnel modifications, road improvements, Iron Gate and Fall Creek hatchery modifications, Yreka pipeline modifications, and dam site preparation between June and November of dam removal year 1 (Table 2.7-1)."

Response to Comment ORG47-35
Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Potential Impact 3.2-15 has been revised to clarify the description of Proposed Project pre-construction activities at Iron Gate Dam facilities by removing "canal" from the description of activities.

For consistency, the description of the Proposed Project pre-construction activities at Iron Gate Dam facilities was also updated in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-4 by removing "canal" from the description of activities. Please refer to Volume III Attachment 1 Section 3.2.5 for these revisions.

Comment ORG47-36
3-166. "Short term" for the hatchery is defined in the Draft EIR as the 8-year operation period. Depending on hatchery operations, discharge water temperatures that are above the receiving water temperatures may occur for short periods, but not consistently for 8-years. Although discharge water temperature increases may occur, it is likely that they would last only a matter of hours. Short duration discharges of minimally higher temperature water would unlikely have an effect on receiving water temperatures and the effect would not

be a continuous 8-year impact. The impact is measured to the receiving water not the discharge water.

Suggested revision (first paragraph):

"While the increase in Fall Creek water temperature and subsequent potential increase in Klamath River water temperature due to hatchery discharges would be small, any increase in water temperature would exceed Thermal Plan water temperature water quality standard for COLD interstate waters, and there potentially would be a significant and unavoidable impact without mitigation on water temperature in the Hydroelectric Reach of the Klamath River due to Fall Creek Hatchery under the Proposed Project. <u>It should be noted that although discharge temperatures may be elevated during the short term, the changes would be very short in duration and would not occur continuously during the 8-year period of operation."</u>

Response to Comment ORG47-36
Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-17 has been revised to clarify the time when elevated water temperatures in the Fall Creek Hatchery (FCH) discharges would be expected to occur under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

<u>Comment ORG47-37</u>
3-212. Clarify text reference to Table 3.3-7. The text should refer to steelhead, not spring Chinook salmon as is currently specified.

Suggested revision (second paragraph, last sentence):

"Table 3.3-7 provides a generalized life history periodicity for ~~spring-run Chinook~~ <u>steelhead</u> ~~salmon~~ life stages, with additional timing provided in Appendix E.3.1.4."

Response to Comment ORG47-37
Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Fish – Anadromous Salmonids – Winter Steelhead* has been revised to correct the typographical error noted in the comment. Please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Fish – Anadromous Salmonids – Winter Steelhead* for these revisions.

<u>Comment ORG47-38</u>
3-324. In the short term, it is likely that summer and winter steelhead would use the additional 80 miles of mainstream and tributary habitat in the Hydroelectric Reach for spawning and rearing (not just migration) beginning in the winter/spring of year 2. Spawning would primarily take place in tributaries and

possibly within riffles or newly formed side channels within the previously inundated reservoir areas. See full reference for text revisions below:

- *Hamilton, J.B., G.L. Curtis, S.M. Snedaker, and D.K. White. 2005. Distribution of anadromous fishes in the Upper Klamath River watershed prior to hydropower dams – a synthesis of the historical evidence. Fisheries, 30:10-20.*

Suggested revision (third paragraph):

"In the short term, adults could first access this reach in winter (summer steelhead) or fall (winter steelhead) of dam removal year 2. <u>Because redband /rainbow trout (Oncorhynchus mykiss sp.) are already present in all free-flowing portions of the Hydroelectric Reach and resident O. mykiss have similar life history requirements for spawning and rearing habitats as steelhead, it is probable that steelhead will rapidly use these reaches once the habitats become accessible. Further, Hamilton et al. (2005) summarizes historical evidence of steelhead using tributary streams in the Hydroelectric Reach, including Camp Creek, Spencer Creek, Shovel Creek, Scotch Creek, and Fall Creek.</u> Steelhead could use this reach as a migration corridor, as most sediment released from the reservoirs would likely be eroded within the first six months after reservoir drawdown (by June of dam removal year 2) and would not impede upstream movement. By late spring of removal year 2, elevated SSCs resulting from dam removal would likely have returned to low levels unlikely to impact steelhead."

Response to Comment ORG47-38

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-10 has been revised to incorporate the recommended text. Please refer to Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* for these revisions.

<u>Comment ORG47-39</u>

3-336. There is research that supports the conclusion that the return of anadromous species will deliver marine-derived nutrients to the Upper Klamath Basin, which could bolster the population of fish species. See suggested revision below. The full references are included here:

- *Bilby, R. E, B. R. Fransen, and P. A. Bisson. 1996. Incorporation of nitrogen and carbon from spawning coho salmon into the trophic system of small streams: evidence from stable isotopes. Can. J. Fish. Aquat. Sci. 53:164-173.*
- *Cederholm CJ, Kunze MD, Murota T., Sibatani A. 1999. Pacific salmon carcasses: Essential contributions of nutrients and energy for aquatic and terrestrial ecosystems. Fisheries 24: 6– 15.*
- *Wipfli, M. S., J. P. Hudson, and J. P. Caouette. 1998. Influence of salmon carcasses on stream productivity: response of biofilm and benthic*

macroinvertebrates in southeastern Alaska, U.S.A. Can. J. Fish. Aquat. Sci. 55:1,503-1,511.

In the long term, the return of anadromous species to the Upper Klamath Basin will deliver marine-derived nutrients (MDN), potentially bolstering the forage base for Lost River and shortnose suckers.

Suggested revision (last paragraph):

"In the long term, reservoir removal associated with dam removal under the Proposed Project would eliminate habitat availability and affect Lost River and shortnose suckers in Lower Klamath Project reservoirs. All individual suckers occurring within these reservoirs would likely be lost within the short term and would not be replaced in the long term. <u>However, the return of anadromous species to the Upper Klamath Basin will deliver marine-derived nutrients (MDN), potentially bolstering the forage base for Lost River and shortnose suckers. The delivery of MDN by spawning anadromous fish and their resulting decomposing carcasses has been linked with the enrichment of aquatic and terrestrial ecosystems through numerous studies (Cederholm et al. 1999). MDN are utilized by stream biota through a variety of pathways and may bolster forage items for native fish species directly, such as through the consumption of eggs, fry, and flesh (Bilby et al. 1996); and indirectly by increasing primary productivity in stream ecosystems, thereby increasing the abundance and biomass of other forage items such as macroinvertebrates (Wipfli et al. 1998)."</u>

Response to Comment ORG47-39

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-13 has been revised to include discussion of the benefits of marine derived nutrients from adult salmon accessing habitat upstream of Iron Gate Dam. Please refer to Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* for these revisions.

<u>Comment ORG47-40</u>

3-341. There is research that supports the conclusion that the return of anadromous species will deliver marine-derived nutrients, which could bolster the population of fish species. See suggested revision below.

Suggested revision (fourth paragraph):

"The Proposed Project would restore access for anadromous salmon and steelhead to habitat upstream of Iron Gate Dam, as described in detail above. Restoration of access would result in anadromous salmon and steelhead potentially interacting with resident redband trout and bull trout, with the potential for competition and predation. These species evolved together in the Upper Klamath Basin of the Klamath River, and co-existed prior to the construction of

dams (Goodman et al. 2011). The return of anadromous species to the Upper Klamath Basin will deliver MDN, potentially bolstering the forage base for bull trout, redband, and other native species. The delivery of MDN by spawning anadromous fish and their resulting decomposing carcasses has been linked with the enrichment of aquatic and terrestrial ecosystems through numerous studies (Cederholm et al. 1999). MDN are utilized by stream biota through a variety of pathways and may bolster forage items for native fish species directly, such as through the consumption of eggs, fry, and flesh (Bilby et al. 1996); and indirectly by increasing primary productivity in stream ecosystems, thereby increasing the abundance and biomass of other forage items such as macroinvertebrates (Wipfli et al. 1998)."

Response to Comment ORG47-40
Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-18 has been revised to clarify more information regarding marine derived nutrients. Please refer to Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* for these revisions.

Comment ORG47-41
3-519. Currently, Mitigation Measure TER-1, standing alone, does not provide for unavoidable wetlands impacts. Therefore, it should be clarified that TER-1 works together with TER-5 for all action alternatives to ensure that the Project achieves the net zero loss of wetland function and value standard. Recommend including TER-5 as revised below in the comment on page 4-166 to mitigation for Potential Impact 3.5-1. For reference, our suggested revised version of TER-5 is included below.

Suggested revision (third paragraph, Potential Impact 3.5-1):

"Mitigation Measure TER-1 Establish a 20-foot buffer around delineated wetlands. The KRRC shall establish a minimum of a 20-foot buffer around all delineated wetlands potentially affected by construction impacts to ensure there will not be any significant environmental impacts to wetlands by deterring heavy machinery from traversing the wetland and preventing runoff pollution from directly entering the wetland where doing so would not result in a significant environmental impact. The buffer may be adjusted (e.g., made larger or smaller) based on site-specific conditions, as determined by a qualified biologist acceptable to USACE, as necessary to ensure adequate protection of the delineated wetlands. To the extent that impacts to wetlands cannot be avoided, KRRC shall comply with mitigation measure TER-5 to ensure no net loss of functions and values. The State Water Board has the authority to include this mitigation measure in its water quality certification for the project, and the measure is therefore feasible and used in this analysis to make a significance determination.

Mitigation Measure TER-5 − Identification, protection, and restoration of wetland and riparian habitats. The KRRC shall conduct a wetland delineation within the limits of construction in accordance with the 1987 U.S. Army Corps of Engineers (USACE) Wetland Delineation Manual (USACE 1987) and applicable Regional Supplements (i.e., Western Mountains, Valleys, and Coast Region [USACE 2010] and Arid West [USACE 2008]). The results of the wetland delineation shall be incorporated into all alternatives, except for the No Project Alternative, ~~the Continued Operations with a Continued Operations with Fish Passage Alternative design~~ to avoid and minimize direct impacts on wetlands to the maximum extent feasible, and wetland areas adjacent to the construction Limits of Work shall be fenced to prevent inadvertent entry. Where avoidance is not feasible the KRRC shall develop a restoration plan to re-vegetate all areas disturbed during construction with a goal requirement of no net loss of wetland or riparian habitat acreage or no net loss of overall functions and values. The restoration plan shall include details on revegetation native seed mixes based on existing species that will be impacted and installation techniques for container plants and seeds. Wetlands established in restored areas would be monitored for five years or until the performance criteria, as defined in the restoration plant that shall be developed, have been met."

Response to Comment ORG47-41

Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Mitigation Measure TER-1 has been modified as requested, except that this sentence "To the extent that impacts to wetlands cannot be avoided, Klamath River Renewal Corporation (KRRC) shall comply with mitigation measure TER-5 to ensure no net loss of functions and values" has not been added because it is not necessary. Under the Proposed Project there is no need for Mitigation Measure TER-5 because the Proposed Project includes a wetland delineation that has been conducted within the Limits of Work at the Lower Klamath Project dams and associated facilities, access and haul roads, and disposal sites, in accordance with the 1987 United States Army Corps of Engineers (USACE) Wetland Delineation Manual. Mitigation Measure TER-5 is only necessary under alternatives that involve construction of a fish ladder because activities associated with fish ladder construction would not otherwise include a wetland delineation. Please refer to Volume III Attachment I Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* for the revisions.

Mitigation Measure TER-5 has been modified as requested. Please refer to Volume III Attachment 1 Section 4.4.5.1 *Alternatives – Continued Operations with Fish Passage Alternative –Terrestrial Resources – Vegetation Communities* for these revisions. Mitigation Measure TER-5 has been added to the alternatives where fish ladder construction will occur (i.e., the Two Dam Removal and Three Dam Removal alternatives). Please refer to Volume III Attachment 1 Section 4.5.5 *Alternatives – Two Dam Removal Alternative –Terrestrial Resources – Vegetation Communities* and Section 4.6.5 *Alternatives – Three*

Dam Removal Alternative –Terrestrial Resources – Vegetation Communities for these revisions.

Comment ORG47-42

3-530. Clarify the wording of Mitigation Measure TER-2.

Suggested revision (second paragraph, last sentence):

"These features of TER-2 will be implemented to reduce the impacts to less than significant ~~such that there is no significant impact~~ on special-status amphibians and reptiles."

Response to Comment ORG47-42

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for these revisions.

Comment ORG47-43

3-531. Clarify the wording of Mitigation Measure TER-3

Suggested revision (first paragraph, last sentence):

"These features of TER-3 will be implemented to reduce the impacts to less than significant ~~such that there is no significant impact~~ on western pond turtles."

Response to Comment ORG47-43

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for these revisions.

Comment ORG47-44

3-561. This statement appears to be missing words between "frogs" and "loosen," or otherwise requires clarification: "If suspended sediment settles further downstream, and/or foothill yellow-legged frogs are present, the presence of settled fine silt in slow moving portions of the river reaches would not likely affect the adhesion of egg masses based on foothill yellow-legged frogs loosen algae and sediment that could enhance the ability of egg masses to adhere to the substrate (Rombough and Hayes 2005)."

Suggested revision: Clarify sentence.

Response to Comment ORG47-44

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* has been revised to clarify the typo and sentence structure. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for these revisions.

Comment ORG47-45

3-562. Based on surveys conducted in 2018, biologist noted the great blue heron colony is no longer active at Copco 1, but has now become active at the Copco Bypass. Suggest removing reference to the great blue heron colony at Copco 1, as it is no longer active.

Suggested revision:

"The loss of aquatic reservoir habitat would also reduce foraging opportunities for fish-eating birds including bald eagle, osprey, merganser, cormorant, egret, and heron ~~(including the great blue heron rookery documented at Copco No. 1 Reservoir~~ (PacifiCorp 2004b)."

Response to Comment ORG47-45

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* has been revised as requested. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for the revisions.

Comment ORG47-46

3-567. Surveys in 2018 indicated a change in the number of turtles at Copco No. 1 and Iron Gate. See revisions below for updated information. This should not change the impact determination.

Suggested revision (third paragraph, fifth sentence):

"Surveys conducted in Copco No. 1 Reservoir in 2002 documented 12 turtles while surveys in 2018 documented ~~31 to 36~~ 42, which ~~are~~ is similar to the anticipated density estimate. Surveys conducted in Iron Gate Reservoir in 2002 documented 8 turtles, while surveys in 2018 also documented ~~17~~ 8, which is lower than the anticipated density estimates."

Response to Comment ORG47-46

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* has been revised to clarify the number of western pond turtles observed. Please refer to Volume III Attachment 1 Section 3.5.5.3 Terrestrial Resources – Potential Impacts and

Mitigation – Special-status Species and Rare Natural Communities for these revisions.

<u>Comment ORG47-47</u>

3-571. The text in the second paragraph describes the use of herbicides. During informal consultation with NMFS under Section 7 of the Endangered Species Act, additional guidance on the use of herbicides was provided by NMFS. See revised language below.

Suggested revision (second paragraph):

Include the following input KRRC received from NMFS during informal Endangered Species Act Section 7 consultation, as applicable, in a revised discussion on herbicides:

<u>"KRRC's evaluation of herbicides for the Biological Assessment concluded that glyphosate formulation Rodeo is associated with the relatively lowest aquatic toxicity among agency-approved herbicides and should be considered if chemical control is determined to be a best practice for IEV management near or adjacent to aquatic systems, presenting less risk than the other herbicides evaluated to aquatic wildlife (including Coho salmon and their prey). Care must be taken to select adjuvants (additions like surfactants) that have low toxicity.</u>

- *<u>Aquatic formulations of glyphosate and imazapyr are favorable for use with adjuvants that have low toxicity.</u>*
- *<u>Glyphosate is effective for control of nearly all of the IEV in the action area. In addition, glyphosate has a short half-life in soil, and thus is less prone to leaching than other herbicides. For these reasons, glyphosate is recommended as the primary herbicide for control of IEV in the action area.</u>*
- *<u>For [Invasive Exotic Vegetation] IEV not easily controlled by glyphosate (i.e., bearded creeper), dicamba and metsulfuron may be preferable due to low average half-lives in soil compared to other herbicides."</u>*

Response to Comment ORG47-47

The text cited in the comment is associated with Section 3.5.5.2 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* Potential Impact 3.5-24. This potential impact analysis focuses on the potential for adverse impacts on terrestrial species (e.g., raptors, terrestrial mammals) as a result of herbicide use during reservoir restoration activities in the newly exposed areas of the reservoir footprints as well as in upland areas. The text revisions suggested in the comment reference herbicide application near or adjacent to aquatic systems, and they reference the potential for aquatic toxicity, which is a related but separate topic that is discussed in EIR Potential Impact 3.2-16 *Short-term impacts to aquatic biota from herbicide application during restoration of the reservoir areas* (pages 3-162 and 3-163).

Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* Potential Impact 3.5-24 has been revised to clarify that potential impacts on aquatic biota are analyzed elsewhere in the EIR. Please refer to Volume III Attachment 1 Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* for these revisions.

Additionally, Section 3.2.5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Mitigation Measure WQ-4 has been revised to clarify that Rodeo is an acceptable aquatic formulation of glyphosate and to distinguish that POEA and R-11 are surfactants that shall be avoided for the purpose of herbicide application. The other revisions suggested in the comment are unnecessary because Mitigation Measure WQ-4 is already consistent with the use of other herbicides possessing the proper characteristics that would minimize toxicity to aquatic biota. However, the guidance from National Marine Fisheries Service (NMFS) is noted and included in the record. Please refer to Volume III Attachment 1 Section 5.7 *Water Quality – Potential Impacts and Mitigation – Inorganic and Organic Contaminants* Mitigation Measure WQ-4 for these revisions.

Comment ORG47-48

3-601. In Table 3.6-4 the units for depth should be feet, not feet above mean sea level. Recommend revising table column headers.

Suggested revision:

"Average Depth" and "Maximum Depth": "(feet ~~amsl).~~"

Response to Comment ORG47-48

Section 3.6.2.2 *Flood Hydrology – Environmental Setting Basin Hydrology – Upper Klamath Basin – Upper Klamath Lake and Link River Dam* Table 3.6-4 has been slightly revised to clarify units of reservoir depth.

Comment ORG47-49

3-701. Section 3.9.4, Clarify text with following revision (note all text would be added to the 2018 EIR, but the strikeout/underline in text below indicates changes from the 2012 EIS/EIR mitigation measure):

Suggested revision (third paragraph):

"Appendix N contains an estimate of "uncontrolled emissions" and an estimate of emissions after implementation of mitigation measures that were proposed as part of the analysis in the 2012 KHSA EIS/EIR. These included Mitigation Measures Air Quality (AQ)-1 (Off-road construction equipment), AQ-2 (On-road construction equipment), AQ-3 (trucks used to transport materials), and AQ-4 (Dust control measures). <u>As conditions of license surrender, KRRC has</u>

committed to implement the following mitigation measures from Appendix N as updated below: ~~Mitigation Measures AQ-1 through AQ-3 required off-road construction equipment and on-road construction equipment and trucks to be equipped with engines that meet certain model year emissions standards. Mitigation Measure AQ-4 required dust control measures to minimize fugitive dust emissions during construction activity.~~

- *AQ-1 – For the construction activities occurring within California, any off-road construction equipment (e.g., loaders, excavators, etc.) that are 50 horsepower or greater must be equipped with engines that meet the EPA Tier 4 Final emission standards for off-road compression-ignition (diesel) engines, unless such an engine is not available for a particular item of equipment. To the extent allowed by California Air Resources Board Off-Road Diesel Fueled Fleets regulations, Tier 3 and Tier 4 interim engines will be allowed when the contractor has documented, with appropriate evidence, that no Tier 4 Final equipment or emissions equivalent retrofit equipment is available or feasible. Documentation may consist of signed written statements from at least two construction equipment rental firms.*
- *AQ-2 – Any heavy-duty on-road construction equipment must be equipped with engines that meet the MY 2010 or newer on-road emission standards.*
- *AQ-3 – Any heavy-duty trucks used to transport materials to or from the construction sites must be equipped with engines that meet the MY 2010 or later emission standards for on-road heavy-duty engines and vehicles. Older model engines may also be used if they are retrofitted with control devices to reduce emissions to the applicable emission standards.*
- *AQ-4 – Dust control measures will be incorporated to the maximum extent feasible during blasting operations at Copco No. 1 Dam. The following control measures will be used during blasting activities as applicable: Conduct blasting on calm days to the extent feasible. Wind direction with respect to nearby residences must be considered. To the extent that blasting cannot be limited to calm days, install wind fencing for control of windblown dust during blasting activities. Design blast stemming to minimize dust and to control fly rock.*
- *These updated Mitigation Measures AQ-1 to AQ-4 are more protective than those in the 2012 KHSA EIS/EIR. Even with the implementation of these mitigation measures, ~~the 2012 KHSA EIS/EIR determined~~ construction emissions from the Proposed Project would still result in significant and unavoidable impacts from NOx and PM10."*

Response to Comment ORG47-49

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality*).

Comment ORG47-50

3-737. Paragraph 1 and Table 3.11-1: Table 3.11-1 includes Cedar Mountain fault zone but not Meiss Lake fault, which is the closest active fault to the Lower

Klamath Project and is within the Cedar Mountain fault zone. However, the text discusses the Meiss Lake fault, but not its relation to the Cedar Mountain fault zone. Recommend reconciling the table information and the text with the following revisions.

Suggested revision (first paragraph, second sentence):

"In California, the nearest active fault to the Lower Klamath Project is the Meiss Lake fault<u>, which is part of the Cedar Mountain fault zone and</u> approximately 5 miles east of the Klamath River near the California-Oregon State line in Siskiyou County."

In Table 3.11-1 under Fault include: "Cedar Mountain fault <u>– Meiss Lake fault.</u>"

Response to Comment ORG47-50
Section 3.11.2.1 *Geology, Soils, and Mineral Resource – Environmental Setting – Regional Geology* has been revised to clarify that the Meiss Lake fault is part of the Cedar Mountain fault zone. Please refer to Volume III Attachment 1 Section 3.11.2.1 *Geology, Soils, and Mineral Resource – Environmental Setting – Regional Geology* for the revision.

<u>Comment ORG47-51</u>
3-765. Mitigation Measure GEO-1: KRRC is committed to protecting surrounding properties throughout drawdown. For example, materials will be stockpiled on-site for immediate road repairs (continuous access will be needed by KRRC and other state agencies, in addition to local residents). Potentially affected properties will be mitigated in advance (buy-out, slope reinforcement, or temporary relocation of resident during drawdown and monitoring). Additional details will be provided in the final Rim Stability Analysis.

Suggested revision (second paragraph):

"~~Following~~ <u>Throughout</u> drawdown activities, and <u>when</u> ~~once~~ the areas are safe to inspect, the KRRC shall inspect any slope failures and implement slope stabilization measures, as appropriate. <u>Additional details will be included in the final Rim Stability Analysis prepared for the project.</u> For any large slope failure that occurs during drawdown or the year following drawdown, KRRC will offset potential impacts by implementing the following actions:

1. Move affected structures or purchase affected property,
2. Re-align affected road segments,
3. Engineer structural slope improvements (e.g., drilled shafts or other structural elements that could be installed to resist slope movement), and
4. Revegetate affected areas."

Response to Comment ORG47-51

Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation,* Mitigation Measure GEO-1 in Potential Impact 3.11-3 has been revised to reflect changes agreed to by the Klamath River Renewal Corporation (KRRC) on March 7, 2020. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 for the final Mitigation Measure GEO-1. The Klamath River Renewal Corporation's (KRRC's) agreement to the final Mitigation Measure GEO-1 supersedes the KRRC's 2019 comments proposing edits to Draft EIR Mitigation Measure GEO-1.

Comment ORG47-51.1

While the best available science suggests that there will not be significant impacts from sediment delivery to the Pacific Ocean nearshore environment, KRRC suggests including language to confirm that KRRC will have sufficient insurance coverage to the extent sediment delivery to the Pacific Ocean nearshore environment requires dredging to maintain marine navigation in, for instance, Crescent City Harbor.

Suggested revision (seventh sentence, first paragraph):

"The short-term (less than two years following dam removal) and long-term (2–50 years following dam removal) effects of the Proposed Project on sediment delivery to the Pacific Ocean would be less-than significant, given the relatively small amount of total sediment input from reservoir sediment release in comparison to the total annual naturally occurring sediment inputs to the nearshore environment. Although the best available science indicates no measurable impacts to the Pacific Ocean nearshore environment, KRRC has committed, as a condition of license surrender, to implement mitigation measures as necessary to address such impacts should they occur and to protect maritime navigation in, for instance, Crescent City Harbor."

Response to Comment ORG47-51.1

The Klamath River Renewal Corporation (KRRC) indicates in this comment that they have committed, as a condition of license surrender, to implement measures as necessary to address impacts to Pacific Ocean Nearshore Environment in the vicinity of the Klamath River mouth should they occur and to protect maritime navigation (e.g., Crescent City Harbor). The EIR does not identify significant individual or cumulative sedimentation impacts from the Proposed Project on the Pacific Ocean Nearshore Environment in the vicinity of the Klamath River mouth and Crescent City Harbor. Therefore, CEQA does not require mitigation for short- or long-term sediment deposition.

Comment ORG47-52

3-826. Clarify text describing various resources that could be eligible for inclusion on the National Register of Historic Places.

Suggested revision (last sentence, first paragraph):

"Resources identified as villages, cairns or burial sites, or other sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis."

Response to Comment ORG47-52

Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* has been revised as requested. Please refer to Volume III Attachment 1 Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* for the revision.

Comment ORG47-53

3-828. Clarify the sentence describing historic artifacts that are present in the Hydroelectric Reach from the Oregon-California state line to Copco No. 1.

Suggested revision (second sentence, first paragraph):

"Historic period refuse scatters, ~~an~~ historical hotel ruin sites, historical ranching sites, and historic roads are also present."

Response to Comment ORG47-53

Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* has been revised as requested. Please refer to Volume III Attachment 1 Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* for the revision.

Comment ORG47-54

3-832. Include Copco No.1 to make the sentence on existing TCRs more specific to that dam.

Suggested revision (first sentence, third paragraph):

"There is at least one TCR that was present at Copco No. 1 before dam construction that would be potentially impacted."

Response to Comment ORG47-54

Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* has been revised as requested. Please refer to Volume III Attachment 1 Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* for the revision.

<u>Comment ORG47-55</u>

3-838. Include Shasta Indian Nation to the list of tribes with TCRs in the Area of Analysis Subarea 1. Resources from other tribes are not known to be in this area.

Suggested revision (first sentence, fifth paragraph):

"Tribal cultural resources known to the Shasta Nation <u>and Shasta Indian Nation</u> to be within the Area of Analysis Subarea 1 include resources identified in PacifiCorp (2004a) and Daniels (2006), as updated by Confidential Appendix Q, Attachment 4."

Response to Comment ORG47-55

Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* has been revised to refer to the Shasta people rather than to a specific Native American entity. Please refer to Volume III Attachment 1 Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* for the revision.

<u>Comment ORG47-56</u>

3-913. Potential Impact 3.17-1 – Suggested revision to reflect the commitments that KRRC intends to implement to reduce the risk of increased public services response times for emergency fire, police, and medical services due to the Proposed Project's construction and demolition activities.

Suggested revision (last paragraph):

"The Proposed Project could result in a significant impact if it results in substantial increases in emergency response times within the Area of Analysis. <u>KRRC has committed to developing a Traffic Management Plan, a draft of which is attached as Appendix O2 to the Definite Plan (Appendix B of this Draft EIR).</u> ~~In general, development of an adequate Traffic Management Plan (Traffic Management Plan)~~ <u>This Traffic Management Plan</u> would mitigate the potential short-term impacts of construction-related traffic and therefore minimize changes to public service response time. Under the Proposed Project, demolition and construction areas would be closed off to the public to reduce hazards. Due to the rural nature and low concentration of roads in the area, most existing roads are currently used, and would continue to be used, by emergency responders and for evacuation routes in the event of fire or other emergencies. The use of these roads for construction activities could interfere with emergency response and evacuation. The potential for substantial interruptions to road access for property owners within the public services Area of Analysis during construction activities would not be a significant impact since alternative routes are or would be made available as part of the proposed Traffic Management Plan ~~(Traffic Management Plan)~~ (Section 3.22 Transportation and Traffic). The KRRC's

Traffic Management Plan is a specialized program tailored to minimize impacts by applying a variety of techniques, including the following:

- *Public Information – use of telephone hotlines, a Traveler Information System via the Project website, local community outreach (meetings, newsletters, etc.), press release(s), and local news media, as appropriate, to ensure the public have easy access to current or upcoming interruptions to the local or state road network*
- *Motorist Information – use of portable changeable message signs, stationary mounted signs, and highway advisory radio to provide advanced notice to motorists of potential traffic delays throughout the project sites and associated access routes*
- *Incident Management – traffic procedures to be adopted in the case of an incident on a road or highway, developed in collaboration with local and state agencies, and in accordance with local and state requirements*
- *Construction Strategies – scheduling of road closures and notifying the public of detours; planning signage and traffic control, including with respect to work zones and construction vehicles; scheduling haul trips to avoid peak hours; identifying emergency detours; managing potential safety hazards from haul vehicles and dust; and providing access for pedestrians and bicycles.*

As a condition of license surrender, the ~~major objectives of the~~ KRRC is committed to ensure that the Traffic Management Plan ~~are to~~ will maintain efficient and safe movement of vehicles through the construction zone covered by activities in the Definite Plan and to provide public awareness of potential impacts to traffic on both haul routes and access roads to the four dams and associated facilities. The Traffic Management Plan outlines the structure and key requirements that would be incorporated by the KRRC's contractor into a final Traffic Management Plan. The final Traffic Management Plan would be informed by KRRC's contractor's specific means and methods for construction~~,~~ and input received from relevant local jurisdictions, which could refine the approach to access and traffic management. KRRC proposes that the final Traffic Management Plan would meet applicable regulatory permit requirements, as well as applicable state and local ordinances, as appropriate (Appendix B: Definite Plan – Appendix O2). By reducing the potential for traffic incidents during construction and demolition activities, implementation of the final Traffic Management Plan would reduce the potential for increased public services response times for emergency fire, police, and medical services.

Construction activities would involve staging and stockpiling areas and equipment that would be kept on-site for the duration of construction. The Limits of Work (Figures 2.7-2 and 2.7-4) would include activities that may result in accidental spills of flammable liquids or use of equipment that generates heat, such as welding, grinding, torch-cutting, gas and diesel generators. Other construction activities could result in open sparks or flame in vegetated open space that could further aggravate the risk of fire. Emergency and Security *services would be provided by the construction contractor, therefore the Proposed Project would not increase the need for emergency services or the number of emergency responders. What is important for the reduction of impacts is that all construction workers have the knowledge and resources to respond to emergencies and all emergency preparation and work are overseen by a designated health and safety manager, which is proposed as part of the Proposed Project. In addition, the Proposed Project (Appendix B: Definite Plan) proposes that responding agencies and departments are made aware of the activities during the construction period so that they can implement their existing regulatory framework, establish an emergency contact process, and include inspections as needed throughout the process.*

In particular, the Proposed Project includes a Hazardous Materials Management Plan (Appendix B: Definite Plan – Appendix 03) to address the management of hazardous materials during Project construction. The Hazardous Materials Management Plan identifies potential hazardous materials that may be encountered at J.C. Boyle, Copco No. 1 and No. 2, and Iron Gate dams and their powerhouses, and the anticipated sampling, testing, abatement, and disposal of hazardous materials. KRRC will update the Hazardous Materials Management Plan, as appropriate, based on the Phase I-Environmental Site Assessment visits and interviews and the Phase II Site Investigation, if needed. The Final Hazardous Materials Management Plan will be submitted to the State Water Board Deputy Director for review and approval. By reducing the potential for hazardous materials incidents during construction and demolition activities, implementation of the Final Hazardous Materials Management Plan would reduce the potential for increased public services response times for emergency fire, police, and medical services.

Mitigation Measure HZ-1 and Recommended Measure TR-1 would reduce the potential impacts related to construction activities since these measures require that the KRRC and its contractor(s) for the Proposed Project submit the additional documentation/details included in the final Emergency Response Plan, Fire Management Plan, Traffic Management Plan, and a Hazardous Materials Management Plan, and they work with applicable agencies prior to the start of construction. Implementation of these two measures would reduce the potential for a short-term increase in personal and public health and safety risks due to the Proposed Project as related to emergency response services. There would be no long-term impacts due to the Proposed Project construction-related activities since the construction would be completed in the short term."

Response to Comment ORG47-56

This comment is generally consistent with Mitigation Measure TR1 – Traffic Management Plan and contains additional statements already in Klamath River Renewal Corporation's (KRRC's) Definite Plan (Volume II *Definite Plan – Appendix O-2 Traffic Management Plan*). The State Water Board acknowledges KRRC's commitment to addressing any potential for impacts to public services due to construction related traffic as a condition of license surrender. Additionally, as noted by KRRC in their comment and elsewhere in the EIR, KRRC will be coordinating efforts with emergency service providers as part of their Emergency Response Plan (ESP), Fire Management Plan (FMP) and Hazardous Materials Management Plan (HMMP). Potential Impact 3.17-1 has been revised to reflect that Recommended Measure TR-1 has been changed to Mitigation Measure TR-1. Please also refer to Master Response CEQ-2.

Please also refer to Master Response HAZ-1.

Comment ORG47-57

3-919. Though outside of the State Water Board's jurisdiction, as a condition of the license surrender, KRRC is committed to working with CAL FIRE to update the Fire Management Plan and to implement Recommended Measure PS-1.

Suggested revision (last paragraph):

"Recommended Measure PS-1 − Fire Management Plan. The KRRC and/or its Contractor(s) shall develop a post-dam removal Fire Management Plan in consultation with the CAL FIRE Siskiyou Unit. The Fire Management Plan shall identify long-term water sources for helicopter and ground crews (including construction and use of proposed dry hydrants, dip ponds, or other alternatives). After reaching agreement on the Fire Management Plan with CAL FIRE Siskiyou Unit, the KRRC and/or its Contractor(s) shall submit the Final Fire Management Plan to the CAL FIRE Siskiyou Unit and implement any portions of the plan for which the KRRC has identified responsibilities. As a condition of license surrender, KRRC is committed to complying with this mitigation measure to reduce any increased challenges in responding to wildland fire in the Klamath Basin due to the implementation of the Proposed Project."

Response to Comment ORG47-57

Please refer to Master Response HAZ-2. While no text revisions are necessary to Recommended Measure PS-1, the additional clarification provided in the comment is noted.

Comment ORG47-58

3-1010. The discussion of Potential Impact 3.20-4 did not incorporate the requirement to conduct project-specific review for individual recreation projects through the use of a checklist authorized by CEQA Guidelines Section 15168(c). In addition, KRRC would implement all applicable mitigation measures set forth in the Draft EIR related to the construction of any new recreational facilities.

Suggested revision:

"As described previously, the Proposed Project involves the development and implementation of a plan to construct new recreational facilities and river access

points along the restored river channel between the California-Oregon border and Iron Gate Dam following dam removal activities. Replacement of recreation facilities would not necessarily be 'like for like', but rather would be designed to accommodate similar levels, if different types of use. This would require the creation of new gravel roads, parking areas and other improvements for vehicle and visitor access to and use of the new river-based recreation sites, which could result in construction-related impacts to the environment, including potential impacts to water quality, terrestrial resources, and historical and/or tribal cultural resources.

While new recreation facilities are part of the Proposed Project, the final location, size, and design of the facilities are still under development. ~~and will be the subject of subsequent approvals. It is thus too soon to conduct a meaningful environmental analysis of the replacement facilities. However, construction and operation of new recreational facilities would undergo any environmental review necessary for the subsequent approvals ,~~The recreation plan takes a programmatic approach to developing recreational facilities and mitigating any impacts attributable to these developments. New recreational facilities are being evaluated in a process that includes California and Oregon state officials, Siskiyou County, Klamath County, the Bureau of Land Management, PacifiCorp, economic development organizations including chambers of commerce, tourism organizations, recreation businesses, local communities, and the broader public. A Final Recreation Plan will be submitted to FERC, and this plan will include any new recreation facilities that are proposed by KRRC. The Final Recreation Plan will be subject to environmental review under NEPA, and mitigation measures will be determined by FERC. If implementation of this plan (at FERC's direction) requires any further state or local approvals, then written checklists will be prepared pursuant to CEQA Guidelines Section 15168, subdivision (c) to ascertain whether formal site-specific environmental review for individual recreational projects will be necessary. Such individual projects shall be subject to applicable best management practices and mitigation measures required by FERC, applicable mitigation measure in this EIR such as Mitigation Measures WQ-1, TER-1 through TER-3, and TER-5, TCR-1 through TCR-3, and any other measures required by an agency with jurisdiction over those individual recreational projects. ~~and any impacts of the construction and operation of the facilities would be mitigated, if feasible, to levels that comply with all applicable laws, regulations, and environmental standards. Because this component of the Proposed Project would not be approved until a later date, for the purposes of this EIR the impacts of this component are not significant.~~ The potential environmental impacts of these new recreational facilities will be reviewed at a project level in subsequent evaluations prior to their development."

Response to Comment ORG47-58

Please refer to Master Response REC-2 for a discussion of how new recreational facilities are considered in the EIR given that the Klamath River Renewal Corporation's (KRRC's) Recreation Plan takes a programmatic approach to developing these facilities and mitigating any impacts attributable to their development.

Comment ORG47-59

3-1034. Include other treated wood such as wood utility poles as noted in Tables 2.7.3, 2.7.5 and 2.7.7 into this section to maintain consistency.

Suggested revision (last paragraph, fourth sentence):

"The dams and hydroelectric facilities within the Proposed Project area may also include items such as transformers, batteries, bushings, oil storage tanks, bearing and hydraulic control system oils, lead bearings, soils or other material contaminated with lead from the use of lead-based paints or plumbing and 700 tons of creosote-treated wood in the wooden stave penstock at Copco No. 2 Dam, as well as wood utility poles (see also Appendix B: Definite Plan – Appendix O3)."

Response to Comment ORG47-59

Section 3.21.2.3 *Hazards and Hazardous Materials – Environmental Setting – Contaminants/Contaminated Sites* has been revised as requested. Please refer to Volume III Attachment 1 Section 3.21.2.3 *Hazards and Hazardous Materials – Environmental Setting – Contaminants/Contaminated Sites* for the revisions.

Comment ORG47-60

3-1050. KRRC commits to working with all federal, state, and local fire suppression agencies to reduce any potential risk of wildland fire attributable to the implementation of the Proposed Project. As CAL FIRE has confirmed, helicopter crews can extract water on the Klamath River and KRRC is working with CAL FIRE to identify specific locations in the Klamath River that are suitable for such extraction. KRRC also proposes changes that better reflect feedback from CAL FIRE regarding the potential impacts of the Proposed Project's implementation on wildland fires in the Klamath Basin. Finally, KRRC agrees with and commits to implement the Recommended Measure PS-1.

Suggested revision (fifth paragraph):

"The Proposed Project would result in the removal of one readily available water source for wildfire services or increased emergency response times if other sources of water are not as readily available. Under the Proposed Project, removal of the Copco No. 1, Copco No. 2, and Iron Gate reservoirs would remove a long-term water source for fire suppression crews after the reservoirs are removed. Absent the identification of replacement sources of water, ~~T~~the removal of the reservoirs could increase turn-around time for helicopters or ground crews refilling with water for fire abatement purposes. However, the initial response times for existing aircraft with fire retardant would not be changed by the loss of the reservoirs. Following dam removal, CAL FIRE has confirmed

that helicopters and ground crews would still be able to extract water from the Klamath River (both the current channel and the channel reaches to be exposed in the current reservoirs following drawdown), Lake Ewauna, and Upper Klamath Lake. Retrieving water directly from the Klamath River is consistent with how wildfires are suppressed along the Klamath River downstream of Iron Gate Dam under current conditions. Ground crews would be adversely affected unless access to Klamath River water continues to be supported under the Proposed Project. Loss of the reservoirs would not affect the use of fire retardant, which is loaded onto aircraft at regional airports (i.e., Redding, Montague, Klamath Falls) and then applied directly to wildfire sites.

With respect to Klamath River access, most helicopter water tanks require three feet of water depth to fill properly, so only deeper pools in the Klamath River would be able to be used by helicopters. CAL FIRE uses the closest available water source that is suitable for fire-fighting, where suitability is determined by local conditions including water flow, depth of pool (2- to 3-foot minimum), amount of debris in pool, shoreline vegetation, and surrounding terrain. Rotor blade length and the length of bucket lines are also determinants, since there must be a safe amount of space to enter and exit the pool site. Individual pilots use their discretion to determine the closest and safest locations from which to withdraw water. KRRC is working with CAL FIRE to assist in mapping exact locations along the Klamath River that are suitable for water extraction during a wildfire based on applicable parameters, which will be included in the final Fire Protection Plan.

Analysis of aerial photos (Google Maps 2018) suggests the presence of pools with suitable conditions for helicopter filling in the currently free-flowing reaches of the Middle and Upper Klamath River, particularly in the reaches between Copco No. 1 and J.C. Boyle reservoirs and downstream of Iron Gate Dam. While source water would be available in the Klamath River in pools located in the river reaches exposed following reservoir drawdown, the travel time involved in accessing the newly formed pools ~~would be~~ may be greater than that for the existing Lower Klamath Project reservoirs because retrieval of water from relatively smaller, more narrow, river pools is more difficult than dipping directly from the broad water surface of a lake or reservoir, and only one helicopter at a time would have access to a given river pool versus multiple helicopters that can draw at one time from a large reservoir. Thus, response and travel times between water fills for helicopter crews ~~would be expected to~~ could increase with the loss of the reservoirs. Wildfires can spread at a rapid speed, and involve high risks. There are a number of factors that contribute to the severity and extent of a wildland fire. It is hard to predict whether any specific factor will contribute to the severity of a fire. In an abundance of caution, the State Water Board finds that ~~A~~any amount of additional response time compared with existing conditions could result in a substantial increased risk of loss, injury, or death involving wildland fires and this would be a significant impact.

To compensate for the loss of reservoir water supply, the Proposed Project includes providing alternate water supply through dry hydrants that would be accessible to ground crews following removal of the dams. Flows in the Klamath River and tributaries are not expected to substantially change post-dam removal, as compared to current flows, and firefighting ground crews could still use the river as a water supply as long as physical access to water is provided. A dry hydrant is a passive, unpressurized system, with a screened intake placed in the channel above the channel bed. An above-ground fire hose is used to connect the intake to truck-mounted pumps (Figure 3.17-1). Placement of the dry hydrant must be in a location of satisfactory depth (during dry conditions), flow rate, and channel stability. The Definite Plan states that dry hydrants are commonly used as water supply for fighting fires in rural areas, and typical dry hydrants and fire truck pumps can supply over 1,500 gallons per minute, which is sufficient for rapid filling of typical water tankers and firefighting apparatus (Appendix B: Definite Plan – Appendix O1).

To assist ground-based firefighting efforts, the Fire Management Plan proposes the development of eight sites near the Copco No. 1 Reservoir and four sites near the Iron Gate Reservoir for installation of permanent dry hydrants from which water trucks and fire engines could draw directly from the Klamath River and larger tributaries (Figures 3.17-2 and 3.17-3). The Proposed Project also includes an evaluation of the potential for riverine pool features to be used for helicopter water filling and development of an associated map of resources that can be used by air-based firefighting crews.

The proposed dry hydrants are likely to be of limited use for firefighting compared with existing conditions because only ground crews can access them (i.e., they are of no use to aerial crews that can access the reservoirs under existing conditions). Hook-ups to the dry hydrants would require standard specifications and existing CAL FIRE pumper trucks would require special equipment such as hard suction lines (a flexible hose would collapse) to successfully draft from the dry hydrants. The ground crews would need to be able to get close to the river to draft from the dry hydrants because firetrucks typically can only lift water over short vertical distances (i.e., 10 to 14 feet, with a maximum 15-foot height from the intake) and drafting from bridges may require too much lift. Decreased response time associated with dry hydrants as compared with aerial crew access of reservoir water via helicopters would be a significant impact since it would increase the risk of loss, injury, or death involving wildland fires. Direct withdrawal from the river using a boat ramp, pumping stations equipped with pumps connected to wells or deep pools in the river, above-ground storage tanks with ready access for transferring water to pumper trucks, are likely to be better options than the dry hydrants proposed by KRRC because these alternatives would be easier to use and thus would reduce ground crew response time. Section 3.17 Public Services includes Recommended Measure PS-1 that requires the KRRC or the Contractor's Safety Officer for the Proposed Project to submit a final Fire Management Plan after reaching agreement with CAL FIRE

Siskiyou Unit on a long-term water source replacement for helicopter and ground crews (including construction and utilization of proposed dry hydrants, dip ponds or other alternatives). KRRC commits to complying with this mitigation measure to reduce any risk in wildland fire in the Klamath Basin due to the implementation of the Proposed Project."

Response to Comment ORG47-60

Please refer to Master Response HAZ-2. While no text revisions are necessary to the identified paragraph, the additional clarification of Klamath River Renewal Corporation's (KRRC's) intentions to reduce risk of wildfires in the comment is noted.

Comment ORG47-61

3-1060. Copco Road description should be updated. The road is approximately 32 feet wide (paved), not 27 feet wide as written.

Suggested revision (fifth sentence):

"Copco Road is a paved, two-lane road in generally good pavement condition between I-5 and Ager Road with few pavement cracks or ruts and is approximately 32 27 feet wide."

Response to Comment ORG47-61

Section 3.22.2.1 *Transportation and Traffic – Environmental Setting – Traffic Flow – Roadways – Copco Road has been revised to clarify that Copco Road* at the designated section is 32 feet rather than 27 feet wide. Please refer to Volume III Attachment 1 Section 3.22.2.1 *Transportation and Traffic – Environmental Setting – Traffic Flow – Roadways – Copco Road* for this revision.

Comment ORG47-62

3-1073. KRRC is committed to implementing the Recommended Measure TR-1 and recommends the following revisions to the language of the measure.

Suggested revision (second paragraph):

"Recommended Measure TR-1 – Transportation and Traffic.

A. The KRRC and/or its contractor(s) shall develop a final Traffic Management Plan (TMP) that provides:

1. Implementation details consistent with all applicable regulatory requirements including the latest version of the Caltrans California Manual on Uniform Traffic Control Devices (MUTCD,Caltrans 2018b), Caltrans Traffic Management Plan (TMP) Guidelines, Oregon Department of Transportation (ODOT) Oregon Supplement to the MUTCD, Federal Highway Administration MUTCD, ODOT Traffic Control Plans Design Manual, and ODOT TMP Project Level Guidance

Manual. KRRC will coordinate ~~and coordination~~ with the noted agencies (Caltrans, ODOT, Siskiyou and Klamath County Public Works and Sheriff's Departments, California Highway Patrol and Oregon State Police, CAL FIRE, Oregon Department of Forestry [ODF] Fire Division, and other emergency response agencies) as part of the detailed design phase and prior to start of construction. Potential conflicts with bicycle and pedestrian use, as well as transit and school bus service, need to be addressed in the Traffic Management Plan. KRRC has proposed Memoranda of Understanding to Siskiyou County and to Klamath County (i.e., good neighbor agreements) to jointly develop and recommend to FERC additional terms and conditions of the Traffic Management Plan that address local interests. The final version of the Traffic Management Plan, after coordination with the above referenced agencies, shall be received by the State Water Board prior to the start of construction.

2. Each road, bridge, and culvert improvement project included in the Proposed Project, or any other road, bridge, or culvert improvement project that is identified as necessary for the Proposed Project, shall be constructed consistent with the latest version of the Caltrans Highway Design Manual (Caltrans 2018c), Caltrans Standard Plans, and Caltrans Standard Specifications, or ODOT Highway Design Manual, ODOT Standard Drawings and Standard Details, and ODOT Standard Specifications, or equivalent, and shall not conflict with any applicable plan, ordinance, or policy regarding performance of the transportation system, traffic safety and/or congestion management within the Area of Analysis. Construction shall not begin until all final designs for road, bridge, and culvert improvement projects included in the Proposed Project have been received and approved, as necessary, by the county and other responsible agencies.

3. The KRRC shall be responsible for repairing and/or rehabilitating ~~any Siskiyou County roadways~~ Copco Road, Ager Beswick Road, Daggett Road, and Lakeview Road within the traffic and transportation Area of Analysis that are damaged or otherwise adversely impacted by Proposed Project activities, such that they are in a condition equal to or better than they were before dam removal activities.

B. The KRRC and/or its construction contractor(s) shall develop an Emergency Response Plan with details and procedures to be put in place to help prevent incidents, to ensure preparedness in the event incidents occur, and to provide a systematic and orderly response to emergencies through coordination with emergency response agencies, as described in Appendix B: Definite Plan − Appendix O4."

Response to Comment ORG47-62

Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* Recommended Measure TR-1 has been changed to Mitigation Measure TR-1 and the terms have been clarified as requested, with the exception of item no. 3, which remains the same. Limiting road repairs to a few roads does not fully address the extent of the potential impact. Any road that is impacted by the Proposed Project should be restored to equal or better than pre-project conditions. Please refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* for this revision.

Comment ORG47-63

3-1077. Potential Impact 3.22-3. Appendix K of the Definite Plan indicates that improvements and upgrades are not anticipated (in some sections where poor pavement condition has been observed) but pavement rehabilitation may be required during or post-construction. The pavement rehabilitation may be used to help mitigate for increase in potential hazards or incompatible uses.

Suggested revision (sentences 8 and 9):

"These sections of roads may not be up to a standard for the transportation of construction equipment, adequate for emergency response, or in a condition adequate for future use after dam removal activities have been completed; however, as described in Appendix K of the Definite Plan, there will be pavement rehabilitation as part of the Proposed Project, which will address the deficiencies in the existing road conditions to the extent necessary."

Response to Comment ORG47-63

Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* for this revision.

Comment ORG47-64

3-1077. Clarify Potential Impact 3.22-5 with respect to safety.

Suggested revision (third sentence, first paragraph):

"If an unacceptable level of risk to non-motorized users is deemed to persist, KRRC's contractor will arrange appropriate detours to allow safe and adequate continued movement for such users ~~to allow continued movement for such users~~ (Appendix B: Definite Plan – Appendix O2)."

Response to Comment ORG47-64

Section 3.22.5 Transportation and Traffic – Potential Impacts and Mitigation has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.22.5 Transportation and Traffic – Potential Impacts and Mitigation for this revision.

Comment ORG47-65

3-1198. In Section 3.24.13, update section references for clarity.

Suggested revision (last paragraph, first sentence):

"Existing conditions for paleontologic resources are as described in Section 3.13.2 3.14.2 [Paleontologic Resources] Environmental Setting. The majority of bedrock deposits within the Area of Analysis for paleontologic resources are not fossil-bearing units. Two mapped geologic units that contain paleontologic resources are present within the Area of Analysis: (1) the unnamed diatomite deposit at Copco No. 1 Reservoir; and (2) the Hornbrook Formation. The diatomite deposit is determined to be of Low Paleontologic Potential. The fossils in the Hornbrook Formation are documented to include megafossils and microfossils, but it is not known if the fossil abundance varies spatially within this geologic unit. The Klamath River cuts across the Hornbrook Formation in the region of Hornbrook, California, along approximately three river miles (Figure 3.13-2). Sub-units within the Hornbrook formation are described in Section 3.13.2 ~~3.14.2~~ [Paleontologic Resources] Environmental Setting. Section 3.13.2 ~~3.14.2~~ also includes consideration of major past or ongoing projects that have impacted, or currently impact, paleontologic resources."

Response to Comment ORG47-65
Section 3.24.13 *Cumulative Effects – Paleontologic Resources* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.24.13 *Cumulative Effects – Paleontologic Resources* for this revision.

Comment ORG47-66
3-1202. Potential Impact 3.24-53, Recommend re-wording title for clarification.

Suggested revision (last paragraph):

"Potential Cumulative Impact 3.24-53 Short-term and long-term effects to forestry resources from the combination of the Proposed Project and wildfire."

Response to Comment ORG47-66
Section 3.24.15 *Cumulative Effects – Agriculture and Forestry* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.24.15 *Cumulative Effects – Agriculture and Forestry* for this revision.

Comment ORG47-67
4-93. In Section 4.3.17, clarify to reflect the commitments that KRRC will implement, as conditions of license surrender, to reduce the risk of increased public services response times for emergency fire, police, and medical services due to the Proposed Project's construction and demolition activities. Commitments apply to all alternatives except the No Project Alternative.

Suggested revision (third sentence):

"Implementation of Mitigation Measure HZ-1 (Section 3.21 Hazards and Hazardous Materials) would reduce impacts for reasons described under the Proposed Project. ~~However,~~ In addition, KRRC has developed a draft Traffic Management Plan that includes mitigation and other protective measures that would be implemented to reduce impacts to public services (Appendix B: Definite Plan – Appendix 02). The final Traffic Management Plan would be informed by KRRC's contractor's specific means and methods for construction and input received from relevant local jurisdictions, which could refine the approach to access and traffic management. KRRC has proposed Memoranda of Understanding to Siskiyou County and to Klamath County (i.e., good neighbor agreements) to jointly develop and recommend to FERC additional terms and conditions of the Traffic Management Plan that address local interests. KRRC is committed to ensuring that the final Traffic Management Plan meets applicable regulatory permit requirements, as well as applicable state and local ordinances. In addition, KRRC has committed to coordinate the implementation of the Traffic Management Plan and Emergency Response Plan to reduce impacts. Overseeing development and implementation of the final Traffic Management Plan and final Emergency Response Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that the Traffic Management Plan and Emergency Response Plan will be finalized and implemented, the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of Mitigation Measure HZ-1 and Recommended Measure TR-1 would reduce impacts to public services, because it cannot require implementation of Recommended Measure TR-1, it is analyzing the impacts under this alternative as significant and unavoidable."

Response to Comment ORG47-67

Please refer to Master Response CEQ-2 for a discussion of why the text of the Final EIR has been revised to reflect that Recommended Measure TR-1 is now Mitigation Measure TR-1. Please also refer to Volume III Attachment 1 Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* Potential Impacts 3.22-1 through 3.22-5 for the revisions.

Please also refer to Master Response HAZ-1.

Comment ORG47-68

4-166. As a preliminary matter, Mitigation Measure TER-5 should apply to all action alternatives to ensure no net loss of wetlands. Currently, Mitigation Measure TER-1, standing alone, does not provide for unavoidable wetlands impacts. Therefore, it should be understood that TER-1 works together with TER-5 to ensure that the Project achieves the net zero loss of wetland function and value standard.

Suggested revision:

"Mitigation Measure TER-1 Establish a 20-foot buffer around delineated wetlands. The KRRC shall establish a minimum of a 20-foot buffer around all delineated wetlands potentially affected by construction impacts to ensure there will not be any significant environmental impacts to wetlands by deterring heavy machinery from traversing the wetland and preventing runoff pollution from directly entering the wetland where doing so would not result in a significant environmental impact. The buffer may be adjusted (e.g., made larger or smaller) based on site-specific conditions, as determined by a qualified biologist acceptable to USACE, as necessary to ensure adequate protection of the delineated wetlands. To the extent that impacts to wetlands cannot be avoided, KRRC shall comply with mitigation measure TER-5 to ensure no net loss of functions and values. The State Water Board has the authority to include this mitigation measure in its water quality certification for the project, and the measure is therefore feasible and used in this analysis to make a significance determination.

Mitigation Measure TER-5 − Identification, protection, and restoration of wetland and riparian habitats. The KRRC shall conduct a wetland delineation within the limits of construction in accordance with the 1987 U.S. Army Corps of Engineers (USACE) Wetland Delineation Manual (USACE 1987) and applicable Regional Supplements (i.e., Western Mountains, Valleys, and Coast Region [USACE 2010] and Arid West [USACE 2008]). The results of the wetland delineation shall be incorporated into all alternatives, except for the No Project Alternative, ~~the Continued Operations with a Continued Operations with Fish Passage Alternative design~~ to avoid and minimize direct impacts on wetlands to the maximum extent feasible, and wetland areas adjacent to the construction Limits of Work shall be fenced to prevent inadvertent entry. Where avoidance is not feasible the KRRC shall develop a restoration plan to re-vegetate all areas disturbed during construction with a ~~goal~~ requirement of no net loss of wetland or riparian habitat acreage and functions. The restoration plan shall include details on revegetation native seed mixes based on existing species that will be impacted and installation techniques for container plants and seeds. Wetlands established in restored areas would be monitored for five years or until the performance criteria, as defined in the restoration plan that shall be developed, have been met."

Response to Comment ORG47-68
Please see response to ORG47-41.

Comment ORG47-69
4-238. In Section 4.5.17, clarify to reflect the commitments that KRRC intends to implement to reduce the risk of increased public services response times for emergency fire, police, and medical services due to the Proposed Project's construction and demolition activities. Commitments apply to all alternatives except the No Project Alternative.

Suggested revision (second paragraph):

"Mitigation Measure HZ-1 would reduce impacts. In addition, the KRRC is developing a Traffic Management Plan to identify mitigation and other protective measures that would be implemented to reduce impacts to public services. It would also be appropriate for the final Traffic Management Plan to include Recommended Measure TR-1. <u>The final Traffic Management Plan would be informed by KRRC's contractor's specific means and methods for construction and input received from relevant local jurisdictions, which could refine the approach to access and traffic management. KRRC has proposed Memoranda of Understanding to Siskiyou County and to Klamath County (i.e., good neighbor agreements) to jointly develop and recommend to FERC additional terms and conditions of the Traffic Management Plan that address local interests. KRRC is committed to ensuring that the final Traffic Management Plan meets applicable regulatory permit requirements, as well as applicable state and local ordinances. In addition, KRRC has committed to coordinate the implementation of the Traffic Management Plan and emergency response plan to reduce impacts.</u> Overseeing development and implementation of the Traffic Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that this plan will be finalized and implemented, at this time the plan is not finalized, and the State Water Board cannot require its implementation. Accordingly, while the State Water Board anticipates that implementation of Mitigation Measure HZ-1 would reduce impacts to public services, because it cannot require implementation of Recommended Measure TR-1, it is analyzing the impacts under this alternative as significant and unavoidable."

Response to Comment ORG47-69
Please refer to response to comment ORG47-67.

<u>Comment ORG47-70</u>
4-296. In last sentence of Section 4.6.17, change impact numbers to 3.17-1 through 3.17-3.

Suggested revision:

"Thus, for reasons described in Section 3.17.5 [Public Services] Potential Impacts and Mitigation, impacts and associated mitigation measures from increased public service response times for emergency fire, police, and medical services due to construction and demolition activities, elimination of a long-term water source for wildfire services substantially increasing the response time for suppressing wildfires, and potential effects on schools services and facilities would be the same under the Three Dam Removal Alternative as those described for the Proposed Project ~~(Potential Impacts 3.5-1 through 3.5-3)~~ <u>(Potential Impacts 3.17-1 through 3.17-3)."</u>

Response to Comment ORG47-70
Section 4.6.17 *Alternatives – Three Dam Removal Alternative – Public Services* has been clarified as requested. Please refer to Volume III Attachment 1 Section 4.6.17 *Alternatives – Three Dam Removal Alternative – Public Services* for the revisions.

Comment ORG47-71
4-320. In last sentence of Section 4.7.17, change impact numbers to 3.17-1 through 3.17-3.

Suggested revision:

"Thus, for reasons described in Section 3.17.5 [Public Services] Potential Impacts and Mitigation, impacts and associated mitigation measures from increased public service response times for emergency fire, police, and medical services due to construction and demolition activities, elimination of a long-term water source for wildfire services substantially increasing the response time for suppressing wildfires, and potential effects on schools services and facilities would be the same under the Three Dam Removal Alternative as those described for the Proposed Project ~~(Potential Impacts 3.5-1 through 3.5-3)~~ (Potential Impacts 3.17-1 through 3.17-3)."

Response to Comment ORG47-71
Section 4.7.17 *Alternatives – No Hatchery Alternative – Public Services* has been clarified as requested. Please refer to Volume III Attachment 1 Section 4.7.17 *Alternatives – No Hatchery Alternative – Public Services* for this revision.

League of Women Voters, Andrew Muse-Fisher, Helen Hutchinson, Rollin Richmond

Comment ORG25-1
The League of Women Voters of California (LWVC) and the League of Women Voters of Humboldt County, California (LWVHC) strongly support the removal of four dams on the Klamath River. The removal of the four dams will effectively improve water quality for humans, fish, and other wildlife and comply with the Clean Water Act water quality objectives. The improved water quality will also provide for the cultural and economic interests of Native Americans, recreational anglers, and the commercial fishing fleet of northern California.

Response to Comment ORG25-1
Thank you for your comment. Please also refer to Master Response GEN-1.

Comment ORG25-2
This support of the proposed project of the Draft EIR is founded on the LWVC's and LWVHC's positions on natural resources, specifically water. The LWVC's position:

- *protect the natural environment in areas of both water origin and water use*
- *reserve stream flows for protection of fish and wildlife habitat and other in-stream uses*
- *encourage off-stream storage; discourage additional on-stream dams*
- *provide for assessment of economic, social, and environmental costs and benefits of water projects*

The LVCHC's position: coordinated interagency planning and action are critical to successful management and to the accomplishment of the following objectives:

- *rivers and streams should be left in their natural states whenever possible, with each case considered on its own merits.*
- *total watershed management, including preservation and restoration should be coordinated by qualified professionals so the economic interests, aesthetic issues, and health concerns can exist in harmony in our county and our future water supply can be provided adequately.*

Response to Comment ORG25-2
Please refer to Master Response GEN-1.

Comment ORG25-3
The State Water Resources Control Board has identified the following Proposed Project objectives, as required under CEQA Guidelines, section 15124, subdivision (b):

In a timely manner:

1. Improve the long-term water quality conditions associated with the Lower Klamath Project in the California reaches of the Klamath River, including water quality impairments due to Microcystis aeruginosa and associated toxins, water temperature, and levels of biostimulatory nutrients.

2. Advance the long-term restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation.

3. Restore volitional anadromous fish passage in the Klamath Basin to viable habitat currently made inaccessible by the Lower Klamath Project dams.

4. Ameliorate conditions underlying high disease rates among Klamath River salmonids. The objectives further the underlying purpose of the Proposed Project (removal of four dams), which is the timely improvement of water quality related to the Lower Klamath Project within and downstream of the current Hydroelectric Reach and the restoration of anadromous access upstream of Iron Gate Dam (the current barrier to anadromy).

These objectives align with the League's positions, and we are pleased to support the Water Board's Draft EIR.

Response to Comment ORG25-3
Please also refer to Master Response GEN-1 and GEN-2.

Mount Shasta Bioregional Ecology Center, Arielle Halpern

Comment ORG26-1 and ORG40-1
On behalf of the Mount Shasta Bioregional Ecology Center, I am writing to voice our support for the removal J.C. Boyle, Copco No. 1, Copco No. 2 and Iron Gate Dams on the Klamath River. The removal of these dams is a critical step in enhancing healthy human-environmental systems in the Klamath Bioregion. The Klamath Bioregion a biodiversity hotspot and one of the four most diverse conifer forests in the world. Benefits including reducing the mortality of juvenile salmonid populations, reducing salmonid diseases, including P. minibicornis and C Shasta. The above challenges are a result of high temperatures, low water flows, and high densities of fish attempting to access upstream habitat currently blocked by the dams. High temperatures and low flows also contribute to toxic blue green algae blooms during summer months which affect wildlife, recreation, and aesthetics.

Response to Comment ORG26-1 and ORG40-1
Thank you for your comment. Please also refer to Master Response GEN-1.

Comment ORG26-2 and ORG40-2
Opponents of dam removal state effects on groundwater/irrigation and energy as potential detrimental results of dam removal. As the DEIR states, the proposed project would have no significant impact on groundwater and irrigation as most agriculture in the area uses diversions from Klamath tributaries.

Response to Comment ORG26-2 and ORG40-2
Comment noted. Please also refer to Master Responses WSWR-1 and GRW-1. This comment also pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG26-3 and ORG40-3
Dams are not used for water supply or for flood control.

Response to Comment ORG26-3 and ORG40-3
Please refer to Master Response WSWR-1 and FLD-1.

Comment ORG26-4 and ORG40-4
According to the Hydropower Technical Benefits Report, the total installed capacity of the four Klamath River hydropower plants is 169 MW, average summer capacity is 55.9 MW and winter dependable capacity is 66.6 MW: These

dams run dependably at approximately 30% of their total capacity. The $400 million dollars it would have taken to upgrade the fish passage and water quality systems and obtain a new operational license from FERC was not cost effective relative to the amount of hydropower these dams generate. Renewables and efficiency measures can replace the energy input without contributing to climate change. A study by the California Energy Commission and the Department of the Interior found that removing the dams and compensating for the loss of power production with efficiency measures and other sources would save PacifiCorp customers up to $285 million over 30 years.

Response to Comment ORG26-4 and ORG40-4
Comment noted. This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG26-5 and ORG40-5
Once again, we would like to voice our support for the removal of the Klamath dams.

Response to Comment ORG26-5 and ORG40-5
Comment noted.

Native Fish Society, Wild Fish Conservancy, Patagonia Inc., Fly Water Travel, University of Montana, Stoecker Ecological, Conrad Gowell, Jake Crawford, Mark Sherwood, Kurt Beardslee, Jamie Glasglow, Hans Cole, Charles Gehr, Jack Stanford, and Matt Stoecker

Comment ORG33-1
Thank you for the opportunity to engage in the environmental review of the Lower Klamath dam removal. Please see the attached request to extend the public comment processes for the Lower Klamath Project draft environmental impact report (EIR). Our partners all agree that the existing comment period is insufficient to review and comment on the documents associated with the project. We respectfully request that you extend the public comment period for an additional 30 days in order for us, and other members of the public, to fully participate in the review of the presented alternatives.

Please let us know that you have received this request and whether or not an extension can be granted.

Response to Comment ORG33-1
Thank you for your comment and for your participation in the environmental review process. CEQA Guidelines section 21091 subdivision (a) requires a minimum 45-day public review period for an EIR. The Lower Klamath Project Draft EIR was released on December 27, 2018 and the public comment period ended February 26, 2019.

Comment ORG33-2

The Native Fish Society, Wild Fish Conservancy, Patagonia, Inc., Fly Water Travel, Jack Stanford, and Matt Stoecker respectfully requests a 30-day extension of the public comment period for the Lower Klamath Project License Surrender submitted to the California State Water Resources Control Board. The originally allotted comment period is insufficient for the scope and importance of this process. I sincerely hope you will consider granting us, and members of the public additional time so we can adequately participate in review of the alternatives presented.

Response to Comment ORG33-2

Please refer to response to comment ORG33-1.

Comment ORG33-3

The Native Fish Society (NFS) is a 501(c)3 conservation non-profit, dedicated to utilizing the best available science to advocate for the protection and recovery of wild, native fish and promote the stewardship of the habitats that sustain them. NFS has 3,300 members and supporters and 89 River Stewards, and 11 Fellows that help safeguard wild fish in their homewaters across the Pacific Northwest. NFS has five River Stewards that live, work, and recreate in the Klamath watershed in both California and Oregon. Furthermore, NPS River Stewards, Staff, and Supporters live, work, and recreate in the Klamath basin who are interested in the recovery of threatened and sensitive populations of wild, native fish.

Wild Fish Conservancy is a 501 (c)3 non-profit that is dedicated to the recovery and conservation of the region's wild fish ecosystems. Through science, education, and advocacy, WFC promotes technically and socially responsible habitat, hatchery, and harvest management to better sustain the region's wild-fish heritage.

Patagonia, Inc. is an outdoor clothing and gear company dedicated to using business to inspire and implement solutions to the environmental crisis. This includes a 40-year hist01y supporting grassroots campaigns and local groups working to remove dams, restore habitat and protect wild rivers and wild fish.

Fly Water Travel is a team of fishing and travel experts exclusively dedicated to arranging trips to the world's fi nest fi shing destinations. Fly Water supports fishing businesses in the Klamath basin and clients who travel to the Klamath waters bed to experience healthy runs of wild, native fish and the clean water necessary for their survival.

Jack Stanford is a Professor Emeritus at the Flathead Lake Biological Station with the University of Montana, where for over 45 years his research focused on the ecology of Pacific Rim salmon rivers.

Stoecker Ecological is a biological consulting firm that specializes in salmon and steelhead restoration across the West Coast.

Response to Comment ORG33-3
Please refer to Master Response GEN-2.

Comment ORG33-4
An extension request from February 26th, 2019 to March 26th, 2019 is being requested in order to provide adequate time for the our organizations, businesses, members and the public to effectively engage in the commenting process and to provide ample time to review the lengthy documents with a thorough review.

Response to Comment ORG33-4
Please refer to response to comment ORG33-1.

Native Fish Society, Wild Fish Conservancy, Patagonia Inc., Fly Water Travel, University of Montana, Stoecker Ecological, World Salmon Forum, Jake Crawford, Conrad Gowell, Mark Sherwood, Kurt Beardslee, Jamie Glasgow, Yvon Chouinard, Hans Cole, Charles Gehr, Jack Stanford, Matt Stoecker, and Bruce McNae

Comment ORG34-1
Please see the following three attachments with comments concerning the Lower Klamath Project License Surrender No. 2016122047. Thank you for the opportunity to submit the following comments.

1. Native Fish Society Group Comments on Draft Environmental Impact Report for the Lower Klamath Project License Surrender No. 2016122047.
These comments are submitted in support of the below document.

2. Shute, Mihaly, & Weinberger, LLP comments representing Native Fish Society on the Draft Environmental Impact Report for the Lower Klamath Project License Surrender (State Clearinghouse No. 201622047).

3. Group Comments previously submitted during the project scoping dated July 23, 2018.

Finally, supporting literature for the referenced documents are included in this dropbox folder, and we will mail a thumb-drive of the supporting materials to the State Water Resources Control Board office.

Please confirm receipt of this email, and contact me directly with any questions or further discussion.

Response to Comment ORG34-1
The State Water Board received the three attachments associated with the cover email, as well as the items provided via “dropbox".

Comment ORG34-2
Thank you for the opportunity to provide comments on the Draft Environmental Impact Report for the Lower Klamath License Surrender Project (“Project”).

We are submitting the following comments that fully support the proposed decommissioning of all four Lower Klamath Project dams and the license surrender, which will improve the biological conditions in the Klamath watershed to benefit sensitive and threatened wild, native fish species, as well as the human and environmental communities who depend on the health of these iconic fish species. Our coalition of scientists, businesses, and conservation groups stress support for decommissioning the four Lower Klamath Dams (Iron Gate, Copco 1 & 2, and J.C. Boyle). Decommissioning all four dams is critical to the recovery and long-term protection of these iconic fish species that provide important subsistence for tribal fisheries, economies for commercial and sport fishing communities along the California and Oregon coast, and sustains the many plants and animals dependent on the return of marine nutrients that contribute to overall watershed health.

Our concerns are centered on the significant environmental impacts that would result from the Project’s proposed hatchery operations, and the lack of description for how the proposed hatchery operations would contribute to the recovery of the watershed’s imperiled fish species. As noted in the DEIR No Hatchery Alternative, the proposed hatchery operations post-dam decommissioning would be detrimental to imperiled Chinook and recovering coho populations and could jeopardize their ability to respond to the benefits of dam decommissioning. As stated in the DEIR, “In the long term, removal of the Lower Klamath Project dams under the No Hatchery Alternative would increase habitat availability, restore a more natural flow regime and seasonal variation in water temperature, improve water quality, and reduce the likelihood of fish disease and algal toxins” which will be beneficial to fall-run Chinook, spring-run Chinook, and coho salmon in the Klamath basin (see DEIR 4-301-324).

Under the No Hatchery Alternative, ceasing hatchery operations along with decommissioning all four Lower Klamath Dams is the superior environmental alternative that will contribute to the long-term restoration of wild salmon and steelhead that are able to benefit from the newly accessible habitat and improved river conditions without the competition from hatchery releases. Importantly, the No Hatchery Alternative is feasible and environmentally superior to the proposed Project, and meets all the Project objectives.

In light of these and the following concerns, we offer our support of the attached comments submitted by SHUTE, MIHALY & WEINBERGER LLP represented by *the Native Fish Society, and urge the State Board to consider and adopt the No Hatchery Alternative. Together, we have a keen interest in the certification and decommissioning of the Project, and our collective organizations, members, partners, and clients have been deeply involved in past and ongoing wild salmon and watershed restoration projects in California, Oregon, and Washington.*

Native Fish Society is a 501(c)3 conservation non-profit, dedicated to utilizing the best available science to advocate for the protection and recovery of wild, native fish and promote the stewardship of the habitats that sustain them. NFS has 3,300 members and supporters and 89 River Stewards that help safeguard wild fish in their homewaters across the Pacific Northwest. NFS has five River Stewards that live, work, and recreate in the Klamath watershed in both California and Oregon. Furthermore, NFS River Stewards, Staff, and Supporters live, work, and recreate in the Klamath basin who are interested in the recovery of threatened and sensitive populations of wild, native fish.

Wild Fish Conservancy is a 501(c)3 non-profit that is dedicated to the recovery and conservation of the region's wild fish ecosystems. Through science, education, and advocacy, WFC promotes technically and socially responsible habitat, hatchery, and harvest management to better sustain the region's wild-fish heritage.

Patagonia is an outdoor clothing and gear company dedicated to using business to inspire and implement solutions to the environmental crisis. This includes a 40-year history supporting grassroots campaigns and local groups working to remove dams, restore habitat and protect wild rivers and wild fish.

Fly Water Travel is a team of fishing and travel experts exclusively dedicated to arranging trips to the world's finest fishing destinations. Fly Water supports fishing businesses in the Klamath basin and clients who travel to the Klamath watershed to experience healthy runs of wild, native fish and the clean water necessary for their survival.

Jack Stanford is a Professor Emeritus at the Flathead Lake Biological Station with the University of Montana, where for over 45 years his research focused on the ecology of Pacific Rim salmon rivers.

Stoecker Ecological is a biological consulting firm that specializes in salmon and steelhead restoration across the West Coast.

World Salmon Forum is bringing together a coalition of scientists, advocates, and foundations dedicated to sustaining wild salmon in response to the dramatic declines in Atlantic and Pacific wild salmon populations facing the imminent risk of extinction.

In conclusion, we submit our comments in support for the Lower Klamath Project decommissioning and license surrender, but remain concerned about the environmental impacts of the proposed Project's hatchery operations at Iron Gate and Fall Creek. We offer our support for the comments submitted by SHUTE, MIHALY, & WEINBERG, LLC represented by Native Fish Society, and urge the State Water Board to consider and adopt the No Hatchery Alternative.

For any follow up, please contact Jake Crawford, Native Fish Society by phone at 503-344-4218 or email: jake@nativefishsociety.org

Response to Comment ORG34-2

As the commenters note, this cover letter is introductory to more specific comments attached. To the extent this cover letter includes topics that warrant further response, these are addressed in responses to the more detailed following comments, ORG34-4 through ORG34-16.

Comment ORG34-3

This firm represents the Native Fish Society on matters relating to the proposed Lower Klamath License Surrender Project ("Project"). On behalf of our client, we have reviewed the Draft Environmental Impact Report ("DEIR") and respectfully submit these comments to help ensure that agency decision-makers fully comply with the California Environmental Quality Act ("CEQA"), Public Resources Code § 21000 et seq., and the CEQA Guidelines, California Code of Regulations, Title 14, § 15000 et seq. ("Guidelines"). This letter follows a comment letter dated July 23, 2018 submitted by the Native Fish Society together with a coalition of scientists, conservation groups, and interested business entities on the Project scoping document. This letter incorporates those July 23, 2018 comments as if fully set forth herein, as well as the references cited therein.

As discussed in those prior comments, the Native Fish Society supports the proposed decommissioning and license surrender, which will improve the biological conditions in the Klamath watershed to benefit sensitive and threatened wild, native fish species. However, it remains concerned about the significant environmental impacts that would result from the Project's proposed hatchery operations and seeks to ensure that those impacts are eliminated or mitigated to the extent feasible, as required by CEQA.

We are pleased to see that the State Water Resources Control Board ("State Board") has taken our client's prior comments into consideration such that the DEIR reveals many of the environmental impacts of the proposed hatchery operations and also considers a "No Hatchery Alternative." However, the DEIR should be corrected and/or augmented to reflect important information regarding hatchery operations, as set forth below. But even based on the information the DEIR currently reveals, it is clear that the proposed Project's hatchery operations would result in significant impacts that can and should be avoided by eliminating those hatchery operations. The No Hatchery Alternative is clearly feasible and *environmentally superior to the proposed Project, and meets all the Project objectives. Therefore, the Native Fish Society urges the State Board to consider and adopt the No Hatchery Alternative.*

Response to Comment ORG34-3

This comment is introductory to more specific comments. To the extent this paragraph includes topics that warrant further response, these are addressed in responses to the more detailed following comments, ORG34-4 through ORG34-16.

Comment ORG34-4

CEQA's most fundamental requirement is that an EIR contain an accurate, complete, and consistent project description. See County of Inyo v. City of Los Angeles (1977) 71 Cal.App.3d 185; see also CEQA Guidelines § 15124. Moreover, CEQA defines a "project" as "the whole of an action." CEQA Guidelines § 15378. As explained in McQueen v. Board of Directors of the Midpeninsula Regional Open Space District (1988) 202 Cal.App.3d 1136, "'[p]roject' is given a broad interpretation in order to maximize protection of the environment." Id. at 1143. As the Supreme Court has explained, this rule ensures "that environmental considerations do not become submerged by chopping a large project into many little ones—each with a potential impact on the environment—which cumulatively may have disastrous consequences." Bozung v. Local Agency Formation Comm. (1975) 13 Cal.3d 263, 283-84. Without a complete and consistent project description, an agency and the public cannot be assured that all of a project's environmental impacts have been revealed and mitigated.

Response to Comment ORG34-4

Volume I Section 2 *Proposed Project* (pages 2-1 to 2-114) is consistent with CEQA Guidelines section 15124 regarding the requirements for a project description.

Consistent with CEQA Guidelines section 15378, the whole of the Klamath River Renewal Corporation's proposed action is analyzed in the EIR, which includes operation of the hatchery for eight years following the decommissioning of Iron Gate Dam, as discussed in Volume I Section 2.7.6 *Proposed Project – Proposed Project – Hatchery Operations* (pages 2-77 to 2-84).

Comment ORG34-5

While the DEIR provides some information regarding proposed hatchery operations, the information is incomplete and at times confusing. To begin, it is unclear the role the hatchery operations are playing with respect to the decommissioning Project. The DEIR reveals that the hatchery operations were initially incorporated as mitigation for dam's blockage of fish passage and habitat. DEIR at 3-247. While hatchery operations may have been adopted for such a mitigation purpose while the dams were in place, those purposes no longer exist *when the dams are removed and, as the DEIR recognizes, the hatchery operations can work at cross-purposes to re-establishing a long-term viable native fish population. See, e.g., DEIR at 4-304, 4-305 ("Negative hatchery effects due to competition, leading to displacement and lower growth, are well documented."), 4-307 ("[H]atchery returning adults can have substantial detrimental effects on native populations. As such, a reduction in hatchery returns … would be a benefit for fall-run Chinook salmon over the long term."). Thus, the hatchery operations do not appear to meet any of the current Project objectives, and in fact would likely hinder most of those objectives, which are to:*

1. Improve the long-term water quality conditions associated with the Lower Klamath Project in the California reaches of the Klamath River, including water quality impairments due to Microcystis aeruginosa and associated toxins, water temperature, and levels of biostimulatory nutrients.

2. Advance the long-term restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation.

3. Restore volitional anadromous fish passage in the Klamath Basin to viable habitat currently made inaccessible by the Lower Klamath Project dams.

4. Ameliorate conditions underlying high disease rates among Klamath River salmonids.

Response to Comment ORG34-5

Consistent with CEQA Guidelines section 15378, the EIR analyzes the whole of the proposed action, and the proposal's ability to meet the project objectives. Considering whether the hatchery operations in isolation from other components of the Proposed Project meet the project objectives is using the incorrect scale for the evaluation. However, it is worth noting that the EIR Executive Summary evaluates the ability of both the Proposed Project and the No Hatchery Alternative to meet the proposed project objectives.

The EIR appropriately summarizes the information provided regarding the hatchery operations component of the Proposed Project.

Comment ORG34-6

The DEIR alludes to the hatchery operations as on-going mitigation, but largely addresses them as part of the proposed Project. The DEIR should clarify whether hatchery operations are intended as on-going mitigation and, if so, which Project impacts the hatchery operations are intended to mitigate. Because, as discussed further below, hatchery operations result in potentially significant impacts in many areas including water quality, aquatic resources, and tribal cultural resources, they are not appropriate mitigation. Alternatively, if the hatchery operations are considered part of the proposed Project, the DEIR *should clarify which Project purpose or objective they fulfill, as the record shows hatcheries do not further any of the listed Project objectives.*

Furthermore, the DEIR lacks necessary detail regarding the hatchery operations themselves. For example, the DEIR states, "[i]t is currently unclear whether the Iron Gate Hatchery facility would be decommissioned in place, demolished, or partly or fully repurposed after the eight-year operational period." DEIR at 2-78. The same uncertainty is identified for the facilities at the Fall Creek Hatchery. DEIR at 2-82. Each of these potential outcomes would result in differing and potentially significant environmental impacts. Therefore, the DEIR should be clear as to what will happen to the hatchery facilities at the end of the eight year period, and what the decommissioning, demolition, or repurposing would entail. Given that the hatchery operations are proposed to continue only for eight years after decommissioning (DEIR at 2-77 to 2-78), there is no reason that the ultimate outcome could not be identified now. Moreover, given the identified significant impacts of hatchery operations, should hatchery operations for any reason not cease after eight years, as analyzed in the DEIR, the State Board and/or other responsible agencies would need to conduct further environmental review and could no longer rely on the EIR's analysis. See Public Resources Code § 21166.

Likewise, the DEIR lacks detail about the location, construction, and operation of hatchery operation facilities, including the diversion, pumps, filtration system, and spawning building for Iron Gate Hatchery, and all the Fall Creek powerhouse and hatchery infrastructure. See DEIR at 2-78 to 2-83. Instead, the DEIR gives only approximations and/or guesses as to these components, and also as to the procedures to be followed if there is not enough surface water to divert for hatchery operations. Additional detail is necessary for an accurate analysis of the facilities' environmental impacts, including to water supply, aquatic resources, and tribal cultural properties that exist in and around the Project area. The EIR should be revised to provide these necessary details so that the public and decision-makers can adequately assess the Project's impacts.

Response to Comment ORG34-6

The EIR does not allude to hatchery operations as ongoing CEQA mitigation for the Proposed Project or the alternatives. As part of the existing conditions description, Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries* states that Fall Creek Hatchery (FCH) was built in 1919 by the California Oregon Power Company in Fall Creek as compensation for the loss of spawning grounds that occurred with the construction of Copco No. 1 Dam and Iron Gate Hatchery was originally constructed in 1962 as mitigation for blockage of fish passage caused by the construction of Iron Gate Dam. The Proposed Project is a restoration project that removes the dams and includes eight years of reduced-level hatchery operations. Please refer to Volume III Attachment 1 for the final

Section 3.3 *Aquatic Resources*. Please also refer to response to comment ORG34-5.

With respect to the potential for future hatchery operations beyond eight years following dam decommissioning, the demolishing of hatchery structures, or the decommissioning of the hatchery in place, the EIR is not required to speculate (CEQA Guidelines section 15145). There is currently no proposal to operate the hatcheries beyond eight years, and there are technical and financial impediments to doing so. However, the Klamath Hydroelectric Settlement Agreement (KHSA) anticipates making a determination regarding hatchery operations after dam removal; the Fall Creek facilities are intended to operate primarily as a conservation hatchery for threatened coho salmon; and stakeholders have expressed concern with hatchery closure. The rate of fisheries recolonization would likely also play a role in any decision whether to extend hatchery operations, remove facilities permanently, or to decommission facilities in place. Therefore, it would be speculative for the EIR to assume that any of these outcomes would occur. To the extent that the long-term disposition of the hatcheries involves activities not analyzed in this EIR, such actions would be subject to separate environmental review.

The detail provided in the EIR regarding the hatchery components of the Proposed Project are provided in sufficient detail to analyze the potential environmental impacts of the proposed changes to hatchery operations, as required under CEQA. Please find assessments of the noted potential hatchery impacts in the following sections:

- Volume III Attachment Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-17;
- Volume III Attachment 1 Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries;*
- Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 through Potential Impact 3.3-10, Potential Impact 3.3-23, and Potential Impact 3.3-24;
- Volume I Section 3.5.5 *Terrestrial Resources – Potential Impacts and Mitigation* Potential Impact 3.5-25 through Potential Impact 3.5-27 (pages 4-314 to 3-574);
- Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-1 (pages 3-676 to 3.679), with revisions in Volume III Attachment 1 Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation*; and
- Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* Potential Impact 3.12-9.

Comment ORG34-7

An EIR's central purposes are to identify a project's significant environmental effects and to evaluate ways of avoiding or minimizing them. Public Resources Code §§ 21002.1(a), 21061. Thus, the alternatives analysis lies at "[t]he core of an EIR." Citizens of Goleta Valley v. County of Santa Barbara (1990) 52 Cal.3d 553, 564; CEQA Guidelines § 15126.6. As the Supreme Court has explained, "Without meaningful analysis of alternatives in the EIR, neither the courts nor the public can fulfill their proper roles in the CEQA process." Laurel Heights Improvement Assn. v. Regents of University of California (1988) 47 Cal.3d 376, 404 (Laurel Heights I). Furthermore and critically, CEQA prohibits public agencies from approving projects as proposed if a feasible alternative would substantially lessen their significant environmental effects. Berkeley Keep Jets Over the Bay Committee v. Board of Port Com'rs (2001) 91 Cal.App.4th 1344, 1354 (quoting Public Resources Code § 21002).

Response to Comment ORG34-7

Lower Klamath Project EIR presents a range of reasonable alternatives to the Proposed Project. Volume I Section 4.1 *Alternatives Selection/Overview* (pages 4-1 to 4-15) discusses 17 potential alternatives in relation to the Proposed Project's underlying purpose and objectives, six of which are examined in detail. Of these six alternatives, two involve removal of all four Lower Klamath Project dams, and four involve two or three dams remaining in place. Potential impacts and beneficial effects are identified for each of these alternatives in the EIR and each will be fully considered by the State Water Board before certifying the EIR (CEQA Guidelines section 15090).

Comment ORG34-8

Here, the DEIR's alternatives analysis properly includes a "No Hatchery Alternative," which is the proposed Project without the eight years of hatchery operations at Iron Gate Hatchery and Fall Creek Hatchery, and would include the removal of the Iron Gate Hatchery. Further, the DEIR properly concludes that the No Hatchery Alternative is feasible and meets Project purposes and objectives. See DEIR at 4-2.

However, the DEIR includes some equivocal language, which should be corrected. In the Executive Summary, the DEIR states:

> *The No Hatchery Alternative would further the underlying purpose and objectives, although the alternative would not meet Objective 2 (to advance the long-term restoration of the natural fish population in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation) as quickly as under the Proposed Project.*

DEIR at ES-20 (emphasis added); see also DEIR at 4-6 ("The [No Hatchery] alternative would further the underlying purpose and most of the project *objectives, although it is not clear at a screening level the extent to which the alternative would meet Objective 2."). However, elsewhere the DEIR clearly states that the No Hatchery Alternative would be more beneficial and quicker than the proposed Project in achieving long-term survival and recovery of native fish species. See, e.g., DEIR at 4-304 to 4-311, 4-319; see also Native Fish Society et al., July 23, 2018 Comments on Project Scoping Document. For example, the DEIR states that the No Hatchery Alternative "would likely increase the rate at which Chinook salmon develop traits adapted to their new habitats upstream of Iron Gate Dam (Goodman et al. 2011). This could increase survival of natural-origin Chinook salmon at a faster rate than with continued hatchery operations under the Proposed Project." DEIR at 4-307 (emphasis added). Likewise, the DEIR states "ending hatchery operations as part of dam removal may result in a more rapid increase in the adult coho salmon population as compared with the Proposed Project." DEIR at 4-311 (emphasis added). Indeed, a scientific paper reviewing the most recent science from NOAA/ National Marine Fisheries Service regarding hatcheries found that there are "no clear-cut examples in which a reintroduction employing hatchery releases yielded a self-sustaining naturalized population." Anderson et al. (2014), "Planning Pacific Salmon and Steelhead Reintroductions Aimed at Long-Term Viability and Recovery," North American Journal of Fisheries Management 34:72–93, at p. 85. Thus, the No Hatchery Alternative clearly meets Objective 2, and would be superior to the proposed Project with respect to this Objective. The DEIR should be amended to reflect this fact.*[1]

Response to Comment ORG34-8

The statement cited in the comment from Volume I *Executive Summary* page ES-20 appears to be the commenters' core concern. This statement is a summary-level comparison of the difference between the Proposed Project and the No Hatchery Alternative in the anticipated long-term timeframe for achieving Objective 2 of the Proposed Project - successful restoration of natural fish populations, with a particular emphasis on restoring the salmonid fisheries. Please also refer to Master Response AQF-2 and the response to comment ORG42-16.

Please note that the sentence on page 4-6 that is referenced in the comment is from Volume I Section 4.1.1.1 *[Alternatives Selection/Overview] Alternatives Selection – Alternatives Carried Forward for More Detailed Analysis*, which provides the rationale for the alternatives that were selected for further analysis in the EIR. It is a preliminary, not a post-analysis, conclusion regarding feasibility and the ability of the alternatives to meet the Proposed Project's purpose and objectives; the EIR then goes on to analyze the alternative in detail in Volume I Section 4.7 *No Hatchery Alternative* (pages 4-301 to 4-323).

Volume I Section 4.7 *No Hatchery Alternative* (pages 4-301 to 4-323) includes a detailed analysis of the No Hatchery Alternative, and finds no significant impacts on aquatic resources.

Fisheries experts note both positive and negative impacts of hatcheries on fisheries, including with in the Klamath River Basin. For example, the Chinook Salmon Expert Panel convened to attempt to answer specific questions related to the Proposed Project compared with existing conditions (Goodman et al. 2011), noted that hatchery production under the Proposed Project has impacts related to disease and competition and natural spawning fish, as well as the beneficial effect of increased abundance for commercial and tribal harvest. Similarly, PacifiCorp and CDFW (2014) evaluates positive and negative hatchery impacts for coho salmon in the Klamath River. Consistent with these analysis, the analysis in the EIR discloses both positive and negative influences of hatchery operations on various salmonid populations and their anticipated recolonization rates. The elimination of hatchery produced fall-run Chinook salmon and coho salmon under this alternative would likely result in a reduction in adult returns post-dam removal for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal are realized. In contrast, under the Proposed Project, both hatchery returns and returns from newly accessible habitat would occur in the short-term, increasing the abundance of total adult returns (natural and hatchery origin) available for harvest and recolonization. Ultimately, the combined salmon population under the Proposed Project is anticipated to increase the rate of recolonization of fall-run Chinook salmon and coho salmon into newly accessible habitat, providing increased resiliency to unforeseen environmental disturbance or other threats to the populations, and more rapid realization of the other benefits of increased habitat access to these populations (e.g., hatchery operations under the Proposed Project would increase population abundance relative to the No Hatchery Alternative).

For spring-run Chinook salmon, the EIR analysis of the No Hatchery Alternative notes that since spring-run are not currently produced at a hatchery, the hatchery only has impacts on the population, without benefits. The Proposed Project does not include an active reintroduction plan for spring-run Chinook salmon. Please note that Oregon Department of Fish and Wildlife (ODFW) has drafted an *Implementation Plan for the Reintroduction of Anadromous Fishes into the Oregon Portions of the Upper Klamath Basin* (T. Wise, ODFW, pers. comm., 2018). ODFW's draft plan includes active reintroduction of spring-run Chinook salmon into tributaries of the Upper Klamath Lake (T. Wise, ODFW, pers. comm., 2019). The EIR does not rely on implementation of this plan, because its timing, funding and implementation are too preliminary and uncertain. However, should it be implemented, it is anticipated that it would accelerate spring-run Chinook salmon recolonization.

The commenter cites Anderson et al. (2014) to state that "there are no clear-cut examples in which a reintroduction employing hatchery releases yielded a self-sustaining naturalized population." However, the examples cited in Anderson et al. (2014) are mostly reintroduction programs for Atlantic salmon, and they are all programs in which hatchery releases within formally inaccessible habitat were the sole mechanism of reintroduction. In contrast, under the Proposed Project hatchery production would be continued for only eight years, dam removal would remove passage barriers, and the primary mechanism of reintroduction would be "natural colonization" (highlighted by Anderson et al. 2014) from salmon (including naturalized and hatchery strays) volitionally accessing former habitat. Examples of hatchery production contributing to successful reintroduction in conjunction with volitional passage include the White Salmon River, Washington, following removal of Condit Dam (Allen et al. 2016), and the Elwha River, Washington, following removal of Elwha Dam and Glines Canyon Dam (Weinheimer et al. 2018).

In addition, as described in Volume I Section 4.7.12 *Alternatives – No Hatchery Alternative – Historical Resources and Tribal Cultural Resources* (pages 4-318 to 4-319), in the short-term the No Hatchery Alternative would reduce the amount of fall-run Chinook and coho salmon present for California Native American tribes that currently use salmon in their diet and consider salmon to be an important part of their culture. This potential short-term impact to the fishery would be greater under the No Hatchery Alternative than under the Proposed Project, because under the Proposed Project the hatcheries would continue to supplement natural adult returns (albeit at a reduced rate of production) until after seven generations or cohorts of fish have been hatched with the benefit from expanded habitat and improved water quality conditions. The short-term reduction in the fishery due to elimination of hatchery-produced fall-run Chinook and coho salmon under the No Hatchery Alternative would represent a material impairment of the Klamath Riverscape as a resource and a substantial restriction of tribal access to the fishery relative to existing conditions. As stated in Volume I *Executive Summary* (page ES-20) the No Hatchery Alternative would not meet Proposed Project Objective 2 (In a timely manner, to advance the long-term restoration of the natural fish population in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation) as quickly as under the Proposed Project.

The Executive Summary has been revised to clarify how the EIR analysis considers the short-term reduction in the fishery due to elimination of hatchery-produced fall-run Chinook and coho salmon under the No Hatchery Alternative relative to existing conditions. Please refer to Volume III Attachment 1 Executive Summary for the revisions.

As stated in Volume I *Executive Summary* (page ES-24), in identifying the environmentally superior alternative for the Lower Klamath Project EIR, it makes sense to evaluate the degree of restoration benefit that the alternatives provide above the current degraded basin condition, as well as the duration and severity of negative impacts, in the context of a project that is intended to provide timely improvement of water quality and the restoration of anadromous fish access upstream of Iron Gate Dam. In looking at the range of benefits and impacts the

State Water Board has identified the Proposed Project as the environmentally superior alternative.

Comment ORG34-9

As set forth more fully below, the DEIR properly reveals that the No Hatchery Alternative would reduce the Project's significant impacts. As discussed below, the No Hatchery Alternative would likely reduce the Project's impacts even further than analyzed in the DEIR. However, even based on the DEIR's analysis alone, it is clear that, because the No Hatchery Alternative is a feasible alternative that would substantially lessen the Project's significant impacts, the State Board cannot approve the Project as proposed and should instead consider and approve the No Hatchery Alternative.

The table below summarizes the DEIR's comparison of environmental impacts between the No Hatchery Alternative and the proposed Project with continued hatchery operations at Iron Gate and the start up of hatchery operations at Fall Creek. As shown, the No Hatchery Alternative reduces or eliminates the Project's significant impacts in numerous impact categories, including water quality, aquatic resources, phytoplankton and periphyton, terrestrial resources, air quality, greenhouse gas (GHG) emissions, tribal cultural resources, aesthetics, recreation, traffic, and noise. Except for one short-term impact discussed below, the No Hatchery Alternative produces the same impacts as the proposed Project in all other impact categories, thereby rendering the No Hatchery Alternative an environmentally superior alternative overall.

<u>Summary of the DEIR's Reported Environmental Impacts of the Project (with Hatchery Operations) as Compared with the No Hatchery Alternative ("NHA")</u>

Environmental Impact	***Impact Comparison***
Water Quality	*The NHA would reduce impacts relative to the Proposed Project, as it would eliminate effluent discharges from Iron Gate Hatchery.* The NHA would eliminate a significant and unavoidable impact of the proposed Project for water temperature and dissolved oxygen in Fall Creek downstream of the proposed Fall Creek Hatchery (Impact 3.2-17). DEIR at 3-171, 4-304.*
Aquatic Resources	*The NHA would reduce impacts to aquatic resources by eliminating a source of the spread of fish disease, removing well-documented competitive pressure between hatchery-derived and natural origin fish, reducing straying, and increasing the sustainability of natural spawning fish populations. The NHA would also eliminate any potential impacts to aquatic resources from diversions from Bogus Creek and Fall*

Environmental Impact	***Impact Comparison***
	Creek necessary for hatchery operations. DEIR at 4-304 to 4-313.
Phytoplankton and Periphyton	*The NHA would reduce impacts to phytoplankton and periphyton conditions relative to the Proposed Project, as it would cease nutrient discharges from Iron Gate Hatchery and would not start discharges from Fall Creek hatchery.* DEIR at 4-313.*
Terrestrial Resources	*Same. Any short term loss of hatchery fish under the NHA could be offset by alternative food sources and would not significantly impact wildlife; long-term benefits of the NHA "would result in an increased prey base and would be beneficial" to terrestrial resources. DEIR at 4-315 to 4-316.*
Flood Hydrology	*Same*
Groundwater	*Same**
Water Supply/Water Rights	*Same*
Air Quality	*"[U]nder the No Hatchery Alternative, operational emissions from the hatcheries would be lower (zero) than those under existing conditions," and would eliminate proposed operational emissions.* DEIR at 4-317 (emphasis added).*
Greenhouse Gas Emissions	*Same regarding construction impacts; for operational impacts the NHA emissions would be lower (zero) than the proposed Project/ existing conditions.* DEIR at 4-318.*
Geology, Soils, and Mineral Resources	*Same*
Historical Resources and Tribal Cultural Resources	*The NHA would (1) be beneficial relative to the proposed Project by returning the Iron Gate Hatchery to more natural conditions in the short term (2) eliminate potential significant impacts to tribal cultural resources from construction of Fall Creek Hatchery (Impact 3.12-1), (3) result in a short term reduction in the fishery and substantial short-term restriction of tribal access to the fishery relative to existing conditions,* and (4) would result in an increase in an availability of salmon species for tribes and thus beneficial in the long-term. DEIR at 4-318 to 4-319.*
Paleontological Resources	*Same*
Land Use and Planning	*Same*

Environmental Impact	***Impact Comparison***
Agriculture and Forestry Resources	*Same*
Population and Housing	*Same**
Public Services	*Same*
Utilities and Service Systems	*Same*
Aesthetics	*The NHA is beneficial relative to the Proposed Project, as it would return/keep areas to/in natural conditions. DEIR at 4-321.*
Recreation	*Same. Any short term loss of hatchery fish under the NHA would not significantly impact recreational opportunities; the NHA would result in "long-term beneficial effects on the scenic quality, recreation, fisheries and wildlife of the California Klamath River wild and scenic river segment." DEIR at 4-322.*
Hazards and Hazardous Materials	*Same**
Transportation and Traffic	*The NHA would result in reduced traffic compared with the proposed Project because there would be no traffic from construction at Fall Creek or hatchery operations. DEIR at 4-323.*
Noise	*The NHA would result in reduced noise compared with the proposed Project because there would be no noise from construction at Fall Creek or hatchery operations. DEIR at 4-323.*

DEIR 4-301 to 4-323.

**As explained below, the DEIR likely understates the benefits of the NHA as compared to the proposed Project and/or overstates any short-term impacts of the NHA.*

Response to Comment ORG34-9

Contrary to the assertion in the comment, the EIR does not determine that the No Hatchery Alternative would substantially lessen the potential impacts of the Proposed Project. The significant impacts of a project and feasible alternatives under CEQA are determined by comparison to the existing condition. The comment's comparison of the No Hatchery Alternative to the Proposed Project, on the other hand, primarily includes assertions that the No Hatchery Alternative would result in greater improvements from the existing condition than the Proposed Project, not that it would reduce negative impacts of the Proposed Project. As discussed in Volume I Section 4.7.2 *Alternatives –No Hatchery Alternative – Water Quality* (pages 4-304 to 4-305) the No Hatchery Alternative would eliminate potential less-than-significant variations in water quality (i.e., water temperature, suspended material, nutrients, biochemical oxygen demand, and inorganic and organic contaminants [water treatment chemicals]), from Iron Gate Hatchery during the eight years following dam removal, where these variations are part of the existing condition (CEQA baseline). The continuation of these less than significant water quality variations for eight years under the Proposed Project is not a reduction in an environmental impact relative to the Proposed Project, as asserted by the comment, because the Proposed Project does not cause an impact compared to existing conditions. The EIR discloses that the potential significant and unavoidable impacts to water quality (water temperature and dissolved oxygen) in Fall Creek and the Klamath River that would occur for eight years following dam removal under the Proposed Project would not occur under the No Hatchery Alternative (Volume I Section 4.7.2 *Alternatives – No Hatchery Alternative – Water Quality* [pages 4-304 to 4-305]).

With respect to the comment's assertions regarding fish disease, competitive pressure, and potential straying, please refer to response to comment ORG34-8. Regarding the comment's assertion that the No Hatchery Alternative would eliminate any potential impacts to aquatic resources from diversions from Bogus Creek and Fall Creek necessary for hatchery operations, as described in Volume I Section 4.7.3 *Alternatives – No Hatchery Alternative – Aquatic Resources* [pages 4-305 to 4-313]), please note that the No Hatchery alternative would result in no change relative to existing conditions. Further, please note that under the Proposed Project there would be no significant impact with mitigation on anadromous salmonid populations due to short-term and long-term Bogus Creek flow diversions for the Iron Gate Hatchery (Section 3.3.5 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-23), and there would be no significant impact on anadromous salmonid populations due to short-term and long-term Fall Creek flow diversions for the Fall Creek Hatchery (FCH) (Potential Impact 3.3-24). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Regarding phytoplankton and periphyton conditions, as discussed in Volume I Section 4.7.4 *Alternatives – No Hatchery Alternative – Phytoplankton and Periphyton* (pages 4-313 to 4-314) the No Hatchery Alternative would eliminate potential less-than-significant discharges of nutrients from Iron Gate Hatchery during the eight years following dam removal, where these discharges are part of the existing condition (CEQA baseline). The continuation of these less than significant discharges for eight years under the Proposed Project is not a reduction in an environmental impact relative to the Proposed Project, as asserted by the comment, because there is no impact under existing conditions. As stated in the EIR, decreases in hatchery nutrient releases would not necessarily result in a beneficial effect on phytoplankton or periphyton conditions downstream of the hatchery discharge. The EIR discloses that the potential significant and unavoidable impacts to water quality (water temperature and dissolved oxygen) in Fall Creek and the Klamath River that would occur for eight years following dam removal under the Proposed Project would not occur under the No Hatchery Alternative (Volume I Section 4.7.2 *Alternatives – No Hatchery Alternative – Water Quality* [pages 4-304 to 4-305]).

With respect to reduced operational air quality, greenhouse gas emissions, and energy under the No Hatchery Alternative, because existing conditions are the baseline against which impacts are measured, the current operational emissions are not significant CEQA impacts (please also refer to *Recirculated Portions of the Draft EIR* Section 4.7.9 *Air Quality* [page RE-4-22]).

Because the Lower Klamath Project dams and associated facilities would be removed in the same manner under the No Hatchery Alternative as the Proposed Project, potential construction-related impacts and associated mitigation measures under the No Hatchery Alternative are generally the same as those described for the Proposed Project, except for the differences discussed in Volume I Section 4.7 *Alternatives – No Hatchery Alternative* (pages 4-301 to 4-323). Where the comment notes that the No Hatchery Alternative would reduce short-term construction-related impacts associated with the Proposed Project (i.e., air quality, greenhouse gas emissions, energy, historical resources and tribal cultural resources, transportation and traffic, noise), please note that the significant impacts of a project and feasible alternatives under CEQA are determined by comparison to the existing condition.

The comment notes that the No Hatchery Alternative would have the same impacts as the Proposed Project (i.e., terrestrial resources, flood hydrology, groundwater, water supply/water rights, geology/soils, and mineral resources, paleontological resources, land use and planning, agriculture and forestry resources, population and housing, public services, utilities and service systems, recreation, and hazards and hazardous materials). Comment noted.

Where the comment notes that the No Hatchery Alternative is beneficial relative to the Proposed Project because it would result in more natural aesthetic conditions, please note that Section 3.19.3 *Aesthetics – Significance Criteria*, Section 3.19.4 *Aesthetics – Impact Analysis Approach*, and Section 4.7.19 *Alternatives – No Hatchery Alternative – Aesthetics* have been revised to clarify the baseline used for the EIR aesthetic resources analysis. In Section 3.19.3 *Aesthetics – Significance Criteria* the first significance criterion has been modified to remove the objectives associated with the Class III Visual Resource Management (VRM) designation and to more clearly identify how a shift in VRM classification relative to the baseline (i.e., existing conditions) is treated in the analysis. The modified criterion also explicitly acknowledges how the analysis was applied in areas where the VRM analysis was not conducted. Additionally, Section 3.19.4 *Aesthetics – Impact Analysis Approach* and Section 4.7.2 *Alternatives – No Hatchery Alternative – Aesthetics* have been revised to align with the clarified significance criteria and to remove any reference to natural conditions, since this is not the CEQA baseline. Please refer to Volume III Attachment 1 Section 3.19.3 *Aesthetics – Significance Criteria*, Section 3.19.4 *Aesthetics – Impact Analysis Approach*, and Section 4.7.2 *Alternatives – No Hatchery Alternative – Aesthetics* for the revisions. For additional discussion of the aesthetics baseline, please refer to responses to comments ORG46-321, ORG46-323, ORG46-324, ORG46-325, ORG46-330, and ORG46-331.

The potential significant and unavoidable impacts to water quality (water temperature and dissolved oxygen) in Fall Creek and potentially the Klamath River would not occur under the No Hatchery Alternative, whereas these impacts would occur for eight years following dam removal under the Proposed Project. However, note that the elimination of hatchery produced fall-run Chinook salmon under the No Hatchery Alternative would delay the attainment of one of the Project Objectives, namely the timely restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation. As discussed in Volume I Section 4.7.12 *Alternatives – No Hatchery Alternative – Historical Resources and Tribal Cultural Resources*, elimination of hatchery produced fall-run Chinook salmon under the No Hatchery Alternative would likely result in a reduction (averaging 35 percent, potentially ranging from 19 to 50 percent based on existing conditions) in adult returns in the fall beginning in post-dam removal year 3 and continuing for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal are realized (please also refer to Volume I Section 4.7.3 *Alternatives – No Hatchery Alternative – Aquatic Resources*, Potential Impact 3.3-7). The elimination of hatchery produced coho salmon would likely result in a reduction in adult returns for a period of one to five years before the benefits of dam removal are realized (please also refer to Volume I Section 4.7.3 *Alternatives – No Hatchery Alternative – Aquatic Resources* Potential Impact 3.3-9). This potential impact to the fishery would be greater under the No Hatchery Alternative than under the Proposed Project, because under the Proposed Project the hatcheries would continue to supplement natural adult returns (albeit at a reduced rate of production) until after seven generations or cohorts of fish have been hatched with the benefit from expanded habitat and improved water quality conditions. The short term reduction in the fishery due to elimination of hatchery-produced fall-run Chinook and coho salmon under the No Hatchery Alternative would represent a material impairment of the Klamath Riverscape as a resource and a substantial restriction of tribal access to the fishery relative to existing conditions. A lack of access to native food sources, including an inability to get salmon due to poor river condition, is primary among the reasons that Klamath Basin Native community food assistance users report a reliance on food assistance, with 70 percent of all surveyed households reporting that they rarely or never have access to their desired foods including salmon (Sowerwine et al. 2019). The potential for the reduction in fish available for tribal harvest results in a potentially significant short-term impact on the Klamath Riverscape as a tribal cultural resource (Potential Impact 3.12-9).

As described in Potential Impact 3.2-17, the temporary exceedances of the water quality standards for temperature at Fall Creek Hatchery are expected to be small (-0.5 – 2.2° F) and to occur intermittently, rather than constantly. Any temporary exceedances of the dissolved oxygen standards resulting from Fall Creek Hatchery are expected to be infrequent under the Proposed Project.

In this instance, in light of the objectives of the Proposed Project, and the degree of harm from the different significant impacts, the significant impact to the tribal fishery as a contributing factor to the Klamath Riverscape is of greater relative weight than the significant impact to water quality. Thus, while both alternatives would confer significant environmental benefits, the Proposed Project is the environmentally superior alternative.

Comment ORG34-10

The benefits of the No Hatchery Alternative are likely even greater than revealed in the DEIR (and as summarized above). This is because the DEIR does not quantify many of the impacts of the existing hatchery operations, which would be eliminated under the No Hatchery Alternative. For example, the DEIR concludes that Iron Gate's hatchery discharges under existing conditions have a less than significant impact on water quality and phytoplankton and periphyton conditions, but does not quantify the relevant factors. DEIR at 4-304, 4-313. Elsewhere, the DEIR admits that "Iron Gate Hatchery currently exceeds its TMDL allocation of zero net discharge of nitrogen, phosphorous and biological oxygen demand" (DEIR at 3-164), but does not specify by how much. According to the State Board's Investigative Order R1-2017-0051, "Review of current hatchery sampling data shows that the Facility discharges approximately 2,500 lbs of nitrogen per year, 500 lbs of phosphorus per year and 14,000 lbs of organic matter per year measured as Biochemical Oxygen Demand (BOD). This represents 0.03% of the overall loading of nitrogen and phosphorus and 0.02% of the overall loading of organic matter to the Klamath River every year." Available at https://www.waterboards.ca.gov/northcoast/board_decisions/adopted_orders/pdf/2017/17 _0051_IronGate_13267.pdf.

Likewise, the DEIR fails to recognize that hatcheries use a substantial amount of formalin and other chemicals in hatchery operations. Thus, by eliminating hatchery operations, the No Hatchery Alternative would result in reduced impacts from hazards and hazardous materials. "The chemicals and aquaculture drugs the Facility uses, or can use, for the treatment and control of disease include oxytetracycline, florfenicol, formalin, providine-iodine complex, hydrogen peroxide, potassium permanganate, and sodium chloride. Chemicals and aquaculture drugs used for anesthesia include MS-222/Finquel, and carbon dioxide." Id.

The DEIR also fails to quantify operational GHG or other air pollutant emissions from Iron Gate Hatchery. DEIR at 4-317 to 4-318. Further, the DEIR fails to *analyze the relationship of water diversions for hatchery operations to groundwater levels (DEIR at 4-316) and fails to recognize population and housing impacts that may stem from operating the two hatcheries for eight additional years (DEIR at 4-320).*

The DEIR should be augmented to include this additional information. Were the DEIR to fully detail the impacts of current and proposed hatchery operations, the benefits of the No Hatchery Alternative would undoubtedly be even more apparent. However, even the analysis the DEIR now contains demonstrates the environmental superiority of the No Hatchery Alternative.

Response to Comment ORG34-10

The comment cites Volume I Section 4.7.2 *Alternatives – No Hatchery Alternative – Water Quality* (page 4-304) and Section 4.7.4 *Alternatives – No Hatchery Alternative – Phytoplankton and Periphyton* (page 4-313), which present the analysis of potential water quality and periphyton/phytoplankton impacts under the No Hatchery Alternative. The existing condition (CEQA baseline) for these environmental parameters for the current hatchery discharges is described in Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-17. Because existing conditions are the baseline against which impacts are measured, the current operation is not a significant CEQA impact.

Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-17 has been revised to provide additional information about Iron Gate Hatchery's current operations, including specification of the total nitrogen, total phosphorus, and organic matter discharges from Iron Gate Hatchery; the specific chemicals and aquaculture drugs used at Iron Gate Hatchery; and the existing requirements for the hatchery to ensure that chemicals are properly stored and disposed of and that any accidentally spilled materials are contained, cleaned, and disposed of properly. Please refer to Volume III Attachment 1 Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* Potential Impact 3.2-17 for the revisions. Additionally, *Section 3.21 Hazards and Hazardous Materials* has been revised to add a reference to Potential Impact 3.2-17. Please refer to Volume III Attachment 1 *Section 3.21 Hazards and Hazardous Materials* for this revision.

Section 4.7.4 *Alternatives – No Hatchery Alternative – Phytoplankton and Periphyton* has been revised to add a reference to Potential Impact 3.2-17. Please refer to Volume III Attachment 1 Section 4.7.4 *Alternatives – No Hatchery Alternative – Phytoplankton and Periphyton* for this revision.

With respect to the comment's concern about GHGs, this topic pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (Greenhouse Gas Emissions and Energy).

Section 4.7.7 *Alternatives – No Hatchery Alternative – Groundwater* has been revised to clarify that the proposed surface water diversions for the hatcheries under the Proposed Project are non-consumptive and the points of diversion and points of return are not located near any groundwater wells (i.e., the point of diversion and point of return for Fall Creek Hatchery (FCH) would be located along Fall Creek between Iron Gate Reservoir and Fall Creek Dam, as shown in Volume I Section 3.7 *Groundwater – Environmental Setting – Local Groundwater Conditions*, Figure 3.7-9 [page 3-655], and the point of diversion and point of return for Iron Gate Hatchery would be located along Bogus Creek near the confluence with the Klamath River as shown in Volume I Section 3.7 *Groundwater – Environmental Setting – Local Groundwater Conditions*, Figure 3.7-10 [page 3-655]). Please refer to Volume III Attachment 1 Section 4.7.7 *Alternatives – No Hatchery Alternative – Groundwater* for the revisions.

Section 4.7.16 *Alternatives – No Hatchery Alternative – Population and Housing* has been revised to clarify that eliminating the need for hatchery operational staff under this alternative would be inconsequential with respect to population and housing. Please refer to Volume III Attachment 1 Section 4.7.16 *Alternatives – No Hatchery Alternative – Population and Housing* for the revisions.

Comment ORG34-11

It also appears evident that the No Hatchery Alternative is feasible, which is defined by CEQA as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors." Guidelines § 15364. Because the Project calls for only eight years of hatchery operations, ceasing those operations upon decommissioning instead would not seem to pose any additional economic, legal, social, or technological impediments, and the DEIR does not reveal any. Indeed, hatchery operations can be costly and thus ceasing such operations sooner would have economic benefits.

Response to Comment ORG34-11

This comment asserts that the No Hatchery Alternative appears to be feasible under CEQA, and to have potential economic advantages in reduced hatchery construction costs. Comment noted. Please see Volume I Section 4.1 *Alternatives Selection/Overview* (page 4-1), Section 4.1.1 *Alternatives – Alternatives Selection* (pages 4-1 to 4-2), and Section 4.1.1.1 *Alternatives – Alternatives Selection – Alternatives Carried Forward for More Detailed Analysis – No Hatchery Alternative* (page 4-6) for the Draft EIR's preliminary assessment of the No Hatchery Alternative as a feasible alternative.

Comment ORG34-12

Further, as discussed, the No Hatchery Alternative is environmentally beneficial. The only potential negative impact the DEIR notes for the No Hatchery Alternative that would not be present with the proposed Project is a short-term loss of catch that could impair tribal access to the fishery relative to existing *conditions. DEIR at 4-319. However, this potential short-term impact should not render the alternative infeasible for at least two reasons. First, CEQA considers a project to have a significant environmental impact if it "achieve[s] short-term, to the disadvantage of long-term, environmental goals." Public Resources Code § 20183(b)(1). As discussed, the DEIR here makes clear that removing hatchery operations is superior to the proposed Project in achieving the long-term stability of the fishery. DEIR at 4-319; supra pp. 5-6. Thus, the State Board should not jettison an alternative that is clearly environmentally superior over the long-term due to one potential short-term impact. Second, it is not clear that the impact should be considered significant even in the short-term. The DEIR elsewhere finds that any short-term impacts from the loss of hatchery fish would be offset by improved conditions for native fish from hatchery removal, including less mortality from disease, less competition, less straying, and better adaptation. See, e.g., 4-304 to 4-313. The DEIR fails to explain why any short-term impacts would not similarly be offset for tribes accessing the fishery.*

Response to Comment ORG34-12

Please refer to Master Response AQF-2 and response to comment ORG42-16.

Comment ORG34-13

In sum, the No Hatchery Alternative is clearly environmentally superior to the proposed Project, meets every Project objective, and is feasible. The State Board should therefore consider this Alternative for adoption. If for any reason the Board should determine that the No Hatchery Alternative is infeasible, the agency must explain the reasons for this determination in detailed findings, which must be both legally accurate and supported by substantial evidence. Public Resources Code §§ 21081(a)(3), 21081.5; CEQA Guidelines §§ 15091(a)(3), (b).

Response to Comment ORG34-13

This comment summarizes conclusion of preceding comments and interprets CEQA. Comment noted. Please also refer to response to Master Response AQF-2 and responses to comment ORG34-11 and ORG42-16.

Comment ORG34-14

If the agency determines and makes adequate legal findings that the No Hatchery Alternative is infeasible, it must also then consider any and all feasible mitigation measures to lessen or avoid the significant impacts stemming from the Project's proposed hatchery operations. For every mitigation measure evaluated, the agency must demonstrate either that the mitigation measure: (1) will be effective in reducing a significant environmental impact; or (2) is ineffective or infeasible due to specific legal or "economic, environmental, social and technological factors." Friends of Oroville v. City of Oroville (2013) 219 Cal.App.4th 832, 842-44; Public Resources Code §§ 21002, 21061.1; CEQA Guidelines §§ 15021(b), 15364.

Response to Comment ORG34-14
Comment noted. This comment interprets CEQA.

Comment ORG34-15
If an agency ultimately determines that mitigation proposed in the EIR is infeasible, it may decline to adopt the measure. However, in that event, as with alternatives to the Project, CEQA requires that the agency explain the reasons for this determination in detailed findings, which must be both legally accurate and supported by substantial evidence. Public Resources Code §§ 21081(a)(3), 21081.5; CEQA Guidelines §§ 15091(a)(3), (b); Village Laguna of Laguna Beach, Inc. v. Bd. of Supervisors (1982) 134 Cal.App.3d 1022, 1032-35. And if the project's impacts will remain significant even after mitigation, the agency must issue an additional statement of overriding considerations, also supported by substantial evidence, demonstrating that the project's benefits outweigh its effects. Public Resources Code § 21081(b); see CEQA Guidelines §§ 15091(f), 15093.

In additional to these procedural requirements, CEQA also has substantive "teeth." The lead agency must actually adopt any feasible mitigation that can substantially lessen the Project's significant environmental impacts. Public Resources Code § 21002; CEQA Guidelines § 15002(a)(3); City of Marina v. Board of Trustees of California State University (2006) 39 Cal.4th 341, 368-69. In addition, the agency must "ensure that feasible mitigation measures will actually be implemented as a condition of development, and not merely adopted and then neglected or disregarded." Federation of Hillside and Canyon Assns. v. City of Los Angeles (2000) 83 Cal.App.4th 1252, 1261 (italics omitted); CEQA Guidelines § 15126.4(a)(2).

An EIR generally may not defer evaluation of mitigation until a later date. Guidelines § 15126.4(a)(1)(B). Rather, an EIR must evaluate each mitigation proposal that is not "facially infeasible," even if such measures would not completely eliminate an impact or render it less than significant. Los Angeles Unified School Dist. v. City of Los Angeles (1997) 58 Cal.App.4th 1019, 1029-31 ("LA Unified").

Response to Comment ORG34-15
Comment noted. This comment interprets CEQA.

Comment ORG34-16
Here, the DEIR identifies several significant and unavoidable impacts from hatchery operations, including on water temperature and dissolved oxygen in Fall Creek downstream of Fall Creek Hatchery. See, e.g., DEIR at 3-171 (Impact 3.2-17). The DEIR claims that no feasible mitigation could be employed to reduce these impacts. Id. However, as demonstrated by the analysis of the No Hatchery Alternative, these impacts could be reduced or eliminated by either reducing or eliminating the hatchery operations. All feasible mitigation options in

this regard must be explored, including but not limited to (1) reducing operations at Iron Gate hatchery and declining to reopen Fall Creek Hatchery; and (2) operating hatcheries with solely a conservation focus. The Native Fish Society does not by this letter endorse any particular mitigation approach, but only reminds the State Board of its obligation under CEQA to consider and adopt all feasible mitigation to reduce or avoid the Project's significant impacts from hatchery operations.

Response to Comment ORG34-16

Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* – Potential Impact 3.2-17 identifies one impact from hatchery operations at Fall Creek that would be avoided under the No Hatchery Alternative. This impact was found to be significant and unavoidable in the short term for water temperature and dissolved oxygen in Fall Creek downstream of Fall Creek Hatchery (FCH). Please refer to Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* – Potential Impact 3.2-17 for discussion of mitigation that was considered to reduce the impacts of Fall Creek Hatchery on water temperature in Fall Creek and the reasons that these options were determined to be infeasible. With respect to dissolved oxygen, the EIR analysis indicates that Fall Creek Hatchery discharges would have a low potential for causing dissolved oxygen percent saturation to become less than Basin Plan dissolved oxygen water quality objectives; however, as a conservative determination, the EIR notes that dissolved oxygen percent saturation in Fall Creek may infrequently decrease below Basin Plan dissolved oxygen water quality objectives and thus there would be significant impact without mitigation in the short term. Other unmitigable adverse impacts identified under the Proposed Project are also identified under the No Hatchery Alternative, and these would occur in the short term, during reservoir drawdown and construction activities associated with hydroelectric facilities removal. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

The comment asserts that a mitigation measure of reducing operations at Iron Gate Hatchery and declining to reopen Fall Creek Hatchery would reduce significant and unavoidable impacts of the Proposed Project. Operations at Iron Gate Hatchery are already being reduced relative to existing conditions under the Proposed Project (see Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – General Water Quality* – Potential Impact 3.2-17), and further reducing its operations would not, therefore, reduce an identified potentially significant impact of the Proposed Project relative to the existing condition. In addition to reduced production at Iron Gate Hatchery not addressing an identified significant impact, declining to open Fall Creek Hatchery is not required to be included in the EIR as a mitigation measure, since it is included and assessed in the EIR as part of the analysis of the No Hatchery Alternative in Section 4.7.2 *Alternatives – No Hatchery Alternative – Water Quality* (page 4-304). In that section the EIR notes that not opening Fall Creek Hatchery would reduce short-term construction-related impacts and operational impacts on water quality in Fall

Creek for the eight years following dam removal. Continued hatchery production is stipulated in the Klamath Hydropower Settlement Agreement (KHSA), and it does not appear possible to achieve the hatchery production levels under the Proposed Project at Iron Gate Hatchery (see Master Response AQF-2). Suitable water temperatures for year-round rearing of coho is not available at Iron Gate Hatchery with infrastructure anticipated to be available following dam removal.

As discussed in Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries*, all hatchery production of coho salmon is already operated for species conservation. Under existing conditions and the Proposed Project, all production of coho salmon is constrained by a Hatchery Genetic Management Plan (HGMP) for the Iron Gate Hatchery (CDFW and PacifiCorp 2014), which redefined the operation of this hatchery from a mitigation hatchery to one now operated to protect and conserve the genetic resources of the Upper Klamath population unit of the Southern Oregon/Northern California Coast (SONCC) coho salmon Evolutionarily Significant Unit (ESU). Included in the HGMP are defined monitoring and evaluation activities to evaluate effects of the hatchery activities on the abundance, productivity, spatial structure, and diversity of the SONCC coho salmon and the magnitude or relative impact of the hatchery program on other actions that influence SONCC coho salmon.

Chinook salmon production currently occurs at Iron Gate Hatchery without a conservation focus per se. Continuation of this baseline condition will not reduce a significant impact of the Proposed Project.

Comment ORG34-17

In sum, the Native Fish Society supports decommissioning and license surrender, but remains concerned about the environmental impacts of the proposed Project's hatchery operations at Iron Gate and Fall Creek. While the DEIR recognizes many of the detrimental effects of hatchery operations, it should be revised to incorporate the additional information identified in this letter. Further, CEQA requires that the State Board reduce or avoid the significant impacts of hatchery operations and construction to the extent feasible. Therefore, the Native Fish Society urges the State Board to adopt the No Hatchery Alternative or, at a minimum, to consider and adopt all feasible mitigation to reduce or avoid the significant impacts from hatchery operations and construction.

Response to Comment ORG34-17

Comment summary noted. Please refer to responses ORG34-4 to ORG34-16 for responses on substantive issues summarized by this comment.

Oregon Wild, Doug Heiken

Comment ORG32-1

Oregon Wild strongly supports the Proposed Project, involving removal of Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle dams and associated facilities.

The Proposed Project will best meet project objectives and provide the greatest ecological gains in this important ecosystem. We do not want concerns about short-term impacts to get in the way of this great dam removal project that will be highly-beneficial in the short- and long-term. In the attached letter we offer a few suggestions to improve the Proposed Project.

Response to Comment ORG32-1
Thank you for your comment. Please refer to Master Response GEN-1.

Comment ORG32-2
Please accept the following comments from Oregon Wild concerning the Draft Environmental Impact Report for 401 Certification of the Lower Klamath Project License Surrender, FERC Project No. 14803, https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/low er_klamath_ferc14803_deir/noa.pdf. Oregon Wild represents 20,000 members and supporters who share our mission to protect and restore Oregon's wildlands, wildlife, and water as an enduring legacy. Our goal is to protect areas that remain intact while striving to restore areas that have been degraded. Oregon Wild has worked for more than three decades to protect and restore the ecological integrity of the Klamath River, the entire Klamath Watershed, and the fish and wildlife that call it home. Our members and supporters have a great affection and connection to this area.

Response to Comment ORG32-2
Comment noted.

Comment ORG32-3
Oregon Wild strongly supports the Proposed Project, involving removal of Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle dams and associated facilities, with a Definite Plan described in EIR Appendix B. The Proposed Project will best meet project objectives and provide the greatest ecological gains in this important ecosystem. We do not want concerns about short-term impacts to get in the way of this great dam removal project that will be highly-beneficial in the short- and long-term. We offer a few suggestions to improve the Proposed Project below.

Response to Comment ORG32-3
Please refer to Master Response GEN-1.

Comment ORG32-4
Oregon Wild supports the Water Board's proposed 401 certification of the Klamath Project Dam Removal and License Surrender because it will lead to significant long-term improvements in the water quality of the Klamath River, especially temperature, dissolved oxygen, pH, and algal toxins. Of course, there are some short-term adverse water quality impacts associated with dam removal, such as the temporary pulse of stored sediments as they mobilize and move

through the system. The dam removal effort must be accomplished with great care to minimize and mitigate these water quality impacts, but because the existing situation is causing a variety of significant adverse water quality problems, the long-term net effect of dam removal on water quality is strongly positive.

Response to Comment ORG32-4
Comment noted.

Comment ORG32-5
The EIR (pp ES-9 to ES-11) provide a nice summary of the beneficial effects of dam removal, which clearly outweigh any adverse effects. This list could be expanded to include: vegetation succession within the reservoir footprint, and all the ecological complexity and self-organization that goes along with succession, such as primary production/consumption, biomass accumulation, large tree habitat, wildlife cover/nesting/feeding, stream shade, dead wood habitat recruitment, carbon storage, and various disturbances that interact with the features listed, etc.

Response to Comment ORG32-5
Comment noted. The list provided in the comment includes various ecological processes, ecosystem forms, and biotic responses that are generally aligned with the expected ecological changes that would occur in the newly exposed reservoir footprints following dam removal and would be promoted by restoration activities included in the Proposed Project to increase habitat complexity and function. For discussion of proposed activities that would improve habitat complexity under the Proposed Project, please refer to Volume I Section 2.7.4.2 *Proposed Project – Restoration Within the Project Footprint – Reservoir Restoration Features* (pages 2-71 to 2-76). For a discussion of carbon storage within the habitat types that would replace the reservoirs, please refer to Section 3.10 *Greenhouse Gas Emissions and Energy*, which was recirculated on December 21, 2019. Please note that benefits listed in the comment that are not discussed in the EIR do not change any of the EIR's impact determinations.

Comment ORG32-6
The listed "terrestrial" benefits of dam removal include "benthic macroinvertebrates." Is this a typo? Maybe the intention was to list benefit to terrestrial invertebrates, which include: mollusks, fungi, lichen, mosses, insects, arthropods, etc.

Response to Comment ORG32-6
Potential impacts on benthic macroinvertebrate populations were evaluated in Volume 1 Section 3.3 *Aquatic Resources* and in Section 3.5 *Terrestrial Resources* as these populations have the potential to be affected by changes in water elevation with the reservoir footprints and water flow, sedimentation, and total suspended sediments in the Klamath River downstream of the Lower

Klamath Project dams, and, in turn, to affect aquatic organisms that feed on them (e.g., fish) and terrestrial organisms that feed on them (e.g., western pond turtle). Many benthic macroinvertebrates also have an aerial life-stage. Please refer to Volume I Section 3.5.5.3 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* Potential Impact 3.5-17 (pages 3-559 to 3-560) for an analysis of the potential impacts on benthic macroinvertebrates present in the reservoir footprint as a result of drawdown and drying of the habitat, and in the Klamath River downstream of Iron Gate Dam as a result of sediment transport and deposition. The analysis indicates that there would be no significant impact in the short term and there would be beneficial long-term effects.

Comment ORG32-7

The existing dams alter river flow and contribute to water quality problems, including toxic algal blooms, low dissolved oxygen, and higher water temperatures. The dams also contribute to fish disease in the lower reaches of the Klamath River. The license surrender and dam removal will revert the Klamath River to more natural seasonal flow conditions resulting in improved water quality, temperature regime, nutrient cycling, chemistry, and sediment storage/mobility. Free-flowing riverine conditions and improved water quality will benefit aquatic habitat and anadromous fish populations by increasing access to historical habitat, restoring mainstem and tributary habitat, and improving biological and physical factors that heavily influence fish populations (e.g., flow conditions, sediment and bedload transport, water quality, fish disease, toxic algal blooms, and water temperature).

We urge the Water Boards to adopt conditions that will minimize water quality impacts, reduce the spread of weeds, and conserve unique species like pond turtles, suckers, salmonids, amphibians, and lamprey, while allowing this important dam removal effort to proceed in an efficient and timely manner.

Response to Comment ORG32-7

Consistent with CEQA Guidelines section 15126.4, the EIR identifies several significant impacts for which mitigation is feasible to reduce environmental impacts. For a summary of the potential impacts and mitigation measures, please refer to Volume III Attachment 1 for the final *Executive Summary* Table ES-1.

Additionally, The State Water Board's draft water quality certification (available online at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/lower_klamath_ferc14803/lkp_dwqc.pdf [Accessed December 11, 2018]) incorporates conditions to minimize impacts on aquatic species. For example, the State Water Board includes conditions to monitor water quality and measures to control erosion and stream sedimentation, monitor anadromous fish (Pacific lamprey, fall-run Chinook salmon, coho salmon, and steelhead), rescue and relocate juvenile salmonids and Pacific lamprey from tributary confluence areas, develop and implement aquatic vegetation management, and develop and implement amphibian and reptile management, which includes surveys and rescue and relocation. Klamath River Renewal Corporation (KRRC) has also included an aquatic resource measure as part of the Proposed Project for sucker species in Copco No. 1 and Iron Gate reservoirs (Aquatic Resource Measure 6 *Suckers*) and removal of invasive species and invasive weed control (Appendix B: Appendix H – *Reservoir Area Management Plan*).

Comment ORG32-8

It is reasonable to expect significant short-term erosion and movement of sediment stored behind the dams to be removed. This will likely cause some short-term impacts on Klamath River ecology. Most of these effects will occur during the first year after dam removal, followed by another pulse during the next 5-10 year high-flow event, which should substantially resolve sediment concerns by moving most of the fine sediments out of the system and naturally sorting and distributing the larger material.

Freshwater mussels are long-lived and an important part of the river ecosystem. We are concerned about sediments smothering downstream mussel beds after dam removal. Can this be mitigated by collecting some mussels from representative downstream areas that are expected to be buried in significant sediments, then replanting them in the same locations are things have sorted out? This might be a worthwhile project for tribal partners.

Response to Comment ORG32-8

As described in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-19, the Proposed Project includes Aquatic Resource Measure AR-7 to salvage and relocate freshwater mussels prior to Lower Klamath Project dam removal. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Comment ORG32-9

The project controls significant acreage of uplands surrounding the project, as well as the footprint of the reservoirs themselves. We urge the agencies to require sound ecological stewardship of those lands so they are not subjected to grazing, logging, mining, or motorized recreation, to the detriment of Klamath River water quality. The EIR says that these lands would be transferred to the States of Oregon and California and/or third-parties, for "public interest purposes." This is too broad. There should be an explicit ecological conservation mandate permanently attached to these lands.

Response to Comment ORG32-9

Comment Noted. At this time, the outcome of the future Parcel B land transfer is speculative with regard to land use. While the lands would be managed for the public interest, this could include open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially other uses. The disposition and transfer of Parcel B lands is discussed in Volume I Section 2.7.10 *Proposed Project – Proposed Project – Land Disposition and Transfer* (page 2-108) and analyzed under several sections (e.g., Volume 1 Section 3.5.5 *Terrestrial Resources – Potential Impacts and Mitigation – Special-status Species and Rare Natural Communities* Potential Impact 3.5-28 [page 3-574 to 3-575]). As noted, the disposition of Parcel B lands will be subject to a process described under the Klamath Hydroelectric Settlement Agreement to determine the disposition of lands. This process will include the ability to identify lands appropriate for conservation, and will include future environmental review under CEQA.

Comment ORG32-10

Weed-free native-only seed mixes should be used for seeding after the reservoir is drawn down. Using sterile wheat may not be a good idea because it may cause a boom in the local small animal population that consumes the wheat AND decimates the native seedbed.

Response to Comment ORG32-10

As defined in Klamath River Renewal Corporation's (KRRC) Reservoir Area Management Plan (Volume II Appendix B: *Definite Plan – Appendix H*), the Proposed Project native grasses, sedges, rushes, forbs and shrubs would be used for seeding in all revegetation zones. A very small amount of sterile wheat may be applied; this small amount should not have significant impacts on the native seedbed and would serve an important role stabilizing soils and providing erosion control.

Comment ORG32-11

We urge the agencies to require planting of native willows and other appropriate trees and shrubs in the reservoir footprint along the newly established river channels and tributaries. This will provide several benefits: (i) provide shade to mitigate temperature problems, (ii) suppress weeds, and (iii) stabilize the loose sediments along the river banks.

Response to Comment ORG32-11

As defined in Klamath River Renewal Corporation's (KRRC) Reservoir Area Management Plan (Volume II Appendix B: *Definite Plan – Appendix H*), the Proposed Project includes several actions to encourage rapid revegetation with native riparian species, including willows, in the reservoir footprints; these actions would ensure a no net loss of wetland or riparian habitat acreage and functions.

Comment ORG32-12

The plan is to salvage ESA-listed Lost River suckers and Short-Nose suckers that use the reservoirs, but this effort is expected to salvage only 10% of the population. We urge the agencies to require genetic testing, and if the fish are not unduly hybridized, then a more aggressive fish salvage effort should be *undertaken. The locations for releasing these salvaged fish must be carefully thought out in advance.*

Response to Comment ORG32-12

As described in Volume I Section 2.7.8.1 *Proposed Project – Proposed Project – Other Project Components – Aquatic Resource Measures – Suckers (AR-6)* (page 2-88), the Aquatic Resource Measure AR-6 includes genetic testing of suckers in the Klamath River and in Hydroelectric Reach reservoirs, and capture as many suckers as feasible (not to exceed 3,000 fish) from within the Klamath River and in Hydroelectric Reach reservoirs and place them into the isolated waterbody of Tule Lake (to ensure hybridized suckers do not mix with sucker populations designated as recovery populations in Upper Klamath Lake). Additional detail is provided in Volume II Appendix B: *Definite Plan – Appendix I*.

Additional comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation.

Comment ORG32-13

The EIR says that livestock grazing may be used as a veg control in the uplands. This is not a good idea, because livestock cause several undesired effects, including: spending disproportionate time in sensitive areas such as riparian areas, grazing non-randomly with greater adverse effects on some desired native species and little to no effect on many undesired species (e.g., thistle).

Response to Comment ORG32-13

As discussed in Klamath River Renewal Corporation's (KRRC's) Reservoir Area Management Plan (Volume II Appendix B: *Definite Plan – Appendix H*), the KRRC would evaluate all methods of invasive species control for both their benefits and their risks to the surrounding ecosystems. KRRC is not proposing to graze livestock in sensitive habitats such as riparian areas. Grazing is proposed in upland habitats that are not considered sensitive riparian areas. Furthermore, to protect planted native species and revegetation efforts and to replace the function of the reservoirs as natural barriers, cattle exclusion fencing would be placed around the reservoir areas after drawdown to prevent cattle from accessing areas of sensitive habitats and restoration areas.

Comment ORG32-14

Dead and down wood plays a critical role in maintaining aquatic and terrestrial ecological structure, function, and process. See Rose, C.L., Marcot, B.G., Mellen, T.K., Ohmann, J.L., Waddell, K.L., Lindely, D.L., and B. Schrieber. 2001. Decaying Wood in Pacific Northwest Forests: Concepts and Tools for Habitat Management, Chapter 24 in Wildlife-Habitat Relationships in Oregon and Washington (Johnson, D. H. and T. A. O'Neil. OSU Press. 2001) http://web.archive.org/web/20060708035905/http://www.nwhi.org/inc/data/GISdata/docs/chapte r24.pdf. It is reasonable to expect a significant shortage of dead wood within the former reservoir footprint. This wood deficit should be mitigated *by importing large wood to kick-start the process of natural wood functions and wood recruitment. Placing lots of large wood in the reservoir footprint will help meet water quality goals by capturing and storing sediment and nutrients. Wood should be placed both in and near the river and tributaries, as well as in uplands. Extra wood near tributary junctions is recommended. Wood for restoration should be obtained from appropriate sites, such as thinning of (young) plantations, (young) juniper removal projects, roadside hazard trees, or nearby reservoir salvage efforts.*

Response to Comment ORG32-14
As described in the Volume 1 Section 2.7.4.2 *Proposed Project – Restoration Within the Reservoir Footprint – Reservoir Restoration Features* (pages 2-71 to 2-76), restoration activities for the reservoir footprints are supporting reservoir-deposited sediment evacuation; enhancing tributary connectivity to the Klamath River; incorporating floodplain features such as wetlands, swales, and side channels; enhancing floodplain roughness to stabilize vegetation; and stabilizing banks and enhancing channel complexity, including with the use of large woody debris.

Additional comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation.

Comment ORG32-15
We also urge the agencies to adopt monitoring and adaptive management requirements specifically designed for learning and application to other similar projects. Dam removal is still a fairly new endeavor with uncertainty about environmental impacts and the spatial and temporal fate of stored sediment. Let's learn from this dam removal effort, so that future dam removal efforts can be even better.

Response to Comment ORG32-15
The Klamath River Renewal Corporation's (KRRC) Proposed Project includes several adaptive management elements for water quality, aquatic resources (i.e., fisheries, including actions to remove migration barriers to Klamath River tributaries and upper reaches of the river, should they occur), and terrestrial resources (i.e., revegetation of the reservoir footprints). Additionally, the State Water Board has issued a draft water quality certification which sets forth monitoring and adaptive management requirements for water quality monitoring. The State Water Board's draft water quality certification is available online at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/lower_klamath_ferc14803/lkp_dwqc.pdf (Accessed December 11, 2018).

Comment ORG32-16
Each substantive issue discussed in these comments should be (i) incorporated into the purpose and need for the project, (ii) incorporated into an EIR alternative,

(iii) carefully analyzed as part of the effects analysis, and (iv) considered for mitigation.

Response to Comment ORG32-16
Comment noted.

Pacific Coast Federation of Fishermans Association, Glen Spain

Comment ORG29-1
In general, both PCFFA and IFR endorse and incorporate herein by reference the written comments to be submitted by Feb. 26, 2019, by the Klamath River Renewal Corporation (KRRC), which we have reviewed and approve. The KRRC editing comments help clarify some areas in the Draft Environmental Impacts Report (DEIR) that are unclear, or which may be duplicative.

Please consider these as our Supplemental written comments on behalf of the Pacific Coast Federation of Fishermen's Associations (PCFFA) and its sister organization, Institute for Fisheries Resources (IFR) regarding the Draft Environmental Impacts Report (DEIR) released Dec. 2018, regarding the proposed State of California 401 Certification for removal of the Lower Klamath Dams within the State of California (i.e., CopCo 1 & 2 and Iron Gate Dam). Please make them part of the permanent public record for this decision-making process. Although our two organizations generally support the separate KRRC comments, PCFFA and IFR are separate legal entities presenting these Supplemental written comments solely on their own behalves, and do not in any capacity speak for the KRRC.

Response to Comment ORG29-1
Thank you for your comment.

Comment ORG29-2
PCFFA and IFR both strongly support the KRRC's ongoing efforts to remove the four Lower Klamath Hydropower Project FERC-licensed dams, including the three of the four dams (CopCo 1 & 2 and Iron Gate Dams) located in California, and which are the subject of the current dam removal project. Removal of these four Klamath Basin dams was agreed to in the Klamath Hydropower Settlement Agreement ("KHSA"), also signed by the dams' owner (PacifiCorp). Indeed, PCFFA and IFR are both signatory Parties to the original and amended KHSA documents as well. Both our organizations support the Proposed Project as the best choice among all the alternatives.

Response to Comment ORG29-2
Please refer to Master Response GEN-1.

Comment ORG29-3
On an initial note, looking at the prior Scoping Comments and other written comments from those (particularly Siskiyou County and the Siskiyou County

Water Users Association (SCWUA)) who have vehemently opposed dam removals in the Klamath, many of their past written comments raised concerns related to water quality and other issues that have already been systematically analyzed and long-since debunked or rebutted by hard science. Nevertheless, to make sure the Record in this action is clear, in our initial comments below we will again puncture the many myths about likely sediment releases from dam removal and other impacts of dam removals that opponents of the Proposed Project are repeating in the media and in their written comments on this DEIR.

In particular, we once again we are still reading or hearing public comments in this process with alarmist language about the "massive amounts of mud" behind the dams, and of "toxic mud" supposedly sitting as "sediment time bombs" behind the dams. But in fact, as the prior NEPA/CEQA (2013) rigorous and multiply peer-reviewed analysis of potential Klamath dam removal impacts indicated, multiple studies of the sediment trapped behind the dams have concluded that not only would most of these sediments released be naturally washed through the system to the sea within about 24 months, but that there are NO significant toxics in those sediments above and beyond natural background levels to be concerned about.

Also, a number of sediment containment and stabilization mitigation measures are contained in the recently released June 2018 KRRC "Definite Plan" that will assure that sediment and other short-term water quality impacts will be minimized or eliminated to the extent that is feasible, given that some short-term impacts are inevitable in order to achieve the many long-term water quality gains that would come from restoring the Klamath River's natural and free-flowing conditions. Additional sediment mitigation measures may also be adopted as part of the proposed 401 Certification process.

The debunked sediment and other specious concerns that continue to be raised by other parties in this process who oppose dam removals can be summarized as follows:

Response to Comment ORG29-3

With respect to sediment erosion, transport, and deposition associated with the Proposed Project, please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775). Please also refer to Master Response GEO-1. With respect to nitrogen and other nutrients, please refer to Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-7 and Potential Impact 3.2-8. Both potential impact analyses conclude no significant impact, or beneficial effects, for nutrient conditions associated with the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation (KRRC).

Comments on the California Draft Water Quality Certification for the Lower Klamath Project should be submitted to the State Water Board's Water Quality Certification Program following the instructions provided at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/lower_klamath_ferc14803.html

The Oregon Water Quality Certification for the Lower Klamath Project is available at: https://www.oregon.gov/deq/FilterDocs/ferc14803final.pdf

Comment ORG29-4

MYTH: "Massive amounts of toxic chemicals are in the sediments behind the dams." – Multiple studies and on-site surveys analyzing the chemical make-up of reservoir sediments have concluded that these sediments pose no significant risk to human health.

Opponents to river restoration often cite the Camp, Dresser, and McKee Study, which first assumes a worst-case sediment scenario, and then speculates that the high cost of such toxic sediment removal would push dam removal into the billions of dollars. However, this report was prepared before, and thus fails to acknowledge the results of, the many later studies referenced in footnotes herein (and in the DEIR itself) which disprove that report's initial (and unwarranted) assumption that significant toxic contamination even exists.

This "fake fact" assertion that there are significant toxic chemical contaminant concerns in sediments behind the dams has also been officially debunked. For instance, the US EPA issued a letter dated 4 November, 2015, on just this issue, noting that multiple studies have shown that there were no significant concerns about any toxic sediment problems in any of the reservoirs raised by any of several comprehensive studies. See ATTACHMENT A for a copy of that EPA letter for the record. In general, detections of potential toxic chemicals in sediment core samples were within the range of natural background levels, and well below the range of significant concern for human health.

And while the Draft DEIR noted that levels of arsenic are naturally elevated in the region (due to its volcanic history), human exposure pathways for arsenic were very limited in this highly rural region:

"Thus, overall the Proposed Project would be unlikely to result in short-term or long-term substantive adverse impacts on human health under possible 'Exposure Pathway 2' [long-term exposure to reservoir terrace and/or river bed deposits] due to arsenic." [DEIR 3-143]

As to other contaminants, the DEIR correctly concluded:

"After consideration of dilution, chromium, lead, and total PCB concentrations would be less than the most stringent human health drinking water standards in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir...." [DEIR 3-144-145]

"Thus, there would be little to no potential long-term potential for adverse impacts to human health from exposure to river water due [to] the release of reservoir sediments and associated inorganic or organic contaminants trapped behind the Lower Klamath Project dams, and there would be no significant impact in the long term for human exposure to inorganic and organic contaminants in the Hydroelectric Reach." [DEIR 3-149-150]

The Draft DEIR analysis also correctly noted that:

"Implementation of mitigation measures WQ-2 and WQ-3 would reduce the short-term significant impact of human exposure to inorganic and organic contaminants in the Middle and Lower Klamath River and the Klamath River Estuary to less than significant." [DEIR 3-150]

We believe that the KRRC has already committed to these mitigation measures.

And as to the impact of released sediments on aquatic, non-human species, the DEIR analysis is that these impacts would also be less than significant.

"Overall, one or more chemicals are currently present in the Lower Klamath Project reservoir sediments at levels with potential to cause minor or limited adverse impacts on freshwater aquatic species in the short term, based results from the Shannon & Wilson, Inc. (2006) study and the 2009–2010 Klamath Dam Removal Secretarial Determination study (CDM 2011), but chemicals present in the Lower Klamath Project reservoir sediments are expected to be mixed and diluted below water quality standards, reducing the likelihood of any substantial adverse impacts on freshwater aquatic species in the short term. In the long term, one or more chemicals are present, but at levels unlikely to cause substantial adverse impacts based on available evidence. Therefore, under the Proposed Project, the short-term and long-term impacts on freshwater aquatic species from exposure to sediment-associated inorganic and organic contaminants during sediment release and transit, and from potential downstream river-channel deposition, in the Middle and Lower Klamath River, would be a less-than-significant impact. [DEIR 3-158]

Response to Comment ORG29-4

Please refer to Master Response WQ-6 for further information about the inorganic and organic contaminants in the reservoir sediments.

Comment ORG29-5

MYTH: "20-30 million cubic yards of sediment behind the dams would wash out and devastate the lower river." – These numbers and their impacts are both greatly exaggerated by Siskiyou County and SCWUA. Only about an estimated 13.1 million cubic yards of sediments in total were actually trapped behind the dams by 2012, an amount that is expected to rise to about 15 million cubic yards by 2020. But of these sediments, only about one-third to two-thirds of the total volume (5 to 10 million cubic yards in 2020) would be expected to wash out to sea over 1 to 2 years, as the river becomes re-channelized, with the rest of these sediments to be replanted and stabilized as new river bank.

The majority of those sediments that would naturally erode and are likely to wash out to sea, however, are fine-grained and so would be easily mobilized by normal river flows and thus are not likely to be deposited in the river channel nor estuary for very long, if at all. In short, most of the mobilized sediment, as noted in the prior NEPA/CEQA (2013) analysis, would naturally wash out to sea within a couple of rainy seasons. The DEIR confirms this modeling prediction.

The less mobilized, larger gravel is also beneficial as it will likely help create gravel and cobble beds below the dams that are highly suitable for salmon spawning and rearing – indeed, the existing dams have systematically starved the lower river of natural recruitment of spawning and rearing gravel as much as 50 stream-miles downriver from Iron Gate Dam. (NEPA/CEQA (2013))

Alarmists warning of massive sediment erosion forget that rivers like the Klamath already, naturally, carry vast amounts of sediment out to sea as part of their natural baseline functioning, through natural erosion.

For instance, the Klamath River already normally carries an average water-year sediment load of about 5.834 million tons/year (which translates to 3.889 million cubic yards of sediment/year at a standard conversion rate of 1.5 tons/cubic yard density), which may be greater or lower depending on total rainfall. Sediment transport models (as noted in the DEIR) in fact indicate that, left completely to natural processes, high concentrations of suspended sediments would occur immediately downstream of Iron Gate Dam for only two-to-three months immediately following reservoir drawdown and removal.

But in fact, multiple reservoir silt stabilization and reseeding/revegetation measures are proposed by KRRC to help keep the downstream sediment flows, and later erosion flows, to a minimum. Data cited in the Definite Plan (June, 2018) estimate that with these mitigation measures in place:

"The Project could release up to 1.2 - 2.9 million metric tons of fine sediment (sand, silt, and finer) downstream from Iron Gate Dam (RM 193.1) over a two-year period (USBR 2011)."

In other words (except for a short-lived initial burst, which would be timed so as to avoid most impacts on migrating fish) additional sediment loads triggered by dam removals would remain within the range of what already naturally occurs in high-flow or wet water years.

The Draft Environmental Impact Report (DEIR) confirms that sediment loads would be manageable as well as short-term impacts. Specifically the DEIR notes:

- *“There would be an estimated 15.1 million cubic yards (14.6 million tons) of sediment stored in the J.C. Boyle, Copco No. 1, and Iron Gate reservoirs by 2020 (USBR 2012).” (DEIR ES-5)*
- *“Anticipated erosion volume due to dam removal into the context of annual basin-wide sediment discharge are estimated to average an annual total sediment supply from the Klamath River to the Pacific Ocean of approximately 5.8 million tons (4 million tons/yr. of fine sediment and 1.8 million tons/yr. of sand and larger sediment (Stillwater Sciences (2010). Farnsworth and Warrick (2007) estimate that the average annual silt and clay discharge is 1.2 million tons/yr.… In dry years the supply of sediment to the ocean could be less than 1 million tons/yr. (Figure 3.11-12). Given these estimates, it is expected that the amount of sediment released during the year of drawdown and dam removal would be similar to that transported by the Klamath River to the Pacific Ocean in a year with average flow, much less than that transported by the Klamath River in a wet year, and greater than that transported by the Klamath River in a dry year. See Section 3.11.5 [Soil, Geology, and Mineral Resources] Potential Impacts and Mitigation and Figure 3.11-12 for further details.” (p. 3-769)” [DEIR 3-103]*
- *“A recent USGS overview report on the sources, dispersal, and fate of fine sediment delivered to California’s coastal waters (Farnsworth and Warrick 2007) found the following:*
    - *Rivers dominate the supply of fine sediment to the California coastal waters, with an average annual flux of 34 million metric tons.*
    - *All California coastal rivers discharge episodically, with large proportions of their annual sediment loads delivered over the course of only a few winter days.*
    - *Farnsworth and Warrick (2007) conclude that fine sediment is a natural and dynamic element of the California coastal system because of large, natural sediment sources and dynamic transport processes.” [DEIR 3-104]*
- *“The short-term (less than two years following dam removal) and long-term (2–50 years following dam removal) effects of the Proposed Project on sediment delivery to the Pacific Ocean would be less-than-significant, given the relatively small amount of total sediment input from reservoir sediment release in comparison to the total annual naturally occurring sediment inputs to the nearshore environment. Bedload sediment effects related to*

> *coarse sediment released by the Proposed Project or sediment re-supply likely would not extend downstream of the Cottonwood Creek confluence (RM 185.1). Therefore, there would be no bedload-related effects in the Klamath River Estuary or Pacific Ocean nearshore environment under the Proposed Project." [DEIR 3-755]*

Response to Comment ORG29-5

Please refer to Master Response GEO-1 for further information regarding fine sediment erosion, transport, and deposition.

Comments on the Definite Plan should be submitted to the Klamath River Renewal Corporation.

Comment ORG29-6

MYTH: "Massive sediment plumes from dam removal will kill all the fish in the lower river for many years to come."—There will clearly be some adverse sediment impacts on fish within the mainstem of the river for a short period of time, but as noted above, these sediments are expected to reach lethal levels for fish only for a short period of time during one single, first-year winter flushing event. The Executive Summary of the DOI Final NEPA/CEQA (2013) EIS/EIR notes:

"While sediment release and other construction related activities during dam removal could cause short-term (1 to 2 years) adverse impacts on fisheries downstream from the Hydroelectric Reach, salmon and other aquatic resources would be expected to return to population levels observed prior to dam removal (in 2010 when the Notice of Preparation was issued) within 5 years……

And of course, these estimates are for the Klamath River and all its dams as a whole, including a contribution by J.C. Boyle. But since the sediments trapped behind J. C. Boyle Dam are relatively minor, that contribution would not be substantial.

The plan for reservoir drawdown to be completed in the high-flow winter season within a single year (2021) is also designed to minimize negative effects of sediment surges on sensitive fish species, particularly federally listed coho salmon. Drawdown will be timed to avoid the major runs of fish, many of which (such as coho) only use the mainstem river briefly each year as a migration corridor, and would thus be safe within their usual tributary habitat during the lethal peak of the mainstem sediment surge.

Response to Comment ORG29-6

The EIR analyzes the potential impacts of elevated suspended sediments on aquatic resources in Section 3.3.5 *Aquatic Resources – Potential Impacts and Mitigation* and Section 3.3.5.9 *Aquatic Resources – Potential Impacts and*

Mitigation – Aquatic Resource Impacts Potential Impact 3.3-1; Potential Impacts 3.3-3 through 3.3-16; and Potential Impacts 3.3-19 and 3.3-20.

Comment ORG29-7

MYTH: "Removing the Klamath dams would eliminate their flood control benefits."—First off, the dams in question were never designed for flood control and thus provide little emergency water storage in the event of flood-level flows. At very best, the reservoirs could physically provide less than 7% attenuation of any 100-year flood event, and then only for a few hours' time, i.e., until their reservoirs were full. At most, this might provide just a 10-hour delay in the peaking of any lower river flooding.

Response to Comment ORG29-7

Comment noted. For additional information regarding the flood hydrology analysis presented in the EIR, please refer to Master Response FLD-1.

Comment ORG29-8

As to any additional flood risk caused by the actual drawdown of the dams themselves during deconstruction, the DEIR correctly has this to say:

"While the release rates that would occur during reservoir drawdown would be greater than the flows at the same time under the existing conditions, and in some months above the historical monthly maximum flow (e.g., September), they would be lower than the overall peak flows for extremely wet years recorded during the period of record in each reach. Because the flows would stay below historical peak flows, they would not change the floodplain or flood risks in comparison to the existing conditions. Thus, the short-term increases in downstream flows and changes to flood risks resulting from reservoir drawdown would be less than significant." [DEIR 3-630, 631]

Reservoir drawdown plans were made with consideration for minimizing flood risks downstream. Controlled releases during reservoir drawdown would not be likely to increase flood risks because they would be kept well within the range of historic flows.

From the California-Oregon border, since these dams were not designed to provide any flood control, the total removal of the dams would pose no additional flood risks:

"Because J.C. Boyle Reservoir provides no storage and the dam typically operates in spill mode at flows above plant capacity (i.e., approximately 6,000 cfs; Table 2-1 in USBR 2012), existing conditions peak flows in the Hydroelectric Reach are not attenuated as a result of J.C. Boyle Dam..... Therefore, under the Proposed Project the 100-yr flood inundation extent on the Klamath River from the Oregon-California state line downstream to Copco No. 1 Reservoir would not change from existing conditions (see also Appendix K). [DEIR 3-634, 635]

Below Iron Gate Dam, however, the situation changes, albeit only slightly:

"Hydrologic and hydraulic modeling of floodplain inundation shows that removal of the Lower Klamath Project dams could alter the 100-year floodplain inundation area downstream of Iron Gate Dam between RM 193 and 174 (i.e., from Iron Gate Dam to Humbug Creek) (USBR 2012). The modeling indicates that the differences between existing conditions and the Proposed Project are minor..... This increased discharge would result in flood elevations that are 1.65 feet higher on average from Iron Gate Dam (RM 193) to Bogus Creek (RM 192.6) and 1.51 feet higher on average from Bogus Creek to Willow Creek (RM 188) (Appendix B: Definite Plan). The impact of dam removal on flood peak elevations would decrease with distance downstream of Iron Gate Dam, and USBR (2012) and the KRRC (Appendix B: Definite Plan) estimated that there would be no significant effect on flood elevations downstream of Humbug Creek (RM 174)....." [DEIR 3-630]

These impacts are significant, albeit they would impact only a small number of structures and then only to a minor degree, but there are a number of mitigation measures the KRRC is already assuming as part of its mitigation obligations under the KHSA, as noted below:

"The KRRC proposes to work with willing landowners to implement a plan to address the significant flood risk for the 36 habitable structures (including permanent and temporary residences) located in the altered 100-year floodplain between Iron Gate Dam and Humbug Creek following dam removal. The KRRC would work with the owners to move or elevate the habitable structures in place before dam removal, where feasible, to reduce the risks of exposing people and/or structures to damage, loss, injury, or death due to flooding. However, flood damage and/or loss of structures that are not feasible to move or elevate would be a significant impact. Final determination of the future 100-year floodplain after dam removal would be made by FEMA. The KRRC is coordinating with FEMA to initiate the map revision process (Appendix B: Definite Plan). The Project Component would also evaluate the river crossings that could be affected by a substantial risk of damage due to flooding. [DEIR 3-632]

The KRRC is actively working with Hornbrook area landowners to fully mitigate these risks wherever possible. Among the various previously proposed additional mitigation measures to minimize flood damage risk that should be adopted in the revised Definite Plan (if they have not already been) are: Mitigation Measure H-1 (install new river flow gages and improve predictive flooding models, thus increasing warning time to residents of any impending flood): new National Weather Service (NWS) warning systems can also be installed to give residents more accurate flood predictions as much as two days in advance.

Response to Comment ORG29-8
For additional information regarding the flood hydrology analysis presented in the EIR, please refer to Master Response FLD-1.

Comments on the Definite Plan or Emergency Response Plan should be submitted to the Klamath River Renewal Corporation (KRRC).

Comment ORG29-9
MYTH: "Keeping the dams would cost far less than tearing them down."— Actually, the financial facts show just the opposite: It would actually cost PacifiCorp ratepayers far more to retrofit and relicense these aging and now economically obsolete dams than to replace their small amount of power from other, newer and much more cost-efficient resources.

The 1956 Federal Energy Regulatory Agency (FERC) 50-year license to operate the Klamath Hydropower Project expired in 2006. PacifiCorp, the company that owns the Klamath dams (J.C. Boyles Dam in Oregon, and CopCo Dams 1 & 2 and Iron Gate Dam in California, in river-descending order), can limp along on temporary one-year FERC license extensions only while an active application for FERC relicensing is pending. That time is coming to a close and a decision on the fate of these dams must soon be made. No privately-owned dam can legally operate without a valid FERC license.

Whatever choice PacifiCorp (also called "Pacific Power" in California) could make, the company's costs of that decision will ultimately be charged to its customer/ratepayers. This is how electrical utilities work. Their only source of revenues is generally the creation of electrical power they then sell to their customers, collecting enough revenues from their customers to fund their operations. This is all tightly regulated by state Public Utilities Commissions (PUCs) in each state where they operate, as the watchdog agencies that assure that their state's customers get charged fair, reasonable – and generally the lowest-cost – power rates for the services they receive.

There are only two legal options for these Klamath Hydropower Project dams, both of which will cost PacifiCorp ratepayers money: (1) either fix them up and relicense them to modern standards, which turns out will cost at least $460 million, and quite likely more than $500 million once all (currently unknown) water quality mitigation costs are added in, with no upper cost cap, according to PacifiCorp testimony to the PUCs, or; (2) decommission and remove these aging dams entirely – which it can now do under the Klamath Hydropower Settlement Agreement (KHSA) for a "capped" cost to its customers of only $200 million, with the rest paid by the State of California.

And according to estimates by FERC, even after all the expensive retrofitting to meet modern standards for relicensing, these dams would then only generate about 61 MW of power on average—about 26% less than they do today.

Relicensing thus means spending a great deal of money for what is actually very little power. In fact, FERC estimated in its 2007 Final Environmental Impact Report (FEIS) on relicensing that even if fully relicensed, the required retrofitting would be so expensive that these dams would then operate at more than a $20 million/year net loss. In short, the Klamath dams are now economically obsolete. This above all reasons is why PacifiCorp is asking for permission to transfer them to the KRRC for removal.

The best current estimate for the total costs of decommissioning and full removal of the four dams, so that the Klamath River and its salmon can once again move freely through them, is about $397.7 million (in 2020 dollars), including various environmental mitigation measures. By implementing dam removal through the KHSA, PacifiCorp thus saves its customers at least another $197.7 million (and perhaps much more) as well as reduces its own company and ratepayer risk and uncertainty. This is another reason the KHSA is a good deal for PacifiCorp customers.

On May 5th, 2011, the California Public Utilities Commission (CPUC) formally confirmed that the KHSA is indeed the most cost effective, least risk and therefore best alternative for PacifiCorp's customers as compared to relicensing. A prior September 16, 2010, ruling by the Oregon PUC came to the same conclusion. A small Klamath dam removal surcharge has been assessed PacifiCorp's Northern California and Oregon customers since those PUC decision to make up the company's $200 million contribution, which will all be in the PUC Trust Funds to use by the KRRC for dam removal by 2020 – at which point PacifiCorp's customers will not have to pay a dam removal surcharge any more.

In short, keeping the Klamath dams would mean extremely expensive fixes for a lot less power, and a Project that would likely lose money for the rest of any new license – losses that customers would ultimately also have to make up for in even higher power rates. The "bottom line" is that it's just a lot cheaper for customers to remove these dams than to keep them. And this is completely ignoring likely economic and jobs benefits of a restored world-class salmon run, a more stable irrigation system and the many other benefits also highlighted in the DEIR.

<u>Comment ORG29-10</u>

MYTH: "The region needs the power that the Klamath Dams provide. Without that power there will be brown-outs and other shortages of electrical supplies."— This is nonsense. When the first Klamath hydropower dams were built starting in 1918, and for a short while afterwards, they were the only source of electrical power for Klamath Falls.

But in today's much more modernized and interconnected world, the electrical power used in southern Oregon and northern California through PacifiCorp can come from anywhere within its massive, six-state power grid, and if purchased through the Bonneville Power Administration (BPA) as a power broker, from even further away.

The reality is that all four Klamath dams combined do not generate very much power. Although the whole Klamath Hydroelectric Project is technically rated for maximum power generation of about 171 megawatts (MW), these dams cannot run at maximum capacity 24/7, especially during summers when turbine flows are lowest.

The entire Klamath Hydropower Project combined actually generated only about 82 MW of power on average over the past 50 years of its license, according to FERC records. This amounts to less than 2% of PacifiCorp's overall power production capacity. By comparison, a single modern electrical power plant can continuously generate 1,000 MW or more, and a single off-the-shelf windpower turbine is rated for power production up to 6 MW.

Response to Comment ORG29-10
Comment noted. This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG29-11
MYTH: "Replacing the power the dams create will increase carbon emissions from the resultant use of carbon generating electric production facilities."

PacifiCorp has no reason and no intention to replace the renewable power from the dams with anything other than more renewables. There is no reason whatsoever that any replacement power would have to be from coal or other CO2-generating sources. There are also strong public policies and economic incentives driving PacifiCorp to divest itself of coal-fired plants generally, which it is in the process of doing, and replacing that energy with carbon-free renewables.

As to replacement power, when Pacific Power was bought by Berkshire-Hathaway in 2005, the Company legally committed to bringing more than 1,400 MW of brand new, cost-effective non-carbon renewable power online by 2015. This is already 17 times more electrical power than the four Klamath dams generate all together. In fact, it has considerably exceeded that goal.

For a company of PacifiCorp's size and expertise, adding a mere additional 82 MW of cost-effective and clean replacement power to its grid after 2021, as it *intends to do under the KHSA, would be an almost trivial task by comparison. It is fair to say that the company has already done so many times over.*

There are many options for the replacement of this power from comparable carbon-free or renewable sources by 2020. The DEIR correctly makes this very clear, as well as factors in the net reduction of the greenhouse gas methane (CH4) from elimination of the reservoirs that emit this other greenhouse gas, which is 28 times more effective as a greenhouse gas than CO2, although shorter-lived in the atmosphere:

"In 2017, PacifiCorp issued an Integrated Resource Plan (IRP) identifying the preferred power generation portfolio over the next 20 years. The IRP indicates that PacifiCorp plans to meet new energy resource needs primarily through new renewable resources and demand management (e.g., energy efficiency measures) over the 20-year (2017–2036) planning horizon. The IRP includes the anticipated loss of Lower Klamath Project hydroelectric generation beginning in 2020. The preferred portfolio also identified a reduction in coal capacity of 3,650 MW through the end of 2036. PacifiCorp projects that between 2017 and 2036 its average annual CO2 emissions would be reduced by 24.5 percent falling from 43.8 million tons in 2017 to 33.1 million tons in 2036 representing an annual average reduction in CO2 emissions of 10.7 million tons (PacifiCorp 2017b).

"Removal of the reservoirs associated with the Lower Klamath Project dam complexes would also result in a reduction in methane (CH4) production. As previously described, CH4 emissions from the reservoirs range from 4,000 to 14,000 MTCO2e per year. Under the Proposed Project, these CH4 emissions would cease to be a factor and would further reduce GHG emissions beyond the projections in the PacifiCorp 2017 IRP.

"Since it is planned in the 2017 IRP for PacifiCorp to add new sources of renewable power or purchase RECs to comply with the California RPS, and removal of the reservoirs would result in a reduction in methane production, it is not anticipated that the replacement of the hydroelectric energy from the Lower Klamath Project dam complexes would result in an increase in GHG emissions from non-renewable power sources. As such, GHG impacts from replacement of the hydroelectric energy from the Lower Klamath Project dam complexes is determined to be less than significant." [DEIR 3-728, 729]

Response to Comment ORG29-11

Comment noted. This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG29-12

MYTH: "Water will be taken away from farmers because taking down the dams will destroy irrigation systems."—The reality is that removing the dams will have *no effect whatsoever on the irrigation system of the federal Klamath Irrigation Project in Klamath and parts of Modoc and Siskiyou Counties. That extensive irrigation system is fed directly from Upper Klamath Lake by diversions at Link River Dam or (in small portion) by numerous small systems allowing direct pumping from the reservoir above Keno Dam, or from Gerber Reservoir, which has no hydrological connection to the Klamath River. That entire federal irrigation systems is hydrologically well above the four PacifiCorp Klamath hydropower dams, and so removal of those dams will not affect the federal Klamath Project water delivery system hydrologically above it in any way.*

There are only a handful of riparian water users along the river below the dams, some of whose existing pumps might be affected by sediments coming down from dam removal on a very short-term basis, but this is only a very few people and those impacts can be readily mitigated through appropriate filtering systems, if they occur at all.

As to the impacts of removing the dams on lower river irrigation flows, the DEIR correctly points out that these impacts would be minimal to zero, as explained as follows:

"Using historical flow data to create a set of flows under future operational prescriptions, USBR (2012) compared modeled surface water flow rates at Iron Gate Dam under the Proposed Project to a dams-in scenario. Modeling results indicate that under the Proposed Project, average monthly flows in the Klamath River just downstream of Iron Gate Dam would only slightly increase or decrease (typically less than approximately 15 percent) depending on month and water year type, compared to existing conditions. The anticipated small relative changes in Klamath Rivers flows are due to the fact that the Lower Klamath Project reservoirs were not designed, nor are they operated, as seasonal storage reservoirs for maintaining downstream flows for irrigation or drinking water diversions. As a whole, the Lower Klamath Project is primarily operated as a run-of-the-river operation, with inflows essentially matching outflows below Iron Gate Dam. Thus, the Lower Klamath Project has only a small effect on daily, monthly, seasonal, or annual flow conditions downstream of Iron Gate Dam. USBR (2012) modeling results indicate that at Seiad Valley, approximately 62 river miles downstream of Iron Gate Dam, surface water flow rates under the Proposed Project would be nearly identical to those under existing conditions." [DEIR 3-677]

Response to Comment ORG29-12

For additional information regarding water supply for agricultural irrigation as analyzed in the EIR, please refer to Master Responses WSWR-1, as well as Volume I Potential Impact 3.8-1 for a discussion of the effect of dam removal on availability of water for diversion and Volume II Appendix M for a discussion of water rights.

Comment ORG29-13

MYTH: "There has been no analysis of the economic damages to Siskiyou County, Modoc County, or other adjacent and directly impacted counties."—This is another obvious factual error. Not only does this DEIR analyze in depth the public service, population and housing, social services and other socioeconomic impacts of the Proposed Project on these counties and their regions, but there are numerous studies of these impacts that were part of the original NEPA/CEQA (2013) analysis done to inform the Secretarial Decision.

Potential impacts on the property values of landowners around Copco Lake and Iron Gate Reservior, potential county property tax revenue changes and other similar economic impacts have all been thoroughly studied and those impacts are well-known. This includes studies of real estate values around the lakes, as well as potential property tax impacts and estimates.

Dozens of these studies are available on the official Klamath Dams web site at: www.klamathrestoration.gov, and specifically from the following link: https://klamathrestoration.gov/keep-me-informed/secretarial-determination/role-of-science/secretarial-determination-studies.

Many of these socioeconomic impacts, however, as noted in DEIR Sec. 5-4, are simply outside the jurisdiction of the State Water Board in that they have nothing to do with water quality impacts per se, as well as are outside what are considered "impacts to the environment" to be considered under CEQA. Those that were deemed within the scope of CEQA were considered in detail in DEIR Sec. 5-4 and elsewhere throughout the document.

Response to Comment ORG29-13

Volume I Section 5.4.1 *Other Required CEQA Discussion and Consideration of Social and Economic Factors – Social and Economic Factors Under CEQA – Consideration of Economic Information for Resources Potentially Affected by Dam Removal* (pages 5-4 to 5-11) summarizes the results of prior economic studies conducted by the U.S. Department of the Interior (DOI) to characterize potential economic costs and benefits, including for commercial fishing and local real estate, of dam removal.

Comment ORG29-14

MYTH: "The data from the former EIS/EIR process for the Secretarial Determination is either too old, or too unreliable, to use in the current DEIR analysis."—Dozens of detailed studies were done in preparation for the NEPA/CEQA (2013) analysis and the then-planned Secretarial Determination. Those studies are all still highly relevant to this 2018 DEIR, and were also subjected to reconsideration by the authors of the 2018 DEIR as to whether any significant changes had occurred, including new information if any. Most of those studies are still quite accurate, and still represent the best available science.

Then too, the original studies for the NEPA/CEQ (2013) process were not only peer-reviewed once, but peer-reviewed a second time by Independent Panels of experts, and then the Secretarial Determination those studies were summarized into was itself later independently peer-reviewed once again. The end result was a robust three distinct levels of independent peer-review to check, double-check and cross-check the conclusions of those studies.

SCWUA frequently cites the concerns about information bias in the Secretarial Determination process raised in allegations in February, 2012, by Dr. Paul Hauser, which became a cause célèbre among dam removal opponents, but SCWUA deliberately neglects to note that those same claims were thoroughly investigated by the Inspector General of the Department of Interior, which commissioned a highly credible, independent scientific review committee that reviewed Dr. Hauser's allegations and unanimously found in its findings report of August, 2012, that there was no substantial merit to Dr. Hauser's accusations of scientific bias in the Secretarial Determination NEPA/CEQA (2013) review or press release process.

Response to Comment ORG29-14

Regarding the use of data compiled for the 2012 Klamath Hydropower Settlement Agreement (KHSA) Environmental Impact Statement (EIS)/ Environmental Impact Report (EIR) analyses in the Lower Klamath Project EIR analyses, please refer to Master Responses WQ-4 and AQF-12. Please note that during the Lower Klamath Project Notice of Preparation public comment period, the State Water Board heard concerns regarding the whistleblowing accusations of Dr. Paul Houser as related to the 2012 KHSA EIS/EIR. After hearing these concerns, the State Water Board staff reviewed the independent investigative panel report regarding Dr. Houser's whistleblower complaint, which indicates that the concerns were related to disagreements on how to present uncertainty in scientific data, rather than about the data or scientific analysis itself. (RESOLVE, 2012 - *Independent Investigation of the Scientific Record Pertaining to the Allegations of Dr. Paul Houser.*) Ultimately, the panel determined that Mr. Houser's complaint did not have merit.

Comment ORG29-15

The DEIS Executive Summary at E-7 discusses the current plan for dealing with Iron Gate Hatchery production under the Proposed Project as follows:

"Fish Hatcheries—During demolition, some Iron Gate Hatchery facilities located at the base of Iron Gate Dam would be removed, along with the cold-water supply and aerator for the hatchery. However, operational components of Iron Gate Hatchery would be retained and modified to continue operations at a reduced rate for just Chinook salmon and to eliminate coho salmon production. The nearby Fall Creek Hatchery, located at Fall Creek just upstream of Iron Gate Reservoir, would be reopened to maintain the current Iron Gate coho salmon production and some Chinook salmon production. The Iron Gate and Fall Creek

hatcheries would remain in operation for eight years following removal of the dams, at which point the hatcheries would cease operations."

It is also the case that Iron Gate/Fall Creek hatchery production need not necessarily cease at the end of 8 years after dam removal has been fully accomplished, only that the promised PacifiCorp funding for that production would cease. At the end of that 8-year PacifiCorp funding term, the reconstructed Iron Gate and Fall Creek Hatcheries should be left in a condition to continue production if that is decided upon by CDFW, based on conditions in the river and the rates of recolonization and associated natural production recovery progress.

We do NOT SUPPORT the "No Hatchery Alternative" in any form. The DEIS notes that under the "No Hatchery Alternative":

"While natural-origin returns typically outnumber hatchery returns, the proportion of the Chinook salmon escapement comprised of Iron Gate Hatchery returns has historically been substantial (~35 percent of age 3 adults; KRTT 2011, 2012, 2015). Eliminating the hatchery goal of releasing around 6 million Chinook salmon smolts and yearlings annually would likely result in a reduction in adult hatchery returns to the Klamath River.....

"Based on historical data (CDFW 2016b), the reduction in returns could average around 16,000 fish beginning in post-dam removal year 3, as the population responds to the benefits of dam removal. Based on the current proportion of hatchery adults in the run, this could represent a short-term reduction in abundance of around 35 percent of age 3 adults on average until production from newly accessible habitat increases adult escapement (anticipated to begin in dam removal year 3, Table 4.6-1). However, depending on the year, the reduction could be as high as 50 percent (the proportion of hatchery return adult spawners in 1993 for example), or as low as 19 percent (the proportion in 1995) (KRTT 2015). [DEIR 4-306, 307]

This alternative would amount to a huge spawner deficit for several years running until natural production could infill into restored habitat, which could take several fish generational cycles to accomplish, especially in the absence of human intervention such as egg out-planting efforts.

There is already a serious, long-term fall-run Chinook spawner deficit affecting the river (see ATTACHMENT B – Klamath Fall-Chinook Escapements (1998-2012)) and an unacceptably high risk of future fall-run Chinook stock extinctions as a result, particularly of the weakest sub-stocks.

It should be noted that historically (i.e., before European colonization and development) the Klamath River is estimated to have produced an average annual 500,000 fall-run Chinook. Today (as seen from ATTACHMENT B) *fisheries managers are hard pressed to assure that the Pacific Fishery Management Council's (PFMC) fall-run Chinook escapement "minimum spawner floor" of 40,700 natural spawners can be met. Suddenly subtracting all hatchery production from the system would simply increase the pressure on the already extremely weakened natural stocks, at least in the short term, from natural predation and other natural mortality factors as well as fishing pressures.*

It is argued in the DEIR that:

"The impact of a reduction in the number of hatchery returning fish is not equivalent to a reduction in the natural-origin population, from a population perspective..... As discussed in detail in Section 3.3.2.3 Habitat Attributed Expected to be Affected by the Proposed Project [Fish Hatcheries], hatchery returning adults can have substantial detrimental effects on native populations. As such, a reduction in hatchery returns under this alternative would be a benefit for fall-run Chinook salmon over the long term. [DEIR 4-307]

However, since our industry is highly dependent on the health of Klamath River fish production generally (both naturally and hatchery generated), and is also highly dependent on hatchery stocks generally, it is our strong preference that the Iron Gate/Fall Creek hatchery complex phase down its production only as natural spawner production increases in areas now blocked by dams. In other words, some proportionality should be maintained between recolonization success with recovery of natural production and reduced hatchery production. This recolonization process may take more than 8 years to complete, and it should be acknowledged that the original 8-year estimate was at most merely an educated guess.

In short, river conditions and real-time salmon recolonization success rates should dictate the hatchery production phase-out time frame, not arbitrary deadlines. And since these factors are by their nature unknown in advance (only estimated), the Hatchery Management Plan (HMP) and CDFW should maintain some flexibility as to the termination dates and phase-out plans for the Iron Gate/Fall Creek hatchery program. Otherwise both our industry and the entire Klamath River salmon-based ecosystem could face abrupt fall-offs in Klamath spawner numbers that would require major adjustments in fisheries management by the Pacific Fisheries Management Council (PFMC) and could cause severe and unexpected disruptions in harvestable salmon availability, including potential coast-wide, at-sea salmon fishery closures that could devastate coastal fishing-dependent communities. The sudden and major loss of between 35% and 50% of all fall-run Chinook spawners from the river would also doubtless have cascading negative impacts on the river's natural salmon-based ecosystems as well.

One simple principle for decreasing the problem of negative hatchery-natural stock interactions, particularly with respect to the problems of hatchery fish *interbreeding with and thus truncating or diluting the natural genetic diversity that fish evolved for survival, is noted in the DEIS as follows:*

"Although eight years of additional hatchery production under the Proposed Project is anticipated to achieve the production levels predicted by the EDRRA model sooner than without continued hatchery production, immediate closure of Iron Gate Hatchery and no production at Fall Creek Hatchery would eliminate most interbreeding of hatchery and natural-origin salmon by post-dam removal year 3, and would likely increase the rate at which Chinook salmon develop traits adapted to their new habitats upstream of Iron Gate Dam (Goodman et al. 2011). This could increase survival of natural-origin Chinook salmon at a faster rate than with continued hatchery operations under the Proposed Project. <u>Goodman et al. (2011) note that this effect would depend, in part, on the degree to which local Chinook salmon stocks have been integrated into the hatchery brood stock and the degree to which the current mixed hatchery and natural-origin spawning population has maintained genetic potential for life history diversity to adapt to conditions upstream of Iron Gate Dam</u>." [DEIR 4-307 – underline added for emphasis]

In short, the Hatchery Management Plan (HMP) for the Klamath mainstem post-dam hatchery system should continue the CDFW's mandate for utilizing only the native wild (natural) fish gene pool as the broodstock for its hatchery program, thus maximizing the gene pool and life history diversity of these salmonids (both natural and hatchery in origin) from all sources that evolved to face Klamath river conditions. Any incidental interbreeding would then simply spread the same genes more widely into the population, increasing – rather than decreasing – overall population resiliency and survival rates.

On no account should non-native stocks be used for hatchery broodstocks. Assuming this policy remains in place, there is no particular advantage to a "no hatchery alternative" so far as avoiding natural-hatchery interbreeding is concerned, and the Proposed Action is clearly better insofar as it will hasten the achievement of full recolonization of those released habitat areas above the dams in line with the EDRRA model. Additional salmon habitat restoration efforts also linked to dam removal mitigation mandates would also be expected to increase river carrying capacity for salmonids generally, thus to reduce inter-fish competition as well as to encourage faster recolonization of currently blocked areas.

As to the potential for the reduction of fish diseases (particularly C. shasta) within the river system, the Proposed Alternative and the No Hatchery Alternative are likely to be equally effective, as both will be accompanied by dam removals which will then not only restore spawning gravel to gravel-deprived areas, but would restore natural annual "flushing flows" considered necessary to mobilize and scour out and thus greatly reduce in-river habitat for the C. shasta polychete worm that is its primary disease vector.

Response to Comment ORG29-15
Section 15126.6 of the CEQA Guidelines requires that an EIR describe and evaluate a reasonable range of alternatives to the project, or to the location of the project, which could feasibly attain most of the basic project objectives but would avoid or substantially lessen any of the significant environmental effects of the project. As stated in Volume I Section 4.1.1.1 *Alternatives – Alternatives Selection/Overview – Alternatives Selection – Alternatives Carried Forward for More Detailed Analysis* (specifically page 4-6), the No Hatchery Alternative emerged from scoping concerns regarding the water source for the Iron Gate Hatchery, and in light of uncertainty regarding whether the Fall Creek Hatchery (FCH) could be timely reopened. The effects of the No Hatchery Alternative on adult returns of fall-run Chinook salmon (the target of commercial fishing efforts) are described in Volume I Section 4.7.3 *Alternatives – No Hatchery Alternative – Aquatic Resources* Potential Impact 3.3-7 (pages 4-306 to 308). Please also note that Potential Impact 3.12-9 and Section 4.7.12 *Historical Resources and Tribal Cultural Resources* discuss the potential effects on fish availability for tribal harvest under the Proposed Project and under the No Hatchery Alternative, respectively. Please also refer to Master Response AQF-2 regarding the fate of hatchery operations under the Proposed Project and alternatives.

<u>Comment ORG29-16</u>
We concur with the DEIR finding (Sec. 5.4.1.1) of both severe economic impacts on the coastal ocean salmon fisheries and the communities those fisheries support as a result of the Klamath dams' impacts on river salmon productivity, and the conclusion of the DEIR that the Proposed Project (i.e., 4-dam removal) will greatly benefit these salmon fishing-dependent communities, as for instance these summaries:

- *Coastal ocean fishing-dependent communities have suffered severe economic impacts due to decreases in fish numbers and related harvest limitations. USBR (2012) identified that the removal of four dams and facilities would result in notable positive regional economic benefits to commercial troll fishing of SONCC coho and Klamath River fall- and spring-run Chinook salmon." [DEIR 5-5,6]*
- *"… dam removal would advance the long-term restoration of natural fish populations in the Klamath Basin, including having a significant beneficial effect on commercial fisheries and an associated significant beneficial economic impact on the coastal commercial fishing industry." [DEIR 5-7]*

As an indication about just how dire decades of Klamath-driven declines and closures have become for the economies of once-prosperous Klamath Management Zone (KMZ) fishing ports, refer to ATTACHMENT C—Declines in KMZ Port Salmon Landings Between 1976-2017. As compared to historic landings for the average of the years 1976-1980 vs. The average of the years 2010-2017, the Port of Eureka has suffered a 96% long-term decline and the Port *of Crescent City has suffered a staggering 98% long-term decline in salmon landings.*

The primary driver of these declines has been the persistent trend of decreasing salmon productivity in the Klamath Basin (see ATTACHMENT B), which in turn has been strongly driven by the enormously negative impacts of the Klamath Dams on salmonid production generally.

Response to Comment ORG29-16
Comment noted.

Comment ORG29-17
We believe that there is overwhelming evidence in the record that the Proposed Project four-dam removal and the restoration of salmonids in the Klamath River back into their historic habitat will result in far more benefits and improvements in overall water quality of the river, as well as restoring the beneficial uses of restored fisheries and wildlife, than any other option. Furthermore, the short-term (mostly 2-years) of disturbance in the system will be well worth the much greater and long-term benefits, particularly since the adverse effects of those short-term impacts can and will be considerably mitigated. We are in agreement with the DEIR support the issuance of the 401 Certification with the current reasonable conditions proposed, and as proposed to be amended by the KRRC comments and our comments herein.

This concludes our supplemental written comments at this time. Thanks for the opportunity for public input, and please make this letter part of the record.

Response to Comment ORG29-17
Please refer to Master Response GEN-1.

PacifiCorp Energy, Tim Hemstreet, Mark Sturtevant

Comment ORG46-1
PacifiCorp fully supports the KHSA as a balanced outcome for its customers, so long as all of the customer protections embodied in the agreement are achieved. Successful settlement implementation will facilitate the policy preferences of the federal government, the states of California and Oregon, Klamath Basin Tribes, and other stakeholders. From the outset, PacifiCorp has consistently held that its customers must be protected against the unknown costs and risks of implementing these policy preferences, and the liability and indemnification provisions of the KHSA were expressly negotiated to accomplish these protections. PacifiCorp remains committed to securing these protections for its customers and continues to work with the KRRC to ensure that adequate protections are in place to satisfy this foundational requirement.

Because the Draft EIR is a critical waypoint for public input and engagement about the full range of potential environmental effects that may result from *removal of four of the dams on the Klamath River, it is important to provide a deeper perspective and context for these comments to the Board. As noted by the Klamath River Expert Panel in its 2011 report on the effects of dam removal on Chinook salmon, Klamath dam removal " is an experiment in that many of the outcomes are difficult to predict, particularly those of greatest interest to stakeholders (e.g., increasing abundance of Chinook salmon)."2 This experiment has been long-advanced by certain stakeholders who believe that dam removal is the only option for improving salmonid fisheries and water quality in the Klamath River. Unprecedented in size, scope, and potential impact, the project involves drawing down three expansive reservoirs, discharging millions of cubic yards of sediment, impacting 225 miles of river within and downstream of the project, and ending hatchery programs that currently conserve listed Coho salmon and support harvest opportunities for Chinook salmon. The project will have significant near-term impacts to these important species, and the hope of the KHSA is that any significant impacts will be outweighed by long-term benefits.*

Dam removal is inherently risky, but the depth of uncertainty around the potential outcome of Klamath dam removal makes this action extraordinary. Some stakeholders have embraced the idea that dam removal will result in overall benefits to the river, while other stakeholders have expressed deep concern about the costs and risks of such an endeavor. Without doubt, this proceeding will highlight this divide and bring the underlying perspectives and analysis of each stakeholder group to the forefront. For PacifiCorp, comprehensive liability protection and indemnification is essential to support prudent utility decision-making. The KHSA's cost cap and liability protections are also central to our utility regulator's authorization for PacifiCorp to participate in the settlement process and collect $200 million in customer funds for dam removal. Without the negotiated protections of the KHSA, ultimate liability and risks from dam removal could likely fall upon PacifiCorp's customers.

Background on KHSA and PacifiCorp Customer Protections

Dam removal on the Klamath River is natural-resource-management decision that PacifiCorp, as a regulated utility, is unwilling to undertake because of the substantial risks and uncertain benefits. PacifiCorp' s perspectives are informed by our past experience addressing fish passage requirements and water quality improvements through new project licenses. This does not mean that PacifiCorp disputes that dam removal may have positive effects on the river. It simply means that the outcome is unknown, the risks are high, and that it would be imprudent to expose PacifiCorp's customers to such far-reaching risks for an uncertain outcome.

Minimizing customer risk was PacifiCorp' s primary goal in joining the original KHSA in 2009 and the amended KHSA in 2016. Faced with the unknown costs and risks associated with obtaining a new Federal Energy Regulatory

Commission (FERC) license for the project, PacifiCorp agreed to support the dam removal project embraced by California, Oregon the federal government, Klamath Basin Tribes, and other stakeholders, as long as four key principles were met: (1) PacifiCorp would transfer the dams to another entity responsible for their removal; (2) our customers' financial contribution to dam removal would be capped; (3) our customers would be protected from the potentially significant liabilities associated with dam removal and its potential known and unknown consequences; and (4) PacifiCorp would continue to operate the dams for the benefit of its customers until the facilities were decommissioned. These principles are bedrock anchors for PacifiCorp' s support of this endeavor and well-known to all KHSA signatories.

Over the past three years, PacifiCorp has worked closely with the KRRC and our other settlement partners to advance the KHSA. The KRRC' s efforts have produced noteworthy progress, but significant uncertainties remain—particularly for PacifiCorp's customers. FERC has yet to approve PacifiCorp and the KRRC's joint license application to transfer the license for the four facilities that are planned to be removed to the KRRC. That approval is a critical component of the KHSA and constitutes a key customer protection for PacifiCorp. FERC must determine that the KRRC has the financial, technical, and legal capacity to become the licensee, and FERC has stated that it will apply a heightened public-interest standard to that determination due to the unique nature of this endeavor. The KRRC is scheduled, on April 29, 2019, to provide FERC with revised cost estimates, a detailed insurance and risk-mitigation package, and the plan to address costs and liabilities that exceed the $450 million in funding available under the KHSA. After receiving this information, FERC may be in a position to rule on the request to transfer the license.

The KRRC also has yet to satisfy certain contractual preconditions to license transfer that protect PacifiCorp and the states of California and Oregon. Most importantly, KRRC must demonstrate that it has adequate funding to complete the project and that it has the capacity to fulfill its obligation to indemnify PacifiCorp and its customers. Central to both the cost and indemnification determinations is KRRC's ability to contract with a liability transfer company (LTC) consistent with KHSA Appendix L. The LTC is a cornerstone of obtaining FERC approval of the application to transfer the license for the Klamath dams to KRRC, so that KRRC can proceed to surrender the license and remove the dams. The LTC will provide a critical financial buffer if dam-removal costs or liability claims exceed the fixed funding available under the KHSA by providing assurances to all stakeholders in this process that a capitalized entity will support the KRRC to respond to potential unforeseen consequences or costs. PacifiCorp expects that our determinations under KHSA Section 7.1.4 will be reviewed by our state utility regulators in Oregon and California to determine whether PacifiCorp's decisions are prudent and in our customers ' best interest.

Compliance with California Environmental Quality Act

The Draft EIR is critical in furthering the work the settlement partners are performing. The Draft EIR is intended to provide the Board and the public, including the KHSA signatories, FERC, and other regulators with a transparent and accurate accounting of potential project impacts. From that accounting, the Board can determine whether to issue or deny a Clean Water Act section 401 Water Quality Certification for the dam-removal project, and what conditions should be imposed on the project to avoid or mitigate significant environmental impacts associated with that decision. The DEIR will also inform the settlement parties about how best to manage risk, and it will help our utility regulators evaluate whether the continued collection of funds from our customers is prudent in light of how customer risks are proposed to be mitigated. And the DEIR will aid FERC to evaluate whether license transfer and dam removal are in the public interest. Ultimately, flaws in the Draft EIR's analysis that confuse, minimize or inaccurately portray existing conditions and potential significant impacts will compromise successful KHSA implementation and dam removal.

While PacifiCorp cannot justify bearing the risk of dam removal, resource agencies—like the Board—can certainly elect to approve a project despite uncertain outcomes or significant risks. But before determining that the risks and significant environmental impacts of dam removal are worth the potential benefits, a factually and legally accurate environmental impact report must be developed, and the Board may be required to adopt a statement documenting why the project should be approved despite significant unmitigated environmental impacts. And the environmental impact report should be based on the most current and best available scientific information. Indeed, the fundamental purpose of CEQA is not to guarantee that significant impacts will not occur from a project, but rather to require an accurate and thorough assessment of potential impacts and uncertainties associated with a project so that agency decision-makers and the public can be properly informed.

In that context, PacifiCorp has taken a hard look at the Draft EIR in an effort to ensure that it is factually accurate and legally sufficient because, as noted above, any technical or legal shortcomings put KHSA implementation and ultimate dam removal at risk. PacifiCorp' s concerns are informed by its long- standing involvement in the Klamath basin as the operator of the Klamath Hydroelectric Project, and reflect our long-standing understanding of the risks and uncertainties associated with dam removal. While our comments are informed by new information, they are consistent with our previous comments on the 2011 U.S. Department of the Interior and California Department of Fish and Game Klamath Facilities Removal Public Draft Environmental Statement/Environmental Impact Report. Once again, our comments have consistently focused on ensuring that the impacts of our facilities are accurately assessed, and the benefits and risks of dam removal and alternatives are accurately portrayed so that agencies can make informed decisions the public is aware of the risks and benefits associated *with a major natural resource action, and PacifiCorp can ensure that its customers are protected from risks that are transparently acknowledged.*

The issues we identify in our attached comments must be addressed to ensure the final EIR and water quality certification are legally justified and defensible. As detailed in our technical and legal comments, the Draft EIR does not meet the requirements of CEQA. Critically, it relies on outdated data, inaccurately evaluates the impacts of sediment discharges and minimizes impacts to listed species while also overstating adverse impacts related to continued operation of the Klamath Hydroelectric Project. Our comments are intended to inform and improve the environmental ana lysis contained in a revise d and recirculated Draft EIR, and further the KHSA signatories' efforts to successfully fulfill all of the conditions of the KHSA.

Response to Comment ORG46-1

Thank you for your comment. As PacifiCorp states in this comment, this cover letter is introductory to more specific comments attached. To the extent this cover letter includes topics that warrant further response, these are addressed in responses to the more detailed following comments, ORG46-2 through ORG46-516.

Comment ORG46-2

Recent field monitoring data (MKWC2016, 2017, 2018; Chesney and Knechtle 2017; Knechtle and Chesney 2017), indicates that the Coho population upstream of Portuguese Creek (including the Scott and the Shasta rivers) is extremely small; perhaps less than 1,000 adults in most years, which is well below the risk thresholds associated with abundance set by NMFS (2014) in the Recovery Plan. While adults mainly spawn in the tributaries, some do spawn in the mainstem Klamath River, and any deposited eggs in the mainstem will die as a result of sedimentation within the spawning areas (see Waters 1995; Quinn 2005) the year dams are removed (See Major Issue 2.4). Juvenile Coho use the mainstem throughout the year (Soto et al. 2016b; Man hard et al. 2018), both for rearing in cool-water and low velocity refuge habitat, and as a movement corridor from natal to non-natal habitat.

The few adult Coho that spawn in the tributaries in turn produce relatively few juveniles. In some streams and in some years, approximately 25 percent of the rearing juveniles will leave the tributary for the mainstem in the winter (Soto et al. 2016b; Manhard et al. 2018). Juvenile Coho moving into the mainstem Klamath River will be subject to increased direct mortality rates, decreased fitness and condition, and likely will be more susceptible to disease. These fish would suffer increased mortality (20–40 percent according to Appendix Table E-10 (DEIR pg. E-36) from high suspended sediment concentrations generated by reservoir drawdown. The DEIR assumes these fish will not leave the tributaries or, if they do, will find refuge in cleaner-water inflows along the mainstem; however, the DEIR does not acknowledge that these cleaner-water areas will be crowded with *fish from the entire river also seeking refuge, nor does the DEIR discuss the corresponding impacts to juvenile Coho from competition or direct predation. If Coho survive to rear in these conditions, these factors could reasonably be expected combine to create juvenile Coho in relatively poor body condition (Ebersole et al. 2006; Weybright and Giannico 2018), which will in turn reduce their survival rate in the ocean (Gorman 2016).*

Iron Gate Hatchery currently operates under a Hatchery and Genetics Management Plan (CDFW and PacifiCorp 2014) that supports an integrated conservation program for Coho Salmon listed as threatened under the Endangered Species Act. Dam removal and associated impacts to Iron Gate Hatchery will likely end this support of the Coho populations. While there is funding for 8 years of continued hatchery operations included in the Klamath Hydroelectric Settlement Agreement (KHSA) under Interim Measure 19, the relocation of the program from Iron Gate Hatchery to Fall Creek and lack of an identified funding source 9 years after dam removal creates uncertainty regarding the ability of hatchery releases to continue to support this population. Currently, an average of 50 percent of the Coho spawning naturally in Bogus Creek and the Shasta River are Iron Gate Hatchery fish (Chesney and Knechtle 2017; Knechtle and Giudice 2018a). When these population are no longer supported by hatchery releases they are likely to dramatically decrease in size. There is no analysis in the DEIR that evaluates the impact of the loss of this hatchery program on Coho populations.

The Proposed Project would add additional stress to outmigrating juveniles; however, the DEIR fails to indicate what this means in terms of the population. The population of Coho is small enough that even a modest increase in mortality rate (either through reduced fitness, predation, or increased susceptibility to disease) could reduce the number of returning adults. Naman and Perkins (2015) noted that on the Trinity River "...because of low population size of unmarked coho [sic] salmon, managers should take measures to limit the mortality of any new fisheries on the natural component of the run." Although this comment is focused on mortality from harvest, the rationale applies equally to the upper Klamath Coho population and mortality that will occur as a result of the Proposed Project. Because the overall Coho population in the Upper Klamath River is already very small, there is a significant and unanalyzed risk that Coho populations would not survive such a mortality event.

Response to Comment ORG46-2

PacifiCorp discusses additionally available analysis and field monitoring data on coho salmon in the Klamath River. Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Fish – Anadromous Salmonids* has been modified to include the new data. Please refer to Volume III Attachment 1 Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Fish – Anadromous Salmonids* for the revisions.

PacifiCorp cites Soto et al. (2016b) and Manhard et al. (2018) to assert that the Draft EIR underestimated the potential impacts of the Proposed Project to juvenile coho salmon produced in tributaries that migrate from tributaries into the mainstem “during winter,” and thus would be susceptible to impacts from suspended sediment.

Impacts to coho salmon resulting from suspended sediment are detailed in Volume II Appendix E Section E.3.2.3 *Results – Coho Salmon* and are summarized in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts – Potential Impact 3.3-9*. The central notion of the PacifiCorp assertion is that juvenile coho salmon use the mainstem throughout the year both for rearing in cool-water and low velocity refuge habitat, and as a movement corridor from natal to non-natal habitat, based on the observations of Soto et al. (2016b). Manhard et al. (2018) does not include new observations or data, but rather draws on the results of Soto et al. (2016b) and others to describe productivity, survival, and migration patterns of coho salmon in the Klamath River Basin.

Soto et al. (2016b) describe migration of coho salmon into the “mainstem Klamath River corridor,” which refers not only to the mainstem Klamath River, but also to side channels, off-channel habitats (alcoves, ponds, and groundwater channels associated with the floodplain), and the lower reaches of small tributaries. These more protected areas of the river corridor all would provide refuge from the anticipated increases in suspended sediment under the Proposed Project. It is these refuge habitat locations that Soto et al. (2016b) documented coho salmon migrating to, whereas juvenile coho salmon rearing in the mainstem is a rare occurrence. Soto et al. (2016b) refer to the observed coho salmon in the mainstem as a “re-distribution migration,” and not mainstem rearing

The EIR assesses the impacts of suspended sediment on coho salmon juveniles that use the mainstem during winter (November 15th through February 14th), and thus this impact is accounted for in the analysis. In addition, Soto et al. (2016b) report that most of the observed re-distribution of juvenile coho salmon from natal streams to these habitats occurs during “spring, early summer, fall, and early winter,” and would avoid the predicted peak in suspended sediment in January of dam removal year 2. The most substantial numbers of migration into the mainstem are observed during spring and early summer (after the peak in suspended sediment), and an extensive re-distribution with the advent of the first fall rain events (prior to the peak in suspended sediment). It is unsurprising that coho salmon would have adapted to avoid periods of naturally high suspended sediment in the Klamath River. In addition to general migration timing, juvenile salmonids also actively avoid exposure to high Suspended Sediment Concentrations (SSCs).

Many of the migrations observed by Soto et al. (2016b) were to locations far downriver from the confluence with the Salmon River, and well within areas predicted to experience similar levels of suspended sediment to existing conditions.

PacifiCorp further asserts that juvenile coho salmon using higher water quality refugia in the mainstem Klamath River corridor would be vulnerable to the effects of increased rearing density, such as competition, predation and poor body condition. However, there is no reason to predict a substantial increase in density in refuge habitats; juvenile coho salmon and other fish are currently using these locations as refuge from seasonally poor water quality in the mainstem Klamath River, and increased migration from tributary natal streams is not anticipated. In addition, although no substantial impact on coho salmon populations is anticipated, the Klamath River Renewal Corporation (KRRC) is implementing Proposed Aquatic Resource Measure AR-2, which is designed to protect coho salmon juveniles using mainstem Klamath River corridor refuge habitat during dam removal years 1 and 2. As further described in the Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts – Potential Impact 3.3-9*, Proposed Aquatic Resource Measure AR-2 includes salvage of juvenile mainstem coho prior to reservoir drawdown, monitoring and salvage during and after dam removal, and ensuring tributary-mainstem connectivity. These actions would effectively reduce the number (and density) of coho salmon juveniles and smolts potentially exposed to periods of high SSCs in the mainstem habitat following dam removal, and therefore reduce the proportion of the population experiencing sub-lethal effects or mortality beyond what is estimated in Appendix E.3.2.3.

PacifiCorp asserts that when coho salmon are no longer supported by hatchery releases they are likely to dramatically decrease in abundance, and that there is no analysis in the Draft EIR that evaluates the impact of the loss of this hatchery program on the coho salmon population.

As described in Volume I Section 2.7.6 *Proposed Project – Proposed Project – Hatchery Operations* (page 2-77), under the Proposed Project, the Fall Creek Hatchery (FCH) would be reopened, and both the Iron Gate Hatchery and Fall Creek Hatchery would continue to operate for a period of eight years following dam removal, with the same level of coho salmon production as under existing conditions. It is uncertain whether Fall Creek hatchery will close at that point, or whether it will continue operation in some capacity. For purposes of analysis, the EIR makes the conservative assumption that the hatchery operations will cease, as there is no concrete plan or identified funding source for continued operation.

Volume III Attachment 1 Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* and Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* provide a detailed analysis of the effect of ending hatchery production for coho salmon after eight years under the Proposed Project. As described, available information indicates that the benefits from dam removal and cessation of hatchery operations would increase adult returns by more than the loss of hatchery progeny.

Please also refer to Master Response AQF-2 for a discussion of the assumption of hatchery closure after eight years.

PacifiCorp asserts that the Draft EIR does not analyze the population level effect of additional stress to outmigrating coho salmon smolts resulting from the Proposed Project, citing Naman and Perkins (2015) to suggest that modest increases in mortality can result in reduction in returning adults.

Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Volume II Appendix E Section E.3.2.3 *Results – Coho Salmon* (pages E-35 to E-38) provide a detailed analysis of the effects on the coho salmon population of short-term impacts to coho salmon rearing in the mainstem, and to outmigrating smolts. The population-level effects of the Proposed Project in the short-term are summarized in Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*. The Naman and Perkins (2015) study on Trinity River fishing assessed mortality to *adult* coho salmon, and its findings are not transferrable to population level effects of stress to outmigrants.

Regarding the Portuguese Creek population and the comment's assertion regarding its risk threshold, please see response to comment ORG46-4. For additional discussion about significance thresholds, please refer to response to comment ORG46-199 and Master Response AQF-9.

Comment ORG46-3

2.1.2 Proposed Project Impacts to Coho Salmon Upstream of Portuguese Creek

The DEIR characterizes the short-term impacts from the Proposed Project on Coho as not significant with application of mitigation. There are several issues with this conclusion. The following discussion focuses solely on the DEIR impact analysis as it relates to sediment transport and does not discuss the DEIR's chosen threshold for significance (loss of 50 percent or more of the total Klamath River Coho population) or other technical issues. The purpose of the following discussion is to provide a more comprehensive overview than is provided in the DEIR regarding the existing upper Klamath River Coho populations, address impacts to these fish from suspended sediment, and clarify the uncertainty associated with the Proposed Project's impacts to Coho Salmon.

Adult Populations. The Coho population in the upper Klamath River and its tributaries is very small (Figure 1). The CDFW has maintained counting stations *on Bogus Creek, Scott River, and Shasta River consistently since 2007 (Knecht le 2019). The population trend over this period has been downward for Bogus Creek and the Shasta River. The Scott River population appears to be larger and more variable in total returns than any of the other tributaries in the upper Klamath River.*

Since 2015, the Mid-Klamath Watershed Council has conducted spawning Coho surveys of tributaries from Bogus Creek downstream to Portuguese Creek (not including the Shasta and Scott rivers). Of the 15 streams surveyed annually, Coho are reliably found only in Horse Creek and Seiad Creek with the occasional fish or two in other streams. Over the 4 years these surveys have been conducted, on average there appear to be about 191 natural-origin Coho per year using these tributaries (MKWC 2016, 2017, 2018, preliminary 2019 data).

Coho return data for Iron Gate Hatchery is available since the hatchery started operating in 1962 (Figure 2). While the long-term average Coho return is 985 fish, this data also illustrates the variable nature of Coho returns over the years. Since 1962, there are only 4 years with more than 2,500 Coho returning to the hatchery, but 13 years with fewer than 250 Coho (Figure 2). Although the last 4 years have seen a gradual increase in adults (Figure 2), it is too soon to tell if this will continue, especially because a similar trend is not apparent in the downstream tributaries.

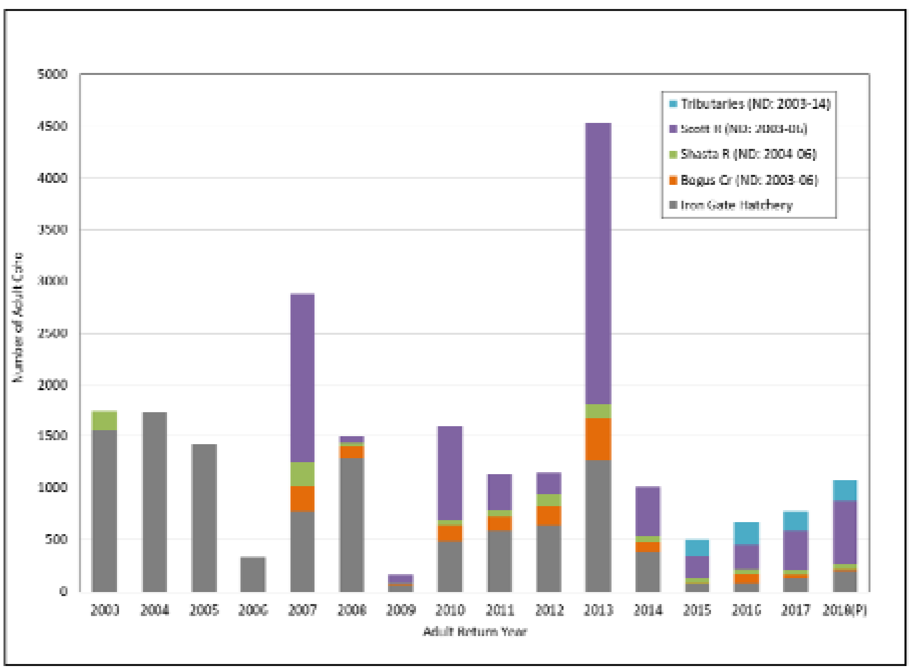

Figure 1. Adult Coho returns to the Klamath River and tributaries upstream of Portuguese Creek. (2018 data is preliminary, Data from COFW 2018b, Knechtle 2019).

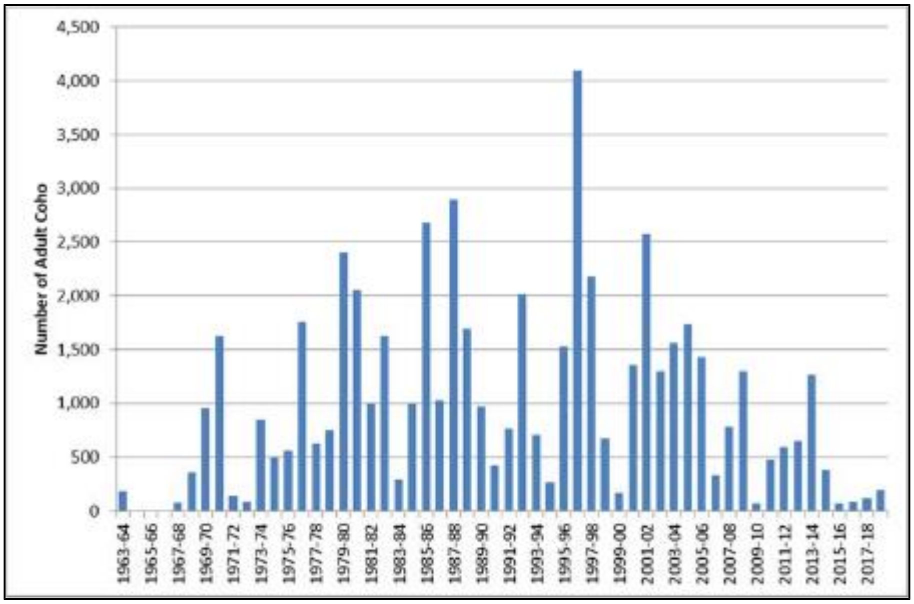

Figure 2. Adult Coho Returns to Iron Gate Hatchery on the Klamath River, 1962 through 2019 (CDFW 2018b).

Juvenile Populations. Juvenile Coho are found in the mainstem Klamath River and its tributaries throughout the year (Soto et al. 2016). Coho spend about a total of up to 18 months in freshwater (from emergence to outmigration) before they migrate to the ocean. During this period, they can exhibit any of several life history patterns. Some spend that entire time in one stream, others move from a creek into the mainstem Klamath River for a while sometimes moving back into the same creek or another stream as river conditions dictate. Still others move into the Klamath River, distribute downstream, and then move into non-natal rearing habitats (creeks, off-channel ponds, groundwater springs, etc.). Soto et al. (2016) indicate that the Klamath River provides important habitat for juvenile Coho throughout the year; during the summer periods this use is likely limited to refugia habitats in or adjacent to the mainstem river. Of particular note for the Proposed Project are the spring and earl y winter redistributions of juvenile Coho from natal streams to non-natal rearing habitat. Soto et al. (2016) hypothesized that juvenile Coho that leave rearing habitat in mid-winter are in search of higher-quality habitat, but are not prone to make long-distance movements.

Response to Comment ORG46-3

PacifiCorp provides a summary of data on coho salmon in the Klamath River upstream of Portuguese Creek. PacifiCorp discusses adult coho salmon return data for Iron Gate Hatchery (CDFW 2018d) that is not included in Section 3.3 *Aquatic Resources*; however, this data is very similar to what was included in Section 3.3 *Aquatic Resources* (CDFW 2016b). Additionally, the natural-origin coho salmon return data to tributaries from Bogus Creek downstream to Portuguese Creek does not change the EIR's analysis of potential impacts to coho salmon due to increased suspended sediments due to the fact that very few coho salmon are expected to spawn in the Klamath River (0-13 redds). This additional information is included in the record, but not added EIR analysis because it does not differ substantively from the data that are already included and discussed, and therefore would not change the analysis, or conclusions of the EIR.

Comment ORG46-4

2.1.3 Coho Mortality from Suspended Sediments

Mainstem Spawning Adults. Even though most Coho spawn in the tributaries, those fish that do spawn in the mainstem would suffer 60-80 percent mortality from sediments mobilized by the Proposed Project (DEIR pg. 3-318). This is up from 20–40 percent present under existing conditions–a 40 percent increase in the mortality rate that is solely attributable to the Proposed Project. Granted this is a small number of individual Coho, perhaps a couple of dozen fish, but the mainstem population could make up about 14 percent of the total population between Portuguese Creek and Iron Gate Dam assuming the average population is about 191 Coho as has been recently documented (not including Bogus Creek) (Table 1). While suspended sediment may kill an added 40 percent of the adults, it is reasonable to expect suspended sediment concentrations would kill 100 percent of the eggs and alevins (newly hatched fish) from mainstem spawning Coho. The DEIR discounts these adult Coho as hatchery fish that did not migrate all the way to the hatchery. That may be the case, but the Iron Gate Hatchery is managed as an integrated hatchery under a Hatchery Genetics Management Plan (HGMP; CDFW and PacifiCorp 2014) with the entire upper Klamath Coho population, making each of these fish of critical importance to the overall population. Currently, Coho returning to Iron Gate Hatchery make up about 65 percent of all returning spawners upstream of Portuguese Creek (including the Scott and Shasta rivers).

Tributary Spawning Adults. When populations are comprised of very few individuals, they can experience difficulties finding mates, which in turn reduces fertilization rates and limits production of young. This in turn results in increased per capita predation rates, and decreased overall survival (Williams et al. 2008). The threshold at which these effects are apparent is the depensation threshold for the population. As noted in Williams et al. (2008) failure to achieve depensation thresholds can exacerbate the rate of decline towards extirpation and extinction. This context is important for the discussion of impacts of the Proposed Project on Coho in the upper Klamath River because populations are generally smaller than these depensation thresholds and therefore, even a small change in abundance can have a substantial effect on the population.

Table 1. Annual counts of adult Coho at Iron Gate Hatchery, video weirs in Bogus Creek, Shasta River, and Scott River, and spawning survey estimates from other tributaries between Bogus Creek and Portuguese Creek from 2003–2018.

Sources: Knechtle 2019; MKWC 2016, 2017, 2018, and preliminary 2019 data)

The Upper Klamath River Coho population as defined in the NMFS (2014) recovery plan, does not include the Scott and Shasta rivers populations or the Iron Gate Hatchery fish. The depensation thresholds for the Upper Klamath Coho population is 425 adult Coho, for the Shasta River it is 531 adult Coho, and for the Scott River it is 441 adult Coho (Williams et al. 2008). The Upper Klamath adult returns have been below this threshold since at least 2013 (spawning estimates for Coho in tributaries between Bogus Creek and Portuguese Creek are not available until 2015; Figure 3). The population in the Shasta River has not been above the depensation threshold for the entire period for which data is available (Figure 4). The Scott River population seems to be slightly more robust than the other two populations with 2 out of the last 5 years above the depensation threshold (Figure 5).

Coho on the Klamath River show a distinct 3-year life cycle, and adult returns are driven by the relative strength of an individual brood year with almost no overlap between years. Review of return data indicates that 2007 is the strongest of the three brood years and led to more adult s returning in 2010, 2013, and so on (Table 1). This is important to consider because if an entire year-class is eliminated, that year class may not re-establish itself.

Most of the tributary spawning adults are likely to have reached their spawning grounds before suspended sediment concentrations in the mainstem become lethal. The DEIR analysis indicates that the median conditions under existing conditions could be expected to have some "moderate habitat degradation and impaired homing" (DEIR Table E-4). Under the Proposed Project, the effects of suspended sediment concentration s under the same median flow conditions are expected to result in

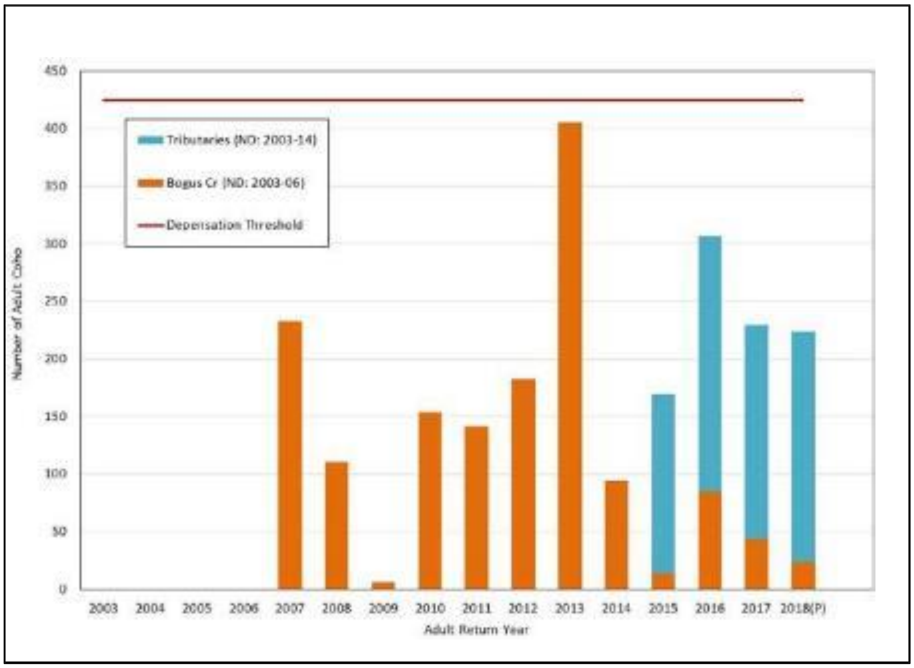

Figure 3. Adult Coho Returns to the Upper Klamath River Population - Portuguese Creek to Iron Gate Hatchery {2018 data is preliminary, Data from CDFW 2018b, Knechtle 2018, Depensation threshold from Williams et al. 2008).

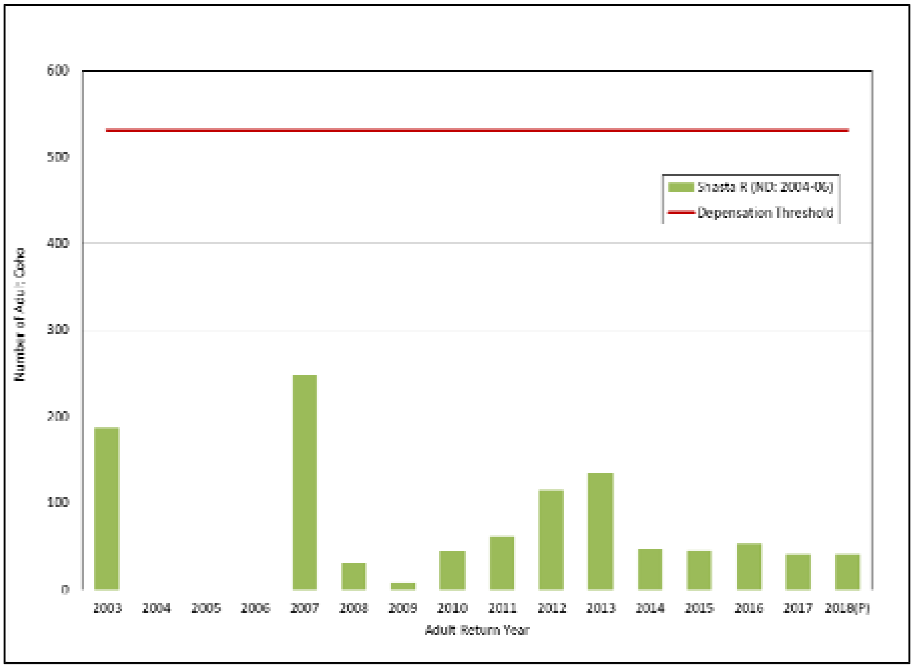

Figure 4. Adult Coho Returns to the Shasta River Population (2018 data is preliminary, Data from Knechtle 2018, Dispensation threshold from Williams et al. 2008).

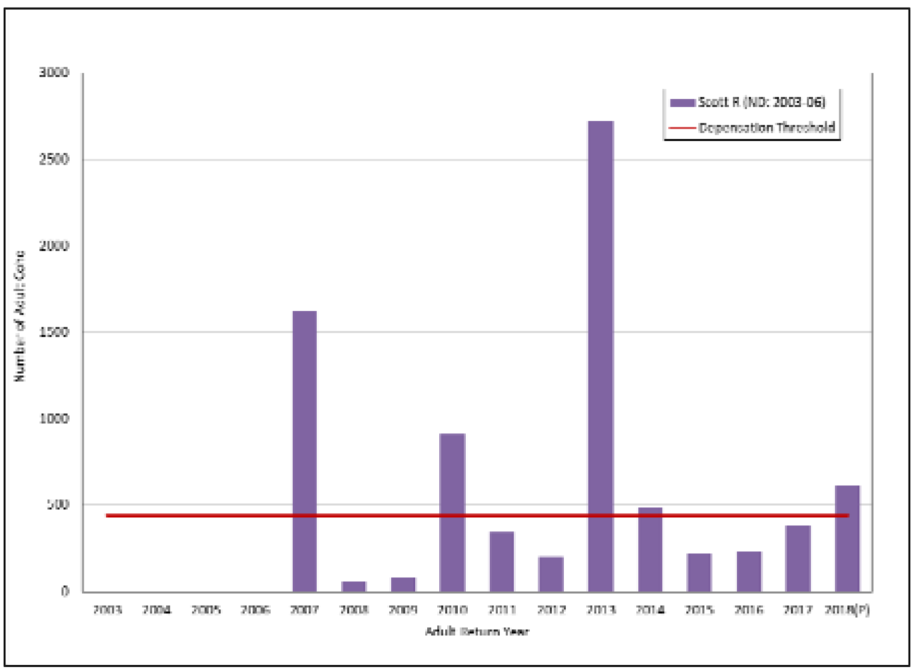

Figure 5. Adult Coho Returns to the Scott River Population {2018 data is preliminary, Data from Knechtle 2018, Depensation threshold from Williams et al. 2008).

"major physiological stress; long-term reduction in feeding; and poor condition " (DEIR Table E-10). This is an increase in adverse conditions associated with the Proposed Project for adult Coho, but still sub-lethal. The reduction in feeding rates are not important for the adults, but changes in condition as a result of physiological stress could reduce fecundity and affect the spawning success even if the adults survive their transit of the mainstem to reach tributaries.

Juvenile Coho in the Mainstem. Juvenile Coho use the mainstem Klamath River throughout the year (Soto et al. 2016), although summer-time use is probably limited to cool-water refugias. About 30 percent of the tagged juvenile Coho in Seiad Creek emigrated from the creek to the Klamath River between the beginning of November, 2010 and the end of February, 2011 (Soto et al. 2016). While Manhard et al. (2018) caution that juvenile Coho migrate in different patterns when coming from different streams, their modeling of migration patterns indicates that between 19 and 24 percent of the juvenile Coho present in a tributary population may leave that tributary during the winter months.

The DEIR assumes that those juvenile Coho that migrate early in the year (January through March) are few in number and would find refuge from elevated suspended sediment concentrations in the mainstem in off-channel habitats, tributary inflows, or tributaries themselves. While fish do actively avoid areas of high suspended sediment concentrations, naturally-generated events do not last for 6-8 weeks like under the Proposed Project. Because of the duration of the Proposed Project-generated suspended sediment concentrations, there would be little escape for Coho leaving tributaries during the winter. It is also reasonable to expect that all the fish (e.g., resident trout, Chinook, Steelhead, etc.) in the river may be trying to access those very same refuge habitats. There is some indication that there may already be density dependent interactions occurring in refuge habitats (Soto et al. 2016). Forcing more fish to use these areas would increase the risk to Coho from predation, competition for space and food, and disease exposure; this potential impact on Coho is not addressed in the DEIR. The DEIR' s assumption that Coho will simply avoid periods of high turbidity does not reflect complexities of actual fish behavior or the likelihood that the Proposed Project could result in high rates of mort alit y of juvenile fish that originated from the tributaries. Because the overall Coho population in the Upper Klamath River is already very small, it is not clear if the populations could survive such a mortality event.

During the January-t o-March drawdown period, suspended sediment concentrations are expected to result in 20-40 percent mortality for all age classes of juvenile Coho in the mainstem (DEIR Table E-10). This is higher than the sub-lethal "moderate to major stress" levels predicted for existing conditions (DEIR Table E-4). Deposition of sediment in mainstem refugia could eliminate these habitat s. Similarly, deposition of sediment at the confluences of tributaries with the Klamath River could eliminate mainstem refugia and limit juvenile access to areas of higher water quality in the tributaries.

The DEIR posits that existing Coho outmigrants face high mortality under existing conditions for a variety of reasons and that the Proposed Project could result in even higher mortality in the spring of 2021 (DEIR pg. 3-319). While the DEIR does not indicate what the incremental change in juvenile mortality may be, it would appear that the upper Klamath River Coho populations are small enough that even a minor change in mortality could have dramatic results on adult escapement and the viability of these populations. Because there are so few juvenile Coho in the river, juvenile Chinook are used as a surrogate for assessing disease levels. The rate of Ceratonova shasta (C. shasta) infection in fish has ranged from about 12 to 96 percent from 2005 through 2015 (Som et al. 2016). As fish become more stressed by environmental condit ions (lack of food, space, increased competition, etc.) they become more susceptible to disease. This would make them more likely to contract common fish diseases including lch (lchthyophthirius multifilis), Columnaris, or Parvicapsula minibicornis, all of which can be lethal.

Response to Comment ORG46-4

Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Volume II Appendix E Section E.3.2.3 *Results – Coho Salmon* (pages E-35 to E-36) are consistent with PacifiCorp's summary of the importance of tributary spawning for Klamath River coho salmon, and the predicted impacts to adult migrating coho salmon from suspended sediment under the Proposed Project. This analysis addresses the concerns raised by PacifiCorp regarding potential sublethal effects to adult migrating coho salmon adults returning to tributaries, including an assessment that few coho salmon adults are predicted to be in the mainstem in January when the highest levels of reservoir sediment would be released.

In Section 2.1.3 of their comment letter, PacifiCorp suggests that the population level impact of the loss of redds from mainstem spawning coho salmon could be 14 percent of the total population between Portuguese Creek and Iron Gate Dam (designated by National Marine Fisheries Service [NMFS] as the Upper Klamath River population following Williams et al. 2006). This estimate appears to be based on the observation of 13 redds in 2001 (equating to 26 adults presumably assuming two adults per redd), and a total adult population of coho salmon in that reach of 191 based on the average of four years of returns from 2015 through 2018 to tributaries in the reach, while excluding returns to the mainstem, Bogus Creek and Iron Gate Hatchery (summarized in Table 1). Presumably Iron Gate Hatchery returns are excluded as it is less likely that those fish would spawn naturally (although, as noted in the EIR, many of the mainstem spawning coho are likely straying hatchery fish). However, there is no logical or scientific basis for excluding Bogus Creek returns, or the mainstem spawning counts from the estimate.

The “14 percent of the total population between Portuguese Creek and Iron Gate Dam” described by PacifiCorp is misleading. The more logical and scientifically defensible estimate of the likely mainstem contribution is presented in Volume II Section E.3.1.3 of Appendix E. In sum, based on the range of escapement estimates of Ackerman et al. (2006), 13 redds (the highest number observed) would be much less than one percent of the natural and hatchery returns combined. Coho salmon are distributed throughout the Klamath River downstream from Iron Gate Dam, and spawn primarily in tributaries (Trihey and Associates 1996, NRC 2004). During their upstream migration, adult coho salmon from the Upper Klamath River Population Unit may travel upstream as far as Iron Gate Dam (river mile [RM] 193.1) and were formerly known to occupy mainstem Klamath River and tributary habitat at least as far upstream as Spencer Creek at RM 232.6 (NRC 2004, as cited in NMFS 2007a). Thus, the mainstem Klamath River functions primarily as a migration corridor for coho salmon. Coho salmon are typically tributary spawners (NMFS 2010a) and based on Magneson and Gough (2006) spawning surveys from 2001 to 2005, only from 0 to 13 redds are typically observed in the mainstem. In 2015, no redds were observed in the mainstem Klamath River between Portuguese Creek (RM 128) and Bogus Creek (RM 192.6) (Hentz and Wickman 2016), and seven were observed in 2017 in the same reach (Dennis et al. 2017).

In addition, PacifiCorp assesses impacts on coho salmon based on the nine historical populations within the Klamath River Basin, which segregates returns from coho salmon upstream of Portuguese Creek into the Upper Klamath River Population. PacifiCorp uses this segregation approach to raise concern regarding the depensation threshold for coho salmon described by Williams et al. (2008), noting that when populations are at lower abundances than depensation thresholds, small reductions in abundance can have a detrimental impact. Assessing the significance of impacts assigned to this historical population unit is misleading. The historical unit is not sufficiently analogous to the present-day population because of the significant curtailment of its historic range, which extended far upstream of Iron Gate Dam. Notably, Williams et al. (2008) describe the highest intrinsic potential for spawning coho salmon in the historical population unit that extended upstream of Iron Gate Dam to Spencer Creek. The comment does not extend the logic of its historic population focus to the benefits of the proposed project – the extension of habitat for this historic population back into its former range. Citing depensation thresholds as a concern without addressing the range is misleading, since the NMFS 2014 Southern Oregon/Northern California Coast (SONCC) Recovery Plan (NMFS 2014) specifically identifies restoring habitat access upstream of Iron Gate Dam as a high priority to recover the coho population and address the current low spawner densities. In addition, the Iron Gate Hatchery operates for the purpose of coho salmon conservation, and, as described in the EIR, would continue to produce coho salmon smolts during and following dam removal, which directly addresses the current low spawning densities of the population and concerns regarding the depensation threshold.

The “small population of Coho in the mainstem Klamath River…” referenced in this comment is not a separate population of coho salmon by the designation of any fisheries regulator and is not a meaningful unit of analysis for the EIR. In the coho recovery plan, NMFS (2014) groups populations with similar geologic and genetic features into seven diversity strata, following the work of Williams et al. (2006). In assessing risk and recovery of the Evolutionarily Significant Unit (ESU), NMFS considers the Interior Klamath River Diversity Stratum, which includes the Middle Klamath River, Upper Klamath River, Salmon River, Scott River, and Shasta River populations designated by Williams et al. (2006). The EIR considers the nine historical populations within the Klamath River Basin in analysis but conducts the analysis of significance consistent with the NMFS 2014 SONCC Recovery Plan, which assesses all of the coho salmon in the Klamath River Basin as part of the same ESU. The EIR acknowledges the low abundance of the coho salmon population consistent with the alarm and concern raised by PacifiCorp. As noted in Volume I Section 2.1 *Project Description – Project Objectives* (page 2-1) the Proposed Project is a restoration project intended to improve fishery conditions.

In Volume II Section E.3.2.3, the maximum of 13 redds observed in 2001 was selected to present the highest potential impact, since this is the highest count observed in over 15 years, while in many years no coho salmon redds were observed in the mainstem. Assuming one female and one male per redd, this could represent at most 26 returning adult coho salmon. Based on average adult returns presented by PacifiCorp in Table 1 of their comments on the EIR (and the maximum of 13 redds assumed to occur in the mainstem), this would be at most less than 1 percent of the coho salmon adult returns upstream of Portuguese Creek. Even if the Williams et al. (2006) Upper Klamath River Unit were adopted (contrary to the NMFS approach for assessing risk and recovery), this would be 8 percent of adult coho salmon returns if Iron Gate Hatchery, Shasta River, and Scott River returns are ignored. PacifiCorp comments do not support an assertation that this level of loss of redd production from infrequent mainstem production of coho salmon would present a substantial short-term decrease in coho salmon abundance of a year class.

PacifiCorp cites Soto et al. (2016b) and Manhard et al. (2018) to assert that the Draft EIR underestimated the potential impacts of the Proposed Project to juvenile coho salmon produced in tributaries that migrate from tributaries into the mainstem “during winter,” and thus would be susceptible to impacts from suspended sediment. Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Volume II Appendix E Section E.3.2.3 *Results – Coho Salmon* (pages E-35 to E-38) provide a detailed analysis of the effects on the coho salmon population of short-term impacts to coho salmon rearing in the mainstem, and outmigrating smolts. The comment suggests that sediment deposition under the Proposed Project may further reduce opportunities to avoid suspended sediment impacts by "filling in" refuge habitat. Such deposition is not predicted under the Proposed Project (see Master Response GEO-1). Additionally, the analysis of impacts to mainstem rearing coho salmon concludes high potential rates of mortality in large part because the assessment conservatively assumes that coho salmon do not locate refuge habitat. Please also refer to response to comment ORG46-2 regarding coho use of the mainstem Klamath River.

Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Volume II Appendix E Section E.3.2.3 *Results – Coho Salmon* (pages E-37 and E-38) includes a discussion of the cumulative impacts of exposure to suspended sediment, water quality, and disease on coho salmon fry, juveniles, and smolts.

Comment ORG46-5

2.1.4 Population Level Impact of the Proposed Project

The DEIR says that "...Coho salmon smolts outmigrating from the Upper Klamath River, Scott River, and Shasta River populations currently have high mortality rates (35 to 70 percent) presumably as a result of poor water quality and disease (Beeman et al. 2007, 2008)"[1] (Appendix E pg. E-38). The Proposed Project would add additional stress to outmigrating juveniles; however, the DEIR fails to indicate what this means in terms of the population. The population of Coho is small enough that even a modest increase in mortality rate (either through direct mortality, or indirect through reduced fitness, predation, or increased susceptibility to disease) could reduce the number of returning adults. With most of the Coho populations below depensation thresholds, it is unclear how these populations would respond to this event.

Uncertainty. The DEIR acknowledges that there is uncertainty associated with the effects of the Proposed Project on Coho. While the DEIR extensively references the Expert Panel report on Coho and Steelhead (Dunne et al. 2011), there is not an adequate discussion of the implications of this uncertainty. Dunne et al. (2011) repeatedly reinforce that what could ultimately happen to the Coho population from the Proposed Project is not clear and note that while there may be a small increase in production from newly accessible habitat, disease and low ocean survival could easily offset this gain. It is also important to recall that the determinations by the Expert Panel included the implementation of the Klamath Basin Restoration Agreement (KBRA), an element that is no longer available to, in part, provide funding and structure for restoration in the basin. If the Expert Panel thought that the outcome was uncertain in 2011, that level of uncertainty has increased in 2019 without the elements of the KBRA that were intended to improve habitat function and result in water quality improvements in the Upper Klamath Basin that might address acknowledged fish passage impediments.

The suspended sediment modeling and the effects analysis relating to Coho attempts to address some of the uncertainty associated with the effects of the

Proposed Project by using the 10^{th}, 50^{th}, and 90^{th}, exceedance probabilities. While helpful if properly done, the analysis in the DEIR uses the sediment transport modeling incorrectly (see Major Issue 2.4 and Brookes 2019), is incomplete, and does not help the reader understand the potential effects of the Proposed Project. The analysis fails to make the connection between the effects of increased suspended sediment concentrations on Coho and the population of Coho present that will be impacted by these changes.

Recolonization at low abundance levels. There are few Coho left in the upper Klamath Rive r populations (Figure 1). Few Coho return to Bogus Creek and even fewer to the Shasta River, and it appears that less than 200 Coho annually spawn in the tributaries of the Upper Klamath from Iron Gate Dam to Portuguese Creek. These populations are below the abundance risk thresholds and mostly below depensation thresholds established in the recovery plan (NMFS 2014, Williams et al. 2008). Although adult straying is a natural event in salmon, it is a relatively infrequent occurrence. The main population from which recolonization could occur is adult Coho returning to Iron Gate or Fall Creek hatcheries. Although straying rates vary greatly amongst species and populations and specific rates are difficult to establish without an abundance of tagging data (see Quinn 2005), if there are only a couple hundred natural Coho in this population to start with there may not be many adults available to stray into the newly accessible habitat. Because all the Coho released from Iron Gate Hatchery are clipped, the number of Coho available to recolonize the areas upstream of Iron Gate Dam can be estimated by the number of natural-origin fish that return to Iron Gate Hatchery annually because the se natural-origin fish are straying into the hatchery. The average number of natural-origin fish entering the hatchery from 1997 through 2017 was 30 adult Coho (Giudice and Knechtle 2018); there is no sex information readily available on these strays so it is impossible to evaluate the true recolonization potential. Even if females make up half of this straying population, 15 pairs of Coho on average does not seem like enough fish to effectively recolonize the area upstream of Iron Gate Dam and any straying that does occur reduces the population size in the source streams.

Hatchery Operations. The ability of Iron Gate Hatchery and the redeveloped Fall Creek Hatchery to capture fish after Iron Gate Dam is removed remains is uncertain. Coho may or may not successfully home to these facilities. The importance of hatchery production in maintaining the Upper Klamath population cannot be overemphasized. Adult Coho escapement data indicate that on average, approximately 50 percent of the Coho spawning naturally in the Shasta River and Bogus Creek were of hatchery origin (Chesney and Knechtle 2017; Knechtle and Giudice 2018). This percentage indicates that all of the natural production in these two streams may only be one generation or less removed from the hatchery. Failure of the hatchery or cessation of the hatchery program could permanently reduce these populations of Coho by 50 percent.

Response to Comment ORG46-5

The comment asserts that the Draft EIR fails to consider population level impacts on coho salmon as a result of predicted mortality to juveniles and smolts under the Proposed Project. Please refer to Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* for an analysis of the population level impacts on coho salmon under the Proposed Project, including consideration of stress to outmigrating juveniles. Please also refer to response to comment ORG46-4 for further discussion of the population-level impacts of the Proposed Project on coho salmon.

The comment also asserts that within the Draft EIR there is not adequate discussion of the implications of uncertainty in the coho salmon population response to dam removal as described by the coho salmon expert panel (Dunne et al. 2011), especially since the Klamath Basin Restoration Agreement (KBRA) is no longer proposed. Please refer to Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*, which addresses uncertainty in predicting the effects of the Proposed Project and specifically describes the concerns related to predicting a population-level response as described by Dunne et al. (2011). Please also refer to Master Response AQF-12 for a discussion of the incorporation of expert panel reports in the analysis of effects in the EIR.

Please note that the central benefits predicted for the coho salmon population under the Proposed Project include increased access to suitable coho salmon habitat upstream of Iron Gate Dam and decreased disease risk, as summarized in Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*. These benefits are not predicated on the actions that were formally included in the KBRA.

The comment also asserts that the Draft EIR uses the sediment modeling results incorrectly and fails to make the connection between the effects of increased suspended sediment concentrations (SSCs) on coho salmon and the population of coho salmon present that would be impacted by these changes. Please refer to the response to comment ORG46-8 for a discussion of the use of sediment transport modeling in the EIR and addressing PacifiCorp's referenced comments. In addition, Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and Volume II Appendix E Section E.3.2.3 Coho Salmon (pages E-35 to E-38) include a detailed analysis of the connection between predicted suspended sediment release and the population of coho salmon that may be present and affected by increased suspended sediment as a result of the Proposed Project.

The comment asserts that 200 coho salmon on average spawn annually within tributaries to the Klamath River, and it estimates that 15 females on average will stray to newly accessible habitat, suggesting that this is not enough fish to recolonize newly accessible habitat. The average of 200 adult coho salmon that the comment cites as being the potential source population of adult coho salmon available for straying into newly accessible habitat is based on observed returns to tributaries to the Klamath River between Portuguese Creek and Iron Gate Dam. However, adult coho salmon returning to Iron Gate Hatchery, Fall Creek Hatchery (FCH), Bogus Creek, Shasta River, and Scott River would also be potential strays into newly accessible habitat. The returns to these additional locations (excluding Fall Creek Hatchery) averages over 1,500 annually, in addition to the 200 returns cited in the comment, based on the data compiled and cited by PacifiCorp (i.e. Knechtle 2019, MKWC 2016, 2017, 2018). As discussed in Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*, recolonization success and rate would be a function of fish straying into newly available habitats (Pess 2009). The comment appears to underestimate the potential for straying of coho salmon adults into newly accessible habitat by only considering straying of natural returns to Iron Gate Hatchery and not considering straying of adults from other areas, or from hatchery origin returning adults to newly accessible habitat. Different salmon species and populations (and even the same populations from year to year) have highly variable straying rates, with hatchery origin spawners straying at a higher rate (Lasko et al. 2014). As discussed in Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries,* data from Ackerman et al. (2006) indicate that substantial straying of Iron Gate Hatchery fish may be occurring into important tributaries of the Middle Klamath River under existing conditions. As discussed in Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*, under existing conditions CDFW and PacifiCorp (2014) estimates that greater than 30 percent of the total adult returns to the upper Klamath River are of hatchery origin, including greater than 70 percent of returns to the hatchery, around 34 percent of returns to Bogus Creek, and around 16 percent of returns to tributaries such as the Shasta and Scott rivers. PacifiCorp cites recent data from Chesney and Knechtle (2017) and Knechtle and Giudice (2018a) to note an even higher proportion of hatchery returns, which would not change the conclusions of the EIR. Between 2004 and 2011 an average of 46 coho salmon hatchery adults per year strayed into Bogus Creek (CDFW and PacifiCorp 2014). Between post-dam removal years 4 and 10, both hatchery returns and returns from newly accessible habitat would occur, providing a likelihood of increased abundance and recolonization of the newly accessible habitat.

As further discussed in Potential Impact 3.3-9 in Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*, coho salmon recolonization of newly accessible habitat was observed following fish ladder installation at Landsburg Dam on the Cedar River, Washington (Kiffney et al. 2009) and following removal of Condit Dam on the

White Salmon River, Washington (Allen et al. 2016). The Landsburg Dam was laddered in 2003, and coho salmon were observed within areas upstream of the dam within the first year. By 2011, salmon (with coho salmon being most abundant) occurred within nearly all of the accessible habitat upstream of Ladsburg Dam. Pess et al. (2011) predicted that within the habitat upstream of Landsburg Dam juvenile coho salmon would establish a population that outnumbered resident salmonid species (e.g., rainbow trout, cutthroat trout) by 40 percent within five years of colonization, suggesting a strong ability of coho salmon to successfully occupy newly accessible habitat.

Without citing specific evidence, the comment expresses the concern that coho salmon may or may not successfully home to the Iron Gate or Fall Creek Hatchery under the Proposed Project, challenging the ability of these hatcheries to operate successfully. As described in Section 2.7.6 *Proposed Project – Proposed Project – Hatchery Operations* (page 2-80), hatchery operations would be managed by California Department of Fish and Wildlife (CDFW) in consultation with the National Marine Fisheries Service (NMFS), as occurs under existing conditions. NMFS and CDFW (2018) submitted a memorandum entitled the "*NMFS and CDFW Technical Staff Recommendation for Klamath River Hatchery Operations in California Post-Dam Removal*" in which facility upgrades to increase attraction to the Iron Gate Fish Hatchery collection facility (including increased attraction flow) are described, as are new collection facilities in Fall Creek, which could include construction of an adult ladder and trap, and/or a new picket and weir with trap at the mouth of Fall Creek. In their memorandum, NMFS and CDFW expressed no concerns for the ability of hatchery collection facilities to capture adult coho salmon for the purpose of maintaining successful operations, and under existing conditions sufficient adults are captured each year to maintain production goals.

Comment ORG46-6

2.2 Klamath River Flow Modeling

In the introduction to the effects analysis in the DEIR, Section 3.1 includes a discussion regarding hydrology information, analyses, and provides a rationale to defend the use of the hydrology analysis found in the Klamath Facilities Removal Environmental Impact Statement (EIS)/EIR (2012 KHSA EIS/EIR; DOI and CDFW 2012). Section 3.1 is cross-referenced over 40 times throughout the DEIR. The hydrology and flow analysis from the 2012 KHSA EIS/ EIR is outdated and inconsistent with the best representation available of existing hydrologic conditions, which is the 2013 Biological Opinion (2013 BiOp) Klamath Basin Planning Model (KBPM) hydrologic results (USBR 2012a). Throughout the DEIR, statements like the following are used to justify use of the 2012 KHSA EIS/EIR hydrology analysis (DEIR pg. 3-96):

...model predictions made using hydrology assumptions adopted for the Klamath Dam Removal Secretarial Determination are still appropriate for assessing

Proposed Project impacts since the NMFS 2013 Biological Opinion mandatory flows are encompassed within the modeled range of flows.

In Section 3.1.6 of the DEIR, the 2012 KHSA EIS/EIR Supplemental Information Report (SIR) (USBR 2016) is cited as supporting information for these statements. Specifically, the DEIR states (DEIR pg. 3-4):

USBR (2016) concluded that the relatively small flow differences between 2013 BiOp and KBRA Flows would not substantively alter the conclusions in the 2012 KHSA EIS/ EIR for those environmental resources that would be affected by flows (i.e., water quality, aquatic resources, flood risk, recreation).

Review of U.S. Bureau of Reclamation (USBR 2016) found that it does not provide additional explanation or information to adequately support the conclusion in the DEIR that the difference from the 2013 BiOp and KBRA flows would not alter the previous conclusions. Additionally, information regarding differences in water supply diversion volumes and storage conditions throughout the basin, such as in Upper Klamath Lake, are not provided in Section 3.1.6 of the DEIR or USBR (2016). Review of the differences in KBRA versus 2013 BiOp flows (see DEIR Figure 3.1.1 and Figure 3.1. 2) clearly indicates that in many months the differences are significant, not small. The use of the 2012 KHSA EIS/ EIR (DOI and CDFW 2012) analyses, when more recent flow information is readily available, indicates that the DEIR does not use the best available science to inform its hydrologic analysis, which then impairs all subsequent analysis that relies upon these hydrologic inputs.

The hydrology data forms the foundation upon which analysis in the DEIR is based. Because the more representative 2013 BiOp KBPM analysis was not used to characterize existing hydrologic conditions, the representativeness and accuracy of the DEIR analyses of the Proposed Project as it relates to hydrology, water quality, and aquatic resources impacts are questionable. This includes the DEIR's conclusions regarding significance of impacts on these resources. The KBRA flows and resultant 2012 KHSA EIS/EIR analysis represents a baseline in which river flows are greater under the KBRA flow assumptions as compared to flows from the 2013 BiOp KBPM analysis, which reduces impacts on water quality and aquatic resources. Not using the updated information available from the 2013 BiOp KBPM results in an overstatement of beneficial water quality and aquatic resources effects from the Proposed Project, and an understatement of adverse impacts associated with the Proposed Project. The DEIR incorrectly and inappropriately states that it is sufficient to "bracket the range of 2013 BiOp flows" (DEIR pg. 3-9) rather than maintain more comparable and updated probability distributions of flow duration and magnitude, but the DEIR fails to provide a discussion of why this bracketing is adequate. The DEIR should include a specific analysis and examples (preferably based on formal statistical analysis) to demonstrate the appropriateness of the DEiR's use of the KBRA flows and 2012 KHSA analysis rather than the 2013 BiOp model.

The Klamath Hydroelectric Project has limited flood control capacity as it is currently operated, and storage in Upper Klamath Lake, which is managed by USBR, is relied upon to provide flood control in the Upper Klamath Basin. Flood storage in Upper Klamath Lake is important in order to reduce the potential for Upper Klamath Lake to overtop levies since hydraulic restrictions at the outlet of the lake and at Link River Dam limit the amount of water that can be released from Upper Klamath Lake. Storage in Upper Klamath Lake is also used to limiting downstream releases that can exacerbate flooding in the Keno Plain, as occurred during the 1964 flood. Thus, Upper Klamath Lake elevations impact the amount of storage available for flood control and ultimately drive the need for pre-emptive flood control releases from Link River Dam. Due to concerns over water surface levels in Upper Klamath Lake to protect endangered suckers and the desire to manage to higher lake levels to protect sucker habitat, Upper Klamath Lake levels are being managed to higher elevations under the 2013 BiOp (see Exhibit A, comment 3.3-46). The USBR changed its flood control management with the 2013 BiOp as compared to earlier flood control operations evaluated in the 2010 BiOp (and as used in the 2012 KHSA EIS/ EIR analysis), resulting in less pre-release of water downstream for flood control purposes. There is no discussion in Section 3.1.6 of the DEIR comparing Upper Klamath Lake storage levels between the previous 2012 KHSA EIS/EIR analysis and the 2013 BiOp KBPM analysis, which drives changed river flows. Thus, the DEIR flood risk analysis does not recognize the changed operating conditions in Upper Klamath Lake that affect routing of the 100-year flood, which may underestimate flood risk impacts associated with the Proposed Project.

Response to Comment ORG46-6

Comment noted. Volume I Section 3.1.6 *Introduction – Summary of Available Hydrology Information for the Proposed Project* has been revised to provide additional background information regarding the 2013 Biological Opinion (BiOp), including clarifying statistical analyses and flow exceedance analyses indicating that the hydrologic model outputs previously developed using the Klamath Basin Restoration Agreement (KBRA) Flows for the 2012 KHSA EIS/EIR are sufficient to estimate conditions under 2013 BiOp Flows for the Lower Klamath Project EIR. As explained in the clarifying revisions to Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, the range of 2013 BiOp Flows is within the range of modeled KBRA Flows approximately 99.9 percent of the time at Keno and Iron Gate dams, and the primary differences between the 2013 BiOp Flows and the KBRA Flows are temporal shifts in the flow distribution within some months and changes in expected flows in different water year types. While the specific timing of flows and the likelihood of exceeding a specific flow during individual months changes between the 2013 BiOp and KBRA flows, modeled 2013 BiOp Flows less than or greater than modeled KBRA Flows would occur too infrequently (i.e., 0.01 percent of the time or less) to substantially alter the range of flow conditions in the Klamath River or previous model results using KBRA Flows. The data source for the 2013 BiOp

Flows was also updated from USBR (2016) to USBR (2010b) and USBR (2019a) to include the longest period of record available for the flow comparison (1980−2011), and new monthly flow exceedance plots have been added to the EIR that also indicate in which months there would be a statistically significant difference in the flow distributions ($p<0.01$ or $p<0.05$). Further, the clarifying revisions to the EIR include a comparison plot of the maximum and minimum monthly exceedance curves for the 2013 BiOp Flows and the KBRA Flows for the 1 to 99 percent exceedance flows at Keno Dam and Iron Gate Dam, which further clearly indicates that the distribution of flow duration and magnitude under the 2013 BiOp Flows is sufficiently similar to that of the KBRA Flows that the hydrologic model outputs previously developed using the KBRA Flows for the 2012 KHSA EIS/EIR are sufficient to estimate conditions under 2013 BiOp Flows. Please refer to Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* for the revisions.

Please refer to Master Response HYD-1 for a discussion of how the 2019 BiOp Flows were considered for the Lower Klamath Project EIR analyses.

Please refer to Master Response FLD-1 for a discussion of the limited flood control capacity of the Lower Klamath Project. With respect to the comment's concern regarding the flood risk analysis and Upper Klamath Lake levels, variations in the Upper Klamath Lake levels between the KBRA, the 2010 BiOp, the 2013 BiOp, and the 2019 BiOp are not explicitly discussed in Section 3.1.6 *Environmental Setting, Impacts, and Mitigation Measures – Introduction – Summary of Available Hydrology Information for the Proposed Project* because the analysis of modeled Klamath River flows at Keno and Iron Gate dams inherently includes the net influence of Upper Klamath Lake variations on flows, and potential impacts within the Area of Analysis under the Proposed Project would be the result of Klamath River flows rather than the Upper Klamath Lake levels. United States Bureau of Reclamation (USBR) uses the Upper Klamath Lake levels in the calculations of Klamath River flows at Keno and Iron Gate dams under the KBRA, 2010 BiOp, 2013 BiOp, and 2019 BiOp, so any variations in the water supply diversion volumes, storage conditions in the basin, and the flood control capacity/storage in Upper Klamath Lake would be incorporated into the flows at Keno and Iron Gate dams. Additionally, the Proposed Project does not make changes to the Klamath Irrigation Project operations criteria or applicable biological opinion(s), so there would be no change in the Upper Klamath Lake levels or the amount of flow released by the Klamath Irrigation Project and the applicable biological opinion(s) under the Proposed Project. Since there would be no change to the applicable biological opinion(s) that specify the Upper Klamath Lake flood release threshold elevations, there would be no impact on the flood storage in Upper Klamath Lake or the potential for Upper Klamath Lake to overtop levees under the Proposed Project. Thus, Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* only discusses the flow variations between the KBRA, the 2010 BiOp, the 2013 BiOp, and the 2019 BiOp to the extent those flow variations would contribute to potential impacts within the Area of Analysis, including those associated with flooding. Please refer to Volume III Attachment 1 for the final Section 3.1.6 *Environmental Setting, Impacts, and Mitigation Measures – Introduction – Summary of Available Hydrology Information for the Proposed Project*.

While there was a flood event during the December 1964 flood in the Klamath Basin, the operational criteria for the Klamath Irrigation Project in 1964 were different from those under the KBRA, 2010 BiOp, 2013 BiOp, or 2019 BiOp. The modeled peak flow releases from Keno Dam under the KBRA, 2010 BiOp, 2013 BiOp, and 2019 BiOp operation criteria do not occur in December 1964. As shown in Figure ORG46-6-1 below, modeled peak flows at Keno Dam under the KBRA and 2013 BiOp operations criteria both occur in January 1997 and they have a similar magnitude (12,854 cfs under the KBRA; 13,136 cfs under the 2013 BiOp), indicating that previous modeling of peak KBRA Flows would characterize peak 2013 BiOp Flows. Modeled peak 2019 BiOp Flows (9,932 cfs) also occur during January 1997, but it is less than the modeled peak KBRA Flows. Analysis of the flood risk impacts using KBRA Flows are expected to overestimate the flood risk impacts under the 2019 BiOp Flows since the modeled peak flow under the 2019 BiOp operations criteria is less than the modeled peak flow under the KBRA operations criteria.

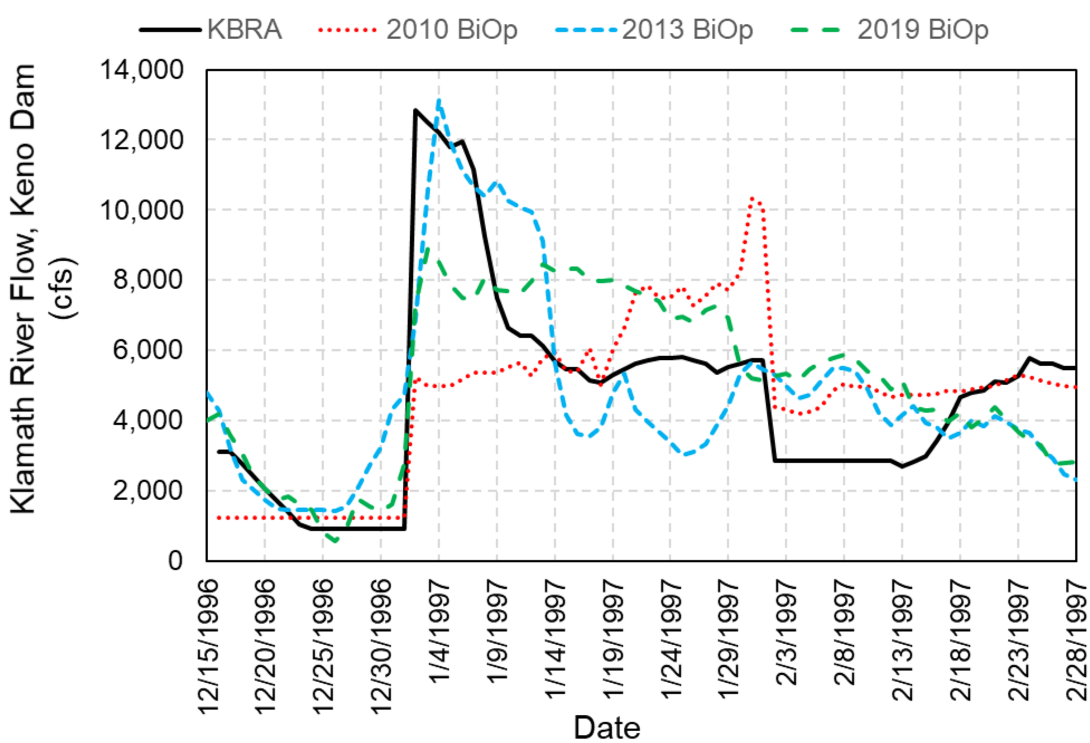

Figure ORG46-6-1. Peak USBR Modeled Klamath River Flow at Keno Dam During January 1997. Source: USBR 2010b, 2019a, 2019b.

Comment ORG46-7
2.3 Water Quality

Upper Klamath Lake is hypereutrophic and is the source of the nutrient loading to the Klamath River. The river itself exceeds phosphorus and nitrogen loading levels typically associated with eutrophic rivers (Dodds 2006; Smith et al. 2003). The DEIR does not consistently acknowledge this or the decades-long timeframe necessary for implementation actions, which remain uncertain, to result in nutrient loading reductions necessary to achieve the Oregon TMDL' s water quality goals in Upper Klamath Lake (ODEQ 2002). Because the flow regime discussed in the DEIR does not accurately represent existing conditions, the water quality modeling and effects analysis that is based on those flows also do not reflect existing conditions nor are they adequate to evaluate the impacts of the Proposed Project. The DEIR acknowledges that "multiple numeric models" (DEIR pg. 3-64) were used in the effects analysis for water quality. The DEIR however, does not use the most recent version of the Klamath Hydroelectric Project water quality model developed by PacifiCorp (2014), which includes numerous model updates and improvements from the version of the model used by ODEQ and others to develop the Klamath River TMDLs. Highlights of the more recent modeling outputs from the PacifiCorp (2014) model are presented here and included in the files that accompany PacifiCorp' s comments.

Water temperatures in the 190-mile lower Klamath River downstream of Iron Gate Dam are generally at or near equilibrium water temperature conditions with the exception of immediately downstream of the dam and in the vicinity of certain tributaries (PacifiCorp 2014). Releases from Iron Gate Reservoir are generally moderated owing to the relatively large reservoir volume and a penstock intake elevation that is about 30 feet below the reservoir water surf ace. These attributes lead to water temperatures that may be at or slightly cooler than equilibrium water temperature during the spring period. The river is considerably smaller in terms of volume per unit length, and thus cools and heats more quickly than the reservoir in response the ambient meteorological conditions.

During the fall period, temperature of water releases from Iron Gate Dam are warmer than equilibrium water temperature due to the thermal lag caused by the reservoir's mass (PacifiCorp 2014). The effect of this seasonal lag is largest in the river just downstream of Iron Gate Dam and diminishes relatively quickly in the downstream direction as the river comes into equilibrium with the local meteorological conditions. PacifiCorp's (2014) water temperature modeling indicates that by the time flows reach the Shasta River (RM 177), the impact of the lag is diminished by approximately 50 percent and continues to diminish in the downstream direction (Figure 6).

Water temperatures are generally at or near equilibrium water temperature conditions over the rest of the lower Klamath River below the Shasta River (RM

177) (PacifiCorp 2014). The major tributaries generally enter the Klamath River at similar temperatures to the river. The overall state of temperature equilibrium may not hold during periods when cold tributary runoff during spring snowmelt runoff or rain on snow events enter the mainstem Klamath River. During warmer periods of the year there are isolated regions at the confluence of many tributaries where inflow water temperatures are markedly colder than the mainstem. These thermal refugia areas may range from a few square yards to several hundred square yards in size depending on the flow and temperature in the tributary, flow conditions in the mainstem Klamath River, and local geomorphology (Sutton et al. 2002). By the time waters reach the Scott River (RM 143), water temperatures indicate minimal seasonal thermal lag and variability in mean daily water temperatures are largely absent, but results may vary among months (Perry et al. 2011). Such results are consistent with PacifiCorp (2014) water quality modeling results (Figure 6). The DEIR repeatedly incorrectly asserts that the temperature effects of releases from Iron Gate Dam are apparent downstream of or to the confluence of the Salmon River (RM 66) (e.g., DEIR pg. 3-78), and that dam removal will provide benefits to outmigrating fish. Such an example is found on pg. 3-277 of the DEIR, where it states (emphasis added), "FERC (2007) concluded that dam removal would enhance water quality and reduce the cumulative effects on water quality and habitat that contribute to disease- induced salmon die-offs in the Klamath River downstream from Iron Gate Dam. In turn, this would benefit salmon outmigrants from tributaries downstream from Iron Gate Dam, such as the Shasta and Scott rivers." This statement is contrary to the best available water quality modeling results, which indicate temperature differences hardly discernible at the Scott River confluence and mean daily temperatures at Iron Gate Dam that are cooler during the juvenile outmigration period as compared to locations further downriver (Figure 7).

PacifiCorp (2014) modeling simulations indicate that the consistently warmest reach of the Klamath River under existing conditions is the reach between approximately Seiad Valley (RM 129) and Clear Creek (RM 98.8). Maximum daily temperatures can reach 30°C and daily minimum temperatures in the 20 to 25°C range are common in this reach during summer (Figure 8). Downstream of this reach, the river experiences considerable accretion and the aspect ratio of the channel changes from a broad shallow stream to a deeper river. As the river approaches the coast, marine influences can moderate river temperatures, but when clear warm conditions prevail, water temperatures respond accordingly. For example, water temperatures at Turwar (RM 6) are cooler overall during spring and summer periods than upriver at Orleans (RM 57) or Seiad Valley (RM 129), with the diurnal range in temperature also more moderated at Turwar (Figure 8). During winter, water temperatures at Turwar are generally warmer overall than at upriver locations (Figure 8) due to milder meteorological conditions at lower elevations.

Because of specific shortcomings created by inappropriate flow data, the complicated interrelated nature of water quality, and the matrix of outdated or flawed water quality models that the DEIR analysis is based upon, it is difficult to discern the actual shortcomings in the water quality discussion in the DEIR. At the most basic level flow rates affect water temperatures which in turn affect dissolved oxygen concentrations, hydraulic retention times, growth of cyanobacteria, nutrient cycling, pH, and so on. Because short-duration adverse water quality events (on the scale of hours to days) can have significant effects on aquatic species, correctly representing the flow regime is critical when assessing potential impacts of a proposed action on water quality. Many of those water quality analysis influence the evaluation of Proposed Project's effects on aquatic species.

Response to Comment ORG46-7

With respect to the comment's assertion regarding Upper Klamath Lake as a continuing source of nutrients to the Lower Klamath Project, please refer to Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin*, which states "The Upper Klamath Basin has naturally elevated levels of phosphorus that combine with human activities (e.g., wetland draining, agriculture, ranching, logging, water diversions), to increase concentrations of nutrients (nitrogen and phosphorus) and suspended sediment, to degrade water quality parameters (e.g., water temperature, pH, dissolved oxygen). This, in turn, affects the water quality entering California." There are also other instances in Section 3.2.2 *Water Quality – Environmental Setting* (e.g., Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients*) and Appendix C *Water Quality Supporting Technical Information* (e.g., Appendix C, Section C.2.1.1 *Suspended Sediments – Upper Klamath Basin – Hydroelectric Reach* and Appendix C, Section C.3.1.1 *Nutrients – Upper Klamath Basin – Hydroelectric Reach*) where the EIR indicates that water quality in Upper Klamath Lake impacts water quality in the Hydroelectric Reach. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

This comment also asserts that the Draft EIR does not reference results from the most recent version of the Klamath Hydroelectric Project (KHP) water quality model. In reviewing the referenced information, it appears that PacifiCorp may have rerun the Klamath River Water Quality Model (KRWQM) in 2014 to produce figures included in its 2014 draft water quality certification application to the State Water Board (reference years 2000 to 2004; Figures 5.2-19 to 5.2-26 in Section 5 and Figures 1-24 in Appendix A of PacifiCorp [2014a]) but did not provide supporting information to substantiate the figures or PacifiCorp's statements in this comment. To thoroughly investigate PacifiCorp's assertions, the State Water Board requested on April 25, 2019, that PacifiCorp provide: 1) all input and output data files (by model reach) for the Klamath River Water Quality Model updated since December 12, 2005, in a Microsoft Excel or tab-delineated .txt file format (.txt format preferred); 2) specific flow assumptions used in PacifiCorp's

KRWQM runs for results presented in the draft 2014 water quality certification application; 4) assumptions used in creating and definitions for existing conditions (EC) and without project (WOP) scenarios included in the habitat suitability analyses reported in Section 5.2.3.3 of the draft 2014 water quality certification application; 5) list of all assumptions and parameters that changed in the 2014 model runs presented in the draft 2014 water quality certification application versus model runs conducted in 2004 and/or 2005; 6) calibration and validation data sets for the 2014 model runs presented in the draft 2014 water quality certification application; and 7) sensitivity analyses conducted for the 2014 model runs presented in the draft 2014 water quality certification application. The 2019 report that PacifiCorp provided in response to the above request from State Water Board included a description of model updates, which were primarily focused on Keno Reservoir, and calibration summary information. The information provided by PacifiCorp in the 2019 report has been incorporated into responses to comments ORG46-17, ORG46-21, ORG46-88, ORG46-90, ORG46-98, ORG46-101, ORG46-122, and ORG46-127, and as described in those responses, this information has resulted in revisions to clarify the EIR. The additional information has not changed any significance determinations and does not otherwise represent significant new information for the EIR.

With respect to the comment's assertion that the water temperature analysis in the Draft EIR does not reflect PacifiCorp (2014), please refer to response to comment ORG46-127.

Daily variations in water quality with the potential to adversely impact aquatic resources under existing conditions are discussed in multiple places in Section 3.2.2 *Water Quality – Environmental Setting* (e.g., Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* and Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen*). Additionally, changes in these daily variations under the Proposed Project are analyzed for multiple water quality parameters in Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* (e.g., Potential Impact 3.2-1 [water temperature], Potential Impact 3.2-10 [dissolved oxygen], and Potential Impact 3.2-11 [pH]) using the available Klamath River Total Maximum Daily Load (TMDL) model and PacifiCorp KRWQM results at an hourly to daily time scale that would characterize these variations. PacifiCorp 2008 and 2014 model results are not presented at an hourly to daily time scale. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment ORG46-8
2.4 Sediment Transport Modeling

The fate and transport of the fine sediment predicted to be released under the Proposed Project is critically important to understanding a wide-range of both short- and long-term environmental impacts. Therefore, the DEIR must include a detailed discussion and supporting numerical or quantitative analysis to *document the expected impacts of the Proposed Project. Because this is a critical area for the effects analysis, PacifiCorp had an independent expert review the sediment transport models and the DEIR's use of the modeling information (see Brookes 2019 which is included in Exhibit C materials).*

In numerous locations throughout the DEIR, there is a repeated conclusion that the fine sediment will be transported the length of the Klamath River and enter the Pacific Ocean. For example, the DEIR states that:

- *"Most of the fine sediment is expected to be transport ed in suspension to the ocean shortly after being eroded. Fine sediment erosion would result in elevated suspended sediment concentrations downstream of Iron Gate Dam in the short term (Stillwater Sciences 2010, USBR 2012)." (DEIR pg. ES-6)*
- *"Over 80 percent of the reservoir sediments are fine sediment (organics, silts, and clays), which are expected to remain suspended in the Klamath River flow as it moves downstream and out into the Pacific Ocean." (DEIR pg. 2-60)*
- *"Because the trapped sediments consist primarily of organic material (e.g., dead algae), silts, and clays, they would be easily eroded and flushed out of the reservoirs into the Klamath River, and would continue to be suspended in the river downstream to the Pacific Ocean." (DEIR pg. 2-68)*
- *"The amount of sediment deposition in the estuary as a result of dam removal is anticipated to be small..." (DEIR pg. 3-83).*

These conclusions represent highly simplified opinions that are not supported by the cited numerical analysis (i.e., Stillwater Sciences 2010; USBR 2012c). The Stillwater Sciences (2010) and USBR (2012c) models both assume that fine sediment behaves as wash load, which by definition does not deposit. The DEIR makes a fundamental error by presenting this assumption as a conclusion of the modeling.

It is reasonable to assume that some proportion of the fine sediment load would behave as wash load (sediment that remains in suspension throughout the river system). However, in the absence of a specific numerical analysis, such an assumption is a broad generalization that only holds true under specific circumstances, presenting significant risk that the wash load flushing would not persist for the duration of the drawdown or the 190 miles of river downstream of Iron Gate Dam. Fine sediment can, and does, settle-out in riverine systems. This is likely to happen in the Klamath River in areas such as backwaters, pools, eddies, slack water, side channels, the estuary, and any floodplains accessed by high flows. Deposition will also occur at the heads of riffles where downwelling will move sediment-laden water into the gravels resulting in deposition of those fine silt s and clays into the interstitial spaces of the riffles; these areas are important spawning habitat for salmon. Deposition of fine sediments into these areas would adversely affect aquatic and riparian biota and important habitat.

Despite the potential significance of the issue to aquatic and fishery resources, analysis of fine sediment transport downstream of Iron Gate was included in a very simple manner in the DEIR's cited references. While the modeling in these cited source materials appears generally technically sound, the models are limited and the DEIR fails to present these model limitations or the uncertainties that remain. Specifically, these areas of uncertainty could substantively affect the analysis in the DEIR include:

- *Errors in estimating the amount and type of stored sediment.*
- *Lack of high flow suspended sediment data.*
- *Definition of the mobilization flow without direct field measurements of sediment movement.*
- *Unknown bed material and channel dimensions that will prevail after dam removal.*
- *Incision and erosion of deposits accumulated behind the dams (e.g. Copco and Iron Gate reservoirs).*
- *Effect of climate change on geomorphology.*
- *Angle of repose of material upstream of dam, which impacts sediment volumes that may be eroded from the reservoirs due to bank failures during drawdown.*
- *The impact of proposed sediment jetting, which is included in the Proposed Action as part of the Definite Plan, but was not included in prior modeling related to sediment volume and transport relied upon in the DEIR.*
- *Cohesive materials (fine silts and clays) that are not addressed in the modeling and this material would behave differently than how it is modeled because of cohesion (the USBR 2012 model is capable of modeling cohesive and non-cohesive sediment transport).*

Because the DEIR does not discuss the uncertainties associated with the numeric modeling, the reader is erroneously led to believe that these models accurately represent conditions likely to occur under dam removal. However, other large-scale dam removal projects, such as on the Elwha River, have had sediment impacts that were not consistent with expectations. The limitations and uncertainties associated with the modeling present significant residual and unaddressed risks that need to be described in the DEIR. Specific areas that need to be addressed include:

1. The DEIR states that a faster drawdown would reduce the time of interaction between flow and reservoir sediment deposits. While this may be true, there are processes involved other than the duration of exposure to erosive forces. The DEIR needs to discuss the rate of erosion because of exposure to higher water velocities generated by a faster drawdown could also produce more slumping and bank failures along reservoir margins because of the pore pressure of water remaining in the sediments and over-steepened banks.

2. The DEIR should analyze the effects of erosion processes operating both upstream and downstream of the dams and within the reservoir footprints (such as lateral channel adjustment following reservoir drawdown), which could extend the duration of downstream sediment effects.

3. The DEIR should identify key sensitive habit at locations downstream of Iron Gate Dam, discuss how susceptible these areas are to deposition, evaluate rates at which deposition could occur, and provide an analysis of effects of deposition on the habitat and resources in those sensitive locations. Some of the key habitats that should be addressed include known Chinook spawning areas and refugia that are important to Coho rearing throughout the year.

4. Spawning sites at the head of riffles where downwelling currents carry oxygenated water into the interstices of salmon spawning sites may be especially vulnerable to deposition (Tompkins and Kondolf 2009). As water is pulled into the gravels, the fine sediment that is suspended moves into the interstices where it is deposited thereby clogging gravel, interrupting important intergravel flow, and reducing survival of deposited eggs or newly hatched fish.

5. The impacts of proposed sediment jetting to remove additional sediments during reservoir drawdown. Sediment jetting as proposed in the Definite Plan was not considered in the modeling work conducted by Stillwater Sciences (2010) and USBR (2012a), and would be expected to increase the amount of sediment discharged from the reservoirs, impacting modeling results.

In summary, while the modeling that was conducted by Stillwater Sciences (2010) and USBR (2012c) may be technically sound, the models are inherently limited. Moreover, the DEIR fails to use these models properly, interprets a basic modeling assumption as a result, does not discuss impacts resulting from deposition of fine sediment downstream of Iron Gate dam that would result from implementation of the Proposed Project, and does not consider changes in the approach to reservoir drawdown (sediment jetting) that may impact model results.

Response to Comment ORG46-8

Comment noted. The first paragraph of the comment cites an independent review of the sediment transport models used in the Draft EIR (Brookes 2019), where the review was commissioned by PacifiCorp and was provided as an attachment to PacifiCorp's comments on the Draft EIR. Paragraph two of the comment includes a bullet list with quotations from the Draft EIR, which provide context for later paragraphs of the comment that are responded to below.

Regarding the third and fourth paragraphs of the comment, which include statements on wash load and settling of fine sediment, please refer to Master Response GEO-1. Master Response GEO-1 explains the fine sediment modeling and analysis approach and the potential for short-term spatially discrete sedimentation impacts.

With respect to the specific points the commenter lists in the second set of bullet points regarding an alleged weakness in disclosing limitations and uncertainty associated with the sediment modeling, it is noted that these points appear to primarily reflect discussions of model uncertainty and sensitivity in USBR (2012a). USBR (2012a), when reviewed in full, provides context and explanation for elements of uncertainty and sensitivity in the SRH sediment models. Responses to the points raised in the second set of bullet points are provided below.

Second Set of Bullet Points, Point 1: The uncertainty in the sediment volume estimates is presented in Volume I Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* Table 2.7-10 (page 2-67), and it is related to the spatial interpolation of sampled sediment flux. Because it is impractical to sample the entire reservoir bed, sediment cores were drilled and sampled, then sediment flux results were spatially interpolated to find the total sediment volume (yd^3) and associated sediment mass (tons) deposited within each reservoir. The spatially distributed core sites are shown in Volume I Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* Figures 2.7-7, 2.7-8, and 2.7-9 (pages 2-62 to 2-64). The uncertainty of the sediment volume estimates is reasonable for sediment yield analyses, which generally use modeling to estimate the order of magnitude of sediment yield. For additional information, please refer to Section 5.6.1.2 *Reservoir Sediment – Current Estimates* of USBR (2012a). Regarding sediment type, this was sampled directly from the spatially distributed sediment cores (USBR 2010a); therefore, there is not considered to be significant uncertainty associated with the type of sediment in the reservoirs.

Second Set of Bullet Points, Point 2: Due to lack of high flow suspended sediment concentration (SSC) data between the dams and Orleans, USBR (2012a) synthesized a relationship between flow and sediment concentrations based on the mass of sediment deposited behind the dams (see USBR [2012a] Section 5.3 *Sediment Loads* page 5-5 for further details). While the lack of high flow SSC data between the dams and the Klamath River at Orleans still introduces uncertainty into the modeled SSCs at high flows, the approach in USBR (2012a) provided a reasonable method to quantitatively resolve a data limitation and estimate the increase in SSCs with increases in Klamath River flow. Overall, USBR (2012a) provides the best available information and quantitative SSC modeling results under reservoir drawdown to analyze the potential impacts from SSCs under the Proposed Project. There are no data or other evidence provided by the comment or publicly available to indicate that additional quantitative analysis, improvements in the precision of the modeling, or changes in the model uncertainty, would alter the result of the analysis in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments*

Potential Impact 3.2-3 that there would be a significant and unavoidable impact for SSCs under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Potential Impact 3.2-3.

Second Set of Bullet Points, Point 3: USBR (2012a, pages 5-4 to 5-8) used reach-averaged hydraulic properties to estimate the flows required for slight and significant bed mobilization under existing conditions. USBR (2012a) recognized that there is uncertainty in defining the bed mobilizing flow without direct field measurements of sediment movement. United States Bureau of Reclamation (USBR), therefore, used a range of shear stress values for probable mobilization, rather than a single value. USBR (2012a) also compared their results with previous studies and found that they returned comparable flow estimates for bed mobilization. Results are summarized in Volume I Section 3.11.2.4 *Geology, Soils, and Mineral Resources – Environmental Setting – Sediment Load* (pages 3-748 to 3-753), which is partially modified in Volume III Attachment 1. As USBR (2012a) used a combined data reporting approach for the two-year sediment model simulations, the report does not forecast potential transient sediment storage and bed mobilization following dam removal. This has been considered in Master Response GEO-1.

Second Set of Bullet Points, Point 4: Regarding the alleged unknown post-dam removal bed material, potential changes to bed material associated with dam removal have been interpreted based on sediment transport model simulations (USBR 2012a) in Volume I Section 3.11.2.4 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation – Sediment Load* (pages 3-748 to 3-753). Regarding the alleged uncertainty due to unknown post- dam removal channel dimensions, exact future channel dimensions cannot be determined by sediment transport modeling or other means. However, sediment transport modeling is used to inform analysis of channel response to dam removal in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and this impact is modified in Volume III Attachment 1. Please also refer to Master Response GEO-1.

Second Set of Bullet Points, Point 5: The Sedimentation and River Hydraulics sediment transport model (SRH-1D) model (USBR 2012a) uses an above water angle of repose to enable simulations of reservoir sediments moving into the fluvial system; therefore, this process is captured in the sediment model outputs discussed in the EIR. The SRH-1D model (USBR 2012a) does not capture more complex processes of slumping and movement of fine sediment into the fluvial system, which is a limitation recognized in USBR (2012a) and discussed below in this comment response. SRH-1D model simulations found that 36 to 57 percent of the sediment stored behind the reservoirs would not erode during drawdown (i.e., would remain in the reservoir footprints) and the physical properties of the sediments mean that they would consolidate with some cracking (i.e., gullying or incision and erosion) (USBR 2012a). The EIR uses information from the model outputs and hydrology theory to assess potential gullying of the reservoir sediment deposits that would remain following drawdown. Please refer to Potential Impact 3.11-5 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* (pages 3-768 to 3-769) and modifications in Volume III Attachment 1. After the initial drawdown, the greatest potential for gullying of reservoir sediments and associated secondary erosion would occur in the short-term period (within two years of dam removal) following sub-aerial exposure of the reservoir sediments, as a surface runoff network establishes. Although the rate of sediment erosion and transport is dependent on the water year types during and following dam removal, rapid consolidation of the remaining sediment deposits following sub-aerial exposure (USBR 2012a), along with hydroseeding and other restoration work (see Section 6.1.1 *Measures to Manage Remaining Sediment* of Volume II Appendix B: *Definite Plan*), mean that elevated concentrations of suspended sediments, with potential to impact water quality and aquatic species, are not expected to occur in the longer term. Some surface erosion of the remaining reservoir sediment deposits may occur during storm events over the long term. Overall, gullying of the reservoir sediment deposits is accounted for in the sediment model outputs (USBR 2012a) and in the EIR analysis.

Second Set of Bullet Points, Point 6: Consistent with CEQA Guidelines section 15125(a), future climate changes are not part of the existing condition against which this EIR compares potential impacts. While climate change predictions are occasionally used in the Lower Klamath Project EIR to provide additional context for potential impact analyses related to the Proposed Project or the alternatives (e.g., Volume III Attachment 1 Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1, Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-8, Volume 1 Section 4.2.2 *No Project Alternative – Water Quality* Potential Impact 4.2.2-1 [pages 4-103 to 4-108]), the predictions are not relied upon for significance determinations associated with the Proposed Project or the alternatives. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and Section 3.3 *Aquatic Resources*. Long-term changes to the existing (and historical) physical environment resulting from dam removal were analyzed for reference periods of up to 50 years (see Volume I Section 3.11 *Geology, Soils, and Mineral Resources* (pages 3-733 to 3-780), using hydrologic and geomorphic theory and quantitative modeling. The sediment models are described in Master Response GEO-1 and include long-term (50-year) simulations focusing on evolution of the riverbed post dam removal and short-term (2-year) simulations focusing on suspended sediment erosion, transport, and deposition during and following drawdown (USBR 2012a). The water flow conditions input to the sediment models (USBR 2012a) are described in ORG46-203 and include allowance for a wide range of flow conditions that could reasonably occur in the future, accounting for Klamath River flows continuing to be controlled by the Keno Dam under the Klamath Irrigation Project post dam removal. Therefore, anticipated future flow conditions reasonably inform the sediment modeling applied in the EIR sediment and geomorphology analysis (see Volume III Attachment 1 Section 3.11-5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5). It is noted that the sediment models (USBR 2012a) were applied to assess sediment erosion, transport, and deposition at the reach scale as intended by the model framework. Finer scale transitory sediment deposition and remobilization is assessed theoretically (see Master Response GEO-1). It is also noted that as gravel supply would be restored following dam removal under the Proposed Project, deposition of gravel and sand is expected within the active channel bed at specific locations between Iron Gate Dam and Cottonwood Creek under the range of modeled flow conditions, regardless of increases or decreases of peak flows. Higher peak flows could transport transitory sediment deposits downstream within shorter timeframes than expected (see Master Response GEO-1). In addition to the model- and theoretical-based analyses of sediment and geomorphology, and as noted in Brookes (2019, page 7), meteorological effects on hydrographs under a range of climate scenarios predicted by Global Circulation Models (GCMs) are considered in Section 11 *Climate Change Effects* of USBR (2012, page 11-1 to 11-9). Temperatures in the Upper Klamath Basin are expected to increase under climate change, and precipitation may increase or decrease. Although there are variations with 'wet' and 'dry' climate simulations, water flows entering the Upper Klamath Lake in late winter and early spring (February to April) are generally excepted to be similar to, or higher than, existing flows, but from late spring through early fall (May to October) flows are generally expected to be similar to, or lower than, existing flows. Winter flows (November to January) could be higher or lower, depending on the climate change scenario (USBR 2012a). Forecasting of sediment erosion, transport, and deposition under climate change scenarios is not undertaken in USBR (2012a). Such modeling is inherently difficult and a limited outcome of advanced research. However, based on the hydrograph modeling results, theoretical knowledge of how sediment and geomorphology may respond has been applied, which is a standard approach in considering climate change effects on sediment movement. If peak flows increase under a 'wet' climate change scenario, this may create a wider channel and floodplain (USBR 2012a); however, flows will continue to be controlled by Keno Dam, thus unintentional geomorphological effects associated with increased flows are not expected to be significant. In addition to changes of water flow, climate change could influence a change of riparian vegetation, affecting bank properties, with or without the Proposed Project; however, potential bank stability changes are speculative. Climate change effects on water flow and sediment movement impacting flood hydrology are considered in response to comment ORG46-288 and no changes to the Volume I Section 3.6 *Flood Hydrology* analysis are required.

Second Set of Bullet Points, Point 7: The angle of repose, which is related to the stability of above-water reservoir sediments, was included in sediment transport modeling by USBR (2012a), and the outputs of the sediment modeling inform

Volume I Section 3.11 *Geology, Soils, and Mineral Resources* (pages 3-733 to 3-780), which is partially modified in Volume III Attachment 1. The assumed angle of repose was conservatively set at 15°. One limitation of the SRH-1D model is that it cannot input a separate angle of repose for fine sediment (silt and clay) than for sand. Although the angle of repose for drained sand may be closer to 30°, the 15° angle was deliberately selected as most representative when modeling fine sediment and sand together with the same angle of repose (USBR 2012a). The sensitivity of the angle was tested in USBR (2012a) by running simulations of the same sediment model with the angle set at 5° and 10°, separately. Decreasing the angle of repose decreased the maximum SSC and increased the duration of elevated SSC impacts (over 100 milligrams per liter (mg/L) for fine sediment, and over 1000 mg/L for sand). This sensitivity output is related to the unlikely scenario of sand re-depositing in Iron Gate Reservoir and subsequently remobilizing when Iron Gate Reservoir is completely drawn down (with almost all the sand remobilizing and entering the fluvial system when the angle of repose is set at 5°) (USBR 2012a). Given that the angle of repose was cautiously considered most representative at 15°, applying the sediment model simulation that used this angle (i.e., the primary SRH-1D sediment model) to the EIR analyses is considered to capture the best available information (see Potential Impact 3.11-5 in Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* [pages 3-765 to 3-775], which is modified in Volume III Attachment 1). While the angle of repose is applied in the SRH-1D sediment model to simulative reservoir sediments moving into the fluvial system, the model assumes instantaneous bank failure and movement of sediment into the fluvial system. The angle of repose does not apply to, or account for, ongoing bank failures (slumping), nor do any of the other sediment model parameters. This is a recognized limitation of the model (see USBR 2012a, pages 9-33 to 9-37 and 23-39 to 23-40). The anticipated small, shallow slumping along upstream embankment slopes during drawdown, when the force of the sediment weight and draining water exceeds the shear strength of the sediment, would not erode enough sediment to substantially change the range of estimates of fine sediment erosion and transport presented in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 – Table 3.11-7 (page 3-768) (see the same table in Volume III Attachment 1). The shear strength of the sediment would increase as the water drains and cohesion would increase as the sediment consolidates, resulting in stabilization of remaining reservoir sediments and reduced potential for slumping. Some localized, small areas of sediment on steeper slopes (greater than 0.2°) surrounding Copco No. 1 Reservoir would remain unstable with potential for slumping post-drawdown (USBR 2012a). As for the discussion of gullying (see above in this comment response), rapid consolidation of reservoir sediments and hydroseeding would reduce potential for bank slumping in the long term (see Volume II Appendix B: *Definite Plan* Section 6.1.1 *Measures to Manage Remaining Sediment*). Therefore, elevated concentrations of suspended sediments, with potential to impact water quality and aquatic species, are not expected to occur in the longer term.

Second Set of Bullet Points, Point 8: For an explanation of sediment erosion associated with sediment jetting, please refer to comment response ORG46-132.

Second Set of Bullet Points, Point 9: Cohesive properties can be input differently in different sediment models. Stillwater Sciences (2008) originally used the peer-reviewed Dam Removal Express Assessment Model (DREAM-1) (Cui et al. 2006a,b) to identify preferred reservoir drawdown options for minimizing suspended sediment impacts to the Klamath River, especially biological resources, downstream of Iron Gate Dam. The DREAM-1 model was designed for simulations where reservoir sediment upstream of dams being removed is composed primarily of non-cohesive fine sediment (sand and silt). The model was considered suitable for assessing reservoir drawdown options, because of the high silt content of the Klamath River reservoirs. USBR (2012a) subsequently applied the SRH-1D model, developed by Huang and Greimann (2010), to examine surface hydrology, groundwater hydrology, hydraulics, geomorphology, and sediment transport within the Klamath River Basin under the No Project Alternative (dams remain in place) and the Proposed Project (dam removal). USBR (2012a) considers cohesive and non-cohesive sediment transport processes within the limits of industry standard numerical sediment transport modeling. Cohesion of the reservoir sediment deposits was considered in the SRH sediment models and reporting that produced the sediment model outputs analyzed in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and modified in Volume III Attachment 1. The erosion rate of cohesive sediment is governed by the simple linear excess shear stress model. The data to support the cohesive parameters was taken from jet tests described in Appendix D of USBR (2012a). Fine sediment (clay and silt) particles would interact with each other, thus were modeled as a single cohesive unit for the purposes of estimating SSCs, longitudinal sediment erosion and transport, and reach-scale sediment deposition (USBR 2012a). The sensitivity of the cohesive erodibility parameter was tested and increasing or decreasing the cohesive sediment critical shear stress from 0.2 Pa to 1.2 Pa, or to 0.03 Pa, respectively, did not have any significant effect on output sediment concentrations, which were essentially the same for each critical shear stress applied (USBR 2012a, pages 9-18 to 9-19). Therefore, the sediment transport results applied in the EIR analyses are not considered to have significant uncertainty with regard to cohesive erodibility.

The comment recommends additional analysis in light of the alleged non-disclosure of model uncertainty in a third set of bullet points. The third set of bullet points are addressed as follows:

Third Set of Bullet Points, Point 1: Please refer to Volume I Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* (pages 2-54 to 2-60), as well as to Volume II Appendix B: *Definite Plan*, for explanations of drawdown periods and rates. Please also refer to Section 3.2.4.2 *Water Quality – Impact Analysis and Approach – Suspended Sediments* for a discussion of the reservoir drawdown rate with respect to sediment discharge. Please see Volume III Attachment 1 for the final Section 3.2 *Water Quality*. As discussed above in this comment response, the angle of repose accounts for instantaneous movement (erosion) of reservoir sediment into the fluvial system in the SRH-1D model, but the model does not account for ongoing channel bank slumping nor for reservoir rim instability. The angle of repose applied for SRH-1D modeling (USBR 2012a) was set at 15 degrees and sensitivity tested at 5 degrees and 10 degrees, with 15 degrees considered most representative of sediment mobilization upon drawdown. Results associated with sediment mobilization at this angle (and associated velocity) are included in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5, which is modified in Volume III Attachment 1. The angle of repose applied in the DREAM-1 model (Stillwater Sciences 2008), which was used for identifying preferred reservoir drawdown options for minimizing suspended sediment, was conservatively set at 10 degrees, and results are generally consistent with USBR (2012a). Regarding channel bank slumping, consideration of ongoing channel bank slumping at different drawdown rates is based on hydrology theory, rather than on quantitative modeling. Pore-water pressure, bank steepness, and the shear strength of the bank sediment relative to the forces of sediment weight and velocity are all factors in the occurrence, or lack of, bank slumping. The sediment pore-water pressure and bank steepness would remain similar over the range of drawdown rates (2 to 5 feet per day) considered. Further, the upper limit of the drawdown rate (5 feet per day) proposed would only increase the maximum average water discharge by 3 to 14 percent of the 2-year peak flow and 1 to 7 percent of the 10-year peak flow (see Volume I Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* [pages 2-54 to 2-60] and modifications in Volume III Attachment 1), which means that the associated relative increase of velocity in fluvial channels downstream of the reservoir footprints would also be slight. To provide context, please refer to Figures 4-7 and 4-9 in USBR (2012a), which show that reach averaged channel velocities in the Klamath River between Iron Gate Dam and Indian Creek are within the range of approximately 3.5 to 4.5 ft/s under median flow conditions and that this range increases to approximately 5.5 to 8.5 ft/s during the 2-year peak flow. As previously noted, the maximum average flow increase during drawdown would be 3 to 14 percent of the 2-year peak flow and 1 to 7 percent of the 10-year peak flow with the upper limit of the proposed drawdown rate (5 feet per day), so the average increase in the Klamath River velocities during drawdown would typically be less than those experienced under the 2-year peak flow. Thus, there would not be a substantial increase in bank erosion, including slumping, with the upper limit of the proposed drawdown rate (5 feet per day) compared with a slightly slower drawdown rate, and the EIR analysis accurately describes the range of potential erosion. Regarding the latter point of reservoir rim stability from above, this is considered separately from channel bank slumping—see Section 3.11.5 *Geology, Soils, and Mineral*

Resources – Potential Impacts and Mitigation Potential Impact 3.11-3 and Master Response GEO-2. Although the significance determination remains unchanged, Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* – Potential Impact 3.11-3 and associated Mitigation Measure GEO-1 has been revised to clarify the potentially unstable slope segments associated with potential slope instability during drawdown and the actions required in relation to this. The proposed drawdown rate (2 to 5 feet per day) is expected to have minimal effect on the stability of the slopes, and as such Potential Impact 3.11-3 does not differentiate the analysis or significance determinations based on drawdown rate. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* for these revisions.

Third Set of Bullet Points, Point 2: Sediment transport modeling was divided into two model segments: an upstream model extending from upstream of J.C. Boyle Dam to downstream of Iron Gate Dam, and a downstream model extending from Iron Gate Dam to the Pacific Ocean (USBR 2012a). Figures 9-28 and 9-29 of USBR (2012a, page 9-35) show modeled reach averaged erosion and deposition depths from J.C. Boyle to Iron Gate dams. The reaches between J.C. Boyle and Iron Gate dams are modeled to have minimal morphological change following dam removal (USBR 2012a), including the reach upstream of Copco No. 1 Dam in California, which shows the least change. The EIR focuses on the potential geomorphological impacts to reaches downstream of Iron Gate Dam, because this is where modeling indicated that there could be potential impacts in California. Please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and modifications to this impact in Volume III Attachment 1. Please also refer to Master Response GEO-1.

Third Set of Bullet Points, Point 3: Regarding sensitive habitat locations downstream of Iron Gate Dam and the effects on these resources, including sediment deposition effects, please refer to Volume III Section 3.3 *Aquatic Resources* and to Master Responses AQF-7 and AQF-10. Regarding sediment deposition specifically, please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and modifications to this impact in Volume III Attachment 1, as well as to Master Response GEO-1. Given that the significance of short-term sediment deposition during and following dam removal is split, with a significant and unavoidable impact between Iron Gate Dam and Cottonwood Creek, and no significant impact downstream of Cottonwood Creek, the associated aquatic impacts are also considered at this spatial scale. As discussed in Master Response GEO-1, the existing sediment models were sufficient to assess potential sediment-related impacts of the Proposed Project against criteria relevant to CEQA, and additional analysis of fine sediment erosion, transport, and deposition, is not necessary for the purposes of the EIR.

Third Set of Bullet Points, Point 4: Regarding fine sediment erosion, transport, and deposition, including behavior in riffles, please refer to Master Response GEO-1, and to Master Responses AQF-7 and AQF-10 for the associated impacts to fish. A more spatially discrete sediment analysis would not change the key findings or impact determinations for aquatic resources. Potential short-term and long-term impacts to critical habitats and Essential Fish Habitats (EFHs), as well to specified salmonid populations, are assessed in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts*. Geomorphological changes, including channel bed deposition, are considered. For coho salmon critical habitat and Chinook and coho EFH, as well as for salmonid populations generally, increased bedload transport and deposition from the removed dams to Cottonwood Creek would improve spawning substrate following dam removal in the short- and long-term (i.e., once elevated SSCs rescind, habitat would be improved). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Third Set of Bullet Points, Point 5: Prefer to response to comment ORG46-132 for a discussion of sediment jetting.

Lastly, although not specifically discussed in the comment, Brookes (2019) makes the incorrect statement that the sediment volumes trapped behind the Lower Klamath Project dams are unknown. The second row below the header of the table in Section 2 (pages 4-5) of Brookes (2019) misinterprets information from USBR (2012a). The fraction of fine (silt- and clay-sized) material trapped behind the dams is known within a reasonable level of uncertainty based upon data from more than 75 sediment cores collected across J.C. Boyle, Copco No. 1, and Iron Gate reservoirs using standard sampling methods (see Table 5-15 [page 5-25] in USBR 2012a, and Table 2.7-10 [page 2-67] and Table 2.7-11 [page 2-68] in EIR Volume I Section 2.7.2 *Proposed Project – Reservoir Drawdown*, as well as Table 3.11-6 [page 3-766] in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-6). While the proportion of the total fine fraction that is silt- versus clay-sized particles was not distinguished during the sediment core sampling, the analysis of sediment erosion potential for the reservoirs is not sensitive to this uncertainty. The known fine sediment fraction is used for estimating SSCs at high flows (USBR 2012a, page 5-5).

Comment ORG46-9

2.5 Greenhouse Gas

The impacts to greenhouse gas emissions resulting from removal of a non-emitting power source and its relation to California climate change policies are inadequately addressed in the DEIR. The qualitative analysis identifies the replacement of hydroelectric power with possible non-renewable energy sources as an indirect impact. This is not an indirect impact but rather a direct consequence of removing a stable and reliable non-emitting generation source *from PacifiCorp' s resource portfolio that can meet the energy needs of approximately 69,000 homes.*

The analysis repeatedly refers to PacifiCorp's 2017 integrated resource plan (IRP; PacifiCorp 2017) and associated plans to increase renewable energy resources on its system over time. While it is the case that PacifiCorp is in the process of decarbonizing its generating resource portfolio, the analysis in the DEIR is inadequate in that what is required is an assessment of PacifiCorp' s system emissions if the Klamath Hydroelectric Project is not removed, or if specific elements of the project are not removed as considered in the Two Dam Removal and Three Dam Removal alternatives. Since PacifiCorp's (2017) IRP assumes the Klamath Hydroelectric Project is removed, it already represents the scenario where the energy and capacity from the Klamath Hydroelectric Project are replaced with existing or incremental resources. Though future capacity resources may be non-emitting, from an operational perspective low-cost energy from a hydroelectric resource displaces a combination of energy resources and wholesale market purchases on PacifiCorp's system that provide similar capacity and dispatch flexibility as the hydroelectric facilities and that do have an emissions profile that is not accounted for in the DEIR. To continue to balance fluctuating loads and resources in real-time, while providing local voltage and frequency support to the transmission system, PacifiCorp will need to call upon non-renewable resources if the Klamath Hydroelectric Project is removed. While PacifiCorp's continued expansion of renewable resources in its generation portfolio can replace zero-emission energy lost as a result of dam removal, the expansion of non-carbon resources that can provide capacity (e.g. storage) will be needed to reduce these impacts over time. For these reasons, these emissions impacts should be acknowledged in the DEIR.

As calculated pursuant to the California Air Resources Board Mandatory Greenhouse Gas Reporting Rule, PacifiCorp's 2017 system emission factor was 0.6844 metric tons of carbon dioxide equivalent ($MTCO_2e$) per megawatt-hour (MWh). Using this factor, the Klamath Hydroelectric Project developments proposed to be removed, which produce 686,000 MWh of generation per year, displace approximately 469,500 $MTCO_2e$ per year. As a point of reference, PacifiCorp's total obligation for emissions reductions under California' s cap-and-trade program in 2017 was 756,736 $MTCO_2e$. Thus, removal of the Klamath project dams will set back PacifiCorp's compliance with mandated emissions reductions and increase its required emissions reductions to achieve California's climate change policy mandates.

The threshold for a potentially significant impact related to greenhouse gas emissions in the DEIR is set at 10,000 $MTCO_2e$ (DEIR pg. 3-719). Though avoided emissions will go down over time as PacifiCorp decarbonizes its system, the DEIR entirely fails to consider the emissions impacts related to removal of hydroelectric facilities that are qualified generation resources under California' s renewable portfolio standard. In a single year, the increased emissions resulting *from removal of the Klamat h Hydroelectric Project will exceed the DEIR' s significance criteria by a factor of nearly 47. Over the expected life of a new potential FERC license—40 years—the increased system emissions would be on the order of 18 million MTCO2e at PacifiCorp's current system emission factor. Granted, revised instream flow requirements under a new license would reduce the generation output of the Klamath Hydroelectric Project, but the failure of the DEIR to consider the potential impact on greenhouse gas emissions due to dam removal reflects a lack of balance in the document that results in adverse environmental impacts of potential dam removal being downplayed. Millions of tons of avoided greenhouse emissions is not an insignificant environmental impact, particularly in the near-term when reducing emissions to avoid the worst impacts of climate change is critical.*

Indeed, prior environmental analysis of Klamath relicensing and dam removal alternatives (FERC 2007; DOI and CDFW 2012) have considered greenhouse gas emissions impacts to be a direct consequence of Klamath dam removal. In its Final EIS, FERC (2007) estimated the greenhouse gas emissions impacts of removing the four Klamath dams proposed for removal to range between 68,600 to 106,330 metric tons of carbon per year, or 251,500 to 389,900 $MTCO_2e$ per year (see Table 4-8 in FERC 2007). Similarly, the 2012 KHSA EIS/EIR (DOI and CDFW 2012) documented emissions impacts from potential dam removal ranging between 341,539 to 396,575 $MTCO_2e$ per year (see Tables 3.10-6 and 3.10-7 in DOI and CDFW 2012). The DEIR considers the emissions impacts of removing non-emitting generating resources as an indirect impact of the Proposed Project, and then only qualitatively discusses those impacts as being not significant given PacifiCorp's plans to continue to add renewable resources. However, robust and readily available quantitative analysis has been conducted on these greenhouse gas emissions impacts but this information is not incorporated into the DEIR.

The DEIR's lack of balance is also reflected in that its greenhouse gas evaluation considers potential emissions of methane from the hydroelectric reservoirs that would presumably be removed as part of the Proposed Project, even though there has been no thorough assessment of methane production at the Klamath Hydroelectric Project. As FERC (2007) stated, "Given the lack of any site specific data concerning methane production at the Klamath Hydroelectric Project, any attempt to estimate net bio-production of greenhouse gases would be speculative, at best." This remains the case, yet the DEIR assessed reduced methane emissions as a potential benefit of the Proposed Project, but completely fails to assess the greenhouse gas emissions impacts of removing qualified, non-emitting renewable resources.

The DEIR's analysis also does not address California's policies in Senate Bill (SB) 100 (De León). Senate Bill 100 increases California's renewable portfolio standard (RPS) to 60 percent by 2030 and establishes a state policy whereby renewable and zero-carbon resources are to supply 100 percent of retail sales to

California end-use customers by December 31, 2045. Any loss of a zero-carbon resource will make this standard more costly and difficult to meet. While removal of the Klamath Hydroelectric Project may not endanger PacifiCorp's ultimate compliance with California's RPS, it will make such compliance more costly. The intent of California' s RPS and its cap-and-trade program is to reduce greenhouse gas emissions and ultimately the impacts of climate change. The removal of an existing non-emitting resource that could continue to serve customers directly contradicts the purpose of these policies and thus should be more fully evaluated in the DEIR.

Additionally, both Oregon and Washington are considering sweeping climate change bills impacting the electric sector in 2019 legislative sessions. Oregon is considering adopting a cap-and-trade program that will link with California's program, while Washington is considering both a cap-and-trade program and a proposal that would require utilities in Washington to achieve 100 percent carbon neutral energy portfolios by 2030. While not certain to pass this year, it is likely that additional policies targeting emissions from the electric sector will be enacted in the near-term. Hydroelectric generation, which is more predictable and reliable than intermittent resources such as wind and solar, will be a critical component of the shift to a low- cost, reliable carbon-free future. In failing to even acknowledge the benefit of the non-emitting nature of the Klamath Hydroelectric Project and its relation to California's extensive climate change policies, the DEIR conflicts with the California RPS goals by not addressing the increase in carbon emissions resulting from implementation of the Proposed Project.

Response to Comment ORG46-9

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG46-10

2.6 Uncertainty in Salmon Production and Recolonization

The DEIR does adequately address the uncertainty associated with salmon production and recolonization and presents an unbalanced view of potential out comes. The DEIR states that the Proposed Project will increase fall-run Chinook Salmon abundance based solely on Hendrix (2011) modeling analysis. To be precise, the Hendrix (2011) analysis uses average habitat productivity data from Pacific Northwest streams to forecast that natural fall-run Chinook Salmon production will increase in the absence of harvest. That is, natural production of the important harvest species in the Klamath Basin will increase if there is no fishing for that species. The Hendrix (2011) analysis has significant limitations and does not present data for hatchery fish returning to Iron Gate Hatchery or Trini ty River Hatchery. This distinction is important because as the DEIR states, Iron Gate Hatchery produces about 50,000 adult fall-run Chinook annually (DEIR pg. 3- 248). This rate of supplementation by Iron Gate Hatchery supports a long-

term average harvest rate of about 28,000 fall-run Chinook (CAHSRG 201 2}. Hendrix (2011} estimates that the Iron Gate Dam to Keno Dam reach of the Klamath River would produce 23,000 adult natural origin fall-run Chinook if there was no harvest of those adults. Even using this flawed no harvest assumption, this is approximately 50 percent fewer fall-run Chinook than the corresponding number currently produced by Iron Gate Hatchery. The DEIR fails to recognize the inherent contradiction in these modeling results: namely, that under the most optimum outcomes, implementation of the Proposed Project would result in the production of substantially fewer fish than under existing conditions without allowing any harvest of those fall-run Chinook. If harvest were to occur at close to the historically average rate, even fewer fall-run Chinook would be available to return to the upper Klamath River.

This discussion illustrates how the DEIR underestimates the importance of fall-run Chinook produced at Iron Gate Hatchery. While the DEIR acknowledges that production targets at the hatchery will be changing under the Proposed Project, it does not accurately address the impacts that will occur from the proposed substantial reduction in Chinook production on fish populations or tribal, recreational, or commercial fisheries. The Proposed Project would reduce the yearling Chinook production by 87 percent and the smolt production by 33 percent. Yearling fall-run Chinook have better survival rates, contribute to the fisheries at a higher rate than Chinook released as smolts, and return to Iron Gate Hatchery at a long-term average rate that is about twice that of smolts (Giudice and Knechtle 2018). This makes the proposed 87 percent reduction in yearling production a much larger proportional impact on fall-run Chinook populations and fisheries. Coupled with this short coming, the DEIR does not adequately address the long-term impacts arising from the eventual elimination of Iron Gate Hatchery production 8 years after dam removal.

The DEIR fails to discuss the results from habitat modeling conducted during FERC relicensing (Oosterhout 2005; PacifiCorp 2005) that compared natural production to current hatchery production of adults. These results should be described in the DEIR to adequately inform the public and decision-makers about the potential impacts of the Proposed Project. The analyses by PacifiCorp (2005) and Oosterhout (2005) should be described, because these two analyses are thorough, incorporate habitat and water quality data specific to the Klamath River, and include potential dam removal scenarios. Unlike the Hendrix (2011} model, these two analyses incorporated actual measurements of stream habitat, water quality, and disease for virtually every river mile from Iron Gate Dam upstream. The data for the two analyses were collected by agencies and PacifiCorp as part of FERC relicensing process and data inputs to the models were reviewed and agreed to by the agencies. In contrast, the Hendrix (2011) model used the more simplified assumption that habitat quality is similar to other streams up and down the West Coast (even though the Klamath River is like no other stream on the West Coast). Thus, the analyses of PacifiCorp (2005} and

Oosterhout (2005} are based on basin-specific scientific information in contrast to Hendrix (2011} that uses generic data.

The DEIR acknowledges that there is uncertainty associated with the effects of the Proposed Project on Coho and Chinook. The DEIR notes that one of the reasons that Hendrix (2011) model results are used in the analysis is that it provided variance estimates of uncertainty, yet the results of this uncertainty analysis are not discussed in the DEIR. This uncertainly analysis needs to be described in the DEIR to fully inform decision-makers and public about the range of potential outcomes of the Proposed Project. The DEIR extensively references the Expert Panel report on Coho and Steelhead where Dunne et al. (2011} repeatedly reinforce the uncertainty around how the Proposed Project could affect the Coho population. Dunne et al. (2011} note that there may be a small increase in Coho production from newly accessible habitat, but also that disease and low ocean survival could easily offset this gain. Dunne et al. (2011) state that any increases in Coho populations are expected to be small through the first 10 years following the Proposed Project. This uncertainty was again voiced by the Expert Panel on Chinook where Goodman et al. (2011) stated that "...achieving substantial gains in Chinook salmon abundance and distribution in the Klamath Basin is contingent upon successfully resolving the following nine factors:"

1. *Resolve water quality issues in Upper Klamath Lake and Keno Reservoir*
2. *Address fish disease*
3. *Salmon successfully colonization of the upper basin*
4. *Harvest is managed to support adequate escapement*
5. *Hatchery straying does not adversely impact natural reproduction*
6. *Predation does not impact salmon populations*
7. *Climate change does not overwhelm production*
8. *Fall flows are adequate to minimize impacts to Chinook*
9. *Dam removal impacts do not have multi-year adverse effects*

While these nine items were written for the report on Chinook, they apply to Coho and the overall success of the Proposed Project as a whole. Because of unknown habitat quality upstream of Iron Gate Dam, the small population of Coho from which recolonization could occur (on average Iron Gate Hatchery annually receives 30 stray natural-origin adult Coho), and the fact that most of those fish are not adapted to habitat upstream of Iron Gate Dam, the DEIR conclusions regarding the success and speed of recolonization are overly optimistic. It is also important to recall that the determinations by both of these Expert Panels included the implementation of the KBRA. The KBRA in part provided funding and structure for basin-wide restoration which could address some of the nine factors listed above. The KBRA expired at the end of 2015 and has not been resuscitated. In Dunne et al. (2011) possible larger gains in Coho production were reported as being contingent on successful implementation of the KBRA. Given that this is no longer available, the level of uncertainty *surrounding the successful outcome of the Proposed Project is even higher than it was 2011. Additionally, the DEIR presents no analysis about potential harvest restrictions that could be necessary to support reintroduction and recolonization of Chinook into habitat areas upstream of Iron Gate Dam. Restrictions on harvest are often necessary to support reintroduction efforts to reduce pressure on populations that are attempting to recolonize formerly inaccessible or inadequate habitat areas. The DEIR provides no analysis of these potential impacts, or the duration of these impacts. Similarly, the Hendrix (2011) model provides no time-scale for natural production sufficient to replace hatchery production to occur and simply assumes that peak natural production occurs immediately after dam removal. There is great uncertainty about impacts to harvest from the Proposed Project which is not portrayed in the DEIR.*

Response to Comment ORG46-10
Please refer to Master Response AQF-8. Regarding effects of reduced hatchery production, please refer to Master Response AQF-3 and response to comment ORG46-35. Regarding harvest, please refer to responses to comment ORG46-248, ORG46-481, and ORG46-487. Regarding actions associated with the Klamath Basin Restoration Agreement (KBRA), please refer to response to comment ORG46-250.

As the comment notes, the Draft Environmental Impact Report (DEIR) acknowledges the Expert Panel report's uncertainty regarding the effects of dam removal on key fish populations. Indeed, Dunne, et al. (2011) and Goodman, et al. (2011) both are referenced in the EIR, were considered as part of the State Water Board's analysis, and will be included in the administrative record. To the extent information was available to inform such analysis, the EIR includes discussion of the sources of uncertainty referenced by the comment, putting overall uncertainty regarding the effects of dam removal on key fish populations into appropriate and meaningful context for the public and decision makers. With regard to factor 1, please refer to Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Water Temperature* and Section 3.3.5.3 *Aquatic Resources – Potential Impacts and Mitigation – Water Quality – Upper Klamath River and Connected Waterbodies* for discussion of water quality in waters upstream of the Hydroelectric Reach under the Proposed Project. With regard to factor 2, please refer to Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*. With regard to factor 3, please refer to Potential Impact 3.3-7. With regard to factor 4, please refer to Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* and Potential Impact 3.3-7. With regard to factor 5, please refer to Section 3.3.2.3 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries – Habitat Attributes Expected to be Affected by the Proposed Project* and Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries*. With regard to factor 6, please refer to Potential Impact 3.3-18. The best available evidence does not indicate that a shift in predation patterns is likely to occur, during or after implementation of the Proposed Project, much less undermine improvements to salmonid populations resulting from conversion of the Hydroelectric Reach to a riverine system. With regard to factor 7, please refer to Potential Impact 3.2-1. With regard to factor 8, please refer to Potential Impact 3.3-7. With regard to factor 9, please refer to Potential Impact 3.3-7, Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project*, and Volume II Appendix E Section E.3.2. However, given that the Expert Panel report was just one of the several lines of evidence considered with respect to those effects – as noted in Master Response AQF-3 – it would be inappropriate to elevate the uncertainty identified by that report to the central role within the EIR's analysis that the commenter suggests. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*, including the subsections listed above.

Comment ORG46-11
• The DEIR does not accurately assess the magnitude of impacts from the Proposed Project on Coho. The DEIR identifies a threshold for a potentially significant impact to Coho Salmon as being a change in "...the abundance (greater than 50 percent reduction) of a year class for aquatic species." (DEIR pg. 3-258.) This definition ignores the fact that over 50 percent of the Coho population returns to the Trinity River (Naman and Perkins 2015; Kier et al. 2018) and would be substantially unaffected by the project. Under this questionable approach, even the extirpation of all Coho from the Klamath River upstream of the Trinity River would not be considered significant because it would affect less than SO percent of a year class of the population. Even though impacts to Coho Salmon may not exceed the significance threshold established by the DEIR, the small population of Coho in the mainstem Klamath River (see Major Issue 2.1) would still be substantially impacted, and should be considered a significant impact. See Communities for a Better Environment v. California Resources Agency (supra, 103 Cal. App. 4th 98).

Response to Comment ORG46-11
Please refer to Master Response AQF-9.

Comment ORG46-12
• The DEIR does not clearly and accurately assess the impacts of the Proposed Project from loss of reservoir storage. The DEIR asserts that because evaporation losses from Copco and Iron Gate reservoirs would be removed under the Proposed Project, more water would be available to the USBR for diversion. However, the loss of reservoir storage and downstream release facilities (namely Iron Gate Dam) would require USBR to release correspondingly larger volumes of water at Keno Dam to achieve required flows downstream to support aquatic and cultural river uses, which would result in flow demands significantly greater than the reduction in evaporative losses.

Response to Comment ORG46-12
Because United States Bureau of Reclamation (USBR) maintains its biological opinion obligations for the mainstem Klamath River regardless of the existence of the Lower Klamath Project, dam removal would not alter the amount of water required for environmental or cultural purposes, or the source of that water. The water source for USBR biological opinion flow obligations is Upper Klamath Lake, not the Lower Klamath Project reservoirs. The Lower Klamath Project reservoirs temporarily store water for hydropower production. By eliminating the evaporative losses that occur under existing conditions due to temporary hydropower storage in the Lower Klamath Project reservoirs, the Proposed Project would reduce the total water volume that USBR must release down the Klamath River to meet biological opinion flow requirements, and therefore, allow USBR to retain additional water available for upstream diversion in the Klamath Irrigation Project. Whether this increase in available supply would contribute to increased instream flows or be used upstream to supplement irrigation deliveries is uncertain, so the EIR discloses the potential increase but does not rely on it for conclusions regarding the impacts of the Proposed Project (see also Volume I Section 3.8.4 *Water Supply/Water Rights – Impacts Analysis Approach*).

Please also refer to Volume I Section 3.8.5 *Water Supply/Water Rights* Potential Impacts 3.8-1 and 3.8-2 (pages 3-676 to 3-680), which discuss the water borrowing agreements made between PacifiCorp and USBR in 2014 and 2018. It is unclear if further water borrowing would occur in the future due to the multiple constraints detailed by USBR and discussed in Potential Impact 3.8-2 (pages 3-679 to 3-680). The EIR's assessment of the unlikelihood of future water borrowing is further bolstered by USBR's elimination of this alternative from further consideration as part of its environmental assessment of the Klamath Irrigation Project operations (USBR 2019).

<u>Comment ORG46-13</u>
• *The DEIR inadequately addresses the impacts of sedimentation on Waters of the U.S. The Klamath River downstream of Iron Gate Dam is a jurisdictional Water of the U.S. and subject to regulation by Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. The release of sediment (bedload movement and suspended sediments) from the Proposed Project will result in fill of these jurisdictional waters. The DEIR analysis does not evaluate or quantify the amount of fill to Waters of the U.S. that would occur downstream of Iron Gate Dam as a result of the Proposed Project.*

Response to Comment ORG46-13
Comment noted. As explained in Volume I Section 3.1.4 *Introduction – Impact Analysis Approach* (page 3-2), the EIR establishes criteria for evaluating the significance of the potential direct and reasonably foreseeable indirect effects on the environment associated with the implementation of the Proposed Project and analyzes those effects. This approach adequately discloses the environmental effects of the Proposed Project. For example, with respect to sedimentation, the

EIR estimates the amount of annual average load sediments from the Klamath River to the Pacific Ocean.

For information on potential impacts from sediment deposition related to geomorphology, flood hydrology, and aquatic and terrestrial habitat, please refer to: Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775) and modifications to this impact in Volume III Attachment 1; Volume I Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain* Potential Impact 3.6-5 (page 3-634 to 3-635); Section 3.3 *Aquatic Resources*; and Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-3. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources* and Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-3.

Note that Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 has been clarified to discuss reach-averaged sediment deposition or erosion and bed elevation change results of both sets of SRH-1D simulations that were undertaken by the U.S. Bureau of Reclamation (i.e., forty eight 2-year simulations and three 50-year simulations) (USBR 2012a). The clarifying edits do not change the conclusions or significance determinations in Potential Impact 3.11-5. Please refer to Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 for the revisions.

As stated in Volume II Appendix B: *Definite Plan* (pages 36 to 37 of the *Definite Plan*), Klamath River Renewal Corporation (KRRC) is coordinating with the U.S. Army Corps of Engineers regarding the Section 404 individual permit associated with implementation of the Definite Plan.

Comment ORG46-14

• *The DEIR's assessment of reservoir drawdown does not address the effects to downstream fish communities of releasing the entire population of Yellow Perch (or any other reservoir fish) from Copco and Iron Gate reservoirs. Hundreds of thousands of Yellow Perch from the reservoirs would be released into the lower river during and after drawdown of the reservoirs. The DEIR does not address the effect of Yellow Perch competing for the same habitat types used by Chinook, federally-threatened Coho, or Steelhead.*

Response to Comment ORG46-14

Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resources Impacts* analyzes the potential effects of introduced reservoir fish species, including yellow perch, competing for the same habitat as native aquatic species in the Klamath River downstream of the Hydroelectric Reach in Potential Impact 3.3-17. As discussed in this impact analysis, dam removal would result in a conversion of lotic (calm water) reservoir habitat, to which yellow perch and other warm water fish species are adapted (Moyle 2002), to high velocity (turbulent) riverine habitat, to which yellow perch are not adapted. As discussed in Section 3.3.2.1 *Aquatic Resources – Environmental Setting – Aquatic Species – Non-native Fish Species*, yellow perch and other non-native reservoir fish prefer habitat with low water velocity, low turbidity, and warm water temperatures. Under the Proposed Project, the conversion of reservoir to riverine habitat would occur during winter high flows, which would be likely to rapidly (within days) displace, and ultimately result in the mortality of, yellow perch and other introduced reservoir species. Additionally, Potential Impact 3.3-18 has been slightly revised to clarify the effect of reservoir conversion on non-native reservoir species. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Under current conditions, high flows can also result in transport of reservoir fish species over Iron Gate dam and into the Klamath River, such that the introduction of these species in the Klamath River would not be a new risk. Gough et al. (2015) report observations of yellow perch and other current reservoir fish species in the Klamath River directly downstream of Iron Gate Dam that have spilled over Iron Gate Dam (or been entrained though turbines), with very few observations of these species farther downstream. In a report prepared for PacifiCorp, CH2MHill (2003) state that reservoir species including yellow perch that survive passage downstream past Iron Gate Dam, “will eventually perish in the downstream riverine habitat.”

Please also refer to the Klamath River Expert Panel findings (Buchanan et al. 2011a), where the panel was convened to assess Lower Klamath Project dam removal effects on resident fish and concluded that dam removal, “…would change reservoir habitat to free-flowing river, which would adversely affect non-native fishes in the lower Klamath basin between Keno Dam and Iron Gate Dam. Abundances of largemouth bass, yellow perch, bluegill, and brown bullhead would significantly decline or be eliminated because their preferred reservoir habitat would be gone.”

Comment ORG46-15

• *A critical effect of the Proposed Project on the river's periphyton community is absent from the DEIR' s analysis and discussion. Under the Proposed Project, the existing periphyton community downstream of Iron Gate Dam will shift upstream. Aquatic vegetation, currently absent under the reservoirs and in the J.C. Boyle Peaking Reach, will colonize the newly exposed stream reaches. Periphyton-related nitrogen fixation in the river would further increase the nutrient loading in the river, exacerbating nutrient impacts to the river and estuary. While the DEIR mentions the extension of periphyton upstream of Iron Gate Dam in the discussion of fish disease (DEIR pg. 3-278), this is not discussed in Section 3.4 Phytoplankton and Periphyton.*

Response to Comment ORG46-15
Section 3.4 *Phytoplankton and Periphyton* does discuss the potential for periphyton colonization in the Hydroelectric Reach and changes in the periphyton community (i.e., shifts in the abundance of periphyton nitrogen-fixing species). Please refer to Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437) and Potential Impact 3.4-5 (pages 3-437 to 3-440) for analysis of periphyton community variations under the Proposed Project due to increased nutrients from upstream dam removal and conversion of the reservoir areas to a free-flowing river.

Please also refer to ORG46-267 for a more detailed discussion of the anticipated changes in the periphyton community under the Proposed Project.

Comment ORG46-15.1
• *The DEIR fails to assess the greenhouse gas emissions impacts of removing renewable generation facilities. Removing non-emitting hydroelectric generation facilities under the Proposed Project will result in millions of tons of additional greenhouse gas emissions, contrary to California climate change policies, and these significant impacts are not disclosed.*

Response to Comment ORG46-15.1
This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG46-16
2.8 Ceratonova shasta Fish Disease Discussion
The DEIR' s assertion that dam removal will lead to reductions in fish disease is based almost entirely on speculation and is unlikely to be realized. Fish disease hosts, triggers, and virulence are unlikely to be substantively changed with the Proposed Project. Recolonization of the project reach by infected salmon will spread the parasite C. shasta upstream of Iron Gate Dam where they will infect the highly abundant population of the polychaete host Manayunkia speciosa. In turn, the infected polychaetes will release the C. shasta actinospore that infects juvenile and adult salmon, which will cause infected salmon to contract the disease ceratomyxosis. The duration of actinospore exposure of juvenile salmon originating from upstream of Iron Gate Dam would be longer than for salmon populations downstream of this point as they must migrate farther to reach the estuary. Additionally, increased spring-time river temperatures following dam removal may increase the prevalence of infection among outmigrating juveniles.

In the analysis of the Proposed Project impacts on fish disease (Section 3.3.5.5), the DEIR indicates that existing conditions contributing to disease in salmonids include (DEIR pg. 3-276):

- *The availability of habitat for the polychaete hosts*

- *Static flows and low velocities that create appropriate microhabitats for polychaete hosts*
- *Congregations of spawned adult salmon with high actinospore loads*
- *Polychaete populations in proximity to spawning salmon*
- *Planktonic food sources for the polychaete hosts from Copco and Iron Gate reservoirs*
- *Water temperatures over 59°F (15°C)*

PacifiCorp agrees that these factors influence infection and mortality rates; however, the DEIR does not accurately represent the possible outcomes of the Proposed Project, or the alternatives, as it relates to disease, specifically ceratomyxosis.

Disease dynamics in the Klamath River from C. shasta infection are incredibly complex and the scientific understanding of them continue s to evolve at a rapid pace. The DEIR (in Section 3.3.2.3) does an insufficient job of presenting an up-to-date discussion of C. shasta effects on salmonids. While C. shasta infection rates have been high at times, the most recent highest levels (2014 and 2015) occurred during extreme drought conditions. The infection rates have declined dramatically since then (Voss et al. 2018), likely for a combination of reasons related to flow, temperature, and fish abundance.

The polychaete host for C. shasta, Manayunkia speciosa, is native to the Klamath River and found throughout the basin. While the densities of this polychaete vary within the basin in response to a variety of factors, they are abundant in the reach downstream of J.C. Boyle Dam, in the Williamson River, and at various locations in the mainstem lower Klamath River from the mouth upstream to Iron Gate Dam.

In Section 3.3 the DEIR recognizes that under the Proposed Project the expected increase in periphytic growth could provide habitat for the polychaetes (DEIR pg. 3-278). However, the DEIR then assumes other factors such as the restoration of bedload sediment transport would offset increases in periphyton-related habitat by enhancing potential scour of polychaetes. The DEIR does not inform the reader that there is very little bedload sediment supply for inducing scour in the Keno Reach, J.C. Boyle Reservoir, J.C. Boyle Bypass Reach, or J.C. Boyle Peaking Reach. The substrate in these reaches is large and the stream beds are stable because: (a) the flows are moderated by upstream dams and storage reservoirs; (b) no tributaries of any consequence enter the system (Spencer and Shovel creeks are not appreciable inputs of sediment); and (c) flows are notably lower here than in downstream reaches where active sediment transport occurs (especially downstream of the Scott River). In sum, these upper reaches will be prime polychaete habitat, with conditions well-suited for abundant polychaete densities, including appreciable organic matter, stable flows, stable stream bed, and stable substrate for polychaetes to colonize. Add to this the DEIR's expectation of producing tens of thousands of Chinook Salmon in this reach *which would provide the myxospores needed to infect polychaetes and expansion of C. shasta throughout the upper Klamath River would result.*

Further, the DEIR does not make use of recent studies that have evaluated the effectiveness of scour as a mechanism for reducing polychaete concentrations. Recent research indicates that while polychaetes may respond to flow changes and be removed from substrates by increasing flows (with specific dislodgment flows that varied depending on the substrate), polychaetes also exhibited a variety of behavioral reactions to flow changes and proved to have relatively high survival rates (M alakauskas et al. 2013). Generally, this research suggests that polychaete populations likely exhibit high resilience to flow-mediated disturbances.

Additionally, the DEIR fails to acknowledge that recent research indicates that the magnitude of high flows that may be necessary to induce scour that could disrupt polychaete habitat (see Shea et al. 2016) are above the thresholds of flows that are expected to be achieved from the Proposed Project. That is, removal of the Klamath Hydroelectric Project is not anticipated to increase peak flows, that result in significant scour events, above conditions that are currently experienced with the hydroelectric dams in place. Thus, recent research indicates that scour may be ineffective at solely combating polychaete densities that contribute to high infectious rates in the Klamath River, and that the expected hydrologic changes from the Proposed Project are unlikely to result in flows that could accomplish scour anyway.

Research by Foott et al. (2016) has shown that relatively few very highly infected adult Chinook carcasses are capable of fully seeding the polychaete populations in the river reaches. This information indicates that C. shasta disease transmission will occur whether salmon spawner density increases of decreases. Reintroduction of Chinook and Coho spawners infected with C. shasta would infect the polychaete hosts through the release of myxospores from fish carcasses. As a result, the Chinook and Coho-specific genotypes of C. shasta would become established in the existing polychaete population and release spores in densities that result in infection of juvenile Chinook and Coho. Based on this information, the DEIR is incorrect to indicate that spreading out the salmon populations would reduce their proximity to polychaete populations and therefore reduce disease effects. In sum, the DEIR' s assumption that the Proposed Project would reduce disease effects is not support ed by the current understanding of fish disease dynamics in the Klamath River.

The DEIR makes reference to the planktonic algae released from Copco and Iron Gate reservoirs as an important polychaete food source that is partially responsible for the abundance of the polychaete host of C. shasta downstream of Iron Gate Dam. While these food sources would no longer be present if the Proposed Project were implemented, the DEIR acknowledges that Keno Reservoir would remain in place and continue to release large amounts of algae *into the Klamath River. Based on KHSA Interim Measure 15 monitoring data and using chlorophyll-a as a surrogate for planktonic algae, it is apparent that Keno Dam would remain a source of planktonic algae for the polychaetes, producing more planktonic algae than is released from Iron Gate Dam (Figure 9). Further, researchers from Oregon State University have routinely harvested polychaetes from the J.C. Boyle Bypass Reach because these populations are some of the densest anywhere in the river (Alexander et al. 2016b). The high densities in this reach are at least partially due to the food supplied from Keno Reservoir and Upper Klamath Lake.*

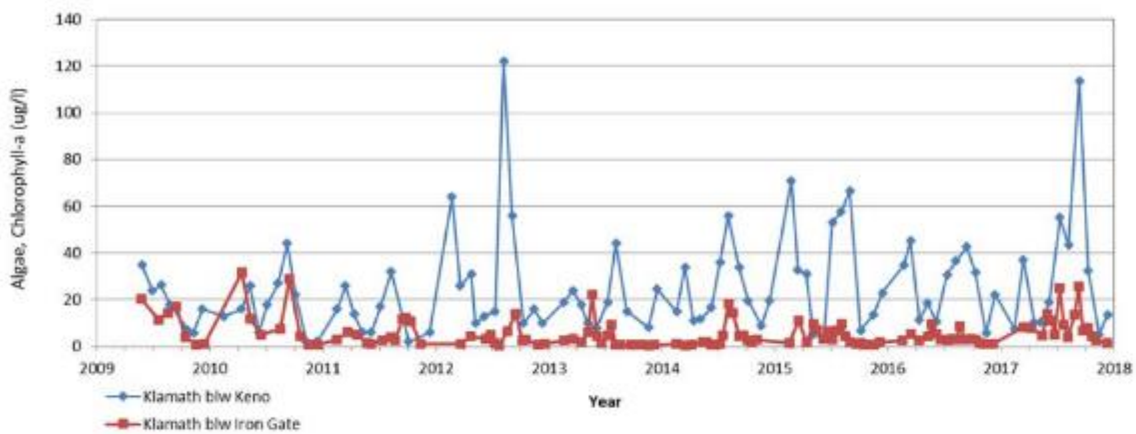

Figure 9. Chlorophyll-a concentrations downstream of Keno Dam and downstream of Iron Gate Dam collected as part of the Klamath Hydroelectric Settlement Agreement Interim Measure 15 monitoring program from 2009 through 2017.

The DEIR asserts that "Dam removal would mean cooler temperatures in the late summer and fall, but slightly warmer temperatures in the spring and early summer" (DEIR pg. 3-2 77). The Klamath Hydroelectric Project dams serve to cool water temperatures during the spring months, which may reduce C. shasta severity in the reach of the river downstream of Iron Gate Dam where the temperature signature from the Klamath Hydroelectric Project is greatest. The DEIR states, and PacifiCorp's prior water quality modeling (PacifiCorp 2006, 2014) confirms, that the spring water temperatures are higher under the Proposed Project. In fact, Figure 3.3-5 (DEIR pg. 3-275) is based on PacifiCorp's water quality modeling for 2002 and is used to describe temperature effects to salmon (Figure 10). The data show that water temperatures would exceed 15°C approximately 2 to 4 weeks earlier with implementation of the Proposed Project (Figure 10). This in turn could increase C. shasta disease rates because polychaete hosts develop spores more quickly under warmer water conditions (Ray et al. 2012). The DEIR spends a great deal of time noting the severity of C. shasta for Klamath River salmonid populations but fails to acknowledge that dam removal has the potential to also exacerbate C. shasta infection prevalence. The

DEIR is required to present both possible positive and negative effects of the Proposed Project.

According to Bartholomew and Foott (2010 as cited in the DEIR), the 59°F (15°C) water temperature criterion that is referenced in the DEIR applies when the infectious dose of C. shasta is low. However, DEIR fails to present the complete finding of Bartholomew and Foott (2010, page 38) that water temperature is not a strong predictor of survival when infectious dose is high. Specifically, Bartholomew and Foott (2010) show substantial effects on salmonids at temperatures ranging from about 55°F to almost 70°F (13°C to 21 °C). Simulated water temperature information presented in the DEIR indicates that water temperatures would reach 13°C in early April for the Proposed Project compared to early May for existing conditions (Figure 10). While the DEIR claims that warmer water temperatures in spring under the Proposed Project would result in earlier fry emergence for mainstem Chinook spawners, this would not be the case for tributary populations. Juvenile migration timing for tributary populations would remain unchanged and the majority of these fish would enter a warmer Klamath River under the Proposed Project, with all of its implications for disease.

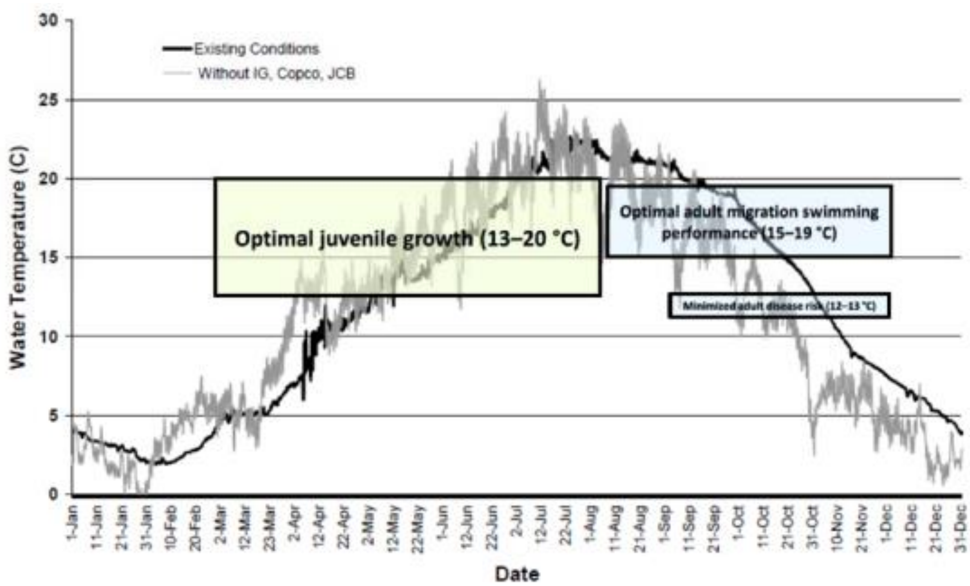

Figure 10. PacifiCorp (2005) simulated hourly water temperatures below Iron Gate Dam based on a dry water year (WY 2002) for existing conditions compared to the Proposed Project (without Lower Klamath Project dams), and USEPA (2003} water temperature criteria for salmonid growth and migration (Reproduction of DEIR Figure 3.3-5, DEIR pg. 3-275).

Routine monitoring of juvenile Chinook outmigration has indicated that water temperature may not be as important as flow in resulting disease infection rates and mortality (see True et al. 2017; Voss et al. 2018). In the discussion of disease, the DEIR should provide a more detailed and accurate summary of the *differences in river flow between alternatives so that possible flow effects on disease are clarified (see Major Issue 2. 2).*

The DEIR indicates that high rates of C. shasta infection downstream of Iron Gate Dam are a function of the concentration of returning salmon spawners at Iron Gate Dam and the hatchery. The DEIR assumes that because the Proposed Project would allow access to new habitat, fish would no longer be concentrated and therefore the rates of C. shasta infection would be reduced. However, as noted by Som et al. (2016), the C. shasta infectious zone has shifted over the years. In the past, samples from Beaver Creek (RM 161) often had the highest actinospore concentrations, but peak concentrations have since moved downstream in some years and in 2016 peak spore counts were obtained near Orleans (RM 58) and Tully Creek (RM 38.5) (Bartholomew et al. 2017). Given that Chinook spawner density in these areas is substantially less than areas closer to Iron Gate Dam, large concentrations of nearby mainstem spawners are not required to produce areas with high C. shasta infection potential. The risk of C. shasta infection is based partially on the number of actinospores per liter of water because as this number increases, so does the dose for each exposed fish. Because flows upstream of Iron Gate Dam steadily decrease to Keno Dam (as fewer tributaries enter the reach), the shifting of adult spawners to upstream areas could result in a higher actinospore densities per liter of water and thus higher exposure rates and corresponding C. shasta disease risk. Thus, the DEIR's assumption that the Proposed Project would spread the spawning adults over a wider area, and that this would in turn reduce C. shasta infection rates and resultant salmonid mortality, is not supported by recent analyses.

The DEIR also does not acknowledge that because water quality conditions in Keno Reservoir could constitute a water quality barrier to adult salmon migration, returning spawners may congregate downstream of Keno Dam. Using the DEIR's logic, a concentration of Chinook in this area would form a new C. shasta infectious hot-spot as this area is just upstream of the J.C. Boyle Bypass Reach, which has some of the largest densities of polychaetes measured in the basin (Alexander et al. 2016b; Bartholomew and Hallett 2017).

The DEIR fails to accurately address the specific Proposed Project objective to "Ameliorate conditions underlying high disease rates among Klamath River salmonids" (DEIR pg. 2-1). The DEIR needs to update the discussion in Section 3.3 to reflect the current understanding of C. shasta on the Klamath River as it relates to Chinook and Coho and then conduct an analysis of potential impacts of the Proposed Project and the alternatives on fish disease. The DEIR should specifically evaluate potential impacts the Proposed Project and the alternatives could have in relation to fish disease. This includes an evaluation of:

- *The impact of a wider range of water temperatures including a complete and accurate analysis of water temperatures as they relate to the different life stages of C. shasta and the susceptible salmonids.*

- *Evaluate the potential for a C. shasta infectious zone to develop downstream of Keno Dam and the impact this would have on salmon recolonization and production.*
- *Evaluate the potential of the river reach extending from Keno Dam to Iron Garn to Dam support polychaete populations and implications for salmon production.*
- *Revisit assumptions regarding salmon spawner density effects, spawner location, and salmon C. shasta infection rates on corresponding polychaete C. shasta infection.*
- *Accurately describe and compare changes in flow between alternatives and how these changes may affect C. shasta infection rates on salmonids.*

Response to Comment ORG46-16

The EIR provides an analysis of the potential risk of fish disease, including *C. shasta*, under the Proposed Project in Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease and Parasites*, which is based on extensive review of existing scientific information regarding factors controlling fish disease in the Klamath River. Please refer to Volume III Attachment 1 for the final Section 3.3 Aquatic Resources. Please also refer to Master Response AQF-6 for a detailed discussion of actinospore density, changes in water temperature downstream of Iron Gate Dam under the Proposed Project, and implications for disease risk. Master Responses AQF-5 and AQF-6 also address flows, and implications for disease risk under the alternatives.

Comment ORG46-17

2.9 Salmonid Migration, Spawning, and Rearing Water Temperature Analysis

This section describes information pertaining to the effects of water temperature conditions on anadromous fish species downstream of Iron Gate Dam. The focus here is to present an evaluation of the effects of water temperature conditions on anadromous salmonid migration, spawning, and rearing in the Klamath River downstream of Iron Gate Dam. This is necessary because the DEIR simply reports conditions as being warmer, or cooler, or more "natural" under the Proposed Project, existing conditions, or an alternative but does not discuss the biological significance, if any, of these changes or differences in temperature. In the following discussion the existing conditions are essentially analogous to the existing conditions within the DEIR, and the without-Project discussion approximates the Proposed Project in the DEIR.

This information and analysis was previously included in PacifiCorp's (2014) application to the State Water Resources Control Board for water quality certification of the Klamath Hydroelectric Project under Section 401 of the federal Clean Water Act. The PacifiCorp (2014) application analyzes water quality conditions within the Klamath Hydroelectric Project area in California, and the controllable water quality factors reasonably available to address the Klamath Hydroelectric Project's contribution to compliance with water quality objectives and protection of beneficial uses as designated in the Water Quality Control Plan *for the North Coast Region (Basin Plan). The DEIR does not reference this available and relatively recent analysis in any way. Current distributions of anadromous species in the lower Klamath River Basin are discussed in the DEIR Section 3.3 and the current population status for Coho Salmon is discussed in Section 2.1 of PacifiCorp' s comments.*

2.9.1 Methods and Criteria
The extent to which the Klamath Hydroelectric Project contributes to current water temperature conditions in the Klamath River downstream of Iron Gate Dam are described in PacifiCorp {2014) based on field observations and supported by water temperature modeling of existing conditions for years 2000 through 2004 at several locations in the Klamath Hydroelectric Project reaches in California. Detailed discussions of water temperature modeling methods and results for the Klamath Hydroelectric Project are provided in PacifiCorp 2004a, 2004b, 200Sa, 200Sb, and 2014.

The potential effects of the Klamath Hydroelectric Project on water temperatures released downstream of Iron Gate Dam were evaluated specifically for fall-run Chinook Salmon, Coho Salmon, and Steelhead (PacifiCorp 2014). Average daily water temperature ranges were used to define suitable, low-to-moderate stress, and high stress/lethal effects for these species (Table 2). Suitable conditions reflect a water temperature range behaviorally selected by a species within which growth and survival are high, and susceptibility to other stressors (e.g., disease) is reduced. Low to moderate stressful conditions reflect water temperatures where growth rates are reduced, behavioral avoidance may occur, and susceptibility to other stressors is increased. High stress/lethal temperatures result in severe physiological impairment, loss of equilibrium, and/or direct mortality (e.g., incipient lethal threshold LT10). The temperature ranges have been synthesized from information available in the scientific literature on the biological response of salmonid life -history stages to water temperature conditions including, but not limited to, McCullough (1999), Sullivan et al. (2000), McCullough et al. (2001), Myrick and Cech (2001), and USEPA (2003).

- *These analyses were performed using the average daily water temperatures derived from modeling for 2000 and 2001existing conditions (with the Klamath Hydroelectric dams present) and without-Project (with dams removed akin to the Proposed Project) scenarios. Three metrics were used for this analysis: annual exposure, degree-day exposure, and habitat suitability. These are the same metric previously used by Bartholow et al. (2005) to evaluate the effects of dam removal on water temperature conditions and habitat suitability for Chinook in the Klamath River .*
- *Annual exposure equals the number of days during the year that water temperatures exceed the literature-based criteria for suitable habitat conditions (referred to as index of annual exposure).*

- *Degree-day exposure equals the sum of the differences between mean daily water temperatures above and below a range of suitable temperatures during the appropriate time periods and locations within the river.*
- *Habitat suitability equals the linear distance within a river reach that average daily water temperatures were within the range identified as suitable habitat conditions. Habitat suitability was also evaluated based on average weekly water temperatures at various locations downstream of Iron Gate Dam (running average).*

Table 2. Literature-based Ranges of Average Daily Water Temperature for Designation of Suitable and Stressful ta Lethal Effects for Target Salmon Species in the Klamath River.

Species	Life-History Stage	Suitable	Low to Moderate Stress	High Stress
Fall-run Chinook Salmon	Adult migration, pre-spawning, spawning	<17	18-21	>21
	Egg to emergence	<12	13-14	>14
	Juvenile rearing and emigration	<15	16-23	>23
Coho Salmon	Adult migration, pre-spawning, spawning	<17	18-21	>21
	Egg to emergence	<12	13-14	>14
	Juvenile rearing and emigration	<15	16-23	>23
Steelhead	Adult migration, pre-spawning, spawning	<17	18-21	>21
	Egg to emergence	<12	13-14	>14
	Juvenile rearing and emigration	<15	16-23	>23
	Steelhead smoltification	<12	13-18	>18

The seasonal distribution of the various salmonid life-history stages in the Klamath River assumed in the assessment (Table 3) are somewhat different than those presented in the DEIR (see Table 3.3-5 for example), but the overall range of life stages is roughly analogous. The seasonal periodicity assumptions reflect when various life stages of a target species will occur in the river and when life stage-specific water temperature criteria apply.

Table 3. Estimated Fish Periodicity-Klamath River, updated to include stakeholder comments to PacifiCorp. Current and potential life history strategies from Iron Gate to Link River dams.

Species/Life stage	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Fall Chinook-Type II (fall juvenile migrant)

Adult migration												
Adult spawning												
Incubation												
Fry emergence												
Rearing												
Juvenile Outmigration												

Note: For anadromous juvenile emigration, timing reflects fish migration from Klamath Hydroelectric Project area, not when they reach the estuary. Anadromous salmonid life histories represent stocks currently in the Klamath Basin from Iron Gate Dam to Salmon River. Dark shading equals peak use period.

In addition to the application of the criteria listed previously (Table 2), there is also the California water temperature objective applicable to the Klamath Hydroelectric Project as set forth in Section 3 of the Basin Plan. The state water temperature objective is:

> *Temperature objectives for COLD interstate waters, WARM interstate waters, and Enclosed Bays and Estuaries are as specified in the "Water Quality Control Pion for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays of California" including any revisions thereto.*
>
> *In addition, the following temperature objectives apply to surface waters:*
>
> > *The natural receiving water temperature of intrastate waters shall not be altered unless it can be demonstrated to the satisfaction of the Regional Water Board that such alteration in temperature does not adversely affect beneficial uses.*
> >
> > *At no time or place shall the temperature of any COLD water be increased by more than 5°F above natural receiving water temperature.*
> >
> > *At no time or place shall the temperature of WARM intrastate waters be increased more than 5°F above natural receiving water temperature.*

Response to Comment ORG46-17

Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Water Temperature* provides a thorough analysis of water temperature dynamics and effects on aquatic resources, including the biological implications of different temperature ranges, under existing conditions. The effects of water temperature on aquatic resources under the Proposed Project are discussed in Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature*. The EIR's analysis of water temperature effects on aquatic resources and conclusions are supported by the substantial evidence discussed in these sections and there are no data provided in PacifiCorp (2014) that are substantially divergent from the data analyzed in the EIR. Please see response to ORG46-127 for a complete discussion of the PacifiCorp (2014) water temperature data analysis. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

<u>Comment ORG46-18</u>

2.9.3 Water Temperature Effects on Anadromous Fish Downstream of Iron Gate Dam

The following discussion summarizes the potential effects of water temperature under existing conditions and a without-Project conditions (analogous to the Proposed Project analyzed in the DEIR) on Chinook, Coho, and Steelhead.

Chinook Salmon

Fall-run Chinook Salmon use the Klamath River downstream of Iron Gate Dam for adult migration, spawning and egg incubation, juvenile rearing, and juvenile emigration. Although fall-run Chinook respond to both high and low water temperatures, the primary focus of concern regarding Klamath Hydroelectric Project operations on habitat suitability has been on seasonally elevated temperatures. As a result, the following analyses emphasize the occurrence of elevated water temperatures (e.g., seasonally low temperatures have been included within the thermal zone identified, for purposes of the analysis of suitable habitat conditions for a given life stage of fall-run Chinook Salmon and other salmonids).

Adult fall-run Chinook Salmon migrate upstream within the Klamath River during the seasonal period from August to October (Table 3). Results of water temperature modeling show a general seasonal pattern with elevated temperatures occurring during August and declining during September and October. Results of the water temperature modeling showed a consistent pattern of diminishing differences in water temperatures between existing and hypothetical without-Project conditions as a function of distance downstream from Iron Gate Dam (RM 190).

Results of the temperature modeling also show that during the fall migration period water temperatures under both existing and without-Project conditions reach a thermal equilibrium where water temperatures are virtually identical under existing and without-Project conditions in the lower reaches of the river below Seiad Valley (RM 129). Klamath Hydroelectric Project operations at Iron Gate Dam, therefore, have no effect on water temperature conditions in these reaches and would not affect water temperature conditions, thermal exposure, or behavioral response of adult fall-run Chinook Salmon entering the Klamath River .

Water temperatures within the Klamath River show a consistent pattern of temperatures considered to be unsuitable for adult upstream migration throughout the entire reach from Iron Gate Dam to Turwar

(RM 6) during August under both existing and without-Project conditions with temperatures decreasing seasonally during September into the range considered to be low to moderately stressful throughout the mainstem river (Table 4). Water temperatures generally decreased and remained within a range considered to be suitable for adult upstream migration beginning in early October and continuing through the end of the migration period. The seasonal pattern in water temperatures was generally similar between 2000 and 2001.

Results of the comparison of the average weekly temperatures (Table 5) showed temperatures above a l6°C average weekly average during approximately 75 to 80 percent of the days within the migration period. The frequency of these average weekly temperatures was similar at mainstem locations extending from Iron Gate Dam downstream to Turwar. This pattern was similar under both existing and without-Project conditions based on analyses of average weekly temperature (Table 5).

The biological significance of the incremental temperature exposure in the reach just downstream of Iron Gate Dam under existing conditions was evaluated to assess potential effects of temperature exposure to pre-spawning adults on subsequent egg viability and hatching success. An investigation of the relationship between temperature exposure for pre-spawning fall-run Chinook Salmon and egg viability was conducted by Mann and Peery {2005). The observed relationship between pre-spawning adult temperature exposure, expressed as degree days above 18 and 20°C and corresponding estimates of percent mortality for incubating eggs from each female, show that the incremental increase in egg mortality over a range of pre-spawning adult temperature exposures is typically less than approximately 5 percent.

Table 4. Habitat suitability based on overage daily water temperatures far adult fall-run Chinook Salmon migration at locations downstream from Iran Gate Dom based on 2000 and 2001 water temperature modeling results for existing conditions (EC) and hypothetical without-Project (WOP) scenarios.

Assuming that a female adult Chinook Salmon entered the Klamath River on September 15 and migrated upstream to spawn in the reach downstream of Iron Gate Dam (equal duration of exposure to temperatures within each reach) the degree-day exposure to water temperatures above 18 and 20°C was estimated to be 14.5 and 59.2 degree-days, respectively under existing conditions and 13.2 and 46.4 degree days under hypothetical without-Project conditions. Under these simulated conditions, temperature exposure under existing conditions would be similar to without-Project conditions and would be expected to contribute to an incremental increase in egg mortality of less than 5 percent. Results of these analyses are consistent with observations for fall-run Chinook Salmon spawned at the Iron Gate Hatchery, which show high egg viability under existing conditions (Kim Rushton, former Iron Gate Hatchery Manager, CDFW).

Fall-run Chinook Salmon egg incubation occurs between October and March (Table 3). Water temperatures show a typical seasonally declining trend during the early portion of egg incubation followed by a seasonal increase in water temperatures during the later period of incubation prior to fry emergence in the spring. Examination of the average weekly temperatures during the egg incubation period (Table 6) showed a similar pattern with approximately 21 percent of the observations exceeding 10°C within the reach immediately downstream of Iron Gate Dam, 20 percent within reach upstream of Shasta River, 25 percent upstream of the Scott River, and 28 percent upstream of Clear Creek under existing project operations. Under the without-Project conditions average weekly water temperatures exceeded 10°C in 17 percent of the observations within the reach immediately downstream of Iron Gate Dam, 18 percent within reach upstream of Shasta River, 20 percent upstream of the Scott River, and 24 percent upstream of Clear Creek.

Results of a comparison of habitat suitability conditions for egg incubation (using criteria in Table 2) under existing and without-Project conditions show a consistent pattern of exposure to elevated water temperatures under both existing and without-Project conditions in early October (Table 6). Water temperature exposure under existing project operations, although declining seasonally, are within the range during early October that would contribute to reduced egg viability. The significance of egg exposure to elevated temperatures during early October under existing project operations is reduced, in part, as a result of fewer salmon spawning during the early portion of the spawning period. The peak of Chinook Salmon spawning occurs during the latter portion of October when seasonally declining water temperatures have less effect on the viability and successful hatching of incubating eggs.

Habitat conditions for egg incubation in the reach down stream of Iron Gate Dam potentially could be improved if water temperatures released from the dam during early to mid-October could be reduced under existing conditions. Reducing early to mid-October water temperatures would be expected to improve potential egg viability for those adult Chinook Salmon spawning early while continuing to *provide water temperatures during the late fall that would be warmer when compared to hypothetical without-Project conditions. Continuing to provide warmer water temperatures under existing conditions that are suitable for egg incubation would accelerate embryonic development and early fry emergence (see Section 2.9.4 below).*

Juvenile Chinook Salmon (ocean type migrants) rearing and emigration occurs between February and July (Table 3). Results of water temperature modeling during the juvenile rearing period has shown that water temperatures are cooler under existing conditions when compared to hypothetical without- Project conditions in the reach immediately downstream of Iron Gate Dam. Temperature modeling has shown that differences in water temperature between existing and without-Project conditions diminish as a function of distance downstream from the dam as water temperatures reach thermal equilibrium within the river.

Table 6. Habitat suitability based on average daily water temperatures for fall-run Chinook Salmon egg incubation at locations downstream from Iron Gate Dam based on 2000 and 2001 water temperature modeling results for existing conditions (EC) and hypothetical without-Project (WOP) scenarios.

suitable: <12°C	low to moderate stress: 13-14°C	high stress: >14°C

For example, for juvenile rearing, the running average weekly temperatures exceeded temperature criterion on 45 days (30 percent) under existing conditions within the Iron Gate Dam reach when compared with 55 days (37 percent) under hypothetical without-Project conditions. In contrast, there was no difference in the frequency of exceeding the temperature criterion between existing and without-Project conditions in the lower reaches of the river upstream of the confluence with the Trinity River or at Turwar (Table 4).

Results of a comparison of habitat suitability at various locations within the river for juvenile rearing and emigration show that water temperature condition s under both existing and without-Project conditions are within the range considered to be suitable for juvenile rearing and emigration throughout the river through approximately late April (Table 7). Beginning in May and continuing through June, water temperatures throughout the river under both existing and without-Project conditions were within the range considered to reflect low to moderate stress. Temperature conditions, particularly within the lower reaches of the river in July were within the range characterized by high stress/lethal under both existing and without-Project conditions.

Exposure of juvenile Chinook Salm on to seasonally cooler water temperatures under existing project operations, primarily within the reach down stream of Iron Gate Dam, would be expected to benefit the overall health and condition of juvenile rearing salmon. Exposure to reduced water temperatures within the Iron Gate Dam reach during the spring and early summer juvenile rearing period would contribute to reduced vulnerability of juveniles to disease and infection Operation of Iron Gate Dam also serves to substantially reduce daily variation in water temperatures during the spring and early summer, which would contribute to a reduction in variation in metabolic demands on rearing juveniles and improve growth, when compared to more highly variable temperature conditions that would occur under without-Project conditions.

Although exposure of juvenile salmon to seasonally reduced water temperatures during the spring and early summer rearing period offers benefits in terms of a reduced risk of disease and infection, it was also determined that exposure to cooler water temperatures under existing project operations would not result in reduced juvenile growth rates. Results of studies by Marine and Cech (2004) show that juvenile Chinook growth rates are virtually identical over a temperature ranges from 13-16°C and 17-20°C reflecting the general range of seasonal temperatures expected to occur during the juvenile rearing period under existing conditions in the reach downstream of Iron Gate Dam. Results of these growth studies show no evidence that lower spring and early summer water temperatures under existing project operations would adversely impact juvenile salmon growth rates.

These analyses demonstrate that existing conditions within the Klamath River reach downstream of Iron Gate Dam provide better rearing conditions for juvenile *fall-run Chinook Salmon when compared to water temperature conditions occurring under hypothetical without-Project conditions. As a result of thermal warming within the river, the benefits of project operations on juvenile rearing habitat diminish with distance downstream of the dam. Within the lower reaches of the river, project operations have no effect on water temperature conditions affecting habitat suitability for juvenile rearing period.*

PacifiCorp's conclusions with regard to Project-related water temperature effects on fall-run Chinook Salmon are supported by other recent independent analyses. In an analysis of the effects on fall Chinook of hypothetical temperature conditions with and without Klamath Hydroelectric Project dams and reservoirs, Bartholow et al. {2005) concluded that water temperature conditions for juvenile rearing life stages are better with Klamath Hydroelectric Project dams and reservoirs than without, especially immediately downstream of Iron Gate Dam. In a subsequent analysis of factors limiting fall Chinook production potential, Bartholow and Henriksen (2006) concluded that water temperature during

suitable: <15°C | low to moderate stress: 16-23 °C | high stress: >23 °C *spawning and egg incubation is not a significant factor affecting fall-run Chinook freshwater production in the Klamath River.*

<u>Coho Salmon</u>
Coho Salmon use the mainstem Klamath River primarily as a migration corridor for the upstream movement of adults and downstream movement of juveniles. Although the majority of Coho spawning, egg incubation, and a substantial portion of juvenile rearing occurs within the tributaries that are not affected by existing Klamath Hydroelectric Project operations, this analysis assumed all life stages of Coho inhabit the Klamath River, and the analysis is useful for those Coho that do spawn in the mainstem. Coho juveniles are known to use the Klamath River throughout the year (Soto et al. 2016; Manhard et al. 2018)

Coho are sensitive to seasonal water temperature conditions that affect quality and availability of habitat for various life stages, growth and survival, behavior, vulnerability to disease, and other biological responses. Although the seasonal time periods of occurrence of Coho vary from those described for Chinook Salmon temperature criteria used in this analysis are similar for the two species (Table 2).

Adult Coho Salmon upstream migration within the Klamath River occurs from approximately mid- September through January (Table 3). Results of temperature analyses show that water temperatures are cooling during the fall and winter Coho adult migration period. As a result of the seasonally cooling temperature conditions, habitat is generally suitable throughout the river under both existing conditions and hypothetical without-Project conditions beginning in approximately October and extending through January (Table 8). In general, there is very little difference in the suitability of river temperature conditions for adult Coho migration under existing and without-Project conditions (Table 8).

Coho Salmon egg incubation occurs from November through April (Table 3). Water temperature conditions during the winter and early spring are naturally low and are generally within the range considered to be suitable for Coho egg incubation. Habitat suitability criteria (Table 9) consistently show that water temperatures are typically within the range considered to be suitable for Coho egg incubation. A comparison of water temperature conditions within the Iron Gate reach show the frequency of occurrence of elevated water temperatures during the Coho egg incubation period is less under existing project operations when compared to hypothetical without-Project conditions (Table 5).

Juvenile Coho Salmon rear within freshwater rivers and tributaries throughout the year (Table 3). Klamath Hydroelectric Project operations result in cooler water temperatures during the spring and early summer months within the reach immediately downstream of Iron Gate Dam when compared to without-Project conditions. Cooler water temperatures during the spring and early summer months within the Iron Gate reach under existing project operations would *improve opportunities and conditions for juvenile Coho rearing and emigration. During the spring and summer months, water temperatures increase within the river, and differences in water temperature conditions between existing conditions and hypothetical without-Project conditions become less as a function of distance downstream from the dam (Table 10). During the mid-summer water temperatures, particularly in the lower reaches of the river, may reach levels under both existing and without-Project conditions that are considered to be highly stressful for juvenile Coho rearing (Table 10).*

Although juvenile Coho may use the mainstem Klamath River throughout the year, this analysis focuses on those fish that use the mainstem Klamath River as a migratory corridor from February through July (Table 3). Water temperature conditions throughout the Klamath River are within the range considered to be suitable for juvenile Coho Salmon emigration during the period from February through approximately mid-May (Table 10). Water temperatures during the spring and early summer months are

*Life stage ends 4/30/2001, but for the sake of including the period from 5/2/2001 through the end of the life stage, this date is also shown.

suitable: <15°C | low to moderate stress: 16-23 °C | high stress: >23 °C *colder within the reach immediately downstream of Iron Gate Dam under existing Klamath Hydroelectric Project operations. Water temperatures within the lower reaches of the river that serve as the migratory corridor for Coho Salmon are not affected by Klamath Hydroelectric Project operations.*

Steelhead

Steelhead are sensitive to exposure to elevated water temperatures. Like Coho Salmon, Steelhead primarily use the mainstem Klamath River as a migratory corridor for upstream adult and downstream juvenile movement. Spawning, egg incubation, and juvenile rearing primarily occur within the tributaries.

Adult Steelhead upstream migration within the Klamath River occurs from approximately September through November (Table 3). Results of temperature analyses show that during the adult Steelhead migration period, water temperatures are cooling during the fall and winter months. As a result of the seasonally cooling temperatures, conditions are generally suitable throughout the river under both existing and without-Project conditions beginning in approximately October and extending through January. In general, there is very little difference in the suitability of river temperature conditions for adult Steelhead migration under existing and without-Project conditions at locations in the lower reaches of the river (Table 11). As a result of the elevated water temperatures within the lower reaches of the river under both existing and without-Project conditions during September, behavior response and entry of adult Steelhead into the river would be independent of Klamath Hydroelectric Project operations.

Steelhead egg incubation occurs from December through April with fry emergence between March and June (Table 3). Water temperature conditions during the winter and early spring are naturally cool and are generally within the range considered to be suitable for Steelhead egg incubation and fry emergence (Table 12). Analysis of average weekly temperatures show that the frequency of temperatures above 12°C is greater under hypothetical without Project conditions within the Iron Gate reach when compared to existing project operations with the differences declining with distance downstream of the dam (Table 5).

During the latter part of the egg incubation period, water temperatures under existing conditions are colder than spring temperatures predicted under the without-Project scenario. Therefore, existing operations would provide better habitat conditions for Steelhead egg incubation and fry emergence within the reach immediately downstream of Iron Gate Dam (both egg viability and rate of embryonic development) when compared to without-Project conditions. Warming within the river during the spring months reduces the temperature difference between existing operations and without-Project conditions as a function of distance downstream from the dam.

Juvenile Steelhead rear within freshwater rivers and tributaries throughout the year (Table 3). As discussed above, seasonal water temperature conditions significantly affect habitat quality and availability for juvenile rearing within the mainstem Klamath River. Klamath Hydroelectric Project operations result in cooler water temperatures during the spring and early summer months within the reach immediately downstream of Iron Gate Dam under existing operations when compared to hypothetical without-Project conditions (Table 13). Cooler water temperatures during the spring and early summer months within the Iron Gate reach under existing project operations would improve opportunities and conditions for juvenile Steelhead rearing. During the spring and summer months water temperatures increase within the river and differences in water temperature conditions between existing and without-Project conditions become less as a function of distance downstream from Iron Gate Dam.

Table 11. Habitat suitability based on overage doily water temperatures for adult Steelhead migration at locations downstream from Iron Gate Dam based on 2000 and 2001 water temperature modeling results for existing conditions (EC) ond hypothetical without-Project scenarios.

Life stage ends 6/30/2000, but for the sake of including the period from 6/29/2001 through the end of the life stage, this date is also shown

suitable: <15°C	low to moderate stress: 16-23°C	high stress: >23°C

During the summer and early fall months, water temperatures throughout the river increase to a range considered a low to moderately stressful for juvenile Steelhead rearing. During the mid-summer, water temperatures may reach levels under both existing and without-Project conditions that are considered to be highly stressful for juvenile Steelhead rearing, particularly in the lower reaches of the river (Table 13). The occurrence of these high temperatures, under both existing and without-Project conditions, limits year-round Steelhead rearing within the mainstem Klamath River (perhaps with the exception of limited microhabitat areas providing coldwater refuges).

Juvenile Steelhead outmigration using the mainstem Klamath River as a migratory corridor occurs primarily during the period from March through June and potentially early July (Table 3). Water temperature conditions throughout the Klamath River are within the range considered be suitable for juvenile Steelhead emigration during the period from March through approximately mid-May (Table 13). Water temperatures during the spring and early summer months are colder within the reach immediately downstream of Iron Gate Dam under existing project operations, however temperatures within the lower reaches of the river that serve as the migratory corridor for Steelhead are independent of project operations. Under existing conditions and without-Project conditions seasonal water temperatures increase during the summer, particularly in the lower reaches of the river, where temperatures are typically within the range considered to be low to moderately stressful during June and high stress/lethal during July.

Summary

As discussed in PacifiCorp (2014), Klamath Hydroelectric Project operations and the presence of Copco and Iron Gate reservoirs do not affect temperature in the Klamath River to an extent that causes biologically significant adverse effects to anadromous fish species that use the reach downstream of Iron Gate Dam at the time of migration, spawning, and egg incubation. Copco and Iron Gate reservoirs create a thermal lag that causes Iron Gate Dam release temperature to be slightly cooler in the spring and slightly warmer during the fall than would theoretically occur in the absence of the reservoirs. However, the thermal lag effect is not detrimental, and may be beneficial, to certain life stages of Chinook, Coho, and Steelhead that use the river downstream of Iron Gate Dam. In addition, as a result of basin climatological conditions and tributary inflows in the lower basin, Klamath Hydroelectric Project operations have no effect on water temperature conditions for Chinook, Coho, and Steelhead within the lower reaches of the Klamath River. The DEIR should incorporate a similar evaluation of the Proposed Project and alternatives to allow for an accurate understanding of the Proposed Project's potential effects on salmonid use of the Klamath River.

PacifiCorp' s conclusions in this regard are support ed by other recent independent analyses. In an analysis of the effects on fall-run Chi nook of hypothetical temperature conditions with and without Klamath Hydroelectric Project facilities, Bartholow et al. (2005) concluded that water temperature *conditions for juvenile rearing life stages are better with the Klamath Hydroelectric Project dams and reservoirs in place than without, especially immediately downstream of Iron Gate Dam. In a subsequent analysis of factors limiting fall-run Chinook production potential, Bartholow and Henriksen (2006) concluded that water temperature during spawning and egg incubation is not a significant factor affecting fall-run Chinook freshwater production in the Klamath River. In the 2006 EPAct trial-type proceeding, the presiding administrative judge ruled, based on the testimony of agency fisheries experts, that existing temperatures conditions will not preclude the various life stages of anadromous fish from successfully utilizing habitat either below or above Iron Gate Dam (McKenna 2007).*

Response to Comment ORG46-18

The modeling results provided in PacifiCorp (2014) do not change EIR conclusions on potential effects on salmonid use of the Klamath River because the PacifiCorp (2014) data do not substantially differ from the data analyzed in the EIR. For additional detail, please refer to response to comment ORG46-17.

Comment ORG46-19

2.9.4 Fall-run Chinook Fry Emergence Timing and Juvenile Growth
The DEIR puts forth a hypothesis regarding the effect that changes in river temperature from the Proposed Project would have on fall-run Chinook fry emergence timing and implications regarding juvenile growth, migration timing, and stress and disease (DEIR pg. 3-272).

The DEIR analysis claims that fall-run Chinook emergence timing would be earlier with the Proposed Project compared to existing conditions. This difference in emergence timing is theorized to result because of warmer water temperatures in the spring under the Proposed Project (Figure 11). However, an inspection of the temperature data in the DEIR (see bottom panel in Figure 11 below) shows that fall water temperatures are about 2 to 5°C cooler and spring temperatures 1 to 2°C warmer for the Proposed Project compared to existing conditions. In short, the degree days lost in the fall are about 2 to 5 times higher than the degree days gained in the spring. A total of 889 degree days are required for fry emergence and is calculated from the day the fish spawned. Thus, it is a combination of fall, winter, and spring water temperature that determines fry emergence date. The DEIR in correctly looks only at the spring degree-days to conclude that emergence timing is delayed under existing conditions as compared to the Proposed Project.

Review of DEIR Analysis

While text presented throughout the DEIR claims an earlier fry emergence timing for fall-run Chinook under the Proposed Project, the data (Figure 11) do not support such an assertion. In fact, the data indicate emergence timing is later for fish spawning on similar dates for the Proposed Project compared to existing conditions. For example, a dot ted line in the middle panel of Figure 11 shows *that under the Proposed Project there are about 120 days to emergence, compared to 60 days for existing conditions for fish spawning mid-September. This results in fry emergence dates of January (Proposed Project) and November (existing conditions) (Figure 11, top panel). This relationship (i.e., later emergence date for Proposed Project) holds for fish spawning until about late November, when emergence date becomes similar for the two alternative, with emergence timing being marginally earlier for the Proposed Project.*

What is unclear in the DEIR, is the meaning of the solid lines in the days to emergence and emergence date panels (Figure 11 middle and top panels). No explanation is provided in the DEIR text as to what the lines denote. Perry et al. (2011), the reference to which this figure is linked, has temperature data but nothing on emergence timing. It is unclear from the DEIR how this figure was actually derived or if Perry et al. (2011) is even the correct source.

Emergence Timing Analysis

Because data from graphs are difficult to precisely interpret and the source material does not contain an adequate explanation, water temperature data for 2004 (an average water year) were used to perform a similar emergence timing analysis in order to verify the conclusions made from interpreting Figure 11. The results of this analysis show fall-run Chinook fry emergence timing is earlier under existing conditions for spawn dates between September 1 and December 1. After this date, emergence timing is predicted to be earlier for the Proposed Project (Table 14). Using data from 2004 and 2006 water years and the same type of analysis generates similar results.

For emergence timing under the Proposed Project to be similar to existing conditions, fall-run Chinook spawning must be approximately 2 to 3 weeks earlier for the Proposed Project. For example, fish spawning on September 29 in the Proposed Project would have about the same fry emergence timing as fish spawning between October 13 and 20 under existing conditions (Table 14). Even with similar fry emergence timing, river temperatures would be warmer at emergence for the Proposed Project.

Whether fall-run Chinook migration or spawn-timing changes under the Proposed Project would be highly dependent on resulting fall stream temperatures. Cooler stream temperatures in the fall should equate to earlier adult migration timing as conditions become more favorable for earlier arriving fish.

However, while the DEIR indicates that stream temperatures in the fall at Iron Gate Dam for the Proposed Project would be cooler, water temperatures would remain largely unchanged downstream of the Scott River (RM 143) through the Klamath Estuary and into the marine near shore environment. Because stream temperatures in the lower river are not affected by the Proposed Project, it is highly uncertain that adult run-timing would change dramatically for fall-run Chinook because they would still encounter warm water temperatures in the *lower Klamath River as they do currently. These conditions, which currently limit upstream migration timing and cause fish to hold in the lower river, would persist under the Proposed Project.*

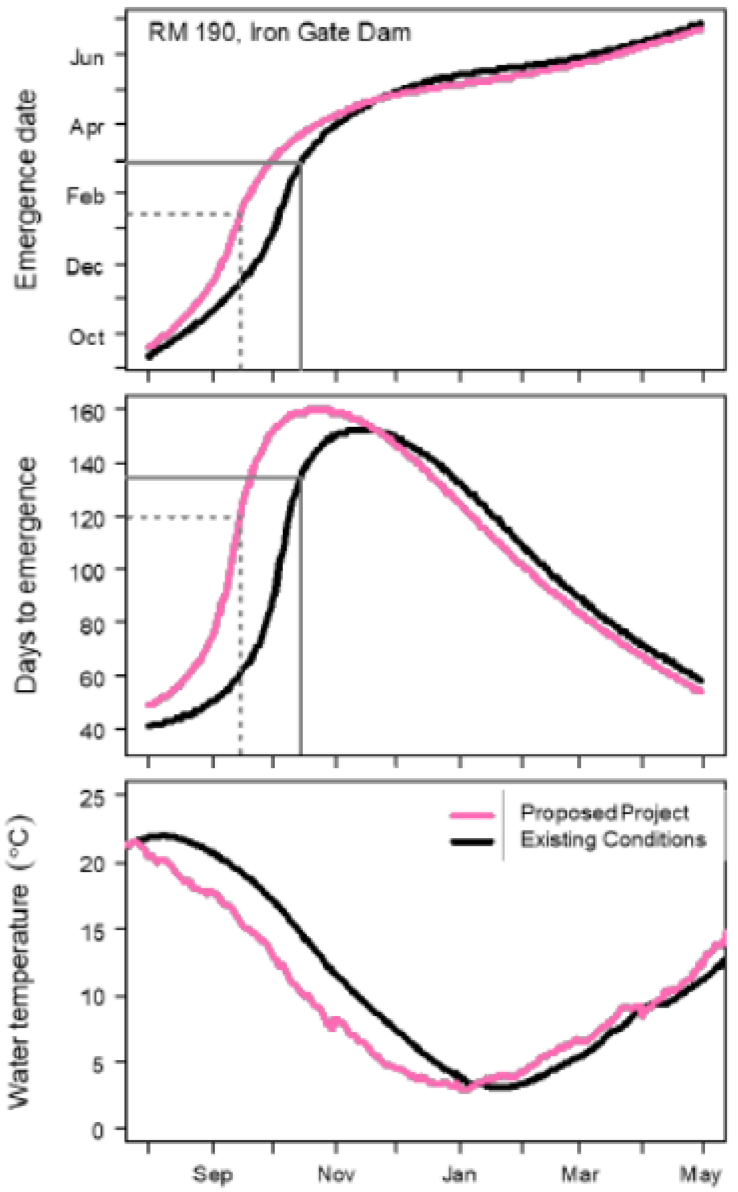

Figure 11. Perry et al. (2011) Modeled Time Series of Average Daily Mean Water Temperature (lower panel) Predicted at Iron Gate Dam (RM 193.1) Under the Proposed Project and existing conditions. Days to emergence (middle panel) and date of emergence (upper panel) for fall-run Chinook Salmon was estimated as a function of spawning date assuming that emergence would occur at 889 degree days (accumulated heat related to development) after spawning (Perry et al. 2011). (Reproduction of DEIR Figure 3.3-4, pg. 3-274).

*Table 14. Spawning date versus emergence timing for the existing conditions and Without Dams (represents Proposed Project alternative) where green cells indicate the alternative with earlier emergence timing.**

	Existing Conditions		Without-Project	
Spawning Date	Emergence Date	#Days	Emergence Date	#Days
1-Sep	19-Oct	49	11-Nov	72
8-Sep	30-Oct	53	13-Dec	97
15-Sep	12-Nov	59	28-Jan	136
22-Sep	28-Nov	68	21-Feb	153
29-Sep	24-Dec	87	11-Mar	164
6-Oct	2-Feb	120	23-Mar	169
13-Oct	13-Mar	152	3-Apr	173
20-Oct	28-Mar	160	10-Apr	173
27-Oct	8-Apr	164	14-Apr	170
3-Nov	16-Apr	165	19-Apr	168
10-Nov	24-Apr	166	23-Apr	165
17-Nov	30-Apr	165	27-Apr	162
24-Nov	4-May	162	29-Apr	157
1-Dec	8-May	159	1-May	152
8-Dec	11-May	155	1-May	145
15-Dec	14-May	151	3-May	140
22-Dec	16-May	146	5-May	135
29-Dec	17-May	140	6-May	129

*Analysis assumes 889-degree days from spawning to emergence. The without-Project data set is from PacifiCorp's (2014) Without Project (WOP) 2004 temperature data.

<u>Disease</u>

Assuming the fry emergence timing analysis above is correct, the statements in the DEIR regarding temperature effects of fish disease on juvenile salmon need to be revisited. For example, water temperatures for the Proposed Project are warmer in the spring than for existing conditions which means losses resulting from C. shasta may also be higher for the Proposed Project as compared to existing conditions simply because of the difference in water temperature (See Major Issue 2.8)

<u>Juvenile Growth</u>

The DEIR (pg. 3-272) states that juvenile Chinook growth rates would be higher for the Proposed Project and this would encourage earlier juvenile outmigration *compared to existing conditions. This statement is correct only when Chinook fry emergence timing is the same; as was discussed above, fry emergence timing is not the same for the Proposed Project as compared to existing conditions (Table 14). Fall-run Chinook fry emergence is earlier for existing conditions for the same spawn date through December 1. Thus, although spring water temperatures are warmer for the Proposed Project, Chinook fry may have up to 30 more days to grow under existing conditions.*

<u>Conclusion</u>
The analysis of fall-run Chinook fry emergence timing and growth for the Proposed Project, existing conditions, and all alternatives to the Proposed Project should be rerun. Once this analysis is complete, the discussion and conclusions in the DEIR need to be reevaluated to accurately present the potential impacts of the Proposed Project and the alternatives in relation to existing conditions. As it stands, the DEIR analysis is incorrect and does not support the conclusions in the DEIR that water temperature changes as a result of the Proposed Project will benefit Coho, Chinook, and Steelhead.

Response to Comment ORG46-19
The EIR considers fall-run Chinook salmon emergence timing under the Proposed Project in Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation –Water Temperature*, including Figure 3.3-4. The analysis does not look only at spring-degree days in relation to fry emergence, but it considers a variety of factors that affect emergence timing, including fall river water temperatures.

The Federal Energy Regulatory Commission (FERC) 2007 Environmental Impact Statement (EIS) concluded that without J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, more rapid cooling of river water temperatures in the fall may also allow for fall Chinook salmon spawning to occur earlier in the fall. This, in turn, would likely result in earlier emergence and growth, and encourage earlier emigration. Contrary to the PacifiCorp comment, the EIR does not claim that earlier spawning timing would necessarily result in earlier migration timing.

Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature – Middle and Lower Klamath River* has been revised to clarify the analysis presented in Figure 3.3-4 and the caption was revised to clarify the solid and dashed lines, and source data. Please refer to Volume III Attachment 1 Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature – Middle and Lower Klamath River* for the revisions.

<u>**Comment ORG46-20**</u>

- *The DEIR Lacks Over all Clarity. The DEIR does not comply with CEQA's requirements that Environmental Impact Reports (EIRs) be organized and written in a manner that will make them "meaningful and useful to decision makers and to the public," (Pub . Res. Code§ 21003 (b)) and that EIRs be* *written in plain language and drafted to be understandable to decision-makers and the public (14 Cal. Code Regs. § 15140; 15147). Throughout the DEIR, the data and information is not presented in a manner designed to adequately inform the public and decision-makers.*

A non-exhaustive list of examples of this problem include:

- *In Section 2 of the DEIR, the project description presents 'dam removal year 1' as being up through December 2020 and 'dam removal year 2' starts in January 2021. Actual removal of facilities is currently scheduled to take place in 2021. As the DEIR discusses impacts in terms of 'dam removal year 1' or 'dam removal year 2', it is easy to get confused about when an event might actually happen. This confusion is compounded in the effects analysis for example, where the DEIR discusses the end of hatchery supplementation in 'post dam removal' year 7, which is presumably 'dam removal year 2' plus 7 years (DEIR pg. 3- 315). Another example of this can be found in Section 3.4.3 (DEIR pg. 3-422) where "short-term" and "long-term" are defined as: "This period [short-term] corresponds to pre-dam removal years 1 and 2, dam removal year 1, dam removal year 2, and post-dam removal year 1 (Table 2.7-1). Long-term is defined as occurring after post-dam removal year 1 (i.e., greater than three years after dam removal begins)." Terminology such as this will confuse the public and decision-makers and should be clarified in the recirculated DEIR; it would be much clearer to use calendar years.*
- *The discussion of cultural resources is so vague and non-specific that it is impossible to tell if the resources potentially affected by the Proposed Project are accurately described. PacifiCorp recognizes the extremely sensitive nature of these resources. There are, however, ways to present information in such a manner that readers understand that the impact analysis was performed correctly and understand the magnitude of the impact.*
- *The analysis of impacts to Chinook and Coho are presented in terms of percent increased mortality with no discussion of population sizes (Appendix Tables E-8 and E-1 0). The impacts to Steelhead however, are presented in actual numbers of fish (Appendix Table E-12). There is an abundance of population data for Chinook and Coho that is not included or considered in the DEIR, which when added in a recirculated DEIR, would allow an analysis to be done in a manner similar to that for Steelhead. By failing to do this analysis, the DEIR disguises the actual effects of the Proposed Project in percentages that the reader is not able to connect to actual populations-particularly populations of Coho that are exceptionally small.*
- *The definition of "short-term impacts" in Section 3.3 Aquatic Resources, is 5 years. In Appendix F, which discusses potential impacts of bedload transport of sediment to aquatic resources, the short-term period is 2 years. Similarly, Section 3.2 Water Quality uses a 2-year period as short*

> *term. The disparity in these timeframes makes the connection between the analysis in one section of the DEIR and the analysis in another extremely difficult to follow. For example, the effects analysis in Section 3.3 discusses short-term impacts to fish from bedload transport and references Appendix F which covers two of these years. The DEIR does not explain what happens in the three extra short-term years necessary to meet the definition of short term in Section 3.3. As a result, the reader' s ability to understand short-term impacts (i.e., Proposed Project impacts occurring over a consistently defined period of years) is compromised.*

Response to Comment ORG46-20

The Lower Klamath Project EIR meets the requirements of Public Resources Code section 21003, subdivision (b), which states that an EIR should be organized and written in a manner that will be meaningful and useful to decision makers and to the public. The EIR contains a list of its contents, including sections to third-level headings, all figures, tables, and appendices; a key for acronyms and abbreviations; an executive summary; an introduction section that plainly and succinctly describes the authorization, purpose, and use of EIR, an overview of the scope and content of the EIR, and summaries of the public process, public involvement, and agency consultation during preparation of the EIR; a detailed description of the Proposed Project and a discussion of the intended uses of the EIR; a thorough analysis and discussion of the environmental resources that may be affected by the Proposed Project, including potential cumulative effects, where each environmental resource area analyzed includes five parts (Area of Analysis, Environmental Setting, Significance Criteria, Impact Analysis Approach, Potential Impacts and Mitigation); a discussion of the alternatives selection process and a detailed analysis of each of six alternatives to the Proposed Project; and numerous technical appendices that present additional, supporting information.

Further, the Lower Klamath Project EIR meets the requirements of CEQA Guidelines section 15140, which states that EIRs shall be written in plain language and may use appropriate graphics so that decision makers and the public can rapidly understand the documents. There are approximately 250 figures in the EIR, many of which were developed to assist the reader in understanding complex scientific concepts (e.g., Figure 2.7-1 depicting the dam removal schedule and the distribution and life-history timing of aquatic species in the Klamath Basin; Figure 3.2-2 depicting the general seasonal pattern of physical, chemical, and biological processes in reservoirs such as the Lower Klamath Project reservoirs, where these processes are relevant to the impact analyses; Figure 3.3-2 and Figure 3.3-3 depicting the lifecycles of organisms that cause fish disease*;* Figure 3.4-10 depicting the transport of blue-green algae from the Upper Klamath Lake into the Upper Klamath River, which is relevant to the impact analyses). Where technical terms must be used in the EIR to succinctly and accurately support the analyses, the technical terms are defined at first use, using parenthetical definitions for short statements, and footnotes for longer statements.

The Lower Klamath Project EIR also meets the requirements of CEQA Guidelines section 15147 regarding technical detail, which states that information contained in an EIR shall include summarized technical data, maps, plot plans, diagrams, and similar relevant information sufficient to permit full assessment of significant environmental impacts by reviewing agencies and members of the public. Of the roughly 200 figures in the EIR, many are maps and schematics that convey spatial information relevant to the EIR analyses in a clear and concise manner. Highly technical and specialized analysis and data (e.g., modeling results) are presented in Volume II of the Lower Klamath Project EIR, which contains the EIR scoping report (Appendix A), the Klamath River Renewal Corporation's (KRRC's) Definite Plan (Appendix B), and nineteen technical appendices, along with excerpted Tribal Trust information and additional information incorporated by reference.

With respect to the comment's assertion that the approach to presenting the facilities removal schedule in the EIR is confusing, because the proposed dam removal activities would span two calendar years, with construction activities (e.g., recreation area facilities removal, power generation facilities removal at Copco No. 1, modifications to dam diversion tunnels) occurring prior to actual dam removal and early drawdown of Copco No. 1 Reservoir beginning prior to drawdown of the other reservoirs, the terminology "dam removal year 1" and "dam removal year 2" are used in the EIR to indicate the anticipated timeframe for removal. Volume I Section 2 *Proposed Project* Table 2.7-1 (page 2-27) presents the proposed Lower Klamath Project schedule and defines the proposed project activities as pre-dam removal years 1−3, dam removal year 1, dam removal year 2, and post-dam removal years 1 through 10, as informed by the KRRC's Definite Plan. Table 2.7-1 is referenced in numerous locations throughout the EIR impact analyses, as appropriate. The aquatic resources analysis also contains a resource-specific schedule that ties the impact analysis to the dam removal years in Table 2.7-1 (i.e., Table 3.3-11 presents the timing of hatchery releases and adult returns under the Proposed Project using the dam removal year terminology). Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

With respect to the comment regarding the use of 'dam removal year 1' and 'dam removal year 2' terminology rather than calendar years, the 'dam removal year' terminology does not tie the EIR analyses to particular calendar years, which may change as the Proposed Project process continues. For example, in 2019, following issuance of the Draft EIR, the KRRC indicated that the project schedule has shifted by a year such that dam removal pre-construction actions would occur May–December 2021 and reservoir drawdown, construction, and mitigation actions would be completed in 2022. Minor updates have been made to Table

2.7-1 based on the information provided in KRRC (2019b); these updates are presented in Volume III Attachment 1 Section 2 *Proposed Project*.

With respect to the comment's assertion that the discussion of cultural resources is vague and non-specific, the EIR presents the available public information characterizing tribal cultural resources in an effort to help the public and decision-makers understand the conclusion that particular impacts under the Proposed Project would be significant and unavoidable (Public Resources Code section 21082.3, subdivision (b)). Any apparent non-specificity or vagueness in the cultural resource descriptions contained within the EIR is a necessary consequence of the need to maintain confidentiality regarding these resources, as CEQA requires (Public Resources Code section 21082.3, subdivision (c)). Please also refer to responses to comments ORG46-292 to ORG46-304. Volume III Attachment 1 presents the final Section 3.12 *Historical Resources and Tribal Cultural Resources*.

With respect to the comment's assertion that the use of percent increased mortality for characterizing the potential effects of dam removal on fish species is not appropriate, please refer to response to comment ORG46-504.

With respect to the comment regarding the varying definitions of short term in the water quality and aquatic resources analyses, please refer to responses to comments ORG46-30 and ORG46-199. Please note that Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* has been revised to clarify the definition of short-term effects. Please refer to Volume III Attachment 1 Section 3.5.4 *Terrestrial Resources – Impact Analysis Approach* for the revisions.

Comment ORG46-21

- *The DEIR Relies on Out of Date Information. The Klamath Basin is a data rich environment. The DEIR background and analyses, however, does not rely on recent data; instead, it relies on older information prepared in the FERC (2007) EIS and the KHSA 2012 EIR/ EIS (DOI and CDFW 2012) that was developed in connection with the Secretarial Determination. There has not been a consistent effort made to present an up-to-date analysis of potential impacts based on the best available data and information. CEQA requires adequate information to ensure that "decisions be informed, and therefore balanced" (Association of Irritated Residents v. County of Modero (2003) 107 Cal. App. 4th 1383, 1398; see also North Coast Rivers Alliance v. Mar in Municipal Water Dist. Bd. af Directors (2013) 216 Cal. App. 4th 614, 642-643).*

  A non-exhaustive list of examples of this issue include:

  - *The stream flow data relies on KBRA flow data and does not take in to account mandatory flows being implemented by the USBR under its 2013 BiOp {NM FS and USFWS 2013). Even the information in the*

DEIR shows that these flows are quite different in some months (see DEIR Figures 3.1-1 and 3.1-2) (See Major Issue 2.2). Data reflecting actual mandatory flows should be used.

- *The DEIR does not reference any of the information and extensive analysis presented in PacifiCorp's (2014) Section 401 Water Quality Certification application for the Klamath Hydroelectric Project. The State Water Board should focus on incorporation of the up-to-date water quality modeling which includes results for water temperatures, dissolved oxygen, nutrients, pH, and other constituents, for Existing Conditions and without-Project conditions as presented in PacifiCorp (2014). PacifiCorp' s application is being provided electronically to the State Water Board with these comments.*
- *The DEIR only includes selective elements from the water quality analysis and data collected under the comprehensive water quality monitoring effort conducted under the KHSA Interim Measure 15 program. The Interim Measure 15 program was developed specifically to inform water quality analysis related to dam removal, is readily available on PacifiCorp's Klamath Hydroelectric Project website2 and is annually updated. All of the Interim Measure 15 data is being provided electronically to the State Water Board with these comments.*
- *The aquatic resources section does not include up-to-date information relating to the status of the Coho Salmon population in the upper Klamath River. Specifically, there is no mention of the annual reports prepared for Iron Gate Hatchery, the Scott River, Shasta River, or Bogus Creek, or the results of Coho spawning surveys on the tributaries between Iron Gate dam and Portuguese Creek which PacifiCorp has been conducting annually since 2015 (see CDFW 2018a , 2018b; Knecht le and Giudice 2018b; MKWC 2016, 2017, 2018; Chesney and Knechtle 2017; Knecht le and Chesney 2017).*
- *It is not clear if the data regarding cultural resources potentially affected by the Proposed Project was updated to reflect the field work conduct ed by the KRRC over the last 2 years.*
- *The recreational use data cited in the DEIR is from 2007, while the Definite Plan provided by the KRRC (see DEIR Appendix B) provides data from 2015. Similarly, use data for whitewater boating used in the DEIR is from 2011 or 2007 when annual data is readily available from the Bureau of Land Management.*

Response to Comment ORG46-21

In compliance with CEQA requirements, the EIR has made a consistent effort to present up-to-date analyses based on the best available data and information.

The statement in the comment that the Draft EIR does not take into account the 2013 Biological Opinion (BiOp) Flows is incorrect. The Draft EIR presents a detailed discussion of the 2013 BiOp Flows in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, and Section 3.1.6.2

Comparison of Klamath River Flows under 2013 BiOp Flows and KBRA Operations Criteria discussed why the hydrologic model outputs previously developed using the Klamath Basin Restoration Agreement (KBRA) Flows for the 2012 KHSA EIS/EIR are sufficient to estimate conditions under 2013 BiOp Flows. Please also refer to responses to comments ORG46-6, ORG46-24, ORG46-24.1, ORG46-25, ORG46-82, ORG46-203, and ORG46-215.

The statement in the comment that the Draft EIR does not reference any information presented in PacifiCorp's 2014 Section 401 Water Quality Certification application for the Klamath Hydroelectric Project (KHP) is incorrect. Please refer to the numerous references to PacifiCorp's current Reservoir Management Plan (Plan), and reports cited within the Plan, in Section 3.2 *Water Quality* and the water quality-related subsections of the No Project Alternative (Volume I Section 4.2) and the Continued Operations with Fish Passage Alternative (Volume I Section 4.4). Volume III Attachment 1 presents the final Section 3.2 *Water Quality*. The water quality modeling reported in PacifiCorp's 2014 Section 401 Water Quality Certification application for the Klamath Hydroelectric Project does not appear to use the 2013 BiOp Flows as the basis for Klamath River hydrology.

With respect to water quality data collected under the Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM15) program, please refer to Master Response WQ-4. As noted, the IM15 data was reviewed for the EIR, and does not present a general departure from previous data sets. The IM15 data was added to prior data analyses, figures, and tables where the IM15 data provided additional information. However, in many instances, consideration of the new data did not warrant changes to existing analyses, figures, or tables.

Regarding the status of the coho population in the Upper Klamath River, please refer to responses to comments ORG46-159 and ORG46-187.

The comment does not specify which field work conducted by the Klamath River Renewal Corporation (KRRC) over the last two years is of concern. Given that PacifiCorp's comment was submitted in 2019, the State Water Board presumes that PacifiCorp is referring to field work conducted during 2017 and/or 2018. As noted in Section 6.2.2 of Appendix L of Appendix B: *Definite Plan*, disposal site areas within the Limits of Work that were not previously surveyed were subject to pedestrian surveys by KRRC in 2017. More specifically, in July 2017, KRRC conducted a cultural resources pedestrian survey inventory of approximately 27 acres at the Iron Gate Dam disposal site. The inventory identified one historic-period archaeological site (LKP-RB-1) and one historic-period isolated find (LKP-EN1-IF). The State Water Board is unaware of additional field work efforts by KRRC in the last two years.

Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of* *the Proposed Project – Summary of California Historical Resources Information System Record Searches*, including Table 3.12-1, has been revised to clarify that these two sites were identified in the 2017 pedestrian survey. Please refer to Volume III Attachment 1 Section 3.12.2.3 *Historical Resources and Tribal Cultural Resources – Environmental Setting – Known Tribal and Historical Resources in the Vicinity of the Proposed Project – Summary of California Historical Resources Information System Record Searches* for the revisions.

Please also refer to Volume III Attachment 1 Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* Potential Impact 3.12-12, which analyzes pre-dam-removal activities that involve disturbance of the landscape, including activities at disposal sites among other locations within the Limits of Work, and Potential Impact 3.12-16, which analyzes ground disturbance associated disposal site restoration along with other sites within the Limits of Work. The two historic-period sites noted above are included in the EIR analyses.

Please note that not all of the required cultural resources inventory and significance analyses will be completed prior to certification of this EIR. Please refer to the introductory paragraphs of Section 3.12 *Historical Resources and Tribal Cultural Resources*. Volume III Attachment 1 presents the final Section 3.12 *Historical Resources and Tribal Cultural Resources*. Please also refer to response to comment LA9-73. Additionally, as stated in Volume I Section 2.7.8.5 *Proposed Project – Proposed Project – Other Project Components – Cultural Resources* (page 2-95), KRRC is preparing a Cultural Resources Plan (Volume II Appendix B: *Definite Plan – Appendix L*) that would identify the cultural resources studies that KRRC has completed, those that are currently ongoing, and others that KRRC anticipates completing in order to comply with regulatory requirements under Section 106 of the National Historic Preservation Act and California Assembly Bill 52.

With respect to available recreational data, information requests were submitted to corresponding facilities and reservoir representatives (e.g., PacifiCorp, California Department of Fish and Wildlife [CDFW], and Bureau of Land Management [BLM]) to obtain the most recent recreational data for Section 3.20 *Recreation* and related analyses in the EIR. Where available, updated information has been added to the EIR. The additional data do not constitute significant new information (CEQA Guidelines section 15088.5(a)). Please also refer to responses to comments ORG46-332 to ORG46-342.

<u>Comment ORG46-22</u>

- *Modifying Language Contained Throughout the DEIR May be Interpreted as Bias towards Certain Outcomes and Conclusions. The DEIR presents information that is misleading, based on opinion without adequate factual or technical support, may be interpreted as suggesting a bias towards certain outcomes and conclusions, and fails to adequately inform the* *public and decision-makers about the environmental consequences of the Proposed Project. This conflicts with CEQA' s policy that EIRs "provide decision makers with information that enables them to make a decision which intelligently takes account of environmental consequences" (14 Cal. Code Regs. § 15151). CEQA requires that an EIR contain facts and analysis, not just an agency' s bare conclusions or opinions (Citizens of Goleta Valley v. Board of Supervisors (1990) 52 Cal. 3d 553, 568), and should, when looked at as a whole, provide a reasonable, good faith disclosure and analysis of potential environmental impacts (Laurel Heights Improvement Ass' n v. Regents of Univ. of Cal. (1988) 47 Cal. 3d 376; California Oak Found. V. Regents of Univ. of Cal. {2010} 188 Cal. App. 4th 227, 269)). An EIR must state the bases for its findings; a bare conclusion regarding an environmental impact without an explanation of its factual and analytical basis is not sufficient (Laurel Heights, supra at 404; Whitman v. Board of Supervisors (1979) 88 Cal. App. 3d 397; People v. County of Kern (19 74) 39 Cal. App . 3d. 830, 841; see also 14 Cal. Code Regs. § 15151).*

A non-exhaustive list of examples of this problem include:

- *In the discussion of screening criteria for chemical contamination, the ecological and human health-based screening levels are intermingled, and it is impossible to tell which is being discussed (DEIR pg. 3-42).*
- *The DEIR references the "current degraded condition" without specifically defining what degraded means or analyzing the meaning or significance of the term (DEIR pg. ES-24).*
- *The DEIR dismissively states that "...some commenters indicated their belief that the Lower Klamath Project reservoirs improve water quality by serving as a sink for phosphorus..." (DEIR pg. 3-14). The fact that Copco and Iron Gate reservoirs are nutrient sinks is not a belief; but rather a fact that the DEIR acknowledges on page 3-27 (See also Kann and Asarian 2007; Asarian and Kann 2005; Asarian et al. 2009). The DEIR provides no analysis of the potential impact of increased nutrient delivery to the Klamath River downstream of Iron Gate Dam, or, importantly, to the estuary after the reservoirs are drawn down.*
- *The DEIR states that "(o]n an annual basis, the majority of nutrients entering a reservoir from a watershed are eventually discharged downstream, with only a small fraction being retained in the reservoir sediments" (DEIR pg. 3 -20). The "only a small" modifier is unsubstantiated and unexplained, and should be replaced with the actual quantity of retention in both the percent of annual loading and mass (in tons).*
- *The DEIR states that "[s]tress associated with high water temperatures can make cold water species more vulnerable to disease and parasites, and have been associated with fish kills in the Klamath River downstream of Iron Gate Dam during low flow periods in late*

summer..."(DEIR pg. 3-236). This sentence misconstrues the effects of Iron Gate Dam on water temperature and in correctly relates the existence of Iron Gate Dam to fish kills in the Klamath River. Taken individually, the various components of this sentence are true: warmer water does make fish more susceptible to disease, disease and parasites have been associated with fish kills in the Klamath River, and the fish kills have occurred downstream of Iron Gate Dam. However, this information is presented in a way to lead the reader to believe that Iron Gate Dam has resulted in fish kills, which is incorrect. Analysis of the 2002 fish kill does not specifically attribute effects from Klamath Hydroelectric Project facilities on the key factors considered to have caused the fish kill (i.e., large returns of Chinook, low flows, warm water temperatures, the pathogens lchthyophthirius and Columnaris) over 150 miles downstream of Iron Gate Dam (CDFG2004).

- *Regarding gravel augmentation downstream of Iron Gate Dam per the Coho Habitat Conservation Plan, the DEIR (pg. 3-235) states that "...details on the extent of downstream movement have not been reported." This statement implies monitoring of gravel placed into the Klamath River was a requirement of the project that was not met. However, downstream movement monitoring was not a requirement of the project, although mobilization of the gravel from its placement site has been reported consistent with the project objectives and gravel monitoring plan established for this work.*
- *Regarding populations of polychaetes, the DEIR (pg. 3-242) states that "abundant polychaete populations that are found in atypically stable habitats." Polychaetes are found in stable and unstable stream habitat and there is nothing atypical about either of these habitat types.*

Response to Comment ORG46-22

The comment addresses the commenter’s disagreement with the use of terminology or presentation of information in the Draft EIR. The use of terms and presentation of information in the EIR is intended to enable decisionmakers and the public to understand the factors that have contributed to the existing environmental condition, and how the Proposed Project and the various alternatives would alter the existing condition. In addition, because the EIR is intended to inform the State Water Board’s decision with respect to potential issuance of a water quality certification for the proposed project under the federal Clean Water Act, the terms and presentation of information are intended to convey the effect of the Proposed Project and various alternatives on water quality at a general level, not just with reference to changes to the existing condition. This is particularly important because the Proposed Project is a restoration project intended to improve the environment over the existing condition in the long term. To accomplish these goals, the EIR uses modifying terms that assist a lay reader’s understanding of the available data. Terms such as “small” or “degraded” are useful in conveying the import of raw data numbers. Although some parties might argue with a specific use of terminology or prefer that information be presented in different ways, the EIR provides the information that allows the public to understand the connection between the existing evidence and the selected action.

Regarding sediment screening criteria, please refer to response to comment ORG46-115.

With respect to use of the phrase "current degraded condition" in Volume I *Executive Summary – Issues to be Resolved* (paragraph 2, page ES-24), the text has been revised to provide additional context for use of this phrase. Please refer to Volume III Attachment 1 *Executive Summary* for the revisions.

Regarding the comment's assertion that use of the term "belief" is problematic in the referenced sentence, please note that each environmental resource area analyzed in Section 3 for the Proposed Project begins with a summary of public comments received during the scoping process for the Lower Klamath Project and in that context it is appropriate to use the term belief. The comment is correct that the Draft EIR cites the scientific literature regarding nutrient retention in the reservoirs. The comment's assertion that the Draft EIR does not analyze the potential impacts of increased nutrient transport to the Middle and Lower Klamath River and the Klamath River Estuary is incorrect; please refer to Section 3.2.5.8 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-7 and Potential Impact 3.2-8 for analysis of the potential short-term and long-term effects of dam removal on nutrient transport. Volume III Attachment 1 presents the final Section 3.2 *Water Quality*. Please also refer to Volume I Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impact 3.4-3 for a discussion of the potential for short-term increase in growth of nuisance periphyton species due to increases in sediment-associated nutrients from release of sediments currently trapped behind the Lower Klamath Project dams (pages 3-433 to 3-435), and Potential Impact 3.4-4 for a discussion of potential alterations in growth of nuisance periphyton species in the Hydroelectric Reach due to increased nutrients and available low-gradient channel margin habitat formed by conversion of the reservoir areas to a free-flowing river and the elimination of hydropower peaking operations (pages 3-435 to 3-437). Please also refer to response to comments ORG46-139, ORG46-140, ORG46-142, ORG46-143, ORG46-145, and ORG46-267.

With respect to the "only small" modifier mentioned in the comment, please refer to responses to comments ORG46-88, ORG46-97, ORG46-98, and ORG46-381.

Regarding the comment's assertion that the Draft EIR misconstrues the effects of Iron Gate Dam on water temperature as related to fish kills in the Klamath River, please refer to response to comment ORG46-174.

With respect to the comment regarding gravel augmentation and PacifiCorp monitoring activities, Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Bed Elevation and Grain Size Distribution* has been revised for clarity. Please refer to Volume III Attachment 1 Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Bed Elevation and Grain Size Distribution* for the revisions.

With respect to the use of the term "atypically" to describe preferred riverine habitat for polychaetes, please refer to response to comment ORG46-183.

Please refer to responses to comments ORG46-98, ORG46-380, ORG46-447, ORG46-453, and ORG46-465, which discuss use of the modifier "adverse" in the Draft EIR alternative analysis.

Comment ORG46-23

- *The DEIR Should Propose Enforceable Mitigation for Significant Environmental Effects. The DEIR states that some mitigation measures are outside the State Water Board's regulatory reach but that they expect "...that the KRRC may agree to implement certain mitigation measures through good neighbor agreements or other legally enforceable mechanisms..." (DEIR pg. 3-2). An EIR must "propose and describe mitigation measures to minimize the significant environmental effects identified" (Pub. Res. Code§§ 21002.l(a), 21100(b)(3;) 14 Cal. Code Regs § 15126.4), and mitigation measures adopted by the agency must be fully enforceable through permit conditions, legally enforceable agreements, or other measures (Pub. Res. Code§ 21081.6; 14 Cal. Code Regs. § 15126 .4(a)(2); see also Pub. Res. Code§§ 21002.l (a), 21100(b)(3); 14 Cal. Code Regs§ 15126.4; ..." Tracy First v. City of Tracy (2009) 177 Cal. App. 4th 912, 937).*

  Additionally, the DEIR concludes that numerous impacts of the Proposed Project are significant and unavoidable, but lacks a consistent discussion regarding why mitigation is not feasible or why an impact is considered unavoidable. The DEIR should set forth the bases for its findings on a project's environmental impacts, and contain an explanation of the reasoning and evidence supporting the DEIR's impact findings (Association of Irritated Residents v. County of Madero (2003) 107 Cal. App. 4th 1383; Napa Citizens for Honest Gov' t v. Napa County Bd. of Supervisors (2001) 91 Cal. App. 4th 342, 359).

  A non-exhaustive list of examples of the problems presented above include:

  - *Recommended, but non-enforceable, mitigation measures are explicitly called out in Section 3.5 Terrestrial Resources in*

Recommended Measures TER-1 through TER-12; Section 3.17 Public Services in Recommended Measure PS-1; Section 3.22 Transport ation and Traff ic in Recommended Measure TR-1.

- *Mitigation Measure WSWR-2, which requires the KRRC to relocate the City of Yreka's water supply pipeline, may have environmental effects of its own that are not analyzed in the DEIR (beyond a brief discussion of construction-generated noise and vibration) per the requirements of Pub. Res. Code Regs. § 15126.4(a)(1)(D).*
- *In Section 3.11 Geology, Soils, and Mineral Resources, Mitigation Measure GE0-1, requires the KRRC to monitor slopes and implement any necessary slope stabilization measures (including roads, structures, etc.). Slope stability for water quality protection may be within the State Water Board's jurisdiction, but roads, structures, and other infrastructure are clearly outside the State Water Board's jurisdiction.*
- *In Section 3.12 Historical Resources and Tribal Cultural Resources, Mitigation Measures TCR-6, TCR-7, and TCR-8 are clearly beyond the State Water Board's ability to enforce.*
- *In Section 3.17 Public Services, Potential Impact 3.17-1 is listed as being potentially significant and unavoidable with mitigation, yet no mitigation is included in the DEIR (DEIR pg. 3-913 to 3-915).*
- *Examples of significant and unavoidable impacts that do not include a discussion of potential mitigation measures or any reasoning as to why that mitigation is not feasible include but are not limited to:*
  - *Impacts 3.23-1, 2, 4, 5, and 6 which all relate to noise levels associated with working two shifts during facilities removal. Mitigation would appear to be feasible by simply scheduling work to occur during normal daytime hours, but the DEIR simply calls the impact significant and unavoidable without any reasoning.*
  - *Impact 3.11-5 regarding deposition of sediment downstream of Iron Gate Dam provides no reasoning for why the impact is considered unavoidable.*
  - *Impact 3.2-3 regarding suspended sediments released by the Proposed Project throughout the Klamath River provides no reasoning for why the impact is considered unavoidable. Mitigation through a slower drawdown or a phased multi-year removal could be considered as a potential mitigation measure to reduce sediment concentrations released into the river.*
  - *Impact 3.2-9 regarding potentially low levels of dissolved oxygen downstream of Iron Gate Dam following removal and release of sediments is categorized as significant and unavoidable with no discussion of potential mitigation. The analysis indicates that reaeration alleviates the impact naturally at points downstream of the Salmon River (RM 65), but does not discuss the possibility of artificial aeration at upstream locations or why this is not feasible.*

Response to Comment ORG46-23
With respect to the comment's general assertion that the Draft EIR does not comply with Pub. Res. Code sections 21002.1(a) and 21100(b)(3) and 14 Cal. Code Regs section 15126.4, please refer to Master Response CEQ-2 for a discussion of the scope of Federal Power Act preemption and how the EIR applied that principle to responsible agencies and to Recommended Measures and Mitigation Measures.

With respect to the comment's general assertion that the EIR needs more discussion regarding why mitigation is not feasible or why an impact is considered unavoidable, please see the responses below to the bulleted list of examples provided by PacifiCorp in its comment, as well as responses to comments ORG46-38, ORG46-73, ORG46-303, and ORG46-306. The comment indicates that the list of examples is "non-exhaustive"; however, CEQA does not require the Lead Agency to speculate regarding other possible examples that the commenter may have intended to include in the comment.

Regarding recommended measures TER-1 through TER-12, PS-1, and TR-1, please refer to Master Response CEQ-2.

With respect to the comment's assertion that Mitigation Measure WSWR-2 does not meet the requirements of CEQA Guidelines section 15126.4(a)(1)(D), please note that relocation of the City of Yreka water supply pipeline after drawdown of Iron Gate Reservoir is included in the set of primary construction activities under the Proposed Project, as described in Volume I Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* (pages 2-84 to 2-86). The potential impacts of this action on water supply/water rights are analyzed in Volume I Section 3.8.5 *Water Supply/Water Rights – Potential Impacts and Mitigation* Potential Impact 3.8-4 (pages 3-682 to 3-683), which is also where Mitigation Measure WSWR-2 is presented. The purpose of Mitigation Measure WSWR-2 is to limit the water delivery outage necessary to reconnect the replacement pipe for the City of Yreka's current water supply pipeline to a maximum of 12 hours for the section of pipe that crosses Iron Gate Reservoir, and to ensure that any work the Klamath River Renewal Corporation (KRRC) undertakes with respect to the water supply intake screens and compliance with fish screen criteria would be completed within the same water delivery outage period. Mitigation Measure WSWR-2 does not propose other construction activities that would be outside of those covered under the Proposed Project, in terms of the spatial location within the Limits of Work, and with respect to the timing of construction activities that would occur during dam removal year 1 and dam removal year 2 (Volume III Attachment 1 Table 2.7-1).

Construction activities associated with the relocation of the City of Yreka water supply pipeline are considered along with the suite of other construction activities under the Proposed Project in the following analyses:

- Volume III Attachment 1 Potential Impact 3.2-4;

- Volume I Potential Impact 3.5-1 (see also Volume I page 3-454 for Proposed Project activities that have the potential to affect terrestrial resources at particular locations including the City of Yreka pipeline location), Potential Impact 3.5-6, Potential Impact 3.5-7, Potential Impact 3.5-9, Potential Impact 3.5-10, Potential Impact 3.5-11, Potential Impact 3.5-12, Potential Impact 3.5-13, Potential Impact 3.5-14, and Potential Impact 3.5-15, as modified in Volume III Attachment 1;
- Volume I Potential Impact 3.11-2;
- Volume III Attachment 1 Potential Impact 3.12-1 and Potential Impact 3.12-12;
- Volume I Potential Impact 3.17-1;
- Volume III Attachment 1 Potential Impact 3.19-6 and Potential Impact 3.19-7;
- Volume III Attachment 1 Potential Impact 3.20-1;
- Volume I Potential Impact 3.21-1, Potential Impact 3.21-2, and Potential Impact 3.21-3;
- Volume I Potential Impact 3.22-1, Potential Impact 3.22-2, and Potential Impact 3.22-3;
- Volume I Potential Impact 3.23-1.

Further, Potential Impact 3.3-22 specifically focuses on the potential impacts to aquatic resources due to short-term noise disturbance and water quality alterations from deconstruction activities and long-term fish screen upgrades from the relocation of the City of Yreka Water Supply Pipeline under the Proposed Project.

As potential construction-related impacts associated with Mitigation Measure WSWR-2 are analyzed with construction-related impacts analyzed under the Proposed Project, and there would be no other potential environmental impacts of this mitigation measure, the EIR is consistent with CEQA Guidelines section 15126.4(a)(1)(D). For construction-related potential impacts associated with air quality, greenhouse gases (GHG), and energy, these portions of the Draft EIR were recirculated on December 21, 2019. Please refer to the recirculated document (*Air Quality* and *Greenhouse Gas Emissions and Energy*).

Regarding the comment's assertion that the aspects of Mitigation Measure GEO-1 that specify measures to avoid or minimize the impacts of slope instability on structures, and roads are outside of water quality certification authority, and that mitigation measures TCR-6, TCR-7, and TCR-8 are beyond the State Water Board's ability to enforce, please refer to Master Response CEQ-2, and specifically the subsection entitled "Other Recommended or Mitigation Measures".

The comment is incorrect that Potential Impact 3.17-1 does not include mitigation. As stated in Volume I Section 3.17.5 *Public Services – Potential*

Impacts and Mitigation Potential Impact 3.17-1 (pages 3-913 to 3-915) Mitigation Measure HZ-1 and Mitigation Measure TR-1 would reduce the potential impacts related to construction activities. The text goes on to state that implementation of these two measures would reduce the potential for a short-term increase in personal and public health and safety risks due to the Proposed Project as related to emergency response services. Table ES-1 also indicates that Mitigation Measure HZ-1 is associated with Potential Impact 3.17-1. Mitigation Measure HZ-1 is under the State Water Board's water quality certification authority and can be found in Volume III Attachment 1 Section 3.21 *Hazards and Hazardous Materials*.

Regarding the comment's concern that significant and unavoidable impacts for Potential Impacts 3.23-1, 3.23-2, 3.23-4, 3.23-5, and 3.23-6 are due to noise levels associated with working two construction shifts and do not include a discussion of why mitigation to schedule construction work during "normal daytime hours" is not feasible, the comment is incorrect that noise impacts under Potential Impact 3.23-1, Potential Impact 3.23-2, Potential Impact 3.23-4, and Potential Impact 3.23-6 are due to noise levels associated with working two construction shifts. As stated in Volume I Section 3.23.5 *Noise – Potential Impacts and Mitigation* Potential Impact 3.23-1 (specifically page 3-1093), given the maximum allowable noise levels identified in the Siskiyou County General Plan Noise Element (Siskiyou County 1978), any use of dozers, jackhammers, and/or tractors during the Proposed Project would constitute an exceedance of County maximum allowable noise levels and this would be a significant impact. As stated in Volume I Section 3.23.5 *Noise – Potential Impacts and Mitigation* Potential Impact 3.23-2 (specifically page 3-1096), construction work during both shifts exceeds the significance criteria at all times because of the high source noise level. As stated in Volume I Section 3.23.5 *Noise – Potential Impacts and Mitigation* Potential Impact 3.23-5 (page 3-1098), noise associated with reservoir restoration activities would add to already significant noise levels for other construction activities and thus would be significant and unavoidable (i.e., is not associated with working two construction shifts). As stated in Volume I Section 3.23.5 *Noise – Potential Impacts and Mitigation* Potential Impact 3.23-6 (pages 3-1098 and 3-1099), blasting at each dam is proposed to occur infrequently, would be restricted to the time between 8 a.m. and 6 p.m., and would be dependent on scheduling; however, daytime vibration impacts to humans would remain significant and unavoidable for outdoor receptors during the blasting activities. While the comment does not define what is meant by "normal daytime hours", proposed blasting activities analyzed under Potential Impact 3.23-6 would occur between 8 a.m. and 6 p.m., which is within "daytime hours" defined as 7 a.m. to 10 p.m. by USEPA (1974) such that the significant and unavoidable impact determination is not associated with working two construction shifts.

With respect to the potential for mitigation to require construction work during "normal daytime hours" for Potential Impact 3.23-4, the Proposed Project schedule requires that major earthworks and removal activities would be performed using two 10-hour shifts (i.e., 20 hours in each 24-hour period), six days per week. Based on analysis of information provided in the Definite Plan, restricting construction activities to a total of fifteen daytime hours (i.e., 7 a.m. to 10 p.m. [USEPA 1974]) would not feasibly allow the amount of excavation and other construction activities required to remove Iron Gate Dam and restoration to occur in the timeframe proposed by KRRC (Appendix B: *Definite Plan)*. Extending the period of construction and restoration activities beyond the timeframe proposed in Table 2.7-1 (please refer to Volume III Attachment 1), would also extend the period of noise and vibration impacts. Regardless, for the reasons described above, an extension of the period of construction would not reduce the significant and unavoidable impacts.

The comment is incorrect that Potential Impact 3.2-3 provides no reasoning for why the impact is considered unavoidable. Please refer to Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-3 for a discussion of why the short-term significant impact of increased suspended sediment concentrations (SSCs) due to dam removal cannot be avoided or substantially decreased through reasonably feasible mitigation, including physical removal of reservoir bottom sediments prior to drawdown, slower drawdown to potentially mobilize less sediment, or altering the timing of drawdown to lessen the potential of precipitation after drawdown and before plantings have stabilized sediments. Given that the mechanism for short-term sediment deposition in the Klamath River downstream of Iron Gate Dam, which is analyzed in Potential Impact 3.11-5, is erosion of the reservoir sediment deposits that results in elevated SSCs as analyzed in Potential Impact 3.2-3, the reasons that the impacts cannot be avoided or substantially decreased through reasonably feasible mitigation described in Potential Impact 3.2-3 also apply to Potential Impact 3.11-5.

With respect to the possibility of artificial aeration to reduce the occurrence of low dissolved oxygen in the Klamath River downstream of Iron Gate Dam during reservoir drawdown, where this water quality impact is analyzed in Potential Impact 3.2-9, the process of re-aeration in a river, including enhancement by artificial means, requires a turbulent mixing distance to incorporate additional oxygen. While adding air or oxygen directly to the river could reduce the distance along the river in which dissolved oxygen concentrations remain below the Basin Plan water quality objective of 90 percent saturation, it would not be possible to ensure that no stretch of river downstream of J.C. Boyle, Copco No. 1, and/or Iron Gate dams would exhibit substantial biochemical oxygen demand (BOD) at the scale of the reservoir drawdown peak monthly flows (i.e., 1,000 to 8,700 cfs in Table 3.2-14) given the relatively high BOD of the suspended sediments that would be mobilized from the reservoirs. Thus, artificial aeration would only provide a marginal benefit to fish during drawdown. Additionally, it would not be feasible to subject the reservoir sediments to pre-oxygenation or pre-aeration prior to reservoir drawdown in order to exhaust the sediment BOD prior to the flows entering the river downstream of J.C. Boyle, Copco No. 1, and

Iron Gate dams, because in the absence of plausible predictions of which sediment deposits would mobilize and which deposits would remain in place, all sediments would have to be oxygenated throughout their entire thickness, where the deposits extend greater than ten feet deep in some locations (Volume I Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* Figures 2.7-7, 2.7-8, 2.7-9 [pages 2-62 to 2-64]). There is currently no known sediment oxygenation technique that could accomplish this degree of pre-oxygenation or pre-aeration at the scale of J.C. Boyle, Copco No. 1, and Iron Gate reservoirs. Overall, the short-term significant impact of increased oxygen demand and decreased dissolved oxygen in the Middle Klamath River upstream of the Salmon River cannot be avoided or substantially decreased through reasonably feasible mitigation involving artificial re-aeration (or oxygenation).

Comment ORG46-24

- *The DEIR Baseline for the Project Is Inconsistent. Baseline conditions are inconsistently described throughout the Draft EIR. Under CEQA, the baseline must be based on conditions at the time the Notice of Preparation (NOP) for the Proposed Project was issued in 2016 (14 Cal. Code Reg s. § 15125(a)). "Environmental conditions must be described as they exist when the notice of preparation is published, or, if a notice of preparation has not been published, at the time the environmental analysis begins" (14 Cal. Code Regs. § 151 25(a)). "These existing physical conditions 'will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant" (14 Cal. Code Regs. § 15125(a); see also Neighbors for Smart Rail v. Exposition Metro Line Constr. Auth. (2013) 57 Cal. 4th 439, 448; Communities for a Better Env't v. South Coast Air Quality Mgmt. Dist. (2010) 48 Cal. 4th 310, 320.)*

  A non -exhaustive list of examples of this problem include:

  - *In the fish disease discussion (Section 3.3.5.5), the DEIR does not present the effects of routine implementation of Court-ordered disease management flows (i.e., surface flushing, deep flushing, or dilution) as part of the existing conditions (see Hoopa Valley Tribe v. National Marine Fisheries Service et al., 230 F. Supp. 3d 1106 (2017)). The DEIR does, however, discuss the effects of these flows on the polychaetes that host C. shasta. While these flows are not included in the modeling used in the DEIR (flows, sediment transport, or water quality) and they are not part of the Proposed Project, USBR will be implementing them through the removal period and has proposed surface flushing flows in their Biological Assessment for reconsultation (USBR 2018 a).*

- *In Section 3.19 Aesthetics, the DEIR misleadingly uses a pre-dam construction baseline to evaluate effects of the Proposed Project and justify a less-than-significant impact to visual resources.*
- *In the alternative s analysis, Section 4, the aesthetics analysis consistently uses the pre-dam construction baseline conditions.*

Response to Comment ORG46-24
As stated in Volume I Section 3.1.2 *Environmental Setting* (page 3-2), pursuant to CEQA Guidelines section 15125, subdivision (a), the environmental setting for comparison is conditions at the time of issuance of the Notice of Preparation for the Proposed Project, which is December 2016 for the Lower Klamath Project EIR. The EIR consistently uses this baseline to define existing conditions for the Proposed Project and the alternatives, although in some cases where information characterizing the baseline is only available using older studies, the analyses acknowledge how those older studies are still relevant to the Proposed Project and the EIR.

Regarding consideration of the 2017 court-ordered flushing and emergency dilution flows in Section 3.3.5.5 *Aquatic Resources – Potential Impacts and Mitigation – Fish Disease*, the EIR acknowledges the re-initiation of consultation on the 2013 BiOp Flows by considering the 2017 court-ordered flushing and emergency dilution flow requirements downstream of Iron Gate Dam as interim flow requirements until completion of formal consultation. The 2017 court-ordered flushing and emergency dilution flows were not modeled as part of existing conditions hydrology for the Proposed Project because they went into effect in February 2017 after the December 2016 Notice of Preparation was filed. Note that the Final EIR has been updated to also include consideration of the 2019 BiOp Flows, as summarized in Master Response HYD-1.

With respect to how the EIR describes the existing condition baseline for aesthetics, please refer to responses to comments ORG46-321, ORG46-323, ORG46-324, ORG46-325, ORG46-326, ORG46-328, ORG46-329, and ORG46-330. Volume III Attachment 1 presents the final Section 3.19 *Aesthetics*. The alternatives analysis of potential aesthetic impacts has been clarified to remove reference to natural conditions.

Comment ORG46-24.1

- *The DEIR Should Reanalyze the No Project Alternative. The DEIR's discussion of the No Project Alternative (DEIR Section 4.2) falls short of CEQA's requirement that analysis of the no project alternative give decision-makers a gauge for measuring the environmental advantages and disadvantages of the project and the alternatives to it (Planning & Conserv. League v. Castaic Lake Water Agency, supra, 180 Cal. App. 4th at 247).*

An EIR's discussion of alternatives to a project must include a no project alternative, including an analysis of the impacts of that alternative. The purpose of discussing the no project alternative is to allow the public and agencies to compare the environmental impacts of approving the proposed project with the effects of not approving it (14 Cal. Code Regs. § 15126.6(e)(1)). "The no-project alternative is a fact-based forecast of the environmental effects of maintaining the status quo" (Planning and Conserv. League v. Castaic Lake Water Agency (2009) 180 Cal. App. 4th 210, 247). Also the no-project alternative allows decision-makers to compare impacts of a proposed project with impacts of no project (Mira Mar Mobile Community v. City of Oceanside (2004) 119 Cal. App. 4th 477) and is necessary to provide decision-makers and public with basic information on impacts of project (Planning & Conserv. League v. Department of Water Resources (2000) 83 Cal. App. 4th 892, 917).

A non -exhaustive list of examples of this problem include:

- *The DEIR indicates that the long-term effects of the No Project Alternative are not discussed because they "would be speculative…and would be contrary to the CEQA Guidelines' mandate to discuss and assess the environmental impacts that would 'reasonably be expected to occur in the foreseeable future'" (DEIR pg. 4-15). The DEIR could have assumed that existing operations simply continued into the future making a uniform set of conditions in both the short and long term against which the Proposed Project and the alternatives could have been compared.*
- *The No Project Alternative analysis includes analysis of the 2017 Court-ordered flushing and dilution flows. The DEIR should make it clear that this order was directed at USBR and not PacifiCorp's operations. The inclusion in this section of the DEIR is confusing because USBR (2018a) proposed to only include surface flushing flows in their update to their operations that is currently undergoing consultation under Section 7 of the Endangered Species Act, a process that is expected to be complete in 2019, well within the short-term period analyzed in the DEIR. The DEIR does not include operations under a new 2019 USBR BiOp in the short-term No Project Alternative.*
- *The hydrology under the 2013 BiOp should have been included in the baseline conditions for the Proposed Project analysis. Using 2013 BiOp flows for the No Project Alternative analysis makes comparisons of this alternative and the Proposed Project inconsistent.*

Response to Comment ORG46-24.1

The EIR is consistent with CEQA Guidelines section 15126.6(e)(2), which states that the No Project analysis shall discuss the existing conditions at the time the

Notice of Preparation is published, or if no Notice of Preparation is published, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services.

As stated in Volume I *Executive Summary – No Project Alternative* (page ES-16), the No Project Alternative describes the environment should the Klamath River Renewal Corporation's (KRRC's) Proposed Project − to decommission the four dams and associated facilities − not proceed. While the EIR describes the foreseeable existing conditions that would continue in the short term under the No Project Alternative, the EIR also clearly discloses that there is significant uncertainty about the long-term disposition of the Lower Klamath Project facilities if the KRRC's Proposed Project does not proceed. Projecting one specific No Project scenario for the long term would be speculative, in light of the fact that the continued operation of the Lower Klamath Project as permitted under annual licenses is infeasible, and would be contrary to the CEQA Guidelines' mandate to disclose and assess the environmental impacts that would "reasonably be expected to occur in the foreseeable future." Please also refer to Volume I Section 4.1.1.1 *Alternatives – Alternatives Selection/Overview – Alternatives Selection – Alternatives Carried Forward for More Detailed Analysis* for additional discussion of the short term and long term conditions associated with the No Project Alternative, as well as Volume I Section 4.2.1.1 *Alternatives – No Project Alternative – Alternative Description* (pages 4-15 to 4-23) for detailed discussion of foreseeable short-term operations, including hydrology, Total Maximum Daily Loads (TMDLs), and Klamath Hydropower Settlement Agreement (KHSA) Interim Measures.

Regarding the 2013 BiOp Flows, the 2017 court-ordered flushing and emergency dilution flows, and the 2019 BiOp Flows, please refer to Volume III Attachment 1 Section 3.1.6 *Introduction – Summary of Available Hydrology Information for the Proposed Project*, which has been revised to include discussion of the 2019 BiOp Flows that were adopted after issuance of the Draft EIR in 2018. The Draft EIR did include the 2013 BiOp Flows as the hydrologic baseline for the EIR analyses, including the baseline for the analysis of the Proposed Project; for additional information, please refer to Volume III Attachment 1 for the final Section 3.1.6 *Introduction – Summary of Available Hydrology Information for the Proposed Project.*

Additionally, Section 4.2.1.1 *Alternatives – No Project Alternative – Alternative Description* has been revised to include discussion of the 2019 BiOp Flows that were adopted after issuance of the Draft EIR in 2018. Please refer to Volume III Attachment 1 Section 4.2.1.1 *Alternatives – No Project Alternative – Alternative Description* for the revisions. Please also refer to Master Response HYD-1 for additional discussion of how the EIR considers the 2019 BiOp Flows.

<u>Comment ORG46-25</u>

- *<u>The DEIR Should Reanalyze Alternatives</u>. The DEIR does not uniformly to present, discuss, and analyze each of the alternatives, including comparing <u>both</u> short- and long-term effects; therefore, it does not satisfy CEQA's requirement that the EIR provide information sufficient to allow an informed comparison of the impacts of the project with those of the alternatives (Kings County Farm Bureau v. City of Hanford (1990) 221 Cal. App. 3d 692, 733 [absence of comparative data precluded meaningful consideration of alternatives]). Omitting such a meaningful analysis prevents decision-makers and the public from making informed comparisons bet ween the alternatives and the Project, precluding meaningful public participation (Laurel Heights, supra.; City of Rancho Palos Verdes v. City Council (1976) 59 Cal. App. 3d 869, 892 [An ElR's analysis of alternatives must be specific enough to allow informed decision-making and public participation; alternatives should be described in sufficient detail to provide information to governmental body that will act and public that will respond through political process]).*

A non-exhaustive list of examples of this problem include:

- *The Partial Removal Alternative includes a series of detailed tables (DEIR Tables 4.3-1 to 4.3-6) with the recommended eligibility of various Klamath Hydroelectric Project facilities under the National Register of Historic Places. This same information was not provided in the No Project Alternative even though that alternative would result in preservation of these resources.*
- *The Continued Operations with Fish Passage Alternative includes implementation of the USBR' s 2013 BiOp flows. These are not included in the existing conditions or Proposed Project discussions.*
- *Climate change effects appear to be included in the Continued Operations with Fish Passage Alternative, but not in the other alternatives or the Proposed Project.*
- *There are no spring-run Chinook Salmon in the Klamath River upstream of the Salmon River. It is unclear why the alternatives evaluate the impacts to a species that does not occur (e.g., DEIR pg. 4-140).*
- *While Table ES-1 presents an alternatives comparison of sorts, not all of the alternatives are evaluated for every impact.*

Response to Comment ORG46-25

The EIR analyzes the alternatives in both the short term and the long term, consistent with the Proposed Project. Please also refer to responses to comments ORG46-201, ORG46-374, ORG46-406, ORG46-422, ORG46-438, and ORG46-439 for discussion of the EIR’s approach to assessing short-term and long-term potential impacts under the Proposed Project and the alternatives.

With respect to the comment's concern regarding historical information presented in the No Project Alternative, Volume I Section 4.2.12 *No Project Alternative – Historical Resources and Tribal Cultural Resources* states that there would be no impacts to Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and the Klamath River Hydroelectric Project District (Potential Impact 3.12-11), because the Lower Klamath Project would remain in place. It is not necessary to repeat the tables presented in the Partial Removal Alternative in the analysis of the No Project Alternative, since both sets of tables would contain the same information regarding National Register eligibility. However, reference to Tables 4.3-1, 4.3-3, and 4.3-5 has been added to Section 4.2.12 *No Project Alternative – Historical Resources and Tribal Cultural Resources* to direct the reader to that information. Please refer to Volume III Attachment 1 Section 4.2.12 *No Project Alternative – Historical Resources and Tribal Cultural Resources* for the revisions. Reference to Tables 4.3-1, 4.3-3, and 4.3-5 also has been added to the Proposed Project impact analysis in Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation*, Potential Impact 3.12-11, to direct the reader to the tabulated eligibility information. Please refer to Volume III Attachment 1 Section 3.12.5 *Historical Resources and Tribal Cultural Resources – Potential Impacts and Mitigation* for the revisions.

The comment's concern that the Proposed Project and the Continued Operations with Fish Passage Alternative use different flows is misplaced: both are analyzed in the Draft EIR using the 2013 BiOp Flows as the existing condition. Please refer to Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and Volume I Section 4.4.1.1 *Alternatives – Continued Operations with Fish Passage Alternative – Introduction – Alternative Description* (pages 4-99 to 4-101). Additionally, please note that the Final EIR has been updated to also include consideration of the 2019 BiOp Flows as a second baseline, which is summarized in Master Response HYD-1. Please also refer to Volume III Attachment 1 for the final Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and Section 4.4.1.1 *Alternatives – Continued Operations with Fish Passage Alternative – Introduction – Alternative Description* for the revisions associated with inclusion of the 2019 BiOp Flows.

Regarding the comment's concern that climate change effects are considered for the Continued Operations with Fish Passage Alternative but not for the Proposed Project and other alternatives, please note that, consistent with CEQA Guidelines section 15125(a), future climate changes are not part of the existing condition against which the EIR compares potential impacts. While climate change predictions are occasionally used in the Lower Klamath Project EIR to provide additional context for potential impact analyses related to the Proposed Project or the alternatives (e.g., Volume III Attachment 1 Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1, Volume III Attachment 1 Section 3.3.5.9 *Aquatic Resources – Potential Impacts* *and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-8, Volume 1 Section 4.2.2 *No Project Alternative – Water Quality* Potential Impact 4.2.2-1 [pages 4-103 to 4-108]), the predictions are not relied upon for significance determinations associated with the Proposed Project or the alternatives. For reasons described in Volume I Section 4.2.1.1 *No Project Alternative – Introduction – Alternative Description* (pages 4-15 to 4-16), the No Project Alternative analysis focuses on the reasonably foreseeable period of 0−5 years, whereas climate change would be anticipated to only significantly influence environmental resources compared to existing conditions in the long term (5+ years). Thus, climate change is not discussed under the No Project Alternative, except to refer the reader to other relevant sections of the EIR where climate change is discussed.

For discussion of why spring-run Chinook are analyzed under the alternatives, please refer to responses to comments ORG46-251, ORG46-426, and ORG46-440.

Each of alternatives is evaluated for the set of potential impacts that would reasonably apply. If a potential impact would not apply to a particular alternative, then the alternative is not listed in association with that potential impact number in Table ES-1. For example, Potential Impact 3.3-17 *Effects on species interactions between introduced resident fish species and native aquatic species due to short- and long-term changes in habitat quality and quantity due to dam removal*, is not evaluated for the No Project Alternative or the Continued Operations with Fish Passage Alternative because neither of those alternatives involve dam removal. Similarly, Potential Impact 4.2.3-1 *Effects on coho salmon critical habitat quality and quantity due to continued operations of the Lower Klamath Project* is not evaluated for the Proposed Project, Partial Removal Alternative, Two Dam Removal Alternative, Three Dam Removal Alternative, or the No Hatchery Alternative because none of those alternatives or the Proposed Project involve leaving all of the Lower Klamath Project dams in place.

Comment ORG46-26

- *DEIR Reliance on Total Maximum Daily Load (TMDL) Modeling and Data Approaches Requires Additional Explanation. The DEIR relies on the flawed TMDLs from Oregon and California without providing a reasonable explanation supporting its TMDL analysis, nor does it adequately summarize the substantial body of technical information discrediting the TMDL modeling approach, nor does the DEIR provide any other substantial evidence supporting the use of the TMDL in the DEIR. As it relates to the TMDL, the DEIR does not fulfill CEQA's requirement that the EIR summarize the main points of disagreement when experts disagree about data or methodology (14 Cal. Code Regs. § 15151). A lead agency may choose among differing expert opinions as long as the EIR identifies arguments correctly and in a responsive manner (Browning-Ferris Indus. v. City Council 1986, 181 Cal. App. 3d 852) which the DEIR fails to do. An* *impact analysis that fails to explain major discrepancies in critical data may be legally inadequate in the absence of evidence supporting the EIR's discussion or resolution of the conflict (Preserve Wild Santee v. City of Santee (2012) 210 Cal. App. 4th 260).*

For example, the DEIR relies extensively on the TMDLs for both Oregon and California reaches of the Klamath River. The State Water Board should be aware that the 2010 temperature TMDL in Oregon (ODEQ 2010) was withdrawn by Oregon Department of Environmental Quality (ODEQ 2015), does not represent the best available information upon which to base the DEIR analysis, and therefore should not be used to set conditions in the Klamath River at the state line. This 2010 temperature TMDL was withdrawn because it was based on modeling that contained substantial errors which, along with other technical deficiencies, overstated the Klamath Hydroelectric Project 's effects on water temperatures in the river, and did not accurately account for natural pollutant loadings and processes (Campbell 2011). An updated version of the nutrient Upper Klamath and Lost River Subbasin TMDL (ODEQ 2018) was released for public comment in mid-2018 and a final version in January 2019 (ODEQ 2019). PacifiCorp understands that a revised temperature TMDL for the Oregon portions of the Klamath River may be complete in Fall 2019.

The California TMDL modeling results are not an appropriate basis for comparing alternatives. PacifiCorp has previously documented substantial technical flaws with the assumptions, modeling, and analyses used in development of the California TMDLs. PacifiCorp's position that the compliance scenarios, technical analysis, and modeling supporting the California Klamath River TMDL are flawed was presented during the development of the TMDL and is contained in PacifiCorp ' s Petition for Writ of Mandate filed to challenge the same (PacifiCorp v State Water Resources Control Board, 2011, case 34-2011-80000769). PacifiCorp's legal challenge has not been resolved, and is currently stayed.[3]

Response to Comment ORG46-26

Regarding Total Maximum Daily Load (TMDL) modeling, please refer to Master Response WQ-5.

Comment ORG46-27

- *The DEIR Lacks Sufficient Analysis of Regional Power Supply in the Utilities Section. The DEIR fails to describe the baseline condition concerning electric utilities and power generation provided by the Klamath Hydroelectric Project, which violates CEQA's requirement that an EIR describe the existing environment in the vicinity of the project from both a local and regional perspective (14 Cal. Code Regs. § 1512S(a)). The DEIR does not describe the potentially significant impacts associated with* *removal of the dams and associated power transmission facilities on electricity service in the region, which violates CEQA's requirement that the EIR identify and describe a proposed project's significant environmental effects (Cal. Pub. Res. Code § 21100(b)(l); 14 Cal. Code Regs. § 15126.2(a)). The DEIR also fails to comply with CEQA's requirements by failing to evaluate potentially significant energy implications of a project (CEQA Guidelines Appendix F (II); Pub. Res. Code § 21100(b)(3)). The environmental impacts to be evaluated in an EIR include (but are not limited to): 1) the project's effects on local and regional energy supplies and on requirements for additional capacity; 2) the project's effects on peak- and base-period energy demands; and 3) the project' s effects on energy resources (CEQA Guidelines, Appendix F (II)).*

The DEIR does not describe the baseline condition concerning electric utilities, the power generated by the Klamath Hydroelectric Project, or the impacts associated with removing those dams and associated power generation and transmission facilities on electricity service in the region. In the DEIR, Section 3.18 Public Services and Utilities, should contain a complete description about the ability to deliver utilities, including electricity. While the Proposed Project likely will not result in new need for local power generation, it will eliminate existing power sources at the hydroelectric dams, and remove local generation resources that provide power in an area without significant generation resources. The impact analysis should address the removal of these utilities, how those utilities will be replaced, and the impacts of that replacement. Because the DEIR fails to do so, it does not satisfy CEQA' s requirements.

Response to Comment ORG46-27

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG46-28

- *The Application of the DEIR's Significance Criteria Is Inconsistent. The DEIR attempts to define significance criteria for each resource area in the DEIR. While this is generally accomplished, the actual definitions are subject to reasonable differing interpretation and, in places, the definitions even contradict each other. CEQA requires that a threshold of significance be an identifiable quantitative, qualitative, or performance level of a particular environmental effect (14 Cal. Code Regs. § 15064.7(a); Protect the Historic Amador Waterways v. Amador Water Agency (2004) 116 Cal. App. 4th 1099, 1107). Inconsistent and insufficient definitions also creates the issue of misapplication of the thresholds of significance. CEQA requires that the EIR consider evidence of potential significant environmental effects, and therefore; a threshold of* *significance cannot be applied in a way that would foreclose the consideration of other substantial evidence tending to show the environmental effect to which the threshold relates might be significant (Comm unities for a Better Environment v. California Resources Agency (2002) 103 Cal. App. 4th 98, 114).*

A non-exhaustive list of examples of this problem include:

- *The term "substantial" or "substantially" is not consistently defined. In Section 3.2 Water Quality, for example, the definition of "substantial" is meaningless (DEIR pg. 3-44) because according to the DEIR "...'substantial'...means the effect on water quality and the support of beneficial uses...is of considerable importance." The DEIR does not define "of considerable importance." This same "of considerable importance" phrase is used in the same manner in Section 3.11 Geology, Soils, and Mineral Resources and is not defined there either.*
- *As an example of an improperly applied threshold of significance, the threshold the DEIR identifies that a short-term impact to Coho Salmon is defined as significant if it would "substantially reduce the abundance (greater than 50 percent reduction) of a year class for aquatic species" (DEIR pg. 3-258). This definition ignores the fact that over 50 percent of the Coho Salmon population returns to the Trinity River (Naman and Perkins 2015; Kier et al. 2018) and would be substantially unaffected by the project. This significance definition also has the absurd result that even a complete extinction of the upper Klamath Coho population would not be considered significant. Under Communities for a Better Environment v. California Resources Agency, supra, 103 Cal. App. 4th 98, the small population of Coho in the mainstem Klamath River upstream of the Trinity River would be substantially impacted, and therefore this impact should be considered significant. This is just one example where the DEIR's significance criteria lack meaningful or adequate definition and application, in contravention of the requirements of CEQA.*
- *In Sections 3.5, 3.6, 3.7, 3.9, 3.15, 3.16, 3.17, 3.19, 3.20, 3.21, 3.22, the term "substantial" is used in the criteria, but is not defined.*
- *In Section 3.8 Water Supply/Water Rights the term "unreasonable injury" is not defined as it applies to water rights.*
- *The first criteria in Section 3.5.3 (DEIR pg. 3-514) says that impacts would be considered significant if they "[r]esult in population-level impacts on state species of special concern, USDA Forest Service sensitive wildlife species on USDA Forest Service lands, or BLM sensitive species on BLM lands." The next bullet (DEIR pg. 3-515) states that an impact would be significant if it would "[r]esult in any of the following to the other types of special-status species[112]:[sic] not listed above: direct mortality or physical harm to individuals...". Footnote 112 goes on to define a long list of sources of special status*

species leaving the reader to attempt to sort out what's to be analyzed at the population level per the first bullet and which could be analyzed at the individual level per the second bullet.

Response to Comment ORG46-28

As stated in Volume I Section 3.1.3 *Environmental Setting, Impacts, and Mitigation Measures – Introduction – Significance Criteria* (page 3-2), in setting criteria for evaluating significance, this EIR relies on scientific and factual data, analysis, consideration of relevant local, regional and state standards, and the questions presented in Appendix G of the CEQA Guidelines. These are then applied as appropriate in the various resource areas.

With respect to the comment's general assertion regarding the definition of "substantial", and the list of EIR sections in which the commenter indicates that "substantial" is not defined, please refer to Master Response CEQ-3.

For a discussion of the significance criterion for coho salmon please refer to response to comment ORG46-199 Item 4.

Regarding use of the term "unreasonable injury," an unreasonable injury to a water right is one that involves interference with the water right that would support a complaint made under Article 10 Section 2 of the California Constitution.

Please refer to Tables 3.5-4 (plants) and 3.5-5 (wildlife) for identification of special-status species, including the agency that lists each species. As described in the significance criterion in Volume I Section 3.5 *Terrestrial Resources – Significance Criteria* (page 3-514) that the comment cites, the population-level criterion applies to three groups of sensitive species: (1) state species of special concern, (2) United States Department of Agriculture (USDA) Forest Service sensitive wildlife species on USDA Forest Service lands, and (3) Bureau of Land Management (BLM) sensitive species on BLM lands. The second significance criterion cited in the comment (page 3-515) applies to all the remaining groups of special-status species. Footnote 112 on page 3-515 provides a listing of these remaining sources for special-status species, drawing together the information from both the plant and wildlife species tables.

Comment ORG46-29

The DEIR Should be Augmented. The DEIR omits inclusion and analysis of significant information critical to an appropriate analysis of the effects of the Proposed Project, much of which is in the existing public record (Pub. Res. Code § 21092.1; 14 Cal. Code Reg s. § 15088.5 [recirculation is generally required when the addition of new information deprives the public of meaningful opportunity to comment on substantial adverse project impacts or feasible mitigation measures or alternatives that are not adopted]; see Mountain Lion Coalition v. Fish & Game Comm'n (1989) 214 Cal. App. 3d 1043 [recirculation *required where draft EIR omitted any analysis of cumulative impacts, and a detailed analysis was first provided in the final EIR]; Vineyard Area Citizens for Responsible Growth v. City of Rancho Cordova (2007) 40 Cal. 4th 412, 447; see also Laurel Heights Improvement Ass'n v. Regents of Univ. of Cal. (1993) 6 Cal. 4th 1112, 1129).*

The DEIR should analyze substantial information cited in these comments concerning significant effects on water quality, Coho Salmon, fill of Waters of the U.S., and loss of Copco and Iron Gate reservoirs as related to instream flows, substantial changes in periphyton communities, impacts associated with greenhouse gas emissions , and impacts from release of reservoir fish from the Proposed Project, which are not addressed in the DEIR but must be addressed in a recirculated DEIR (14 Cal. Code Regs. § 15088.5(a)(1)).

If new mitigation measures or alternatives are considered in response to comments, the DEIR should be augmented and provided for additional public review and comment (South County Citizens for Smart Growth v. County of Nevoda (2013) 221 Cal. App. 4th 316, 330); Laurel Heights Improvement Ass'n v. Regents of Univ. of Cal. (1993) 6 Cal. 4th 1112; CEQA Guidelines (14 Cal. Code Regs. § 15088.5(a)(3)); In Spring Volley Lake Ass' n v. City of Victorville (2016) 248 Cal. App. 4th 91, 108).

Response to Comment ORG46-29

The concerns raised by PacifiCorp in this overarching comment (i.e., concerns that the Draft EIR should analyze substantial information cited in the PacifiCorp comments about significant effects on water quality, coho salmon, fill of Waters of the U.S., loss of Copco and Iron Gate reservoirs as related to instream flows, periphyton communities, greenhouse gas emissions, and release of reservoir fish to the Middle and Lower Klamath River) are set forth in more detail throughout PacifiCorp's comment letter. They are accordingly addressed by the set of detailed responses to comments ORG46-2 through ORG46-516.

Comment ORG46-30

In the Draft Environmental Impact Report's (DEIR's) impacts and alternatives analyses, "short-term" is variably defined. For example, for analyses of water quality, dam-released sediment, and sediment resupply, short-term is generally defined as 2 years following dam removal (e.g., DEIR pgs. ES-6, 3-44, 3-760, 3-77S). For the aquatic resources impact analysis, short-term is defined as less than S years following dam removal (e.g., DEIR pg. 3-2S8). In the alternatives analysis, short-term is considered to be less than 5 years (e.g., DEIR pgs. 4-15, 4-24, 4-26). Correspondingly, long-term is defined as occurring greater than 2 years after dam removal for water quality and sediment resources (DEIR pg. 3-44) and greater than 5 years after dam removal for aquatic resources (DEIR pg. 3-258). These variable definitions pose a dilemma in that long-term water quality and sediment impacts overlap with short-term impacts to fish and other aquatic biota. In the case of water quality and sediment impacts on fish, this overlap underestimates the severity of short-term impacts, particularly as they pertain to *fish and other resources. The DEIR does not account for this when evaluating the severity and significance of short-term impacts. This discrepancy will mislead the public and decision-makers about the actual short- and long-term impacts of the Proposed Project across the various environmental resources and alternatives.*

Response to Comment ORG46-30

The definition of short term is provided for each EIR environmental resource area analyzed under the Proposed Project and the alternatives, and each definition is selected for a period of time that is relevant to the resource and type of impacts being analyzed. For the Proposed Project and dam removal alternatives, short term is often defined as the two- to three-year dam removal construction period, but this time period is not the most appropriate period of analysis for all resource areas (e.g., fisheries uses a period of five years because for most aquatic resources this represents one to two generations [see Volume III Attachment 1 Section 3.3.3 *Aquatic Resources – Significance Criteria*]). The No Project Alternative does not involve construction and so a two- to three-year short-term construction period is not relevant to this alternative; instead, a five-year period is the most relevant short-term period based upon the anticipated duration of the FERC proceeding for relicensing of the hydroelectric facilities (see Volume I Section 4.2.1.1 *Alternatives – No Project Alternative – Introduction – Alternative Description* [page 4-15]).

The Draft EIR does not underestimate the severity of short-term water quality and sediment impacts to fish by having different definitions of short term for water quality-focused impact analyses versus fisheries-focused impact analyses. This is because the short-term fisheries impact determinations are not dependent on whether the short-term water quality impact determinations are significant; rather, the fisheries impacts analysis considers the potential effects of water quality parameters (e.g., water temperature, suspended sediment concentrations [SSCs], algal toxins) independently from the water quality impacts analysis and in combination with other aspects of the Proposed Project and alternatives that would affect fisheries (e.g., Aquatic Resource Measures).

Overall, presenting specific definitions of short term for each resource area and alternative better informs the public and decision-makers about the potential short- and long-term environmental impacts of the Proposed Project and the alternatives consistent with CEQA Guidelines section 15126.2 (a).

<u>Comment ORG46-31</u>

The DEIR states "approximately 36 to 57 percent of the total sediment stored in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs by 2021 is expected to be eroded and transported downstream during the drawdown period and the year following dam removal (i.e., short-term), which is equivalent to 5.4 to 8.6 million cubic yards (1.2 to 2.3 million tons)."

These eroded volumes estimates are very large numbers that are difficult to put into perspective; it would be helpful for the DEIR to relate the eroded volume estimates to the average annual sediment load to provide context. These estimates also indicate that approximately 6.5 to 9.7 million cubic yards of sediments would be retained in the reservoirs after initial reservoir drawdown. The DEIR should address the longer-term effects caused by these retained sediments that could occur during future high flow events.

Response to Comment ORG46-31

Regarding the background annual sediment loads, please refer to Volume I Section 3.11.2.4 *Geology, Soils, and Mineral Resources, Environmental Setting – Sediment Load* Table 3.11-3 (pages 3-749 to 3-750). Please also refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 and modifications in Volume III Attachment 1. Specifically, Volume I page 3-769 of this impact places the anticipated erosion volume due to dam removal into the context of annual basin-wide sediment discharge. For further explanation, please refer to Stillwater Sciences (2010, pages 27–29), which discusses the ratio of modeled sediment release from dam removal to cumulative average annual basin sediment delivery. Downstream of the Dillon Creek confluence (river mile [RM] 85.5), the lower estimate of sediment load release from dam removal is less than the average annual basin sediment delivery. Downstream of the Trinity River confluence (RM 43.5), the median estimate of sediment load release from dam removal is less than average annual basin sediment delivery.

Regarding background suspended sediment concentrations (1961−2008), please refer to USBR (2012a) Section 9.2.1.2 *Future Geomorphology and Sediment Transport Conditions, Dam Removal Alternative, One-Dimensional Simulation of Reservoir Drawdown and Erosion of Reservoir sediment – Background Sediment Loads*. Additionally, please refer to Volume II Appendix C Section C.2 *Suspended Sediments* (pages C-14 through C-23).

Regarding long-term effects relating to reservoir sediments, please refer to Potential Impact 3.11-5 (pages 3-768 to 3-769) in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* and modifications to this impact in Volume III Attachment 1, and to ORG46-8 for information on erosion and stabilization of reservoir sediment deposits.

Comment ORG46-32

The DEIR contains the repeated conclusion that the fine sediment predicted to be released during drawdown will be efficiently and shortly locations transported all the way to the Pacific Ocean. For example, on page ES-6, the DEIR states: "Most of the fine sediment is expected to be transported the report in suspension to the ocean shortly after being eroded. Fine sediment erosion would result in elevated suspended sediment concentrations downstream of Iron Gate Dam in the short term (Stillwater Sciences 2010, USBR 2012)."

For example, on page 2-60, the DEIR states: "Over 80 percent of the reservoir sediments are fine sediment (organics, silts, and clays), which are expected to remain suspended in the Klamath River flow as it moves downstream and out into the Pacific Ocean."

For example, on page 2-68, the DEIR states: "Based on estimated annual sediment deposition rates, an approximately 15.13 million cubic yards (4.16 million tons [dry weight]11) of sediment would be present behind the dams by 2020 (USBR 2012c) (Table 2.7-10). Because the trapped sediments consist primarily of organic material (e.g., dead algae), silts, and clays, they would be easily eroded and flushed out of the reservoirs into the Klamath River, and would continue to be suspended in the river downstream to the Pacific Ocean."

The notion implied in these statements is highly simplified. Some deposition of fine sediment would occur downstream during high discharges when flows go over-bank and inundate the floodplain - a scenario that could occur during drawdown. In addition, at lower discharges when flows remain in-channel, fine sediment likely would deposit in backwaters, alcoves, side-channel inlets and outlets, and areas along the channel margins. Fine sediment that deposits in backwater areas such as alcoves and side-channels could adversely affect aquatic and riparian biota and habitats and could become remobilized in subsequent high flow events, extending the duration of sediment impacts on aquatic biota. For example, fine sediment can infiltrate spawning gravels and significantly impact spawning success. The DEIR should be revised and recirculated to include this analysis.

The transport and deposition of the fine sediment predicted to be released under the Proposed Project is fundamentally important to understanding a wide-range of environmental impacts, both short-term and long-term. Therefore, the DEIR should include a more detailed discussion and supporting numerical or quantitative analysis to document the expected impacts from fine sediment transport and deposition.

Analysis of fine sediment transport and deposition downstream of Iron Gate is not included in either of the DEIR's cited references (i.e., Stillwater Sciences 2010 and USBR 2012c). In general terms, the 1-D modeling used in the DEIR's cited references (i.e., Stillwater Sciences 2010 and USBR 2012c) is a computationally efficient means to assess overall sediment loads for many miles of river, over several years, and for multiple scenarios. However, the 1-D modeling has germane limitations in that it cannot simulate the distribution of sediment erosion and deposition in the river, particularly across the channel or in split or side channels. The modeling also assumes that fine sediment would behave as wash load, which by definition is sediment that remains in suspension and does not deposit. However, while the DEIR's cited references (i.e., Stillwater Sciences 2010 and USBR 2012c) intend this as only a simplifying assumption of *the 1-D modeling, the DEIR appears to couch this basic modelling assumption as a finding from the model.*

This is a global comment that applies to all statements which conclude that the fine sediment predicted to be released during the drawdown will be transported to the Pacific Ocean without any discernible deposition in the river reaches downstream of Iron Gate Dam.

Response to Comment ORG46-32
Please refer to Master Response GEO-1 and ORG46-8.

Comment ORG46-33
Regarding the Phytoplankton and Periphyton section, there is no discussion of periphyton benefits expected to occur as a result of the Proposed Project such as those to seasonal nutrient uptake and sequestration, photosynthesis, habitat, and food web. Such benefits should be acknowledged (see detailed comments on Section 3.4).

Response to Comment ORG46-33
Please refer to Volume III Attachment 1 Potential Impact 3.2-8, Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437), and Volume I Potential Impact 3.4-5 (pages 3-437 to 3-440) for discussion of the potential impacts to nutrients and periphyton under the Proposed Project, including the influence of periphyton on nutrient uptake and sequestration along with the general importance of periphyton in aquatic food webs. Please refer to Volume III Attachment 1 Potential Impact 3.2-10 and Potential Impact 3.2-11 for discussion of the potential impacts of periphyton to dissolved oxygen and pH from photosynthesis and growth, respectively, under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Periphyton growth in the Klamath River under the Proposed Project would potentially create habitat, contribute to the food web, uptake, sequester, or contribute nutrients on a seasonal basis, and contribute to daily variations in pH and dissolved oxygen due to photosynthesis and respiration, but the magnitude of these potential effects would depend on the extent of periphyton growth that would occur. The response of periphyton in the Klamath River under the Proposed Project is subject to many competing processes that could either accelerate or hinder periphyton growth. While the Proposed Project would likely result in periphyton growth in the newly created low gradient river channel within the Copco No. 1 and Iron Gate reservoir footprints, there is considerable uncertainty about the exact extent and types of periphyton that would occur. As a result of this uncertainty, the EIR avoids overstating the potential for benefits related to periphyton under the Proposed Project.

Comment ORG46-34

Regarding the Water Quality section, adverse impacts associated with increased turbidity include burying and scour of aquatic vegetation (e.g., periphyton, macrophytes), which could limit or preclude growth. The resultant effects would include: lack of photosynthesis (oxygen production), lack of nutrient uptake, lack of cover and food for macroinvertebrates, and lack of cover and food for juvenile fish rearing. Such effects should be acknowledged in the DEIR. Additionally, TMDLs have been established for the Klamath River to address nutrient impairment. The removal of Copco and Iron Gate reservoirs, which retain 18 to 21 percent of total nitrogen and 12 to 16 percent of annual phosphorus loading from the Klamath River (PacifiCorp 2006; Kann and Asarian 2005, 2007; Asarian et al. 2009), should be acknowledged in the DEIR as potentially having adverse impacts on Klamath River water quality. The long-term impacts of increased nutrient delivery to the Klamath River downstream of Iron Gate on water quality has not been evaluated in the DEIR. See comments 3.2-53 to 3.2-55 and 3.4-5 below.

Response to Comment ORG46-34

Please refer to Volume I Section 3.5.5 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-3 (pages 3-521 to 3-522) for a discussion of the short-term and long-term impacts of dam removal on wetland habitat, including aquatic macrophytes such as cattails (*Typha spp.*), bulrushes, pondweeds (*Potamogeton spp*.) and coontail (*Ceratophyllum demersum*), downstream of the Lower Klamath Project dams due to erosion or sediment deposition. As stated in Volume I Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* (page 3-392), since no surveys have been conducted to determine the relative distribution or biomass of large aquatic plants (i.e., macrophytes) in the Klamath River, they were not discussed further in Volume I Section 3.4 *Phytoplankton and Periphyton*. However, to address the concerns raised in the comment, the following provides additional consideration of potential impacts to large aquatic plants (i.e., macrophytes), referencing the EIR impact analyses for periphyton where the discussions overlap.

With respect to the comment regarding scour of aquatic vegetation due to increased turbidity, please refer to Volume I Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impact 3.4-3 (pages 3-433 to 3-435) for an analysis of the short-term potential impacts of dam removal on periphyton abundance in the Klamath River, including scour of periphyton during drawdown of the reservoirs. Under existing conditions, periphyton abundance in the Klamath River naturally decreases after high flows associated with storm events as the periphyton communities in the river reduce to a thin layer of scour-resistant diatoms (Asarian et al. 2015). The magnitude of drawdown flows in the Klamath River downstream of Iron Gate Dam would not exceed the range of flows occurring under existing conditions (see Volume I Section 3.6.2.2 *Flood Hydrology – Environmental Setting – Basin Hydrology* [pages 3-590 to 3-621] for additional details) and the drawdown flows would occur between November 1 and March 15 when high flows would naturally occur in the Klamath River due to winter storms, so periphyton scour during drawdown and dam removal is anticipated to be within the range occurring under existing conditions. As such, variations in water quality due to reductions in periphyton abundance during dam removal would be within the range occurring under existing conditions and there would be no significant impact. While larger aquatic plants (i.e., macrophytes) may also be present in quiet backwater areas in the Klamath River in addition to periphyton, no known quantitative or species-specific information about these aquatic plants has been collected in the phytoplankton and periphyton Area of Analysis, as noted in the introduction of Volume I Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* (page 3-392). The potential impacts of erosion and deposition associated with dam removal on macrophytes within wetland habitats downstream of Iron Gate Dam are addressed in Volume I Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impacts 3.4-3, 3.4-4, and 3.4-5 (pages 3-433 to 3-440) and Section 3.5.5.1 *Terrestrial Resources – Potential Impacts and Mitigation – Vegetation Communities* Potential Impact 3.5-3, as revised in Volume III Attachment 1. The potential impact of dam removal on larger aquatic plants within the main river channel (i.e., not wetlands or riparian habitats) is expected to be similar to the potential impact of dam removal on periphyton (see Volume I Potential Impact 3.4-3 [pages 3-433 to 3-435]) since the larger aquatic plants in the main river channel grow in similar habitats as periphyton. Thus, scour of larger aquatic plants and variations in the abundance of larger aquatic plants in the Klamath River is anticipated to be within the range occurring under existing conditions and would not result in a significant impact under the Proposed Project.

With respect to the comment regarding burying of aquatic vegetation due to increased turbidity, the abundance of periphyton and larger aquatic plants (i.e., macrophytes) would potentially be altered by coarse reservoir sediment deposition in the Klamath River from Iron Gate Dam to approximately Cottonwood Creek (river mile [RM] 185.1) (USBR 2012a) since sediment transport modeling of dam removal indicates coarse reservoir sediments would deposit in this reach, with reach-averaged deposition of gravel and sediment estimated to be from 0.9 feet to 1.7 feet between Bogus Creek (RM 192.68) and Willow Creek (RM 187.8) (see Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5). As previously stated in Volume I Section 3.4.5 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impact 3.4-3 (pages 3-433 to 3-435) and Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5, there would be minimal deposition of fine sediments in the Klamath River due to reservoir drawdown and high winter flows (note that revisions in Potential Impact 3.11-5 in Volume III Attachment 1 do not change this conclusion). If rain and snowmelt levels are high during drawdown, relatively less deposition of coarse reservoir sediments would occur in downstream reaches, as there would be higher flows in the system to flush out reservoir sediments (Stillwater Sciences 2008). Please refer to Volume III Attachment 1 for Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5.

In the short term, reach-averaged sedimentation levels of 0.9 to 1.7 feet are not expected to substantially negatively impact periphyton or larger aquatic plants downstream of Iron Gate Dam since periphyton and larger aquatic plants are generally adapted to this scale of perturbation due to seasonal and inter-annual sedimentation dynamics typical of dynamic river systems. Burial of existing periphyton and larger aquatic plants with coarse reservoir sediment would reduce the abundance of periphyton and larger aquatic plants in localized areas immediately following sediment deposition, but periphyton and larger aquatic plants would be expected to re-colonize these sediment deposits within the short term (i.e., three years after dam removal begins or sooner), similar to the way scoured streambeds and new sediment deposits on the streambed are recolonized after naturally occurring high winter flows. Thus, there would be a less than significant effect on periphyton and larger aquatic plant abundance downstream of Iron Gate Dam due to localized short-term sediment deposition caused by dam removal.

Overall, short term scour and burial of existing periphyton and larger aquatic plants would potentially reduce the abundance of periphyton and larger aquatic plants in localized areas in the Klamath River under the Proposed Project, but this decrease in periphyton and larger aquatic plant abundance would be within the range occurring under existing conditions and periphyton and larger aquatic plants would recolonize and regrow. In the long term, scour and deposition associated with dam removal, drawdown flows, and reservoir sediment transport under the Proposed Project would return to background rates (see Volume III Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 for more details). Thus the identified processes would not significantly change the existing range of periphyton and larger aquatic plant abundance in the Klamath River.

With respect to the comment regarding the potential for reduced rates of photosynthesis and oxygen production from aquatic vegetation due to increased turbidity, modeled suspended sediment concentrations (SSCs) in the Klamath River under the Proposed Project during the two primary periphyton and larger aquatic plant growth seasons (i.e., May to October[9]) that would occur in dam removal year 2 and post-dam removal year 1 are within the estimated range of background SSC concentrations (e.g., 1 to 100 milligrams per liter [mg/L] at Orleans between May and October depending of water year type [USBR 2012a]), and they are typically on the low end of that range (i.e., less than 50 mg/L).

[9] Periphyton and aquatic macrophytes are generally dormant during November through April and/or river flows are too high to conduct surveys.

While SSCs would potentially increase above 50 mg/L for approximately 2 weeks or less during the primary periphyton and larger aquatic plant growth season in some water year types during dam removal year 2 and post-dam removal year 1, because the modeled concentrations are within the estimated range of background SSC concentrations, they would not be anticipated to significantly alter periphyton and/or larger aquatic plant growth, including associated rates of photosynthesis and oxygen production, due to reduced light availability under the Proposed Project. Because there are no quantitative data on variations in periphyton and larger aquatic plant growth, rates of photosynthesis, or the amount of associated oxygen production, due to changes in SSC (or turbidity) in the Klamath River or other comparable rivers, the magnitude of changes in periphyton and larger aquatic plant growth, photosynthesis, and oxygen production due to increased SSCs cannot be explicitly quantified. Further, the comment does not provide additional evidence or data that turbidity (or SSCs) in the Klamath River following dam removal would limit or preclude growth of periphyton and/or larger aquatic plants. Overall, increases in SSCs in the Klamath River under the Proposed Project would not significantly inhibit periphyton or larger aquatic plant (i.e., macrophyte) growth compared to the baseline condition. As such, it would not cause significant effects through the various pathways the comment posits.

With respect to the comment regarding nutrient retention in Copco No. 1 and Iron Gate reservoirs, please refer to Volume III Attachment 1 Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 for a discussion of the long-term alterations in nutrients to the Klamath River downstream of Iron Gate Dam from lack of interception and retention by the dams and conversion of the reservoir areas to a free-flowing river. Volume III Attachment 1 presents the final Section 3.2 *Water Quality*. Please also refer to response to comment ORG46-88 for a discussion of how Section 3.2.2.1 *Water Quality – Environmental Setting –Overview of Water Quality Processes in the Klamath Basin – Nutrient cycling in reservoirs and internal loading* has been clarified to specify the most recent calculated annual nutrient retention amounts for the Lower Klamath Project dams (Asarian et al. 2009).

Additionally, Appendix C, Section C.3.1.1 *Hydroelectric Reach* (pages C-24 to C-33) has been revised to clarify the amount of variability in seasonal nutrient retention/release from the reservoirs by adding a discussion of the May 2005 to December 2007 (i.e., the time that nutrient data were measured by Asarian et al. [2009]) time series for Copco No. 1 and Iron Gate reservoirs. Please refer to Volume III Attachment 1 Appendix C, Section C.3.1.1 *Hydroelectric Reach* for the revisions.

Please also refer to responses to comments ORG46-122, ORG46-123, ORG46-139 and ORG46-140 for further discussion of the analysis of nutrient retention in the Copco No. 1 and Iron Gate reservoirs.

Please also refer to Volume I Section 3.4.5.1 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Phytoplankton* Potential Impact 3.4-2 (pages 3-426 to 3-433) and Volume I Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impact 3.4-4 (pages 3-435 to 3-437) and Potential Impact 3.4-5 (pages 3-437 to 3-440) for analysis of the alterations in the phytoplankton and periphyton growth due to increased nutrients under the Proposed Project.

Comment ORG46-35

The loss of production from Iron Gate Hatchery, which contributes a substantial portion of the Tribal, commercial, and sport fishing Chinook salmon harvest, would seem to be an unavoidable adverse impact of the Proposed Project, but this impact is not discussed in the Executive Summary. The contribution of Iron Gate Hatchery to Chinook harvest has averaged about 28,000 per year (California HSRG 2012).

Response to Comment ORG46-35

Section 3.3.5.6 *Aquatic Resources – Potential Impacts and Mitigation – Fish Hatcheries* discusses the likely effects of eight years of hatchery production following dam removal, including an analysis of the sources of hatchery and natural production likely to occur each year of dam removal and following dam removal through post-dam removal year 10. The potential for natural production of salmon smolts upstream of the current location of Iron Gate Dam is discussed for each species in Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* and is based on extensive review of scientific literature, and in the case of fall-run Chinook salmon Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7, a quantitative life-cycle model (Hendrix 2011). This analysis concludes a likelihood of successful recolonization and robust fall-run Chinook salmon production following dam removal and eight years of hatchery operation. Please also refer to Master Response AQF-2.

Please refer to Section 3.3.5.9 *Aquatic Resources – Potential Impacts and Mitigation – Aquatic Resource Impacts* Potential Impact 3.3-7 for an analysis of the effects of a reduction in hatchery production on the escapement of fall-fun Chinook salmon, and Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources – Potential Impacts to Tribal Cultural Resources* Potential Impact 3.12-9 for a discussion of the potential impacts of reduced hatchery production on tribal fisheries. Please also refer to Master Response AQF-3.

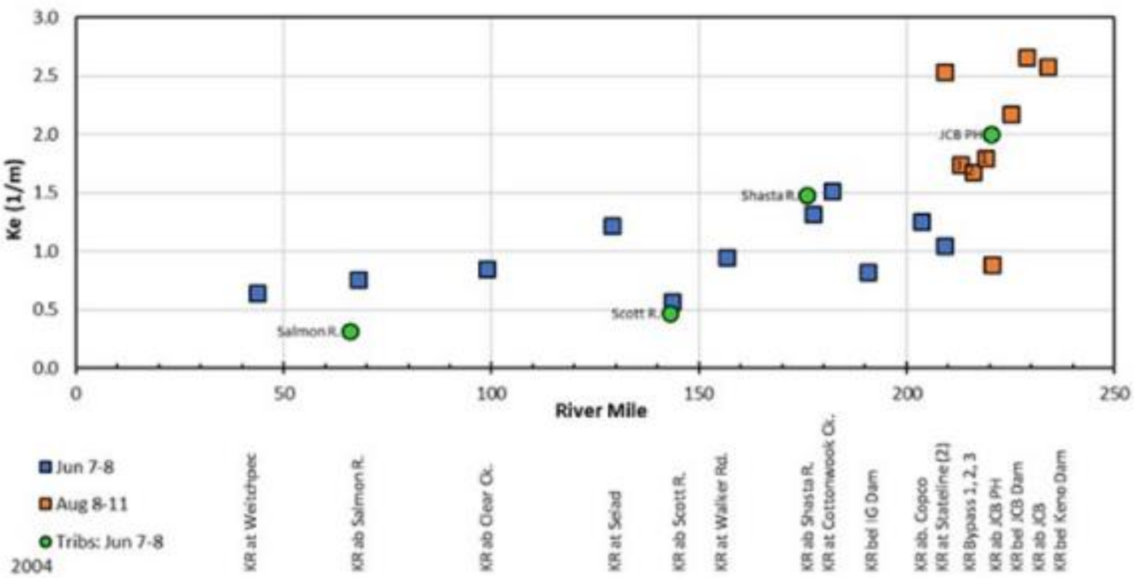
Comment ORG46-36

Regarding the Phytoplankton and Periphyton section, there is no reason on and why growth of periphyton would be restricted to the margins of the stream. Light limitation, which would be the element restricting periphyton growth, is not a restricting factor for much of the growing season in the Klamath River *downstream of Iron Gate Dam but can be a factor in the river upstream of Copco Reservoir.*

Light conditions in aquatic systems are typically characterized based on irradiance values for photosynthetically available radiation (PAR). Light limitation is assumed to occur beneath water depths associated with "onset saturation" values of PAR, which are values that occur when photosynthesis for typical macrophytes and diatoms produces excess oxygen. Onset saturation values in aquatic systems are typically less than about SO µmol PAR m·2 s·1 (Kirk 1994). Previous PAR measurements in the Klamath River have been used to calculate light extinction coefficients (PacifiCorp 2004a, 2014), which can then be used to calculate the depth of water where onset saturation occurs.

The approximate range of light extinction (Ke) measurements are O.S/m to 1/m in the Klamath River downstream of Iron Gate (see graph below). Based on this Ke range and a maximum PAR intensity of 1800 µmol PAR m· 2 s·1 (measured) at the water surface, the saturation compensation value of SO µmol PAR m·2 s·1 (per Kirk 1994) is reached at depths of about 11 to 20 feet. The vast majority of the Klamath River downstream of Iron Gate Dam is less than 11 feet in depth during the growing season. This indicates that light is generally not limiting periphyton growth in the Klamath River downstream of Iron Gate Dam.

By comparison, the approximate range of Ke measurements are 1.0 / m to 2.5/ m in the Klamath River upstream of Copco Reservoir (see graph below). This higher range of Ke measurements is atributable to the large organic loads contributed to the upper river by Upper Klamath Lake (PacifiCorp 2004a, 2014). Based on this Ke range, the saturation compensation value is reached at depths of about 5 to 11 feet. The depth of the Klamath River upstream of Copco Reservoir is more variable, with an appreciable portion is 5 to 11 feet or more in depth during the growing season. This indicates that light is likely limiting periphyton growth in many areas of the Klamath River upstream of Copco Reservoir.



Response to Comment ORG46-36

The EIR analysis for Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437) determined that potential periphyton growth within the Hydroelectric Reach would be most likely to occur along the channel margins since potential disruption of periphyton growth by increased flow variability during storm flow (see also Volume I Potential Impact 3.6-3) and more frequent river bed sediment movement (see also Volume I Potential Impact 3.11-5) under the Proposed Project would be more likely to limit periphyton growth in the middle of the river channel than along the channel margins. As acknowledged in Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437), there are multiple processes that influence periphyton establishment and growth (e.g., light availability, nutrient availability, water temperature, seasonal flow variations, sediment transport), so light availability alone would not determine the extent of growth within the channel.

Additionally, variations in the light extinction measurements upstream and downstream of the Oregon-California state line presented in the comment cannot be conclusively attributed to longitudinal differences in the Klamath River since the measurements upstream and downstream of the Oregon-California state line were collected at different times of the year when algal-derived (organic) suspended sediments in the Klamath River that would potentially influence light extinction measurements likely would be different. Light extinction measurements upstream of the Oregon-California state line were primarily conducted during August 8 to 11 (year not specified in the graph) when algal growth would likely be peaking, but light extinction measurements downstream of the Oregon-California state line were primarily conducted during June 7 to 8 (year not specified in the graph) when algal growth may be less. Light extinction (Ke) measurements varied abruptly near the same location (i.e., Oregon-California state line) between June (Ke approximately 1.0/m) and August (Ke approximately 2.5/m), suggesting the variations between the upstream and downstream light extinction measurements is potentially due to seasonal rather than longitudinal differences. As such, the longitudinal variations in light extinction should be considered for each period separately only. While there are likely variations in the light extinction between the upstream and downstream reaches of the Klamath River, additional data would be needed to determine that variation throughout the Klamath River.

While Volume I Potential Impact 3.4-4 explained why increased flow variability and sediment transport under the Proposed Project would likely limit periphyton growth to the channel margins, Potential Impact 3.4-4 has been revised to clarify that there is potential for periphyton growth in the Hydroelectric Reach wherever suitable habitat conditions occur in the river channel. Please refer to Volume III Attachment 1 Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* for the revisions.

However, the overall effect of the Proposed Project would likely increase periphyton in the portions of Copco No. 1 and Iron Gate reservoir footprints with suitable habitat for periphyton growth due to the creation of new, previously uncolonized low gradient river channels. Periphyton growth would be most likely to occur along the channel margins with shallower water depths, more light availability, warmer water temperatures, and lower probability of seasonal sediment transport and scour, but periphyton growth could also occur elsewhere in the channel where ever suitable habitat conditions exist. While there is considerable uncertainty, there is the potential under the Proposed Project that nuisance periphyton species could be part of the periphyton assemblages that grow in the new low gradient river channels. The nuisance periphyton species would potentially provide habitat for the polychaete worm (*Manayunkia speciosa*) that is the intermediate host of the fish parasites *Ceratomyxa shasta* and *Parvicapsula minibicornis*. Thus, if there were a short-term or long-term increase in growth of nuisance periphyton species due to increases in available habitat, especially along channel margin areas within the Copco No. 1 and Iron Gate reservoir footprints of the Hydroelectric Reach, potentially result in a new or further impairment of designated beneficial uses. It would therefore be a significant impact.

Comment ORG46-37

The DEIR states "efforts aimed at meeting Klamath River total maximum to the daily loads (TMDLs) are not analyzed for the short term under No Project Proposed Alternative because the basin response to the restoration measures to Project meet the TMDLs during the short term is too speculative." The DEIR is not clear in this section or elsewhere in the document whether and how the TMDLs are relied upon for analysis of short-term impacts for other alternatives. The DEIR also does not include a specific single location in the document where the rationale, assumptions, and approach for long-term impacts using the TMDLs are described.

Response to Comment ORG46-37
The EIR discusses the Total Maximum Daily Loads (TMDLs) where it is appropriate to do so (i.e., analyses about or related to water temperature, dissolved oxygen, pH, and nutrients). *Executive Summary* has been revised to clarify that the 'various efforts' and the 'restoration measures' cited in the text are referring to the same thing. The same statement in Section 4.2.1.1 *Alternatives – No Project Alternative – Introduction – Alternative Description* has also been revised. Please refer to Volume III Attachment 1 *Executive Summary* and Volume III Attachment 1 Section 4.2.1.1 *Alternatives – No Project Alternative – Introduction – Alternative Description* for the revisions.

Regrading TMDLs please also refer to Master Response WQ-5.

Comment ORG46-38
If the impacts are increasing in severity toward the right of the table, Significant and Unavoidable should be the final column. Switch the final two columns and indicate when there is no feasible mitigation for a specific impact.

Response to Comment ORG46-38
A significant and unavoidable impact is not necessarily more severe than a significant and unavoidable impact with mitigation. The impact severity depends on the resource in question, the details of the analysis, and the details of feasible mitigation. If there is no feasible mitigation for a particular impact, then there is no mitigation provided in the mitigation column. The footnote to Table ES-1 shown below has been repeated at the front of the table to be more easily seen by the reader.

"* Indicates a Significant and Unavoidable Impact that would be reduced to No Significant Impact with Mitigation if one or more Recommended Measures were to be implemented. Due to federal preemption, the State Water Board cannot guarantee the implementation of Recommended Measures."

For additional information regarding federal preemption and the Lower Klamath Project, please refer to Master Response CEQ-2.

Comment ORG46-39
The coding of long-term Potential Impacts 3.17-2 (Public Services) as significant and unavoidable with mitigation does not match the significance statement on page 3-919 (significant and unavoidable). The coding in Table ES-1 appears correct because the text on page 3-919 indicates that even with mitigation response time would increase, and any additional response time is defined as significant on p 3-916.

Response to Comment ORG46-39
The *Executive Summary – Summary of Proposed Project Effects, Potential Impacts, and Potential Cumulative Impacts* Table ES-1 has been revised to state

that in the long-term (L) for Potential Impact 3.17-2, impacts under the Proposed Project (PP), Partial Removal Alternative (PR), Two Dam Removal Alternative (2R), Three Dam Removal Alternative (3R),and No Hatchery Alternative (NH) would be significant and unavoidable. Likewise, the No Project (NP) has been corrected to be 'No Significant Impact'. These minor modifications to Table ES-1 are consistent with the analysis presented in EIR Section 4 *Alternatives*. Please refer to Volume III Attachment 1 *Executive Summary of Proposed Project Effects, Potential Impacts, and Potential Cumulative Impacts* for the revisions.

Comment ORG46-40

The potential impacts 3.10-1 and 3.10-2 contained in Table ES-1 related to Greenhouse Gas Emissions do not acknowledge the emissions impacts of removing hydroelectric generating resources that are qualified renewable resources under the California Renewal Portfolio Standard. Previous environmental analysis of potential removal of the Klamath Hydroelectric Project dams have evaluated a range of emissions impacts. FERC (2007) estimated an increase in carbon emissions impacts of removing the four Klamath dams to range between 68,600 and of 106,330 metric tons of carbon per year (FERC 2007, Table 4-8) while the Department of the Interior (DOI) and California Department of Fish and Wildlife (CDFW) (2012) estimated that removal of the hydroelectric facilities would result in an increase in regional emissions impacts from potential dam removal ranging between 341,S39 to 396,575 metric tons of carbon dioxide equivalent (MTC02e; see Tables 3.10-6 and 3.10-7 in DOI and CDFW 2012) assuming PacifiCorp attains the California Renewable Portfolio Standard of 33 percent renewable energy in 2020. The DEIR fails acknowledge the emissions impacts related to dam removal and only evaluates the increased emissions impacts related to dam deconstruction activities. However, the DEIR does state that removing the reservoirs would reduce methane emissions from the reservoirs. It is inconsistent for the DEIR to describe the potential for reduced methane emissions from Klamath Hydroelectric Project reservoirs - emissions which have never been documented and that FERC (2007) described as "speculative" - while failing to acknowledge or even attempt to quantify the emissions increase that will result from dam removal. The Klamath Hydroelectric Project generates carbon-free energy that can power the equivalent of approximately 70,000 homes. The Klamath Hydroelectric Project also provides voltage support, dependable capacity necessary to meet planning reserve and reliability standards mandated by the North American Energy Reliability Corporation. The Klamath Hydroelectric Project also provides ancillary services such as spinning reserve and voltage support that contribute to the reliability of the transmission system that cannot be entirely replaced through renewable energy resources. PacifiCorp will need to rely on the remainder of its generation fleet and market purchases to make up power lost from the Klamath Hydroelectric Project, and those sources, while increasingly renewable, have higher emissions than the Klamath Hydroelectric Project. The DEIR should be revised and recirculated to evaluate these impacts.

Response to Comment ORG46-40

This comment pertains to a portion of the Draft EIR that was recirculated on December 21, 2019. Please refer to the recirculated document (*Greenhouse Gas Emissions and Energy*).

Comment ORG46-41

Potential impacts 3.22-1 through 3.22-6 (Transportation and Traffic) should be coded as Significant and Unavoidable because the State Water Resources Control Board (State Water Board) cannot ensure implementation of that mitigation.

Response to Comment ORG46-41

The EIR's analysis of traffic and transportation impacts has been revised for the Proposed Project (PP) and for the Partial Removal Alternative (PR), Two Dam Removal Alternative (2R), Three Dam Removal Alternative (3R), and No Hatchery Alternative (NH) to reflect that traffic impacts referenced in the comment now are identified as less than significant with the implementation of Mitigation Measure TR-1. Table ES-1 has been revised accordingly. It is not clear whether the hydroelectric project owner or operator would implement traffic measures, including Implementation of Mitigation Measure TR-1, through 'good citizen' agreements under the Continued Operations with Fish Passage Alternative (CO) and it is unclear how these measures would be enforced. Thus, the significance determination has not been changed for the Continued Operations with Fish Passage Alternative. Please refer to Master Response CEQ-2. Please refer to Volume III Attachment 1 Table ES-1, Section 3.22 *Transportation and Traffic* and Section 4 *Alternatives* for the revisions.

Comment ORG46-42

This table of potential impacts shows no quantified data associated with each alternative, study area, or resource type (e.g., tribal, historic period archaeological, historic built environment) that allow for an effective comparison between alternatives and the Proposed Project. The numerous cultural resources studies previously conducted for the Klamath Hydroelectric Project identified tribal cultural resources, historic-period Resources) archaeological resources, and historic built environment resources using records searches, surveys, and consultation with tribes and local agencies. As-yet identified resources certainly will be found during future phases of the Proposed Project; however, known quantifiable data should be shared in the DEIR as a way to effectively compare alternatives and the Proposed Project while preserving the confidential nature of that data.

Response to Comment ORG46-42

As the title indicates, Table ES-1 is a summary of impacts and mitigation measures identified for the Proposed Project and six alternatives, across all resource areas, at specific geographic locations (where appropriate), and for the short term and long term timeframes analyzed in the EIR. It would not be appropriate for Table ES-1 to also present detailed quantified data for tribal, historic period archaeological, and/or historic built environment resources, as suggested by the comment. Greater detail, including known non-confidential resource data, can be found in Volume III Attachment 1 Section 3.12 *Historical Resources and Tribal Cultural Resources* and in the corresponding alternative subsections in Volume I Section 4 *Alternatives*.

Comment ORG46-43

We recommend referencing the USBR hydrology, hydraulic, and sediment transport study as 2011 even though an errata was issued in 2012.

U.S. Bureau of Reclamation (USBR). 2011. Hydrology, Hydraulics and Sediment Transport Studies for the Secretary's Determination on Klamath River Dam Removal and Basin Restoration, Technical Report No. SRH-201102, including Jan 2012 errata. Prepared for Mid-Pacific Region, Bureau of Reclamation, Technical Service Center, Denver, Colorado.

Response to Comment ORG46-43

The citation provided on the title page of United States Bureau of Reclamation's (USBR's) report is "Reclamation (2012). Hydrology, Hydraulics and Sediment Transport Studies for the Secretary's Determination on Klamath River Dam Removal and Basin Restoration, Technical Report No. SRH-2011-02. Prepared for Mid-Pacific Region, US Bureau of Reclamation, Technical Service Center, Denver, CO." The EIR Volume I correctly cites this report as a 2012 publication.

Comment ORG46-44

Neither J.C. Boyle or Copco No. 1 have functional low-level outlets as indicated on the table.

Response to Comment ORG46-44

Section 2.3 *Proposed Project – Existing Lower Klamath Project Features,* row six of Table 2.3-1, has been revised to clarify the type of feature that allows water to flow past the dams under existing conditions. References to diversion culverts/tunnels are no longer associated with J.C. Boyle and Copco No. 1 dams in Table 2.3-1, since these features are not functional under existing conditions. Please refer to Volume III Attachment 1 Section 2.3 *Proposed Project – Existing Lower Klamath Project Features* for the revisions.

Comment ORG46-45

Lost River and Shortnose suckers were listed in 1988 (53 FR 27130) not 1998 as listed in the text.

Response to Comment ORG46-45

Volume I Section 2.6.1 *Proposed Project – Project Background – Water Conflicts in the Klamath River Basin* has been clarified as requested. Please also note that the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III.

Please refer to Volume III Attachment 1 Section 2.6.1 *Proposed Project – Project Background – Water History in the Klamath River Basin* for the revision.

Comment ORG46-46
The DEIR states that the Klamath Tribes have experienced their 92nd year without access to salmon yet provides no supporting evidence for this point. This year count does not correspond to the completion date for Copco No. 1 in 1918 which did block fish passage.

Response to Comment ORG46-46
The timeline in Volume I Section 2.6.1 *Proposed Project – Project Background – Water Conflicts in the Klamath River Basin* has been modified to correct the year count to be 93 years. Please also note that the title for Section 2.6.1 of the EIR has been revised for clarity in Volume III. Please refer to Volume III Attachment 1 Section 2.6.1 *Project Background – Water History in the Klamath River Basin* for the revisions.

Comment ORG46-47
The timeline (in Section 2.6.1) is incomplete in terms of it missing any PacifiCorp actions (like the issuance of the original Project license in 1954, relicensing application in 2004, implementation of a Habitat Conservation Plan (HCP) for Coho salmon in 2014, the use of reservoir storage to benefit USBR irrigators and river flows in 2014 and 2018}, and so on. There is also no mention of water quality issues and cyanobacterial blooms in Upper Klamath Lake that will persist following potential dam removal.

Response to Comment ORG46-47
This section focuses on major events associated with water-related disputes in the Klamath Basin and is not intended to be a comprehensive history of water use and/or management in the basin.

Comment ORG46-48
The second half of this paragraph has no bearing on the content of the DEIR and should be removed.

Response to Comment ORG46-48
As described in Volume I Section 2.6.1 *Proposed Project – Project Background – Water Conflicts in the Klamath River Basin* (page 2-22), the second half of the paragraph referenced by the commenter is included in the EIR to acknowledge the broader context within which the issue of dam removal currently exists in the Klamath Basin.

Comment ORG46-49
While basically accurate, this discussion omits mention of the current FERC status. The text should clarify that at this time, PacifiCorp is still the sole owner of the entire Klamath Hydroelectric Project and that FERC has not acted on the

transfer request let alone the surrender request. Significantly, FERC has not yet evaluated the Definite Plan (presented in DEIR Appendix B) or conducted analysis in accordance with the National Environmental Policy Act (NEPA) to determine if the Definite Plan should be modified to reflect dam safety concerns or mitigate potential environmental impacts.

Response to Comment ORG46-49

The EIR states that PacifiCorp currently owns and operates the Lower Klamath Project, and that, among other authorities, Federal Energy Regulatory Commission (FERC) must approve and set conditions for transfer of ownership and decommissioning (please refer to Volume I Section 2.4 *Surrounding Land Ownership and Land Use* [page 2-16] and Section 2.6.2 *Relationship with Klamath Hydroelectric Project* [pages 2-22 to 2-23]).

Comment ORG46-50

Using the term 'Dam Removal Year 1' to refer to Proposed Project actions that occur before dams are actually removed is confusing to the reader.

Response to Comment ORG46-50

As shown in Volume I Table 2.7-1, Dam Removal Year 1 is the year that drawdown and dam removal begins (i.e., Copco No. 1 Dam drawdown and dam removal begin in November and December). Drawdown and dam removal are the primary actions in the Proposed Project, and these actions involve impacts that are distinct from other types of actions in this multi-year project. Therefore, it is helpful to the reader to designate a timeframe based on the start of these actions.

Comment ORG46-51

This figure oversimplifies the relationship between reservoir drawdown and the fish life cycles on the Klamath River. Based on the other information in the DEIR, suspended sediment loads could extend well through the spring following drawdown yet the figure limits this to early March for Copco No. 1 and Iron Gate reservoirs. This is misleading. Also, this figure is missing Eulachon, an anadromous and ESA-listed species found in the lower Klamath River. Coho adult migration may end in December at Iron Gate Dam, but in the tributaries downstream of Iron Gate Dam it can extend into early January (MKWC 2015, 2016, 2017).

*Why is there a * for Copco 1 which according to the footnote means "No significant release of sediment expected" yet there is no information presented to support this assertion?*

Response to Comment ORG46-51

Section 2.7 *Proposed Project – Proposed Project* has been revised to clarify that based on the distribution and life-history timing of aquatic species in the Klamath Basin, only a portion of fish populations are likely to be present in the mainstem

Klamath River during the reservoir drawdown period, which is also the period of greatest sediment transport, and to refer the reader to Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-3 for additional information. Figure 2.7-1 has been revised to include eulachon and to make associated updates to the figure legend associated with this species and reservoir drawdown timing. Coho salmon spawning timing is shown for mainstem Klamath River, and not the tributaries, since it is the life history timing within the mainstem that is relevant for assessing impact of sediment release illustrated by the figure. Please refer to Volume III Attachment 1 Section 2.7 *Proposed Project – Proposed Project* for the revisions.

Comment ORG46-52

The Proposed Project includes the cessation of power generation at Copco No. 1 in fall 2020. As per Section 7.3.3 of the Klamath Hydropower Settlement Agreement (KHSA), cessation of generation before December 31, 2020, requires that additional value to customers be identified. Unless that is included, the Proposed Project should be revised to accurately reflect the requirements of the KHSA.

Operations of Copco No. 2 following drawdown of Copco No. 1 are unclear from the Proposed Project discussion in the DEIR. PacifiCorp would not continue to attempt to operate Copco No. 2 after drawdown of Copco No. 1. Once the sediment from Copco Reservoir begins to mobilize, operations of Copco No. 2 would not be feasible.

Response to Comment ORG46-52

The Klamath River Renewal Corporation's (KRRC's) Definite Plan (2017) proposed that generation of power at Copco No. 2 Dam (with sediment-laden flow) would continue for up to four months after January 1, 2021 (or until May 1, 2021) to offset lost revenue from shutting Copco No. 1 down prior to January 1, assuming that the Copco No. 2 generating equipment will be capable of operating under such conditions. As noted in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, the shift in the Proposed Project Copco No. 2 drawdown timing from January 1 (Appendix B: *Detailed Plan*) to May 1 (Appendix B: *Definite Plan*) would not change the anticipated magnitude or timing of significant impacts due to elevated suspended sediment concentrations (SSCs) in the Hydroelectric Reach during dam removal year 2. The State Water Board notes that the KRRC has now proposed that dam removal year 1 – which includes the cessation of power production at Copco No. 1 – would be 2021. This is after the December 2020 date in the Klamath Hydropower Settlement Agreement (KHSA).

While in general, comments on the Definite Plan should be submitted to the KRRC, the State Water Board notes PacifiCorp's statement that the company would not continue to operate Copco No. 2 Powerplant once the sediment from Copco No. 1 Reservoir begins to mobilize and after drawdown of Copco No. 1

Reservoir. The EIR indicates that Copco No. 2 Reservoir drawdown would occur in May of dam removal year 2, as proposed by KRRC (see Volume I Section 2.7 *Proposed Project – Proposed Project* Table 2.7-1 and Figure 2.7-1 [as modified in Volume III Attachment 1]), and the analyses assume continued production at Copco No. 2 Powerhouse because the need to halt production is speculative. The EIR also acknowledges the uncertainty related to continuing Copco No. 2 Powerplant operation by stating that if Copco No. 2 Powerhouse is not capable of operating under sediment-laden conditions, then drawdown of this reservoir would still use the penstock (Volume I Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* [specifically page 2-57]).

Please note that the State Water Board issued a draft water quality certification which sets forth Condition 3 requiring that Copco No. 2 Reservoir drawdown conclude no later than March 15 of the year following initiation of Copco No. 1 Reservoir drawdown.

Comment ORG46-53

The discussion of operations of the low-level outlets seems to have gotten confused with the spillways. Presumably once reservoirs are drawn down, there would be no complete refill such that the spillways at Iron Gate or Copco dams could be activated.

Response to Comment ORG46-53

Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* has been revised to clarify the reference to the diversion control tunnels and structures, rather than the spillways. Please refer to Volume III Attachment 1 Section 2.7.2 *Proposed Project – Proposed Project – Reservoir Drawdown* for the revisions.

Comment ORG46-54

Once Iron Gate Reservoir is below the spillway elevation, the only way to pass water out of the reservoir is through the turbine, bypass valve at the turbine, or the low-level outlet. The powerhouse will be offline and unavailable and the spillway will be well above the water surface elevation. It is unclear from this paragraph what the intent is, but the facilities would not be able to spill this water and so inflow greater than the capacity of the low-level outlet would accumulate in the reservoir. The list of flood capacities seems inappropriate and does not include March-May which includes the peak snowmelt period.

Response to Comment ORG46-54

Volume I Section 2.7.2 *Proposed Project – Reservoir Drawdown* has been revised to clarify that the spillway at Iron Gate Dam would not be used unless Iron Gate Reservoir were to fully refill, and the diversion control gates would be used for passing water through the dams. Additionally, the flood capacities have been corrected and text regarding dam removal timing has been included to indicate that during dam removal of all four dams, the drawdown of Iron Gate

Reservoir would maintain enough capacity to pass a 1 percent probable flood for that time of year, in order to reduce the potential for flow to overtop the Iron Gate Dam embankment (Volume II Appendix B: *Definite Plan*). This statement includes the spring runoff period. Further, removal of Copco No. 1 Dam sections and Copco No. 2 Dam would begin after May 15 of dam removal year 2, and removal of Iron Gate would occur between June 1 and September 30 of dam removal year 2, the dams would retain their existing flood capacity during the peak snowmelt period. Please refer to Volume III Attachment 1 Section 2.7.2 *Proposed Project – Reservoir Drawdown* for the revisions.

Comment ORG46-55

This paragraph has the same flow control issues as the one on the previous page (see comment 2.12). With J.C. Boyle Powerhouse offline, use of the power intake and the power canal to move water would require use of the emergency spillway which seems unlikely. The DEIR also fails to consider the possibility of flood flows during spring when snowmelt is most likely. J.C. Boyle Reservoir would be drawn down by mid-March like the rest of the reservoirs.

Response to Comment ORG46-55

Section 2.7.2 *Proposed Project – Reservoir Drawdown* has been revised to clarify that because removal of J.C. Boyle Dam would occur beginning in mid-June of dam removal year 2, the dam would retain its existing flood capacity during the peak snowmelt period. Please refer to Volume III Attachment 1 Section 2.7.2 *Proposed Project – Reservoir Drawdown* for the revisions.

Comment ORG46-56

The DEIR states that "Release flows would add water to the otherwise existing flows in the river (i.e., Keno Reservoir releases and tributary inflows)." This is true, but if the Klamath River Renewal Corporation (KRRC) is releasing water from Copco and Iron Gate reservoirs as part of drawdown, PacifiCorp expects that USBR will release the minimum necessary to achieve biological opinion (BiOp) target flows at the Iron Gate U.S. Geological Survey (USGS) gage and not release anything above the absolute minimum from Keno Dam to J.C. Boyle Dam. All that extra water would be retained in Upper Klamath Lake by USBR for other uses.

Response to Comment ORG46-56

The paragraph referenced in the comment discusses the range of release flows that would occur in the Klamath River due to drawdown of the three larger reservoirs, and contextualizes these flows by providing the 2-year and 10-year peak flows in the Klamath River at the three reservoir locations. It does not rely on any assumptions regarding United States Bureau of Reclamation's (USBR's) operations during drawdown. As noted in the reference paragraph, more detail regarding release flows and associated assumptions is in Volume I Section 3.6.5.1 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain*.

Comment ORG46-57

The DEIR does not include any of the 2017 reservoir sediment boring data to collected by the KRRC.

Response to Comment ORG46-57

To the State Water Board's knowledge, there were no sediment cores collected from the Lower Klamath Project in 2017. In February 2018, Klamath River Renewal Corporation (KRRC) collected eleven sediment cores at Copco No. 1 Reservoir to characterize and analyze the stability of the sediment deposits present around much of the rim of the reservoir and within the reservoir bed, and three sediment cores at Iron Gate Reservoir to characterize past landslides and to inform design of the replacement water supply pipeline for the City of Yreka (Volume II Appendix B: *Definite Plan – Appendix E*). No sediment cores were collected at J.C. Boyle Reservoir.

The 2018 sediment core data were not collected to further characterize the composition or thickness of the sediment deposits for the purpose of informing estimates of the total amount of sediment present in the reservoir footprints or how much sediment would erode during reservoir drawdown, which are the focus of the discussion in Volume I Section 2.7.3 *Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown*.

The sediment core data referenced in Section 2.7.3 are spatially distributed across the reservoirs and the depth of the cores (i.e., record length) is sufficiently long that pre-reservoir sediment could be distinguished, thus the data are considered technically sound for providing an estimate of the volume of reservoir sediment deposits (see Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants*). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*. Using more recent sediment core data would not be expected to change the range of stored sediment estimates presented in Volume 1 Section 2.7.3 *Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* Table 2.7-10 (page 2-67) and Volume I Section 3.11.2.5 *Geology, Soils, and Mineral Resources – Environmental Setting – Reservoir Sediment Storage and Composition* Table 3.11-4 (page 3-754). The uncertainty of the reservoir sediment volume estimates is reasonable for sediment yield analyses, which generally use modeling to estimate the order of magnitude of annual sediment yield.

Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* has been revised according to the above discussion. Please refer to Volume III Attachment 1 Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* for the revisions.

Please also note that the February 2018 sediment cores do provide additional information useful for the assessment of potential sediment instability along the reservoir rims and within the deposits on the reservoir beds during and immediately following reservoir drawdown, and as such are discussed in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-3 (pages 3-761 to 3-765).

Comment ORG46-58

The DEIR states that 80 percent of the reservoir sediment is composed of fine sediment but other references in the DEIR (e.g., Stillwater Sciences 2010, USBR 2012c) say the value is 85 percent.

Response to Comment ORG46-58

Silt and clay comprise 84.8 percent of reservoir sediments, averaged across J.C. Boyle, Copco No. 1, and Iron Gate reservoirs (see Volume I Table 2.7-10 in Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* (page 2-67) and Table 3.11-4 in Section 3.11.2.5 *Geology, Soils, and Mineral Resources – Environmental Setting – Reservoir Sediment Storage and Composition* (page 3-754). Therefore, stating "over 80 percent of the reservoir sediments are fine sediment" and "more than 80 percent fine sediment" is accurate.

Comment ORG46-59

This section of the DEIR should include a discussion of how the sediment size classes are distributed spatially within the reservoir and what impact that spatial variability has on the mobilization of the respective sediment classes during drawdown. For example, larger particles are often preferentially located at the head of the impoundment and these head areas will be the first areas exposed to steeper water surface slopes and increased bed shear stress during the drawdown.

Response to Comment ORG46-59

Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* (pages 2-60 to 2-69) Section 2.73 *[Proposed Project] Reservoir Sediment Deposits and Erosion During Drawdown* (pages 2-60 to 2-69) of the EIR has been clarified revised in Volume III to include information on the spatial patterns of sediment accumulation in the reservoirs. Please refer to Volume III Attachment 1 Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* for the revisions. Coarse-grained sediments are concentrated near the primary inlets of the J.C. Boyle, Copco No. 1, and Iron Gate reservoirs, and in the Copco No. 2 Reservoir where minimal reservoir sediment accumulation has occurred (USBR 2010; USBR 2012a). These coarser particles may be mobilized during drawdown but are unlikely to be transported substantial distances downstream because total water discharge during drawdown would be similar to, or less than, the historical seasonal 10-year flood. The coarser particles may be mobilized in later flood events but are not modeled to be transported past Cottonwood Creek (USBR 2012a). Although, Section 2.7.3 *[Proposed Project] Reservoir Sediment Deposits and Erosion During Drawdown* (pages 2-60 to 2-69) discusses sediment erosion during drawdown, please note that this subject is more comprehensively addressed in Potential Impact 3.11-5 in Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* (pages 3-765 to 3-775), which is modified in Volume III Attachment 1.

Comment ORG46-60

The figures in the DEIR showing sediment depths should be updated to reflect data collected by the KRRC during studies to support removal, including detailed bathymetric mapping and additional geotechnical investigations. This would help address the "uncertainty in sediment volume estimates" (DEIR pg. 2-65).

Response to Comment ORG46-60

The primary technical reports relating to in-reservoir sedimentation are USBR (2010) and USBR (2012a). Volume I Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* has been clarified by adding information characterizing in-reservoir sediment deposition. Please refer to Volume III Attachment 1 Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown* for the revisions. Bathymetric figures for Copco No. 1 and Iron Gate reservoirs are already included in Volume I Section 2.7.2 *Proposed Project – Reservoir Drawdown,* Figure 2.7-5 and Figure 2.7-6 (pages 2-55 and 2-56). These figures represent the most recent data, the Klamath River Renewal Corporation (KRRC) and their consultants have not provided the State Water Board with any new information.

Regarding the uncertainty of sediment deposit volumetric estimates, please refer to comment response ORG46-8.

Comment ORG46-61

The DEIR states that "Whether the actual reservoir sediment volumes are on the higher end or the lower end of the uncertainty estimate, the dam removal approach and the significance of potential impacts due to sediment transport during reservoir drawdown would remain the same." The DEIR should explain why the significance of potential impacts associated with downstream sediment transport during the drawdown is unrelated to the total volume predicted to be transported. This conclusion appears tied to the DEIR's incorrect assumption that fine sediment released during the drawdown would remain in suspension in the 190-mile-long reach downstream of Iron Gate Dam to the Pacific Ocean (see Major Issue 2.4 and comment 3.5-8). However, some fraction of the total fine sediment load will settle out in the riverine system, such as on the channel margins, back waters, pools, or point bars. Therefore, it follows that the magnitude of the impact would be directly related to the volume of sediment estimated to transported downstream.

Response to Comment ORG46-61
The statement quoted by the commenter explains that the EIR has considered the potential lower and upper estimates of sediment deposits that would mobilize during drawdown, and that deposited sediment volumes within this range do not result in a change to the breadth or severity of potential impacts analyzed in the EIR. This is because: a) for water quality, exceedances of 100 mg/L suspended sediment concentrations (SSCs) over a continuous two-week exposure period would occur for a similar number of months during and following drawdown for the range (lower and upper estimates) of sediment volume expected to mobilize (see Volume III Attachment 1 Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3). Additionally, please refer to Volume II, Appendix D, Section D.2 for a discussion of how and why the State Water Board chose the significance criteria for potential water quality effects; b) for geomorphology, the anticipated morphological responses are not expected to differ substantially while sediment volumes are within an order of magnitude (see Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 [pages 3-765 to 3-775] and modifications to this impact in Volume III Attachment 1); and c) the potential impacts to aquatic organisms are related to both SSCs and morphological change (see Volume III Attachment 1 *Aquatic Resources*).

Please also refer to Master Response GEO-1, relating to fine sediment erosion, transport, and deposition, and morphological responses.

Comment ORG46-62
The DEIR states "Sediment jetting would be focused in the six areas where restoration actions are proposed within the Copco No. 1 Reservoir footprint (Figure 2.7-11) and the three areas where restoration actions are proposed within the Iron Gate Reservoir footprint (Figure 2.7-12)." It is not clear from the referenced figures where sediment jetting will occur as these areas are not called out in the figures.

Response to Comment ORG46-62
Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown*, Section 2.7.4.2 *Proposed Project – Proposed Project – Restoration Within the Reservoir Footprint – Reservoir Restoration Features,* Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, and Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 have been clarified to indicate the location of sediment jetting. Please refer to Volume III Attachment 1 Section 2.7.3 *Proposed Project – Proposed Project – Reservoir Sediment Deposits and Erosion During Drawdown*, Volume III Attachment 1 Section 2.7.4.2 *Proposed Project – Proposed Project – Restoration Within the Reservoir Footprint – Reservoir Restoration Features,* Volume III Attachment 1 Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, and Volume III

Attachment 1 Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 for the revisions.

Comment ORG46-63

Sediment jetting was not included in the modeling conducted by USBR (2012). The DEIR needs to explain how this activity would affect suspended sediment concentrations and should be discussed to determine if sediment jetting will increase the amount of sediment mobilized from the reservoirs, which could presumably increase the magnitude and/or duration of sediment impacts downstream.

Response to Comment ORG46-63

With respect to the potential for additional inputs of sediment due to the proposed sediment jetting during reservoir drawdown, Table 3.2-12 (page 3-86) presented in Potential Impact 3.2-3 in Volume I Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments,* includes explicit consideration of the volume and percentage of sediment that would be eroded by sediment jetting, separate from sediment transport analyzed by the U.S. Bureau of Reclamation (USBR) 2012 model. The column in Table 3.2-12 entitled "2020 Sediment Volume Erosion[3,4] (cubic yards)" includes the volume of sediment that would be eroded by drawdown plus sediment jetting, and the "Percentage of 2020 Sediment Volume Transported by Sediment Jetting (%)" presents the amount of sediment that would be mobilized via sediment jetting as a fraction of the total reservoir sediment deposits to be eroded. Sediment jetting would be conducted in a limited number of locations within the reservoir footprints and in a manner that would not erode significant additional masses of surficial sediment compared with the original USBR (2012a) estimates of sediment mobilization, which did not include sediment jetting. As such, the assessment in Potential Impact 3.11-5 in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* (pages 3-765 to 3-775), is accurate. The analysis in Potential Impact 3.11-5 is consistent with both USBR (2012a) and Section 3.2 *Water Quality* of the EIR. Please also refer to Master Response WQ-3.

Comment ORG46-64

The DEIR states "A faster drawdown rate would reduce the time of interaction between the flow and reservoir sediment deposits, thus reducing the overall amount of sediment erosion, whereas a slower drawdown rate would increase the time of interaction between the flow and reservoir sediment deposits, thus increasing the overall amount of sediment erosion. It is expected that increasing the previously modeled maximum drawdown rate of 2.25 to 3 feet per day (USBR 2012c) to the Proposed Project maximum drawdown rate of 5 feet per day (Appendix B: Definite Plan - Appendix P) would slightly decrease the total amount of sediment erosion that occurs during drawdown."

The DEIR needs to clarify the basis for this stated conclusion. As written, this statement is an oversimplification of a complex set of interrelated forces. A faster drawdown rate might reduce the duration of direct erosion, but it might increase the rate of erosion resulting from the steeper water gradient (higher velocities) and increase the probability of slump failures due to increased pore-pressure. In addition, the numeric model used in the DEIR does not account for erosion from slump failures. Therefore, the conclusion in the DEIR that a faster drawdown rate would result in lower total mass erosion is not accurate. Rather, it is possible that a faster drawdown rate would produce higher volumes of eroded sediment.

Response to Comment ORG46-64
Please refer to response to comment ORG46-8.

Comment ORG46-65
The DEIR states "The previously modeled maximum drawdown rate would result in 36 to 57 percent of erosion of the sediment deposit from the reservoirs (Table 2.7-11) and increasing the drawdown rate to 5 feet per day would most likely result in an amount of erosion toward the lower end of the estimated range or slightly lower." See the comment 2.22 above regarding effects of drawdown rates on potential erosion.

These eroded volume estimates are very large numbers that are difficult to put into perspective; it would be helpful for the DEIR to relate the eroded volume estimates to the average annual sediment load to provide context. These estimates also indicate that approximately 6.5 to 9.7 million cubic yards of sediments would be retained in the reservoirs after initial reservoir drawdown. The DEIR should address the longer-term effects caused by these retained sediments that could occur during future high flow events.

Response to Comment ORG46-65
Regarding sediment erosion during drawdown, please see ORG46-8.

In terms of relating the potential mass of sediment erosion to the average annual sediment load, please refer to response to comment ORG46-31.

Regarding the potential long-term effects related to the sediment retained within the reservoirs after drawdown, please refer to Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-768 to 3-769) and modifications to this impact in Volume III Attachment 1, and to ORG46-8.

Comment ORG46-66
According to the KHSA, PacifiCorp is to provide funding for up to 8 years of operations of Iron Gate Hatchery following decommissioning. What happens to

the hatchery after that period of time is unclear, but it is speculative to assume that it would cease to function entirely.

Response to Comment ORG46-66
The EIR acknowledges that there is uncertainty as to whether the Iron Gate Hatchery facility would be decommissioned in place, demolished, or partly or fully repurposed after the eight-year operational period (Volume I Section 2.7.6.1 *Proposed Project – Proposed Project – Hatchery Operations – Iron Gate Hatchery*, page 2-77). In light of the lack of identified funds for operation, a scenario involving continuing operation is speculative. Please also refer to Master Response AQF-2.

Comment ORG46-67
The auxiliary trap at the Iron Gate Hatchery already exists. While there is other construction work proposed to occur at the hatchery, there is no new construction for this item.

Response to Comment ORG46-67
Section 2.7.6.1 *Proposed Project – Proposed Project – Hatchery Operations – Iron Gate Hatchery* has been clarified as requested. Please refer to Volume III Attachment 1 Section 2.7.6.1 *Proposed Project – Proposed Project – Hatchery Operations – Iron Gate Hatchery* for the revision.

Comment ORG46-68
It would appear that there is not enough water to operate Iron Gate Hatchery during certain months of the year (in both spring and fall) and the DEIR does not propose a viable alternative. The DEIR says that recirculation and early release 'would be studied' to see if they meet the goals. Early smolt releases would have an effect on overall returns of adult Chinook salmon and should be evaluated as an alternative hatchery operations in the effects analysis. These fish would be smaller than target sizes and may not survive as well as those released later in the season.

Response to Comment ORG46-68
Based on available flow data for Bogus Creek (Volume I Figure 2.7-14), the Iron Gate Hatchery water supply may not be sufficient to provide for all of the three hatchery raceways for short periods of time during fall and winter months under dry conditions; however, since the hatchery raceways would not be used for rearing Chinook salmon smolts during the fall and winter, this would not present a concern. It is also possible that during some years Iron Gate Hatchery could experience a deficit of up to 4 cubic feet per second (cfs) to operate the hatchery for several consecutive days in the mid- to late spring, when Chinook salmon smolts would be rearing in the raceways. Each of the three rearing ponds at Iron Gate Hatchery requires 2.25 cfs to operate, for a total 6.75 cfs requirement for the raceways. A temporary deficit of 4 cfs could result in one to two rearing ponds experiencing insufficient flows to operate, requiring an "early" release of

one- to two-thirds of Iron Gate Hatchery rearing smolts to the Klamath River. As the intended release period for Chinook salmon at Iron Gate Hatchery is April through May (mid- to late spring), smolts released in mid-April of some years would not necessarily be released earlier than would otherwise occur, or they may only experience release a few weeks earlier than would otherwise occur. Smolts released early in the season may be slightly smaller than smolts released later in the season, and therefore they could experience somewhat lower riverine and marine survival than their larger counterparts (Scheuerell et al. 2009, Feldhaus et al. 2016). Chinook salmon yearlings (which have higher survival) would be raised at Fall Creek Hatchery (FCH) and would not be affected by reduced instream flows in Bogus Creek.

In sum, there is potential that in some years, one- to two- thirds of Chinook smolts rearing at Iron Gate Hatchery may be released slightly earlier than would occur if more water were available in Bogus Creek. Overall, the infrequent occurrence of the potential for early smolt release for a proportion of Chinook smolts from Iron Gate Hatchery, and the small difference in timing (and therefore smolt size and survival) is unlikely to result in a significant reduction in returns of adult fall-run Chinook salmon to the Klamath River.

Comment ORG46-69

The DEIR states that "As Fall Creek Hatchery is part of PacifiCorp's Klamath project...facilities are subject to the terms of any new FERC action for 2082." While the Fall Creek Development (diversions, penstock, powerhouse, tailrace, etc.) are in the FERC license, the Fall Creek Hatchery is not in the current license for the Klamath Hydroelectric Project (P-2082). Reference to any terms and conditions for Fall Creek Development (including the hatchery facilities) is speculative and should be removed from the DEIR.

Response to Comment ORG46-69

Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* and Section 4.7.1 *Alternatives – No Hatchery Alternative – Introduction* have been clarified as requested. Please refer to Volume III Attachment 1 Section 2.7.6.2 *Proposed Project – Proposed Project – Hatchery Operations – Fall Creek Hatchery* and Section 4.7.1 *Alternatives – No Hatchery Alternative – Introduction* for the revisions.

Comment ORG46-70

This figure is out of date and does not represent the current proposed improvements at the Fall Creek Hatchery. PacifiCorp's understanding is that the two settling pond locations shown in the inset on this figure were removed from consideration because of cultural resource concerns and that the settling pond is currently planned to go where the figure shows the lower rearing tanks. The DEIR needs to be updated to reflect the actual proposal.

Response to Comment ORG46-70
The Proposed Project description is based on the information provided in Volume II Appendix B: *Definite Plan – Appendix H* and acknowledges that selection of the settling pond site is pending cultural resources investigations and consultation with tribes with historical and cultural connection to the area (see Volume I Section 2.7.6.2 *Proposed Project – Hatchery Operations – Fall Creek Hatchery*, page 2-81). Additionally, Volume I Section 2.7.6.2 *Proposed Project – Hatchery Operations – Fall Creek Hatchery* Figure 2.7-15 (page 2-83) states in the legend that the location of the Fall Creek powerhouse and hatchery infrastructure is approximate.

Additionally, as listed in Section 3.12.5.1 *Historical Resources and Tribal Cultural Resources –Potential Impacts and Mitigation – Potential Impacts to Tribal Cultural Resources* Tribal Cultural Resources Mitigation Measure TCR-1, the KRRC shall develop, in consultation with Affected Tribes, a Historic Properties Management Plan. In part, the Tribal Cultural Resources Management Program (TCRMP) shall include site-specific mitigation measures for potentially affected TCRs [Tribal Cultural Resource]. The TCRMP shall provide for ongoing consultation or site-specific mitigation refinement with the relevant Affected Tribe(s) with a traditional and cultural affiliation to an impacted TCR, as appropriate and feasible consistent with the schedule for Project implementation.

Mitigation Measure TCR-1 further states, "Consistent with KHSA [Klamath Hydroelectric Settlement Agreement] Section 7.6.6, the TCRMP shall also include recommended measures to identify, avoid, minimize, or mitigate adverse impacts to TCRs during rehabilitation and expansion of Fall Creek Hatchery (FCH), consistent with California Public Resources Code section 21084.3(a) and (b). Please refer to Volume III Attachment 1 for the final Section 3.12 *Historical Resources and Tribal Cultural Resources.*

The EIR thus discloses the potential for changes to the Fall Creek Hatchery plans based on cultural resources.

Comment ORG46-71
Similar to the comment on the Fall Creek Hatchery, the DEIR does not accurately represent the Proposed Project, which would limit the upstream distribution of anadromous fish in Fall Creek such that they would not be provided access to either of the areas where the City of Yreka diverts water thereby eliminating the need for updated fish screens.

Response to Comment ORG46-71
Section 2.7.7 *Proposed Project – City of Yreka Water Supply Pipeline Relocation* has been revised to include the Klamath River Renewal Corporation's (KRRC's) updated proposal to include a permanent fish passage barrier at the Fall Creek Hatchery (FCH), located approximately 200 to 300 feet downstream of both Dams A and B (KRRC 2019a), such that there would be no need for updates to

the City of Yreka's Dam A or B existing diversion intake structures. This would reduce by 200 to 300 feet the approximately one mile of increased habitat for anadromous salmonids upstream of Iron Gate Dam that would occur under the Proposed Project; however, as discussed in Potential Impact 3.3-24, the proportion of anadromous salmonids anticipated to use the habitat in Fall Creek is relatively minor in comparison with the totality of newly accessible habitat upstream of Iron Gate Dam under the Proposed Project and there would be no change in significance determinations in the EIR. Please refer to Volume III Attachment 1 Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* for the revisions.

Comment ORG46-72

Daggett Road bridge gets completely replaced under the Proposed Project. The DEIR references the "...existing timber traffic bridge along Daggett Road..."

Response to Comment ORG46-72

Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* has been clarified as requested. Please refer to Volume III Attachment 1 Section 2.7.7 *Proposed Project – Proposed Project – City of Yreka Water Supply Pipeline Relocation* for the revisions.

Comment ORG46-73

Except for the salvaging of overwintering fish from the mainstem Klamath River, AR-2 does nothing to minimize the impacts of high loads of suspended sediments juvenile salmonids migrating from the tributaries. This means that AR-2 is not a true mitigation measure for many of the impacts associated with the Proposed Project.

Response to Comment ORG46-73

As described in Volume I Section 2.7.8.1 *Proposed Project – Other Project Components – Aquatic Resource Measures*, Aquatic Resource Measure AR-2 proposes three primary actions to reduce short-term suspended sediment impacts to outmigrating juvenile fish: (1) salvaging mainstem overwintering juvenile salmonids prior to reservoir drawdown; (2) maintaining tributary-mainstem connectivity to ensure volitional fish passage between tributaries and the Klamath River (in conjunction with AR-1 efforts); and (3) developing a water quality monitoring network, trigger thresholds, and plan for salvaging and relocating juvenile fish from tributary confluence areas to cool water tributaries or nearby off-channel ponds. These actions are included in the Proposed Project and are not subject to CEQA Guidelines section 15126.4. As proposed by Klamath River Renewal Corporation (KRRC), these actions are appropriate in scale and type to offset anticipated impacts to juvenile salmonids from release of sediment under the Proposed Project. However, as discussed in Volume III Attachment 1 Potential Impact 3.3-1, mitigation measures AQR-1 and AQR-2 would be required to increase certainty of the effectiveness of the aquatic resource measures AR-1 and AR-2 and to reduce the short-term significant adverse impacts of the Proposed Project on coho salmon critical habitat. Mitigation measures AQR-1 and AQR-2 are consistent with CEQA requirements for feasible, enforceable, and proportional mitigation, as detailed in CEQA Guidelines section 15126.4.

Comment ORG46-74

The DEIR indicates that the KRRC recreation plan is proposing a trail from J.C. Boyle to Iron Gate even though this crosses property that would be retained by PacifiCorp. No easement or easement-related discussions have occurred that would make this a reasonably foreseeable action. PacifiCorp recognizes that the DEIR says that the KRRC "may" provide these recreational opportunities, but inclusion of them in the DEIR misleads the reader into thinking that these are actually proposed. If they are truly proposed, then the DEIR needs to evaluate the impact of constructing, operating, and maintaining these elements of the Proposed Project.

Response to Comment ORG46-74

The Klamath River Renewal Corporation's (KRRC's) Definite Plan (2017) proposes that new river-based opportunities may include a new trail between J.C. Boyle Dam and the Iron Gate Fish Hatchery. Additional detail about land ownership is provided in Volume II Appendix B: *Definite Plan – Appendix Q*, where KRRC recognizes that the new trail would need to cross PacifiCorp Parcel A lands, Bureau of Land Management (BLM) lands, private lands, and potentially United States Forest Service (USFS) lands. For discussion of how the EIR considers the level of detail in KRRC's Recreation Plan, please refer to Master Response REC-2. This discussion notes that recreation plans are still under development. The EIR thus describes the proposed action, but also notes that the recreation components of the action are subject to change. Please also refer to Volume III Attachment 1 for the final Section 3.20 *Recreation*.

Comment ORG46-75

The DEIR says the Proposed Project would alter the 100-year floodplain immediately downstream of Iron Gate Dam but does not explain the cause or the nature of the alteration.

Response to Comment ORG46-75

As described in Volume I Section 2.7.8.4, *Proposed Project – Other Project Components Downstream Flood Control* (page 2-95) is part of the description of the applicant's Proposed Project. Volume I Section 3.6 *Flood Hydrology* describes the environmental resources that may be affected by the Proposed Project and is the more appropriate location for a detailed discussion of the causes and nature of expected floodplain alteration under the Proposed Project. More specifically, Potential Impact 3.6-3 (pages 3-630 to 3-633) presents the analysis of the causes and nature of the expected floodplain alteration under the Proposed Project.

Comment ORG46-76

There are two concerns with this discussion. First, given that more sediment has accumulated behind the dams since USBR completed their floodplain modeling in 2012 and that material would be moved downstream under the Proposed Project, the DEIR needs to explain why the modeling from 2012 is still accurate. Second, what happens if, after dam removal, FEMA decides that the 100-year floodplain is substantially higher than that generated by USBR in 2012 and there are MORE structures in this zone that should have been protected? Who is responsible for providing flood protection for those additionally at-risk structures? The DEIR also needs to state how was the 0.5 foot (ft) threshold chosen as the level at which flood mitigation was required.

Response to Comment ORG46-76

As discussed in Volume I Section 3.11.5 *Geology, Soils, and Mineral Resources – Potential Impacts and Mitigation* Potential Impact 3.11-5 (pages 3-765 to 3-775), United States Bureau of Reclamation's (USBR's) hydraulic modeling approach used estimated sediment volumes that would be deposited behind the dams by 2020 (USBR 2012). The primary reservoir drawdown period for the Proposed Project would occur in early 2022. The increase in sediment volume between 2020 and 2022 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, such that model results using the anticipated 2020 sediment volumes would still be applicable to the Proposed Project.

Hydraulic and sediment transport modeling conducted by USBR (2012) used methods consistent with accepted standards detailed by Federal Emergency Management Agency (FEMA) (2018). While the commenter speculates that FEMA could determine that the 100-year floodplain following dam removal is substantially greater (i.e., higher) from that modeled by USBR (2012) and that therefore, more structures could be at risk under a FEMA determination, the comment provides no particular reason why the USBR's (2012) floodplain delineation is incorrect or any reason to conclude that FEMA intends to re-delineate the floodplain. The comment does not explain why the USBR's modeling is an inaccurate assessment of the changed floodplain inundation, or that a different assessment would be either much larger, or a more accurate description of flood risk. Given the consistency of modeling approaches used by USBR with FEMA standards, it would be speculative to anticipate that FEMA would expand the 100-year floodplain such that the number of structures located in the altered 100-year floodplain would change materially from those identified by Klamath River Renewal Corporation (KRRC) in the Definite Plan, regardless of whether the altered floodplain boundary is provided by USBR (2012) or by FEMA as part of a future map update.

Regarding the use of a 0.5 foot threshold used in determining the area of potential significant impacts to the Klamath River floodplain, Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain* and

Volume II Appendix B: *Definite Plan* (page 270), explain that USBR (2012b) and KRRC have estimated that below Humbug Creek any change to the floodplain will be less than 0.5 feet, and that changes of less than 0.5 feet would not result in a significant effect. As FEMA does not recognize changes in flood elevations less than 1 foot, the application of a 0.5-foot change in flood elevation to rule out areas that could be significantly affected is a conservative approach to determining the potential effects of the Proposed Project on the Klamath River floodplain. Please refer to Volume III Attachment 1 for the revised Section 3.6.5.2 *Flood Hydrology – Potential Impacts and Mitigation – River Floodplain*.

Comment ORG46-77

The DEIR states that "The Draft Cultural Resources Plan, submitted with the Definite Plan CITE [sic], describes consultation completed by the date of submission by KRRC and PacifiCorp, acting as FERC's non-federal representatives..."

- *CITE appears to be a missing citation*
- *PacifiCorp is only involved tangentially in the consultation process*
- *The KRRC has been leading this effort and is responsible for all of the material in the Definite Plan including the Cultural Resources Plan.*

Response to Comment ORG46-77

Section 2.7.8.5 *Proposed Project – Proposed Project – Other Project Components – Cultural Resources* has been amended from the description in the Definite Plan and clarified to emphasize that Klamath River Renewal Corporation (KRRC) is leading the consultation process. The reference to "CITE" has been removed, as the citation was already in the text. Please refer to Volume III Attachment 1 Section 2.7.8.5 *Proposed Project – Proposed Project – Other Project Components – Cultural Resources* for the revisions.

Comment ORG46-78

The Traffic Management Plan represents coordination with the Oregon Department of Transportation, Caltrans, Klamath and Siskiyou counties, and the Oregon State Police/California Highway Patrol. However, the DEIR does not mention whether the Traffic Management Plan represents coordination with local towns, communities, and neighborhoods. These communities will be directly impacted by the Proposed Project and the DEIR should expand the discussion of outreach to include local towns, communities, neighborhoods, citizen's groups, and businesses.

Response to Comment ORG46-78

Please refer to Volume I Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* (starting on page 3-1069) for a discussion of transportation-related impacts. As specifically noted in Volume I Section 3.22.5 *Transportation and Traffic – Potential Impacts and Mitigation* (page 3-1072), "The Proposed Project includes a draft Traffic Management Plan (Traffic Management

Plan) that identifies the key requirements that would be incorporated by the construction contractor into a final Traffic Management Plan. According to Appendix B: *Definite Plan – Appendix O2*, the Traffic Management Plan is a specialized program tailored to minimize impacts by applying a variety of techniques such as *Public Information, Motorist Information, Incident Management and Construction Strategies*. The major objectives of the Traffic Management Plan are to maintain efficient and safe movement of vehicles through the construction zone covered by activities in the Definite Plan and to provide public awareness of potential impacts to traffic on both haul routes and access roads to the four dam complexes". Definite Plan Appendix O-2 Traffic Management Plan, Section 1.2 further describes these 'Management Strategies' proposed to minimize construction-related traffic delays and maintain safe movement of vehicles during implementation of the Definite Plan".

As noted in their Draft EIR comments (ORG56), Klamath River Renewal Corporation (KRRC) has committed to addressing all potential traffic conflicts as part of their Final Traffic Management Plan (TMP). KRRC states that they are committed to ensuring that the TMP *"will maintain efficient and safe movement of the vehicles through the construction zone covered by activities in the Definite Plan".* The KRRC's comment also states that the *"Final TMP would be informed by KRRC's contractor's specific measures and methods for construction and input received from relevant local jurisdictions."* The TMP specifically describes a public outreach process.

Comment ORG46-79

In the first line of this table and footnote #2, the DEIR indicates that the Interim Measures Implementation Committee (IMIC) would continue to function following implementation of the Proposed Project. This is not the case; the IMIC would cease to exist when the KHSA is fully implemented. Additionally, footnote #2 references the Priority List of Projects and funds to be provided by PacifiCorp for water quality projects. Although this is accurate, it should only be attached the table entry for Interim Measure 11; as is noted in PacifiCorp (2018c) this water quality fund would be overseen by a steering committee and while member organizations may be similar to the IMIC, it would not be the IMIC.

PacifiCorp has no responsibility to continue any of the interim measures except Interim Measures 19 and 20 past decommissioning.

Response to Comment ORG46-79

References to Interim Measures Implementation Committee (IMIC) continuation following implementation of the Proposed Project have been corrected throughout the EIR to acknowledge that the IMIC would cease to exist when the Klamath Hydropower Settlement Agreement (KHSA) is fully implemented. Table 2.7-19 and reference to footnote number 2, within Section 2.7.9 *Proposed Project – Proposed Project – KHSA Interim Measures* have been revised according to the above discussion. For consistency, Table 3.24-1 in Section 3.24.1

Cumulative Effects – Introduction – Analysis Approach and Table 4.2-1 in Section 4.2.1.1 *Alternatives – No Project Alternative – Introduction – Alternative Description – KHSA Interim Measures* have also been revised per the above discussion. Please refer to Volume III Attachment 1 Section 2.7.9 *Proposed Project – Proposed Project – KHSA Interim Measures*, Section 3.24.1 *Cumulative Effects – Introduction – Analysis Approach*, and Section 4.2.1.1 *Alternatives – No Project Alternative – Introduction – Alternative Description – KHSA Interim Measures* for the revisions.

Comment ORG46-80

The transfer of lands from PacifiCorp's ownership to the KRRC is included in the transfer application for the lower Klamath Project that is pending before FERC.

Response to Comment ORG46-80

Section 2.7.10 *Proposed Project – Proposed Project – Land Disposition and Transfer* has been revised to clarify that this transfer is the subject of the KRRC's *Joint Application for Approval of License Amendment and License Transfer* submitted to Federal Energy Regulatory Commission (FERC) on September 23, 2016. Please refer to Volume III Attachment 1 Section 2.7.10 *Proposed Project – Proposed Project – Land Disposition and Transfer* for the revisions.

Comment ORG46-81

The inclusion of the statement "Because CEQA requires analysis of potential impacts and mitigation measures that are outside the State Water Board's regulatory purview for the Proposed Project, this EIR discusses and analyzes the effects of some mitigation measures that would not be enforceable by the State Water Board. It is the State Water Board's understanding that the KRRC may agree to implement certain mitigation measures through good neighbor agreements or other legally enforceable mechanisms (Appendix B: Definite Plan -Section 1)" leads to confusion in the document about which of these measures are enforceable by the CEQA lead agency, despite the footnotes, and it would be inappropriate to rely on any speculative agreements as the basis for the DEIR to reduce an impact to less than significant [Pub. Res. Code§ 21002.l (b); CEQA Guidelines§ 15126.4(a)].

Response to Comment ORG46-81

Please refer to Master Response CEQ-2.

Comment ORG46-82

In addition to the topics raised in Major Issue 2.2, the following specific changes should be made to Section 3.1.6:

- *A description of differences in assumptions and analytical methods used to derive the model results.*
- *Figures and charts should include clear definition of the parameter and time periods presented, including the hydrologic period used.*

- *A complete discussion of why it is sufficient to "bracket the range of 2013 BiOp flows" rather than maintain more comparable and updated probability distributions of flow duration and magnitude.*
- *Specific examples that demonstrate the robustness of the DEIR's assumption that merely bracketing the range of flows is sufficient to assess impacts.*

Response to Comment ORG46-82

Please refer to response to comment ORG46-6, which provides a response to the comment letter's identified Major Issue "2.2 Klamath River Flow Modeling". Additionally, Section 3.1.6 *Introduction – Summary of Available Hydrology Information for the Proposed Project* has been revised to clarify assumptions and analytical methods used to derive the hydrologic model results by explicitly stating how the Biological Opinion (BiOp) flows during fall/winter and spring/summer periods are calculated, to provide updated figures that include the most extended hydrologic period available for each flow comparison, and to provide additional discussion of how the range of 2013 BiOp Flows is within the range of modeled KBRA Flows approximately 99.9 percent of the time at Keno and Iron Gate dams. As discussed in response to comment ORG46-6 and revisions to Section 3.1.6, while the specific timing of flows and the likelihood of exceeding a specific flow during individual months changes between the 2013 BiOp and KBRA flows, modeled 2013 BiOp Flows less than or greater than modeled KBRA Flows would occur too infrequently (i.e., 0.01 percent of the time or less) to substantially alter the range of flow conditions in the Klamath River or previous model results using KBRA Flows. Please also refer to Master Response HYD-1 and Volume III Attachment 1 Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*.

Comment ORG46-83

The DEIR states "cold air temperatures and precipitation generally occur from November to March, corresponding to periods of higher flows and paragraph on colder water temperatures. Warmer air temperatures and drier conditions occur from April to October, corresponding to periods of lower flows and warmer water temperatures." These statements erroneously attribute water temperature conditions solely to air temperature changes. Water temperature responds in a more complex manner to heat exchange associated with meteorological parameters that include solar radiation, relative humidity (or wet bulb or dew point temperatures), wind speed, barometric pressure, as well as air temperature.

Response to Comment ORG46-83

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* provides a summary of general water temperature trends within the Klamath Basin. The following statement in this EIR section notes general seasonal trends in air temperature and precipitation and the *corresponding* general seasonal trends in water temperature and Klamath

River flows, and does not imply or assert that water temperature conditions are caused solely by air temperature changes: "Cold air temperatures and precipitation generally occur from November to March, corresponding to period of higher flows and colder water temperatures. Warmer air temperatures and drier conditions occur from April to October, corresponding to period of lower flows and warmer water temperatures." As set forth in Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* water temperatures in the Klamath River are the result of multiple heat exchange processes, including short wave radiation (i.e., solar radiation), long wave radiation, sensible heat transfer, latent heat transfer (i.e., evaporation), heat transfer across the streambed, and advective and diffusive/dispersive heat transfer (i.e., flow and mixing) in the river, as well as groundwater interactions. Please see Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment ORG46-84

Regarding "River and reservoir water temperatures," the DEIR's general description that cooler water is released from reservoirs in spring and warmer water is released in early fall is not a universal tenet. This description is overly simplistic and does not account for reservoir residence time, stratification, outlet works, operations, and other factors.

Regarding Figure 3.2-2, algal toxins should probably not be on this graphic; recommend that the figure use the term "Algae" instead.

Response to Comment ORG46-84

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin – River and Reservoir Water Temperatures* provides a summary of the general water temperature trends within the Klamath Basin. While there are occasional exceptions to the general water temperature trends that cooler water is released from the reservoirs in spring and warmer water is released in early fall, historical data from 2010 to 2017 downstream of Iron Gate Dam support the accuracy of the stated general trends as discussed in Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* and Appendix C, Section C.1 *Water Temperature*. The specific water temperature conditions in the Hydroelectric Reach, Middle and Lower Klamath River, Klamath River Estuary, and Pacific Ocean Nearshore Environment are analyzed in Potential Impacts 3.2-1 and 3.2-2, so variations between the measured and modeled water temperature conditions downstream of Lower Klamath Project reservoirs and the general water temperature trends presented in Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin – River and reservoir water temperatures* would not alter the analysis of potential impacts in the EIR. Additional factors that can influence the water temperature trends in rivers within and downstream of reservoirs, including installation of a powerhouse intake barrier/thermal curtain, are discussed further in the aforementioned EIR sections.

Figure 3.2-2 represents the intensity of algae growth with darker green shading in surface waters, as noted in the figure caption. Algal toxins are specified on the figure because they are released when algae (i.e., phytoplankton) blooms die, as noted in the text accompanying Figure 3.2-2.

Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

Comment ORG46-85

The DEIR states "Releases or this deeper, oxygen depleted water from the bottom of the reservoir can cause serious problems for downstream fish and other aquatic biota." This statement should include: "...if release waters are not oxygenated through the outlet facilities and/or powerhouse, or through other means." While this statement can be true in general, it does not necessarily apply to the existing Klamath Hydroelectric Project where intakes for the powerhouses are not at the bottom or the reservoir. There is also no evidence that dissolved oxygen has ever been a problem downstream or Iron Gate Dam as is implied in the DEIR. The discussion should more accurately reflect existing conditions.

Response to Comment ORG46-85

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* has been clarified as requested. Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* for the revision.

Appendix C, Section C.4.2.1 *Iron Gate Dam to Salmon River* provides a discussion of dissolved oxygen data from 2001 to 2016 in the Klamath River from Iron Gate Dam to its confluence with the Salmon River. Data show dissolved oxygen conditions immediately downstream of Iron Gate Dam regularly falling below 8.0 milligrams per liter (mg/L) and the current Basin Plan minimum dissolved oxygen criteria based on percent saturation. Dissolved oxygen data (in mg/L and in percent saturation) in the Klamath River immediately downstream of Iron Gate Dam (river mile [RM] 193.1) measured by PacifiCorp using a multi-parameter sonde are summarized from June 2008 to December 2016 in Appendix C, Section C.4.2.1 *Iron Gate Dam to Salmon River* Table C-4. The summary specifically highlights the average monthly dissolved oxygen percent saturation has continued to exhibit in recent years dissolved oxygen percent saturation values below the Basin Plan minimum dissolved oxygen criteria during portions of the year, with the majority of measured low dissolved oxygen saturation values occurring from August through November. Please refer to Volume III Attachment 1 for the final Appendix C *Water Quality Supporting Technical Information*.

Comment ORG46-86

In the discussion or "Reservoir mixing and dissolved oxygen," the DEIR states "In late fall, thermal stratification typically breaks down as the surface water layer cools and wind mixing or the water column occurs. This process is called reservoir turnover (Figure 3.2-2)." This discussion belongs in Section 3.2.2.2 Water Temperature.

Response to Comment ORG46-86

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* has been slightly modified to move the sentence below from the end of the *Reservoir mixing and dissolved oxygen* sub-section to the end of the preceding *River and reservoir water temperature* sub-section. Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* for the revision.

Comment ORG46-87

In the discussion of "Phytoplankton in reservoirs," the DEIR states "This can result in wide daily swings in dissolved oxygen and pH, which is stressful to aquatic biota." The Klamath River is naturally weakly buffered and within both reservoir surface waters and in river waters the pH can vary considerably over a day during summer periods (PacifiCorp 2004a, 2014). These pH swings will occur in this weakly buffered aquatic system with or without reservoirs (PacifiCorp 2004a, 2014).

The remainder of paragraph 2 (pg. 3-20) focuses on toxin producing algae and toxins. The DEIR should clarify that there are always times or locations where the reservoirs do not have toxin producing algae present. In addition, PacifiCorp has installed and maintained a barrier curtain in Iron Gate Reservoir to segregate surface waters and limit release of phytoplankton to downstream reaches. Although operational refinements and investigations are still going on, work to date indicates that the barrier curtain successfully segregates the surface waters and reduces release of surface waters were most of the cyanotoxins are found (Watercourse 2016; PacifiCorp 2017b).

Response to Comment ORG46-87

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* discusses the general effects of hydroelectric project operations on water quality. Please see Section 3.2.2.6 *Water Quality – Environmental Setting – pH* and Appendix C, Section C.5 *pH* for a more specific discussion of pH existing conditions in the Klamath River, including the weakly buffered nature of the Klamath River. Please see Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a* for a more specific discussion of the algal toxins under existing conditions in the Klamath River.

Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

The discussion in Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin – Phytoplankton in reservoirs* regarding algal toxins indicate that blue-green algae blooms and algal toxins can occur seasonally, not that they are always present throughout the reservoirs during any time of the year. Whether or not there are always times when or locations where the reservoirs do not have toxin-producing algae present has no bearing on overall compliance with water quality standards for these algae or algal toxins.

Please refer to Volume I Section 4.2.2 *Alternatives – No Project Alternative – Water Quality – Suspended Sediments* Potential Impact 4.2.2-2 (pages 4-109 to 4-111) for a discussion of the effects to date of the intake barrier/thermal curtain on releases of blue-green algae [cyanobacteria] downstream of Iron Gate Dam.

The text has been revised to amplify other statements in the EIR indicating that the Klamath River is a weakly buffered system. Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting –Overview of Water Quality Processes in the Klamath Basin* for the revisions.

Comment ORG46-88

In the discussion of "Nutrient cycling in reservoirs and internal loading," the DEIR states "On an annual basis, the majority of nutrients entering a reservoir from a watershed are eventually discharged downstream, with only a small fraction being retained in the reservoir sediments." The "only a small" modifier is biased and should be replaced with the actual quantity of retention in percent and mass (in tons). The magnitude of nutrient retention has been calculated for Copco and Iron Gate reservoirs combined at 12 to 16 percent of the total phosphorus inflow and about 18 to 21 percent of the total nitrogen inflow (PacifiCorp 2006; Kann and Asarian 2007; Asarian and Kann 2005; Asarian et al. 2009).

The DEIR states "During reservoir turnover when the stratification breaks down, these nutrient rich waters are mixed throughout the reservoir water column and the nutrients can be released downstream, resulting in a secondary (fall) phytoplankton bloom (which includes blue-green algae)." However, the DEIR does not describe or address the dynamics of destratification in the reservoir, including the fact that Copco 1 and Iron Gate reservoirs are two large reservoirs in series which can affect the turnover of Iron Gate Reservoir depending on conditions in Copco Reservoir.

The DEIR suggests that downstream releases of nutrients can lead to phytoplankton blooms in the river. This is undocumented, and late in the year has a low chance of occurring. Complete destratification and a return to isothermal conditions typically occurs in Iron Gate during November or

December, which is after the growth season for phytoplankton is over (see PacifiCorp 2014).

Response to Comment ORG46-88

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been clarified to specify the most recent calculated annual nutrient retention amounts for the Lower Klamath Project dams (Asarian et al. 2009). While these annual nutrient retention amounts are cited in PacifiCorp (2014), the magnitudes of the most recent annual nutrient retention for Copco No. 1 and Iron Gate reservoirs in Asarian et al. (2009) differ from previous studies due to earlier studies either analyzing nutrient data from only part of a year or improving the methods for estimating nutrient retention in the reservoirs.

Kann and Asarian (2005) and PacifiCorp (2006) analyze nutrient data from March/April to November 2002, so the nutrient retention estimates in those citations do not represent *annual* nutrient retention. Asarian et al. (2009) analyzes nutrient data from May 2005 to December 2007, while Asarian and Kann (2007) analyzes nutrient data from May 2005 to May 2006, but the estimates of nutrient retention in Copco No. 1 and Iron Gate reservoirs for May 2005 to May 2006 changed between Asarian and Kann (2007) and Asarian et al. (2009) because Asarian et al. (2009) had more accurate accounting of the effects of hydropower peaking, incorporated ungaged flows, and used multiple regression models to estimate nutrient load. Please see Asarian et al. (2009) for more details on the methodological improvements and resulting differences in nutrient retention estimates in Copco No. 1 and Iron Gate reservoirs between Asarian and Kann (2007) and Asarian et al. (2009). Please refer to Volume III Attachment 1 Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin – Nutrient cycling in reservoirs and internal loading* for the revisions.

Comment ORG46-89

The DEIR states "Slow transport of water downstream and modified timing and magnitude of river flows can affect the growth of periphyton downstream of hydroelectric dams." Although this statement can be true in the larger-scale and the Klamath Hydroelectric Project reservoirs do impound water, the overall flow rates in the Klamath River are largely unaffected by the hydroelectric dams due to their lack of active storage capacity, with the exception of the peaking reach between J.C. Boyle Powerhouse and Copco Reservoir. Downstream of Iron Gate Dam, flow rates under current operations, particularly during summer periods when periphyton growth occurs, will be similar to those under the Proposed Project because they would continue to be managed by USBR with essentially the same target flow rates (USBR 2018b). Under current operations, periphyton is limited to the river margins, and growth in the inundated river channel is absent due to depth and light limitation.

The DEIR states "Natural scouring of periphyton populations can be diminished downstream of large dams due to altered flows and interception of coarse sediment movement by the dam, leading to seasonal occurrence of large periphyton mats that can cause water quality problems and provide abundant habitat for fish parasites." However, the flow rates downstream of Iron Gate Dam under current operations during summer (when much of the periphyton growth occurs) will be similar to those under the Proposed Project. Periphyton colonizes the channel bed after winter flows abate and will extend continuously throughout the river reaches from J.C. Boyle Reservoir to the Iron Gate Dam site following potential dam removal.

The DEIR needs to further update this discussion with recent observations from the Klamath Fish Disease Workgroup that the polychaete worms that are the intermediate host for fish parasites are also found in high densities in sand/silt habitat and on boulders (see True et al. 2016). The DEIR should also acknowledge that the Klamath Hydroelectric Project does not meaningfully reduce the magnitude of river flows downstream of Iron Gate Dam that would be necessary to result in periphyton scouring. Prior analysis conducted by USBR shown that river flows will not appreciably change as a result of potential dam removal (USBR 2011) due to the small amount of active storage in the reservoirs. Dam operations can achieve flow variability downstream of Iron Gate Dam to provide biological benefits that can mitigate for potential impacts related to flow modifications. Reservoir storage can also be activated to provide for special flow releases downstream of Iron Gate Dam to mitigate fish disease in the Klamath River as has occurred in recent years (PacifiCorp 2018b).

The DEIR states "Periphyton can influence riverine water quality by affecting nutrient cycling and diel (i.e., 24-hour cycle) fluctuations in dissolved oxygen and pH." However, the impact of an additional 30 miles of periphyton and macrophytes on water quality has not been addressed in the DEIR.

Response to Comment ORG46-89

Section 3.2.2.1 *Water Quality – Environmental Setting – Overview of Water Quality Processes in the Klamath Basin* summarizes the ***general*** influence of hydroelectric project operations on water quality. The discussion of the general influence of hydroelectric project operations on periphyton growth downstream of reservoirs such as the Lower Klamath Project reservoirs is meant to provide background context for the potential physical, chemical, and biological effects of dams, rather than the details of the specific effects that have been documented the Klamath River due to the presence of the Lower Klamath Project dams. The specific details about water quality existing conditions in the Klamath River are discussed in Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* through Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants*. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

The specific details about periphyton growth downstream of Iron Gate Dam are discussed in Volume I Section 3.4.2.4 *Phytoplankton and Periphyton – Environmental Setting – Middle and Lower Klamath River – Periphyton* (pages 3-418 to 3-420).

Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project* summarizes the influence of the Lower Klamath Project dams on habitat for aquatic resources in the Klamath River, including a summary of the influence of the Lower Klamath Project dams on diseases and parasites. Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to be Affected by the Proposed Project – Disease and Parasites* specifically states that polychaete worms are present in a variety of habitat types, including runs, pools, riffles, edge-water, and reservoir inflow zones, as well as sand, gravel, boulders, bedrock, aquatic vegetation, and they are frequently found among mats of filamentous periphytic algal species (e.g., *Cladophora sp.*) that traps fine sediment and detritus (Bartholomew and Foott 2010). As such, an additional citation about the habitats of polychaete worms is unnecessary. Additionally, the comment citation to True et al. (2016) does not support the comment's assertion that polychaete worms are found in high densities in sand/silt habitat and on boulders because True et al. (2016) did not collect or report any data on the habitats where polychaete worms are found. True et al. (2016) collected fish samples from five reaches in the Klamath River and analyzed the prevalence of *Ceratonova shasta* and *Parvicapsula minibicornis* parasite infections with variations in water temperature and flow. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Potential Impact 3.2-8, Potential Impact 3.2-10, and Potential Impact 3.2-11 provide a discussion of the potential impacts of periphyton growth on nutrients, dissolved oxygen, and pH. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Please refer to response to comment ORG46-34, ORG46-136, ORG46-137, ORG46-146, ORG46-149, ORG46-266, ORG46-451 for additional discussion of the influence of periphyton and macrophytes on water quality conditions in the Klamath River. Please refer to response to comment ORG46-267 for additional information regarding the potential impacts of the Proposed Project on the distribution of periphyton and macrophyte communities in the Klamath River.

Comment ORG46-90

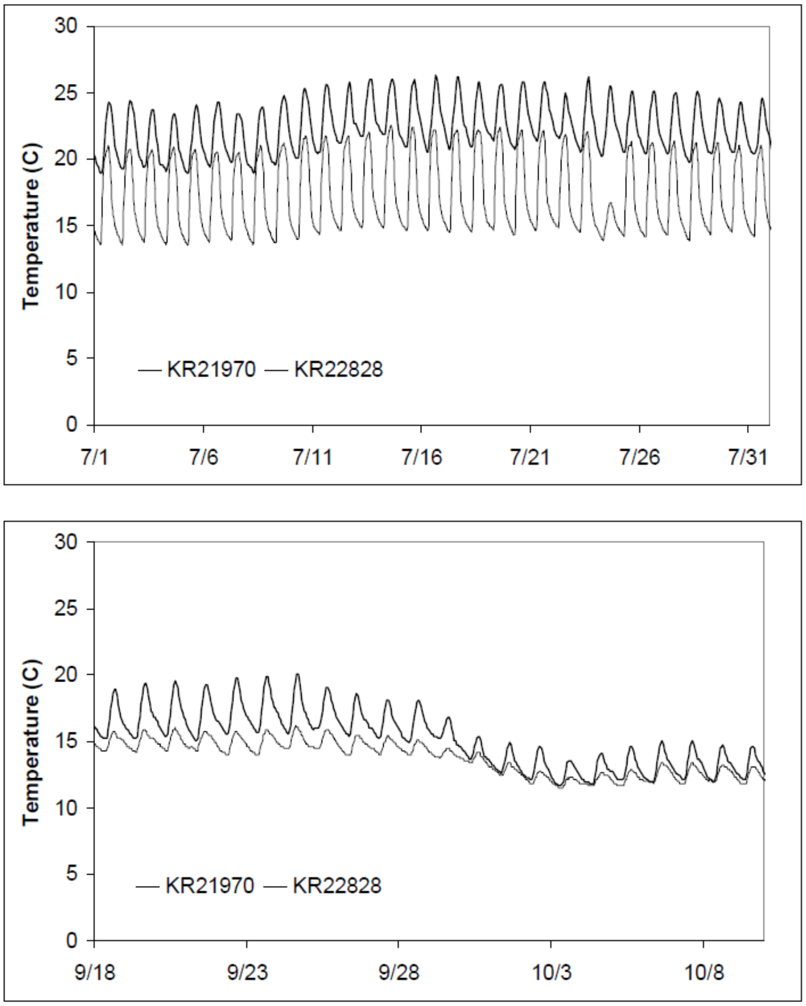
The DEIR states "While natural diel (24-hour) water temperature variations occur in the river, daily peaking operations at J.C. Boyle Powerhouse (river mile [RM) 225.2) result in an increase in the daily water temperature range in the Bypass Reach because warmer reservoir discharges are diverted around this reach (see also Section 2.3.1 J.C. Boyle Dam Development) and cold groundwater springs enter the river and dominate remaining flows." The DEIR should clarify that *bypassing waters around this reach result in a notably cooler river and reduced diurnal range (not increased) because of the dominance of spring inflows in the bypass reach.*

The DEIR incorrectly states that "At the upstream end of the Peaking Reach, the natural, cold groundwater input into the Bypass Reach, combined with fluctuations in river flow due to hydroelectric power operations in the Peaking Reach also produces an observed increase in daily water temperature range above the natural diel water temperature fluctuations (Kirk et al. 2010)." Peaking flows are derived from water stored in J.C. Boyle Reservoir and are large relative to those likely to exist if the J.C. Boyle Development were not in place and USBR was managing flow releases for salmonids out of Keno Dam. Both factors lead to a diel range that is more attenuated under existing conditions than would occur under a no dams scenario such as the Proposed Project.

Response to Comment ORG46-90

J.C. Boyle Bypass Reach water temperatures are typically cooler from May to September and warmer from November to March than ambient river temperatures upstream or downstream and daily variations in water temperatures are reduced due to spring inflows to the J.C. Boyle Bypass Reach with a relatively constant water temperature (approximately 11 to 12°C) throughout the year (PacifiCorp 2004a-1; Kirk et al. 2010).

Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* correctly states J.C. Boyle hydroelectric power operations produce an increase in the daily water temperature range above the natural diel water temperature fluctuations in the J.C. Boyle Peaking Reach. As detailed in PacifiCorp (2004a-1) Figures 3.7-7a and 3.7-7b (reproduced below), the Klamath River water temperature and daily water temperature variations are greater during peaking operations than non-peaking flows. PacifiCorp (2004a-1) Section 3.7.1 *Water Temperature* (page 3-13) specifically states that the diurnal range of water temperature variation is larger in the peaking reach downstream of the J.C. Boyle Powerhouse during peaking operations and the range of daily water temperature variation downstream of the powerhouse is greatly reduced when no peaking operations occur (i.e., constant daily discharge). The water temperature data under non-peaking flows from 2002 (Figures 3.7-7a and 3.7-7b from PacifiCorp [2004a]) indicate that the water temperature and daily water temperature variations would decrease under the Proposed Project after J.C. Boyle Dam is removed and peaking operations cease.



Figures 3.7-7a and 3.7-7b from PacifiCorp (2004a-1). Klamath River water temperature measured in 2002 at KR22828 (approximately river mile [RM] 233.3) (upper curve in both plots) upstream of the J.C. Boyle Reservoir and at KR21970 (approximately RM 224.45) (lower curve in both plots) downstream of the J.C. Boyle Powerhouse during peaking operations (top plot) and during non-peaking flows (bottom plot).

Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify the water temperature conditions in the J.C. Boyle Bypass Reach and the Peaking Reach. Please refer to Volume III Attachment 1 Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* for the revisions.

Comment ORG46-91

The DEIR mentions the powerhouse intake barrier curtain in Iron Gate Reservoir installed by PacifiCorp under Interim Measure 11. The principal purpose of the barrier curtain is to segregate surface waters in Iron Gate Reservoir and thereby reduce concentrations of blue-green algae releases to the Klamath River. A *byproduct of the curtain is slightly cooler release temperatures (Watercourse 2016; PacifiCorp 2017b).*

The DEIR concludes that "modest" water quality improvement is possible with the curtain but suggests such improvement would not be adequate to achieve compliance with the Water Quality Plan or Klamath River TMDLs. Aside from PacifiCorp's position that the Klamath River TMDLs are technically flawed (as explained in TMDL-specific comment 3.2-34), the DEIR does not accurately point out that the powerhouse intake barrier curtain in Iron Gate Reservoir installed by PacifiCorp under Interim Measure 11 is a prototype for testing and design refinement. The curtain is not designed and installed, nor is it operated to achieve compliance with the thermal plan included in the TMDL.

The DEIR also does not adequately explain or assess the results of the studies conducted on the prototype intake barrier curtain in Iron Gate Reservoir. These studies indicate that the curtain is effective at isolating near-surface waters of Iron Gate Reservoir upstream of the curtain (e.g., Watercourse 2016; PacifiCorp 2017b). Water quality samples, physical measurements, velocity profiles, and field observations of conditions consistently identified that waters of the photic zone, where the majority of blue-green algae occur, were largely isolated to the upstream side of the curtain. Water that ultimately passed under the curtain was drawn from deeper, cooler depths in regions of Iron Gate Reservoir upstream of the curtain. Regarding blue-green algae concentrations, monitoring results indicated reductions in Aphanizomenon (97 percent), Microcystis (82 percent), microcystin (70 percent), and chlorophyll-a (61 percent) occurred downstream of Iron Gate Dam when compared to surface samples collected at a depth of O .S meter upstream of the barrier curtain (Watercourse 2016; PacifiCorp 2017b).

Response to Comment ORG46-91

Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* explains and assesses the results of the intake barrier/thermal curtain studies with respect to its influence on water temperature. In addition, Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* notes that a purpose of the powerhouse intake barrier/thermal curtain was to isolate surface waters in Iron Gate Dam to reduce downstream releases of blue-green algae in the reservoir. Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify that the primary purpose of the intake barrier/thermal curtain is to manage blue-green algae releases to the Klamath River. The intake barrier/thermal curtain tested in 2014 was referred to as a prototype and the current intake barrier/thermal curtain installed in 2015 has not been described as a prototype in published, publicly available PacifiCorp reports on its operation and performance since then (PacifiCorp 2016a, 2017a, 2018a). Water temperature improvements from operation of the intake barrier/thermal curtain would be potentially limited by the need to access water with higher dissolved oxygen concentrations to comply with dissolved oxygen standards, with the curtain completely rolled up during portions of 2017 to maximize dissolved oxygen concentrations for aquatic life (PacifiCorp 2018a). Please refer to Volume III Attachment 1 Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* for the revisions. Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* is focused on the water temperature under existing conditions, so it does not summarize the influence of the intake barrier/thermal curtain on blue-green algae, chlorophyll-*a*, or microcystin.

The potential water temperature improvement from the intake barrier/thermal curtain is considered modest relative to the magnitude of the thermal lag caused by Iron Gate Reservoir during summer through fall (i.e., mid-June to early-November). Monitoring results indicate that the curtain reduces the entrainment of *Aphanizomenon flos-aquae*, *Microcystis aeruginosa*, microcystin, and chlorophyll-*a* into the Iron Gate Powerhouse intake and subsequent release downstream into the Klamath River during the period the intake barrier/thermal curtain was in use (PacifiCorp 2016a, 2017a), but the magnitude of the reduction varies widely over time for some parameters such that the 72- to 96-hour average percent reduction reported in the comment would not fully characterize the intake barrier/thermal curtain performance. While 72-hour average percent reduction of *Aphanizomenon flos-aquae* (i.e., 97 percent) reasonably represents the 24-hour percent reduction of *Aphanizomenon flos-aquae* range (i.e., 93 to 99 percent), the *Aphanizomenon flos-aquae* cell count still exceeded the California Cyanobacteria Harmful Algal Bloom (CCHAB) Human Health Secondary Trigger Level for Total Potentially Toxigenic Cyanobacteria [blue-green algae] Species of 4,000 cells/mL in two measurements (i.e., 9/2/2015 18:00 and 9/3/2015 2:00). The 72-hour average percent reduction of *Microcystis aeruginosa* from the intake barrier/thermal curtain is 82 percent, but the 24-hour percent reduction of *Microcystis aeruginosa* ranges from 74 to 92 percent. Additionally, the ranges in the 24-hour percent reduction of microcystin (i.e., 25 to 84 percent) and chlorophyll-a (i.e., 1 to 89 percent) are significantly different from the 72- or 96-hour average percent reduction (70 percent for microcystin; 61 percent for chlorophyll-a) (PacifiCorp 2016a). It is also worth noting that monitoring results from 2016 show a relatively large percent reduction in the total cyanobacteria and total *Microcystis aeruginosa* from upstream of the curtain to downstream of Iron Gate Dam, but the total cyanobacteria and total *Microcystis aeruginosa* downstream of Iron Gate Dam exceeded the CCHAB Human Health Secondary Trigger Level for Total Potentially Toxigenic Cyanobacteria [blue-green algae] Species during multiple sampling events. Water quality monitoring data from 2017 and 2018 downstream of Iron Gate Dam also show multiple exceedances of the Klamath Total Maximum Daily Loads (TMDLs) phytoplankton chlorophyll-a target (i.e., 10 ug/L) and multiple microcystin posting limits (e.g., 6 ug/L for CCHAB Warning TEIR I; Table 3.2-10) (Watercourse Engineering, Inc. 2018, 2019). An analysis of the intake barrier/thermal curtain performance during 2017 or 2018 has not been published and PacifiCorp continues to test and refine the intake barrier/thermal curtain design and operations.

Overall, the available data show the intake barrier/thermal curtain would potentially reduce transport of *Aphanizomenon flos-aquae*, *Microcystis aeruginosa*, microcystin, and chlorophyll-*a* from Iron Gate Reservoir into the Klamath River downstream of Iron Gate Dam, but the data do not indicate that this measure would consistently reduce *Aphanizomenon flos-aquae*, *Microcystis aeruginosa*, microcystin, and chlorophyll-*a* such that they would no longer cause an exceedance of water quality standards, cause an exceedance of CCHAB trigger levels, or achieve the Klamath TMDLs phytoplankton chlorophyll-a target of 10 ug/L for Copco No. 1 and Iron Gate reservoirs during the May to October growth season.

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the influence of the powerhouse intake barrier/thermal curtain on chlorophyll-a and microcystin concentrations in the Klamath River downstream of Iron Gate Dam. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

As discussed in ORG46-384, Section 4.2.2 *No Project Alternative – Water Quality – Chlorophyll-a and Algal Toxins* Potential Impact 4.2.2-*7* has been revised to clarify the influence of the powerhouse intake barrier/thermal curtain on chlorophyll-a and microcystin concentrations in the Klamath River downstream of Iron Gate Dam under the No Project Alternative. Please refer to Volume III Attachment 1 Section 4.2.2 *No Project Alternative – Water Quality – Chlorophyll-a and Algal Toxins* Potential Impact 4.2.2-*7* for these revisions.

Volume I Section 4.4.2.2 *Continued Operations with Fish Passage Alternative – Water Quality – Suspended Sediments* Potential Impact 4.2.2-2 (pages 4-109 to 4-111) provides a discussion of the results of the intake barrier/thermal curtain studies with respect to its influence on blue-green algae and organic suspended material under the Continued Operations with Fish Passage Alternative. As explained above, available data indicate the intake barrier/thermal curtain would reduce *Aphanizomenon flos-aquae*, *Microcystis aeruginosa*, microcystin, and chlorophyll-*a* downstream of Iron Gate Dam when it is deployed, but the available data do not indicate that this measure would improve algal-derived (organic) suspended material such that that there would no longer be an exceedance of water quality standards, CCHAB trigger levels, or the Klamath TMDLs phytoplankton chlorophyll-a target of 10 ug/L for Copco No. 1 and Iron Gate reservoirs during the May to October growth season.

Section 4.4.2.6 *Continued Operations with Fish Passage Alternative – Water Quality – Chlorophyll-a and Algal Toxins* Potential Impact 4.2.2.7 also has been revised to clarify the influence of the powerhouse intake barrier/thermal curtain on chlorophyll-a and microcystin concentrations in the Klamath River downstream of Iron Gate Dam under the Continued Operations with Fish Passage Alternative. Please refer to Volume III Attachment 1 Section 4.4.2.6

Continued Operations with Fish Passage Alternative – Water Quality – Chlorophyll-a and Algal Toxins Potential Impact 4.2.2.7 for these revisions.

Comment ORG46-92

The DEIR should include a discussion of the magnitude of "relatively low" diurnal temperature range downstream of Iron Gate Dam, and how that range is associated with intake depth in Iron Gate Reservoir.

Response to Comment ORG46-92

Please refer to Appendix C, Section C.1.2.1 *Water Temperature – Mid- and Lower Klamath Basin – Iron Gate Dam to Salmon River* (pages C-4 to C-10), especially Figures C-3 to C-6 (pages C-6 to C-8), for details on the relatively low variability in water temperature immediately downstream of Iron Gate Dam compared to Klamath River locations farther downstream.

Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify the influence of the Iron Gate Dam intake structure on water temperature downstream of Iron Gate Dam. The intake barrier/thermal curtain tested in 2014 was referred to as a prototype and the current intake barrier/thermal curtain installed in 2015 has not been described as a prototype in published, publicly available PacifiCorp reports on its operation and performance since then (PacifiCorp 2016a, 2017a, 2018a). Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including the revisions to Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature*.

Comment ORG46-93

The DEIR states "Water temperatures in the Klamath River Estuary are linked to temperatures and flows entering the estuary, salinity of the estuary and resulting density stratification, and the timing and duration of sand berm formation across the estuary mouth." The DEIR should state that meteorological conditions are a large factor as well. While coastal "fog" and ocean-water input minimizes extreme water temperature much of the time, short duration heat spells (e.g., clear weather in the late summer and early fall) can quickly lead to elevated Estuary temperatures.

Response to Comment ORG46-93

Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* has been revised to clarify the influence of meteorological conditions on water temperature in the Klamath River Estuary. Please refer to Volume III Attachment 1 Section 3.2.2.2 *Water Quality – Environmental Setting – Water Temperature* for the revisions.

Comment ORG46-94

The DEIR states that the trapping of fine sediments does not appear to be a critical function of the Lower Klamath Project reservoirs with respect to the overall system, citing that only 3.4 percent of the annual sediment load originates *from the upper and middle Klamath River. This statement appears intended to demonstrate that the fine sediment load flowing into the reservoirs is nominal relative to the overall basin and thus has little impact to the river system. However, adopting a basin-scale perspective neglects to acknowledge the relative importance of the upstream sediment load at the reach-scale, for example, for the reaches immediately downstream of Iron Gate Dam where the relative proportion of the sediment load that comes from upstream of the reservoirs is nearly 100 percent. The relative proportion of sediment originating from upstream of the reservoir system may only be 3.4 percent for the basin as a whole but may be close to 100 percent of the annual load for the reach immediately downstream of the reservoirs. Therefore, from the reach-scale perspective, the local impact may be more significant.*

Response to Comment ORG46-94

Appendix C, Section C.2.1.1 *Hydroelectric Reach*, especially Figure C-13, provides a discussion of the trapping of suspended materials within individual reservoirs. Please refer to Volume III Attachment 1 for the final Appendix C *Water Quality Supporting Technical Information.* Please refer to Volume I Section 3.11.2.4 *Geology, Soils, and Mineral Resources – Environmental Setting –Sediment Load* (pages 3-748 to 3-753) for a discussion of trapping of bedload materials.

Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* has been updated to clarify the Lower Klamath Project dams' influence on suspended material in the reaches immediately downstream of the dams. Please refer to Volume III Attachment 1 Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* for the revisions.

<u>Comment ORG46-95</u>

The DEIR does not explain the seasonal periphyton and macrophyte growth on the bed of the Klamath River downstream of Iron Gate Dam, and how that extensive growth contributes to the Klamath River organic matter load. Periphyton and macrophyte growth in the Klamath River is extensive, particularly upstream of the Scott River, where sediment transport frequency is lower. Growth is made possible by nutrients transported downstream from upstream sources including natural geologic nutrients (Shasta River springs, springs downstream of J.C. Boyle Dam, and sources from Upper Klamath Lake and in the Upper Klamath Basin), inputs at Upper Klamath Lake via nitrogen-fixing blue-green algae Aphonizomenon flos oquoe, and anthropogenic activities along the mainstem (including Upper Klamath Lake and upstream sources) and in tributaries. Periphyton and macrophytes convert bioavailable nutrients to plant biomass, and subsequent senescence yields particulate organic matter to the Klamath River. With removal of the dams under the Proposed Project, the spatial extent of periphyton and macrophytes would increase by approximately 30 miles (from Iron Gate Dam through what is now J.C. Boyle Reservoir). The *impacts of this substantial spatial increase in periphyton and macrophytes on water quality are not addressed in the DEIR.*

Response to Comment ORG46-95

Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* summarizes the ***existing suspended sediment*** conditions in the Klamath River. Please refer to Volume I Section 3.4.2.4 *Phytoplankton and Periphyton – Environmental Setting – Middle and Lower Klamath River – Periphyton* (pages 3-418 to 3-420) for discussion of the seasonal periphyton (including macrophytes) abundance in the Klamath River downstream of Iron Gate Dam. Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* provides a summary of organic suspended material in the Klamath River and Appendix C, Section C.2 *Suspended Sediments* provides additional discussion of organic suspended material in the Klamath River based on measurements of total organic suspended material in the Klamath River, so periphyton (including macrophyte) contributions to the organic suspended material is inherently included in this discussion. However, the relative magnitudes of the phytoplankton and periphyton contributions to organic (algal-derived) suspended material in the Klamath River have not been and cannot be quantified from the available data since measurements of organic (algal-derived) suspended material in the Klamath River do not distinguish between the potential sources of the organic suspended material. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information.*

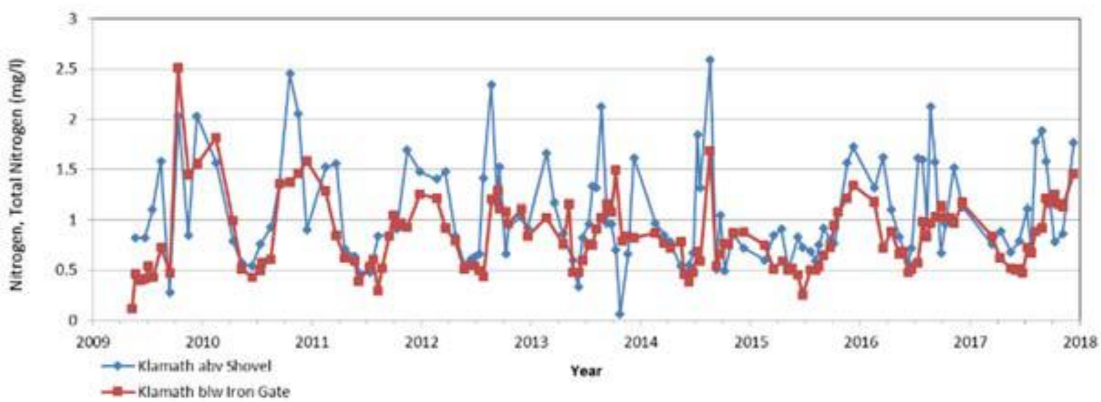
Potential Impact 3.2-6 provides a discussion of the potential changes in organic (algal-derived) suspended material in the Klamath River under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Potential Impact 3.2-6.

Volume I Potential Impact 3.4-4 (pages 3-435 to 3-437) provides a discussion of the potential changes in periphyton growth in the Hydroelectric Reach under the Proposed Project. However, Potential Impact 3.4-4 has been revised to address other comments (e.g., ORG46-36), so please also refer to Volume III Attachment 1 Section 3.4.5.2 *Phytoplankton and Periphyton – Potential Impacts and Mitigation – Periphyton* Potential Impact 3.4-4 for the revisions. Please refer to response to comment ORG46-267 for additional information regarding the potential impacts of the Proposed Project on the distribution of periphyton and macrophyte communities in the Klamath River.

Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* has been revised to clarify that the discussion of existing organic suspended material conditions in the Klamath River includes the contribution of periphyton. Please refer to Volume III Attachment 1 Section 3.2.2.3 *Water Quality – Environmental Setting – Suspended Sediments* for the revisions.

Comment ORG46-96

The DEIR states "On an annual basis, nutrients typically decrease slightly through the Hydroelectric Reach due to settling of particulate matter and associated nutrients in Copco No. 1 and Iron Gate reservoirs..." However, the critical aspect of the residence time through the reservoirs is absent from this discussion. Using data from KHSA Interim Measure 15 monitoring, the attenuation and lag through Project reservoirs (for example from upstream of Copco Reservoir at the Klamath above Shove l Creek site to downstream of Iron Gate Dam) is apparent. In the data presented below, the annual outflow in total nitrogen was notably less than the annual inflow in total nitrogen. This nutrient loading lag effect is also assessed in PacifiCorp (2006).



Response to Comment ORG46-96

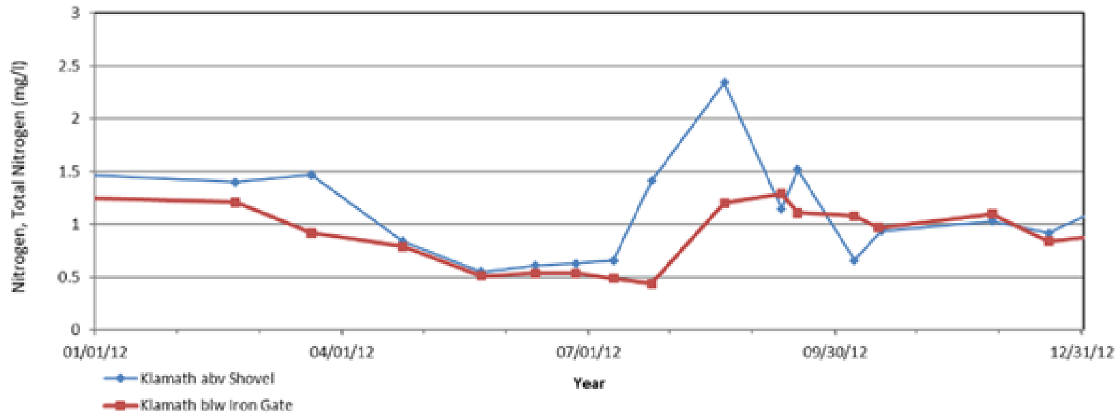
Contrary to the assertion in the comment, Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* does acknowledge that seasonal nutrient variations are a combination of processes, including reservoir residence times. Please refer to the beginning of the next paragraph for the following statement: "Seasonal variations in concentrations of Total Nitrogen (TN) and Total Phosphorus (TP) occur in the Klamath River downstream of Iron Gate Dam, due to a combination of nutrient storage and release from the water column and reservoir sediments, varying water concentrations at the elevation of the penstock intakes, residence times, and possible atmospheric losses through denitrification (for TN only) (Asarian and Kann 2011)." Thus, the Interim Measure 15 (IM15) nutrient data presented in this comment do not conflict with the EIR discussion of annual and seasonal nutrient cycling in the reservoirs.

Appendix C, Section C.3.1.1 *Hydroelectric Reach* provides further discussion of the temporal lag in nutrients due to the hydraulic retention time of the Lower Klamath Project reservoirs. Please refer to Volume III Attachment 1 for the final Appendix C *Water Quality Supporting Technical Information*.

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been clarified with further discussion of seasonal nutrient dynamics in the Lower Klamath Project reservoirs from Appendix C, Section C.3.1.1 *Hydroelectric*

Reach. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions.

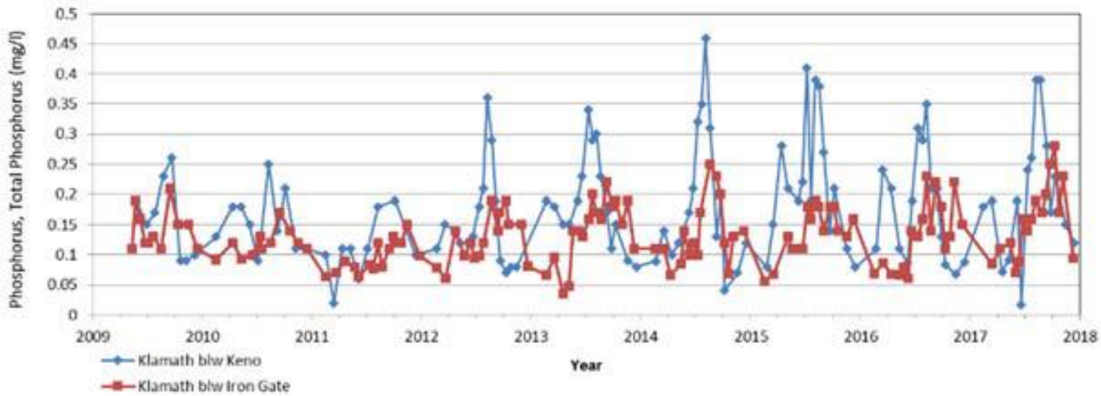
Comment ORG46-97



The DEIR states "Seasonal nutrient releases occur during periods of in-reservoir phytoplankton growth, and, in the case of TP [total phosphorus), can also result in downstream transport of bioavailable nutrients to the Lower Klamath River where they can stimulate excessive growth of periphyton (aquatic freshwater organisms attached to river bottom surfaces)." While nutrients sourced from the sediments do occur, the overall concentrations (or loads) are minor compared to the loads conveyed into the reservoirs via the Klamath River. Production occurs year-round, albeit seasonal maxima occurs in the late spring through early fall. While seasonal nutrient release occurs during periods of <u>*peak*</u> *in-reservoir production, this nutrient release coincides with periods of thermal stratification and hypolimnetic anoxia - a necessary condition. However, thermal stratification also impedes mixing of hypolimnetic waters with surface waters (i.e., epilimnion) where the vast majority of primary production occurs. Thus, while nutrient release occurs during the peak primary production period, these nutrients are trapped in the hypolimnion and unavailable to promote surface water productivity. Further, the thermoclines in both Copco and Iron Gate reservoirs associated with seasonal stratification are located downstream of the invert of the intake works at both dams. Thus, little hypolimnetic water is entrained in the outlet works, and little nutrient enriched water is released to downstream river reaches.*

The DEIR overstates this contribution and attributes seasonal variations downstream of the reservoir, in part, to this internal loading of the reservoirs. However, the inflowing Klamath River is by far the dominant source of nutrients into these reservoirs. Typical summer flows into (and through) Copco and Iron Gate reservoirs are on the order of 900 to 1,000 cubic feet per second (cfs). Given that Copco and Iron Gate reservoir storages are approximately 40,000 acre-feet and 50,000 acre-feet, respectively, and both stratify seasonally, these flow rates result in residences times of several weeks. Large upstream organic matter and nutrient loads are thus conveyed continuously throughout summer into these reservoir s and having a dominant impact on reservoir water quality

{PacifiCorp 2006, 2014). This can be clearly seen in the KHSA Interim Measure 15 data for total phosphorus concentrations at the Klamath River at Keno Dam as compared to the Klamath River downstream of Iron Gate Dam (see below).



Response to Comment ORG46-97

Appendix C, Section C.3.1.1 *Hydroelectric Reach* provides further information about the seasonal release of nutrients from in-reservoir production, including a discussion that total phosphorus (TP) released from sediments in Copco No. 1 and Iron Gate reservoirs during summertime anoxia remains in the hypolimnion until the reservoirs begin to turn over in the fall, rather than being released to downstream river reaches during the summer period of peak periphyton growth. Data from the reservoirs and downstream of Iron Gate Dam also indicate that some release of TP may occur between August and November, which could stimulate downstream periphyton growth during the late summer and fall. Please refer to Volume III Attachment 1 for the final Appendix C *Water Quality Supporting Technical Information*.

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* focuses its summary of existing nutrient conditions on increasing or decreasing nutrient trends through the Hydroelectric Reach and the Lower Klamath Project reservoirs rather than presenting a comparison of the magnitude of nutrients being transported by the Klamath River or exported from the Lower Klamath Project reservoirs. Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* does not overstate the contribution of the nutrient releases from reservoir sediments because it only discusses the total magnitude of the nutrients in the Klamath River downstream of Iron Gate Dam. As discussed in Asarian et al. (2009) and cited in Appendix C, Section C.3.1.1 *Hydroelectric Reach*, nutrients being transported by the Klamath River into the Hydroelectric Reach and the Lower Klamath Project reservoirs are the dominant source of nutrients into these reservoirs and comprise the majority of nutrients being transported downstream of the reservoirs. While nutrient releases from reservoir sediments are typically a small percentage of the incoming nutrients to reservoirs, these sediment releases can result in nutrients downstream of one or more of the reservoirs being greater than nutrients upstream of the corresponding reservoir (Asarian et al. 2009). As noted in response to comment ORG46-96, the discussion of nutrient loading accounts for the effect of residence time in the Lower Klamath Project reservoirs.

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify that nutrients being transported into the Hydroelectric Reach and the Lower Klamath Project reservoirs from upstream sources are the dominant source of nutrients into these reservoirs and comprise the majority of nutrients being transported downstream of the reservoirs. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revision. The clarification does not change the results of the impact analysis.

Comment ORG46-98

The DEIR recognizes that the Copco No. 1 and Iron Gate reservoirs act to retain particulate matter and nutrients on an annual basis but characterizes the resulting decrease in particulate matter and nutrients as "slight." What this modifying adverb actually means in this instance is clearly debatable. A similar use of "slight" or "very small" is used throughout the DEIR when discussing nutrient retention effects of the reservoir s (e.g., DEIR pgs. 3-114, 3-115, 3-117, 3-118, 3-137, 3-431, 3-846). For example, on page 3-117, even after making the unrealistic assumption of full compliance with TMDL load allocations, the DEIR characterizes annual increases in total phosphorus of 10 to 15 micrograms per liter (µg/L) as "very small," when in fact such increases are arguably substantive. Furthermore, on page 3-116, the DEIR states "...TP [total phosphorus] concentrations in the Middle and Lower Klamath River would increase by approximately 2 to 12 percent for the June–October period if the dams were to be removed, while increases in TN [total nitrogen] concentrations would be relatively larger, at an estimated 37 to 42 percent for June through October and 48 to 55 percent for July through September (see Figure 3.2-18)." It is inaccurate to characterize changes in nutrient loading of up to 55 percent as either "slight," "very small," or "relatively larger." In fact, given the large inflowing nutrient loads to Copco Reservoir, particularly the large loads emanating to the Klamath River from Upper Klamath Lake, the substantial net retention provided by Copco and Iron Gate reservoirs (618 and 38 metric tons of nitrogen and phosphorus annually, respectively; Asarian and Kann 2007) is an important process for reducing nutrient loads to the Klamath River downstream of Iron Gate Dam.

The DEIR goes on to conclude that the loss of this long-term nutrient retention following reservoir elimination is "No Significant Impact" for the Proposed Project and the other partial dam-removal alternatives (e.g., see Table ES-1). On the other hand, the DEIR describes in several places that Copco No. 1 and Iron Gate reservoirs do not retain but rather release nutrients on a seasonal basis and the DEIR concludes that elimination of this seasonal release would be a "Beneficial Effect" of the Proposed Project and the other partial dam-removal alternatives (e.g., see Table ES-1). This differing characterization of annual versus seasonal *nutrient retention in Copco No. 1 and Iron Gate reservoirs is not supported with any analysis and instead represents a bias in which the significance of long-term nutrient retention in the reservoirs is downplayed and the significance of seasonal effects is elevated.*

Regarding the seasonal effects related to reservoir nutrient retention or release, the DEIR does not adequately explain or account for the substantial variability in these assumed seasonal effects as evident in the calculated input and output nutrient loading values. Moreover, the DEIR' s analysis of the reservoirs' seasonal nutrient loading and retention does not adequately explain or account for the hydraulic residence time of water in the reservoirs. The reservoir residence times are considerable, allowing for processes such as decay and settling to occur. These processes are important to recognize and consider when assessing the roles of nutrient retention in the system. If inflow and outflow nutrient conditions are compared for a time interval that is less than water residence and travel time through the reservoirs, it is easy to mistakenly identify the reservoirs as sources of nutrients. For example, as discussed in PacifiCorp (2006), Copco Reservoir inflows may indicate higher levels of total nutrients than Iron Gate Reservoir outflows. However, Iron Gate is actually further reducing the input from Copco Reservoir because of the considerable residence time in Iron Gate Reservoir; that is, total nutrients in Copco Reservoir inflows has been reduced as the "peak" passes through the reservoirs.

Response to Comment ORG46-98

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify the most recent calculated annual nutrient retention amounts for the Lower Klamath Project reservoirs (Asarian et al. 2009) and what is meant by the use of "slight" when describing nutrient retention. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions according to the following discussion. The magnitudes of the most recent annual nutrient retention for Copco No. 1 and Iron Gate reservoirs in Asarian et al. (2009) differ from previous studies cited by PacifiCorp (2014) and the comment (i.e., Asarian and Kann [2007]) due to earlier studies either analyzing nutrient data from only part of a year or improvements in the methods for estimating nutrient retention in the reservoir, as discussed in detail below.

Kann and Asarian (2005) and PacifiCorp (2006) analyze nutrient data from March/April to November 2002, so the nutrient retention estimates in those citations do not represent *annual* nutrient retention. Asarian et al. (2009) analyzes nutrient data from May 2005 to December 2007, while Asarian and Kann (2007) analyzes nutrient data from May 2005 to May 2006. The estimates of nutrient retention in Copco No. 1 and Iron Gate reservoirs for May 2005 to May 2006 changed between Asarian and Kann (2007) and Asarian et al. (2009) because Asarian et al. (2009) had more accurate accounting of the effects of hydropower peaking, incorporated un-gaged river flows, and used multiple regression models to estimate nutrient load. Please see Asarian et al. (2009) for more details on the methodological improvements and resulting differences in nutrient retention estimates in Copco No. 1 and Iron Gate reservoirs between Asarian and Kann (2007) and Asarian et al. (2009).

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify the analysis of seasonal nutrient retention or release with the most recent calculated seasonal nutrient retention or release amounts for the Lower Klamath Project reservoirs (Asarian et al. 2009). Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions.

Appendix C, Section C.3.1.1 *Hydroelectric Reach* also has been revised to clarify the variability in the seasonal nutrient retention/release from the reservoirs considered in the impact analyses using the May 2005 to December 2007 time series of Copco No. 1 and Iron Gate reservoir nutrient retention/release estimates, including adding Asarian et al. (2009) Figures 23 through 26 (see below) showing this nutrient retention/release variability for Copco No. 1 and Iron Gate reservoir. Please refer to Volume III Attachment 1 Appendix C, Section C.3.1.1 *Hydroelectric Reach* for the revisions.

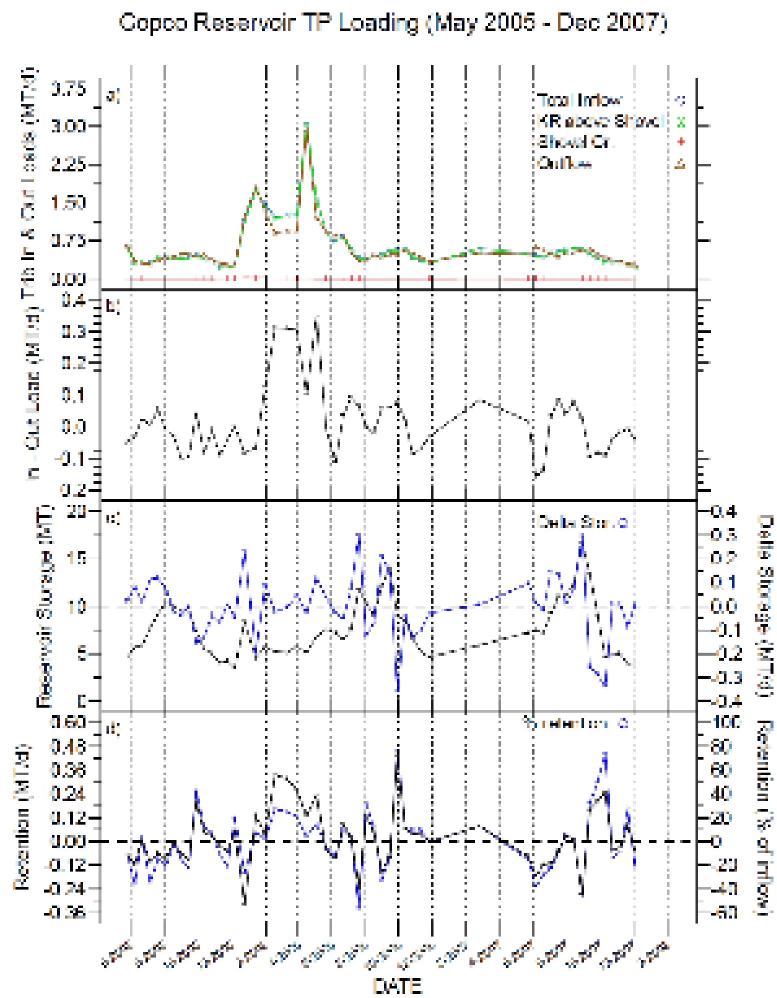


Figure 23 from Asarian et al. (2009). Time Series of Copco No. 1 Reservoir Total Phosphorus Loading, May 2005 to Dec 2007. Each Point Represents Data from an Entire Sampling Interval (Approximately Biweekly) and is Placed at the Midpoint of the Two Adjacent Sampling Dates. Horizontal Dashed Lines are Placed at Zero for Delta Storage and Retention.

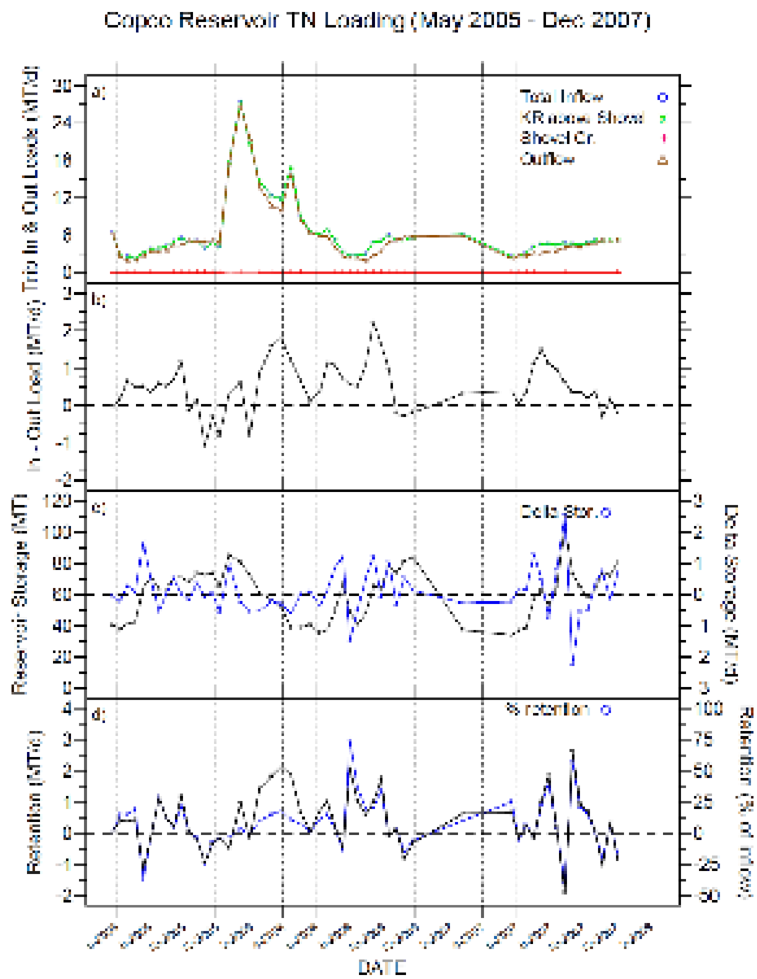

Figure 24 from Asarian et al. (2009). Time Series of Copco No. 1 Reservoir Total Nitrogen Loading, May 2005 to Dec 2007. Each Point Represents Data from an Entire Sampling Interval (Approximately Biweekly) and is Placed at the Midpoint of the Two Adjacent Sampling Dates. Horizontal Dashed Lines are Placed at Zero for Delta Storage and Retention.

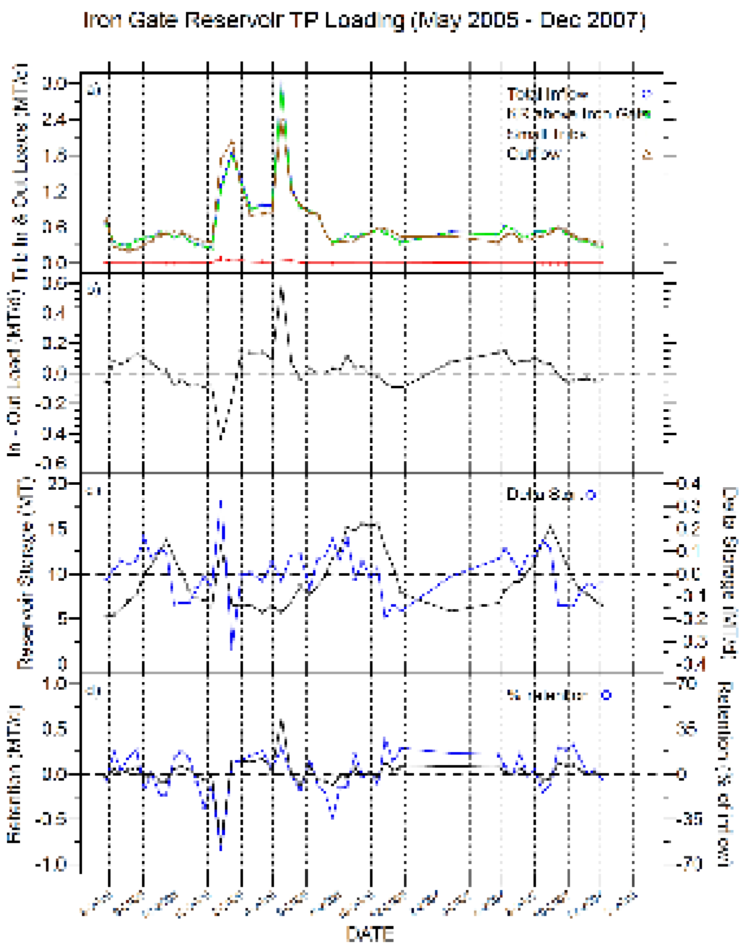

Figure 25 from Asarian et al. (2009). Time Series of Iron Gate Reservoir Total Phosphorus Loading, May 2005 to Dec 2007. Each Point Represents Data from an Entire Sampling Interval (Approximately Biweekly) and is Placed at the Midpoint of the Two Adjacent Sampling Dates. Horizontal Dashed Lines are Placed at Zero for Delta Storage and Retention.

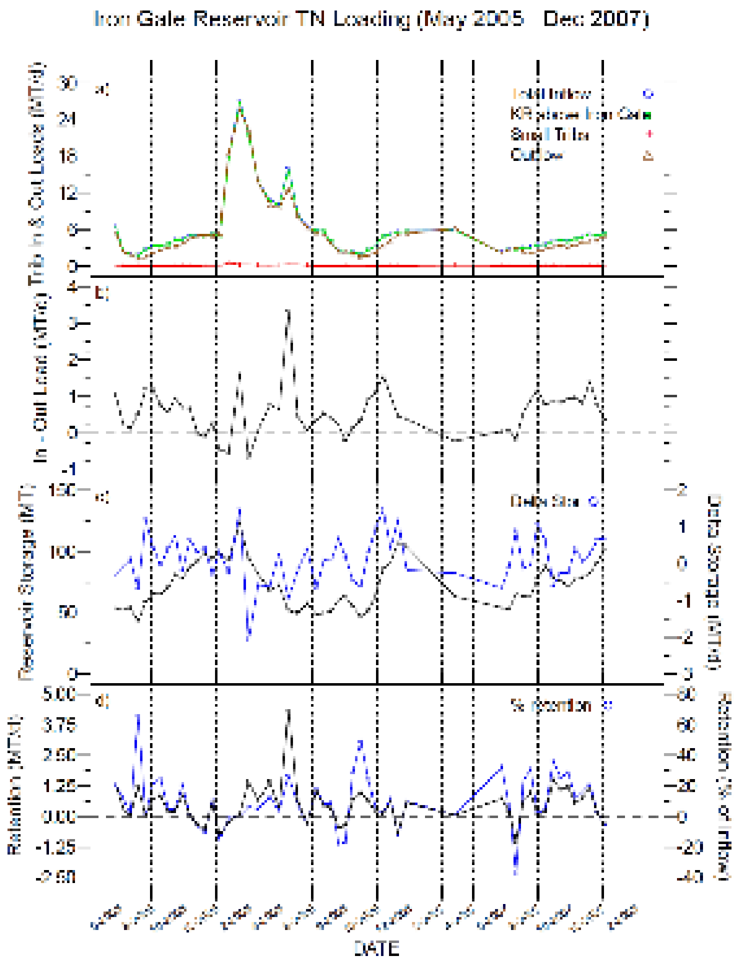

Figure 26 from Asarian et al. (2009). Time Series of Iron Gate Reservoir Total Nitrogen Loading, May 2005 to Dec 2007. Each Point Represents Data from an Entire Sampling Interval (Approximately Biweekly) and is Placed at the Midpoint of the Two Adjacent Sampling Dates. Horizontal Dashed Lines are Placed at Zero for Delta Storage and Retention.

As necessary, estimates of nutrient retention or release in Asarian et al. (2009) account for the hydraulic residence time of water in the reservoirs and its influence on nutrient retention and release, so the comment’s assertion that the EIR nutrient retention or release discussion does not adequately account for the reservoir residence time is incorrect. Asarian et al. (2009) calculated the hydraulic residence time for Copco No. 1 and Iron Gate reservoirs from May 2005 to December 2007. As explained by the comment, the hydraulic residence time of water is important to consider when evaluating upstream and downstream nutrient trends over a time scale similar to the inflows/outflows since the effect of the hydraulic residence time on nutrients would have a similar magnitude as the effect of inflows/outflows on nutrients. However, the hydraulic residence time becomes less important to consider as the time scale increases since the magnitude of the inflows/outflows would become much larger than the magnitude of the hydraulic residence time. The hydraulic residence time does not need to be explicitly considered in the seasonal (e.g., 3 month) or annual estimates of nutrient retention because these time scales are approximately three times or greater than the average hydraulic residence time calculated for Copco No. 1 and Iron Gate reservoirs from May 2005 to December 2007 (i.e., approximately 5 days during high winter and spring flows and approximately 15 to 25 days during summer low flows for Copco No. 1 Reservoir and approximately 3 to 10 days during winter/spring and approximately 25 to 30 days during summer for Iron Gate Reservoir). Seasonal and annual estimates of nutrient retention or release in Asarian et al. (2009) would accurately quantify the nutrient dynamics in Copco No. 1 and Iron Gate reservoirs.

Additional comments about the use of adverbs like “slight” or “very small” describing the magnitude of nutrient changes appear to be unrelated to Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients*; rather they appear to be related to Potential Impact 3.2-8 and several other locations in the EIR. While the comment’s overall point about the potentially subjective meaning of adverbs is noted and clarifications to the magnitude of “slight” or other adverbs are incorporated in the relevant sections of the EIR, the specific example presented in the comment is an incorrect interpretation of the discussion in Potential Impact 3.2-8 since “very small” was used to describe the 0.01 to 0.015 mg/L annual increase in Total Phosphorus (TP) and “relatively larger” 0.1 to 0.125 mg/L annual increase in Total Nitrogen (TN) estimated by the *Klamath River Total Maximum Daily Load (TMDL) model,* but the previous discussion of percentage increases in nutrients after dam removal (i.e., approximately 2 to 12 percent increase in TP during June to October or a 27 to 42 percent increase in TN during June to October and a 48 to 55 percent increase in TN during July through September) is related to a *different* model: the Yurok Tribe analysis. Potential Impact 3.2-8 clearly explains that these results are from different models because after the sentence stating the “very small” increase in TP and “relatively larger” increase in TN, the EIR specifies: “It should be noted that while following the same relative trend as the Yurok Tribe analysis, the absolute increases predicted by the Klamath River TMDL model for the “TMDL dams-out” California scenario (TCD2RN) are much lower (e.g., 0.1–0.125 mg/L TN increase for the TMDL model vs. 0.1 to 0.5 mg/L TN increase for the Yurok Tribe analysis).”

Comparing the Klamath River TMDL model results of a “very small” 0.01 to 0.015 mg/L annual increase in TP and “relatively larger” 0.1 to 0.125 mg/L annual increase in TN with the measured nutrient concentrations listed in Figure 3.2-18 (i.e., existing [with dams]), the “very small” annual increase in TP is 6 to 9 percent and the “relatively larger” annual increase in TN is 9 to 14 percent. Thus, Potential Impact 3.2-8 does not characterize a change in nutrient loading of up to 55 percent as “slight”, “very small”, or “relatively larger.” Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* and Potential Impact 3.2-8.

Comment ORG46-99

These paragraphs do not adequately address the role of primary production and associated impacts on water quality in the Klamath River. The Klamath River is weakly buffered and existing seasonal primary production can readily produce pH in excess of 9 coincident with elevated water temperatures, particularly between Iron Gate Dam and the Scott River. Further, review of periphyton data indicates that the lower Klamath River is nitrogen-limited in late summer, as evidenced by the dominance of Epithemia sorex. Epithemia sorex contains endosymbiotic cyanobacteria in many of the cells, which fix atmospheric nitrogen for use by the cells. The seasonal dominance by Epithemia sorex (as well as other nitrogen-fixing periphyton) are a source of nitrogen to the Klamath River that are not discussed in the DEIR. Also, there is minimal light limitation in much of the Klamath River from Iron Gate Dam to the Trinity River creating good growing conditions for periphyton.

The DEIR states "Measured levels of TP [total phosphorus] in the estuary are typically below 0.1 mg/L during summer and fall (June–October) and TN [total nitrogen] levels are consistently below 0.7 mg/L (June–October)." These total nutrient values mean little without some context that establishes the bioavailable, inorganic forms of nutrients, such as ammonia, nitrate, and orthophosphate, which are more directly usable for primary production. Primary production can occur at very low values of inorganic nitrogen and phosphorous based on their half saturation constants, e.g., 0.014 milligrams per liter (mg/L) and 0.003 mg/L respectively (Tetra Tech 2009). These half saturation constant values are far lower than the estuary concentrations presented in the DEIR.

Response to Comment ORG46-99

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* summarizes the measured nutrient concentrations in the Middle and Lower Klamath River, specifying that in-river nutrient spiraling processes by phytoplankton and periphyton strongly affect nitrogen concentrations in the Klamath River. Please refer to Volume III Attachment 1 Appendix C, Section C.3.2 *Mid- and Lower Klamath Basin* for further discussion of seasonal variations in the nutrients due to primary productivity in the Klamath River, including quantification of the overall nutrient variations in the river due to nutrient removal processes (e.g., storage in phytoplankton/plant biomass) and nutrient production processes (e.g., nitrogen fixation).

The influence of primary production on other water quality parameters is discussed under the relevant water quality parameter sections in the EIR. Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen*, Section 3.2.2.6 *Water Quality – Environmental Setting – pH*, and Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* provides a summary of the influence of primary production in the Klamath River on dissolved oxygen concentrations, pH, and chlorophyll-*a* concentrations, respectively. Section *Water Quality – Environmental Setting* – 3.2.2.6 *pH* specifically discusses the photosynthesis-driven daily and seasonal variations in pH due to primary production. Appendix C, Section C.4 *Dissolved Oxygen*, Appendix C, Section C.5 *pH*, and Appendix C, Section C.4 *Algal Toxins and Chlorophyll-a* provide further discussion of the influence of primary production in the Klamath River on dissolved oxygen concentrations, pH, and chlorophyll-*a* concentrations, respectively. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

Please refer to Section 3.4.2.4 *Phytoplankton and Periphyton – Environmental Setting – Middle and Lower Klamath River – Periphyton* (pages 3-418 to 3-420) for a discussion of the periphyton communities in the Klamath River during summer, including the prevalence of *Epithemia sorex*, *Epithemia turgida*, and *Rhopalodia gibba*, which all contain cells of cyanobacteria [blue-green algae] that live inside the diatom cells to help the diatoms fix nitrogen. Total nitrogen (TN) measurements in the Klamath River discussed in Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* and Appendix C, Section C.3.2 *Mid- and Lower Klamath Basin* would include all sources of nitrogen, including TN from nitrogen fixing periphyton that seasonally dominate the periphyton community in the Lower Klamath River. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

Appendix C, Section C.3.2.3 *Klamath River Estuary* provides a discussion of the ammonia, nitrate, and orthophosphate nutrient concentrations measured in the Klamath River Estuary. Primary production can occur at very low values of inorganic nitrogen and phosphorus. The half-saturation constants for inorganic nitrogen and phosphorus represent the upper concentration at which algae growth is directly proportional to nutrient concentrations (Cole and Wells 2015). Nutrient concentrations greater than the half saturation constants indicate that there are sufficient nutrients available to meet primary productivity growth needs and nutrient concentrations in excess of those half saturation constants would have a diminishing influence on algae growth. Please refer to Volume III Attachment 1 for the final Appendix C *Water Quality Supporting Technical Information*.

In the Klamath River Estuary, inorganic phosphorus (i.e., soluble reactive phosphorus) ranges from approximately 0.004 to 0.102 mg/L, so it is consistently greater than the phosphorus half-saturation constant reported in Tetra Tech (2009) (i.e., 0.003 mg/L), indicating that phosphorus is not limiting algae growth in the estuary. Inorganic nitrogen (i.e., ammonia and nitrate plus nitrite) ranges from approximately 0.011 to 0.348 mg/L, with approximately 70 percent of the measurements representing the primary phytoplankton and periphyton growth season (i.e., May through October) at greater than the nitrogen half-saturation constant reported in Tetra Tech (2009) (i.e., 0.014 mg/L). Since measured inorganic nitrogen concentrations are typically greater than the nitrogen half-saturation constant, nitrogen generally does not limit algae growth in the estuary. Further, nitrogen-fixing periphyton species that dominate in the lower Klamath River reaches and likely dominate periphyton communities in the estuary would be able to obtain nitrogen from the atmosphere for growth, so nitrogen is unlikely to limit algae growth in the estuary even during the periods when the inorganic nitrogen concentrations are less than the nitrogen half-saturation constant.

Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* has been revised to clarify that measured nutrient levels in the Klamath River Estuary typically exceed the half-saturation constant and so may, at times, promote algal growth at levels that cause nuisance effects or adversely affect beneficial uses. Please refer to Volume III Attachment 1 Section 3.2.2.4 *Water Quality – Environmental Setting – Nutrients* for the revisions.

Comment ORG46-100

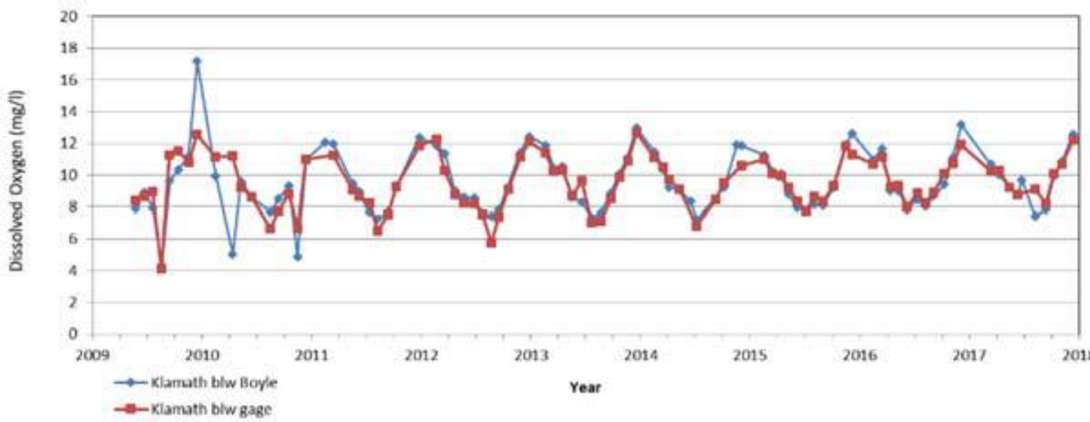
The text in this paragraph focuses solely on blue-green algae and relates all dissolved oxygen conditions to this group of algae, suggesting there are no other algae present or that have an impact on dissolved oxygen conditions. Blue-green algae should be replaced with "phytoplankton" in this text.

Response to Comment ORG46-100

Section 3.2.2.5 *Water Quality – Environmental Setting –Dissolved Oxygen* has been revised to clarify that dissolved oxygen in the reservoirs is mainly driven by phytoplankton, especially large blue-green algae blooms. Please refer to Volume III Attachment 1 Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* for the revisions.

Comment ORG46-101

While there is some variation in dissolved oxygen concentrations in J.C. Boyle Reservoir, the DEIR erroneously states that "This variation can affect dissolved oxygen concentrations further downstream in the California portion of the Hydroelectric Reach." A simple review of the KHSA Interim Measure 15 data indicates that dissolved oxygen levels downstream of J.C. Boyle Dam (labeled "Klamath blw Boyle" in figure below) are essentially identical to those downstream of the J.C. Boyle Powerhouse (Klamath blw gage in figure below). The DEIR acknowledged that high gradient stream reaches increase dissolved oxygen to near saturation for the reach from Keno Dam to J.C. Boyle Reservoir. The DEIR fails to note that the same effect is found downstream of J.C. Boyle Dam. The reaeration rate is sufficient that by the time waters reach the California-Oregon state line the dissolved oxygen levels in the river are near saturation and any deficit introduced from J.C. Boyle Reservoir has been largely ameliorated via mechanical reaeration.



Response to Comment ORG46-101

The Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM 15) dissolved oxygen concentrations are discrete measurements conducted at an approximately two-week to monthly frequency, so they would not characterize the dissolved oxygen variations that occur at the sub-daily time scale of peaking flows. Dissolved oxygen concentrations in the Klamath River would need to be measured at a sub-daily (e.g., hourly) time scale to represent the dissolved oxygen concentration variations resulting from peaking flows with low dissolved oxygen concentrations. While the comment is correct that fast-moving, turbulent flows in the J.C. Boyle Peaking Reach of the Klamath River provide aeration of river water, Klamath River Water Quality Model (KRWQM) and Total Maximum Daily Load (TMDL) modeling of dissolved oxygen concentrations in the J.C. Boyle Peaking Reach indicate that during the summer and fall hydropower peaking flows can release lower dissolved oxygen water from J.C. Boyle Reservoir that potentially affects dissolved oxygen concentrations farther downstream in the California portion of the J.C. Boyle Peaking Reach.

KRWQM modeling of dissolved oxygen concentrations shows dissolved oxygen concentrations upstream and downstream of J.C. Boyle Powerhouse are similar during non-peaking periods, but dissolved oxygen concentrations decrease downstream of J.C. Boyle Powerhouse during hydropower peaking operations (see Figure 4.8-42 below; PacifiCorp 2004a-1). Once peaking operations stop, the dissolved oxygen concentrations downstream of J.C. Boyle Powerhouse become the same as dissolved oxygen concentrations upstream of J.C. Boyle Powerhouse. The pattern of lower dissolved oxygen concentrations during peaking operations and higher dissolved oxygen concentrations during non-peaking periods that is apparent in the modeled dissolved oxygen concentrations downstream of the J.C. Boyle Powerhouse under existing conditions, is also apparent in dissolved oxygen concentration data at the J.C. Boyle Powerhouse measured in 2019 (see Figure ORG46-101-1 below). The 2019 measured data indicate that the dissolved oxygen modeling is correctly characterizing dissolved oxygen dynamics downstream of the J.C. Boyle Powerhouse.

A comparison of the modeled dissolved oxygen concentrations “above Copco” (i.e., downstream of the Oregon-California state line) under existing conditions and under “without-Project” (i.e., dam removal) conditions indicates that the low dissolved oxygen concentrations associated with hydropower peaking operations produce lower dissolved oxygen concentrations for several hours each day as compared with conditions under a dam removal scenario (see Figure 4.8-42 below; PacifiCorp 2004a-1). TMDL dissolved oxygen modeling results at the Oregon-California state line shown in EIR Figure 3.2-19 also indicate periods of lower dissolved oxygen concentrations in the summer under existing conditions (i.e., “TMDL dams-in” [T4BSRN] scenario) as compared with the Proposed Project (i.e., “TMDL dams-out, Oregon” [TOD2RN] scenario), further supporting the notion that hydropower peaking operations have the potential to influence dissolved oxygen concentrations in the California portion of the J.C. Boyle Peaking Reach.

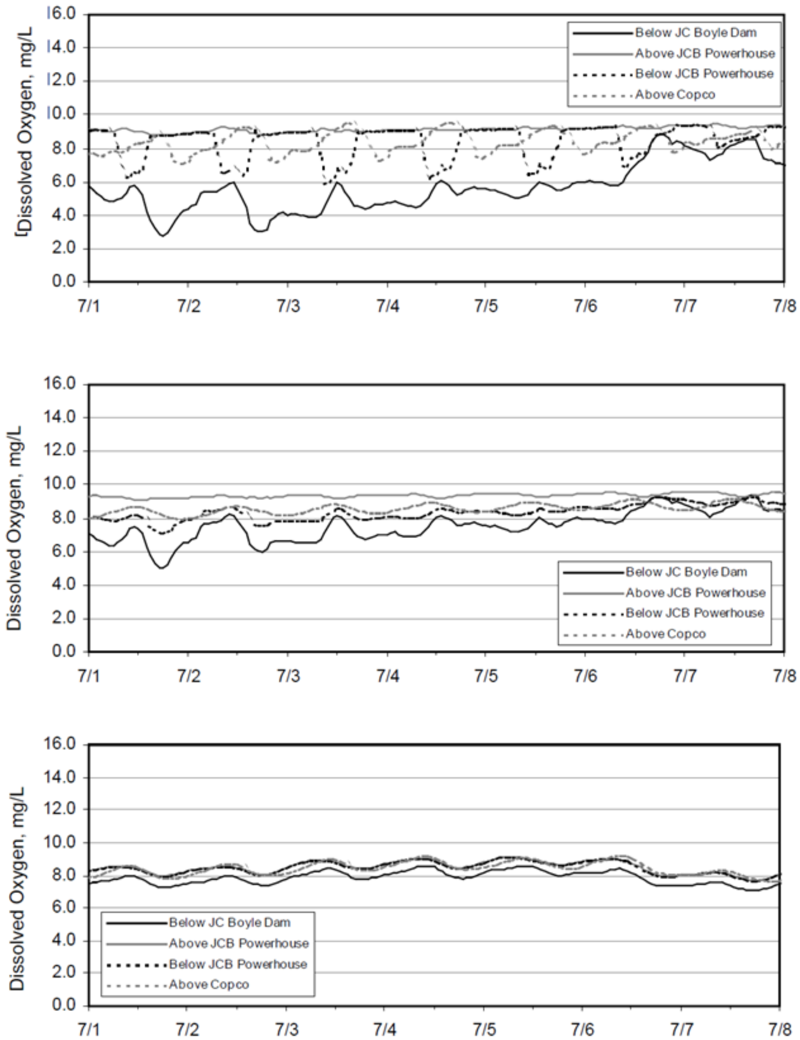


Figure 4.8-42 from PacifiCorp (2004a-1). J.C. Boyle Bypass and Peaking Reach Dissolved Oxygen, 2000: EC [Existing Conditions] (Top), SF [Steady Flow] (Middle), WOP [Without-Project] (Bottom). Note: The Without-Project (WOP) Conditions Modeled in PacifiCorp (2004a-1) Included the Removal of Keno Dam in Addition to Removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate Dams.

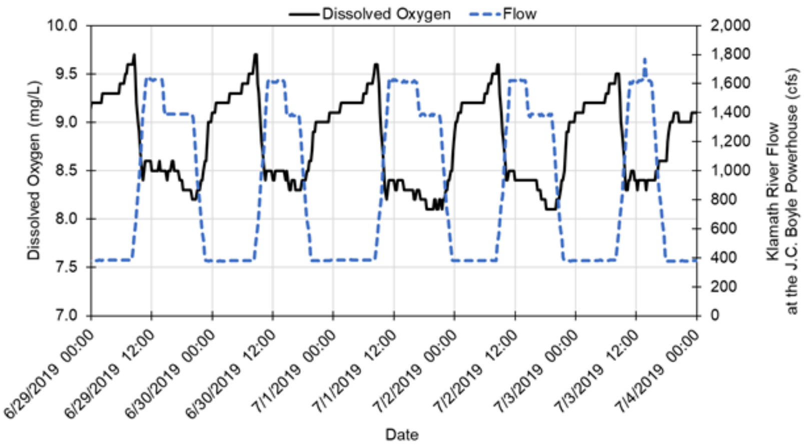

Figure ORG46-101-1. Dissolved Oxygen and Klamath River Flow Measured at the U.S. Geological Survey (USGS) 11510700 Gage Downstream of J.C. Boyle Powerhouse. Source: USGS 2019.

Data directly documenting the influence of low dissolved oxygen concentrations in J.C. Boyle Reservoir on dissolved oxygen concentrations at the Oregon-California state line are unavailable, but USGS dissolved oxygen data measured downstream of the J.C. Boyle Powerhouse indicate that hydropower peaking flows diverted from J.C. Boyle Reservoir decrease dissolved oxygen concentrations in the J.C. Boyle Peaking Reach downstream of the powerhouse, and modeling results consistently indicate that hydropower peaking operations potentially impact dissolved concentrations in the California portion of the Hydroelectric Reach. The data set thus indicates that variations in dissolved oxygen concentrations in J.C. Boyle Reservoir can affect dissolved oxygen concentrations farther downstream in the California portion of the Hydroelectric Reach.

Comment ORG46-102

The DEIR states "The low surface dissolved oxygen levels and their occurrence later in the season at Iron Gate Reservoir is believed to be associated with seasonal algal blooms, as dead algal cells are decomposed by aerobic organisms, exhausting dissolved oxygen in reservoir bottom waters and sediments." The DEIR should clarify that low surface concentrations of dissolved oxygen are associated with seasonally diminishing photosynthesis and continued algae biomatter loading from Upper Klamath Lake and other upstream Klamath River sources. Stratification persists through October for Copco Reservoir and well into November for Iron Gate Reservoir, precluding anoxic bottom waters from mixing with surface waters as is alluded to in the DEIR. Fall cooling and deepening of the epilimnion may contribute to lower dissolved oxygen water; however, the process of fall cooling deepens the epilimnion and increases its volume, and lower primary production cannot overcome the continued oxygen demand associated with organic matter (and associated oxygen demand) in Klamath River inflows.

Response to Comment ORG46-102

Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* has been revised in Volume III Attachment 1 to clarify that the period of low surface dissolved oxygen in Iron Gate Reservoir corresponds with the period when photosynthesis by algae would decline and organic matter from upstream sources increases, such that the incoming organic matter would also contribute to reduced surface dissolved oxygen concentrations in the reservoir. Please refer to Volume III Attachment 1 Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* for the revisions.

<u>Comment ORG46-103</u>

The DEIR states "Daily fluctuations in dissolved oxygen (ranging from 1 to 3 mg/L per day) measured in the Klamath River immediately downstream from Iron Gate Dam have been attributed to daytime algal photosynthesis and nighttime bacterial respiration in the upstream reservoirs." This sentence should be corrected to "...algal and bacterial respiration..." The DEIR also should clarify that releases from the reservoir experience modest diurnal variation. Additionally, monitoring locations "immediately downstream of Iron Gate Dam" are some 1,000 feet downstream of the dam. Mechanical reaeration occurs in this reach between the powerhouse and the monitoring equipment, as does aquatic vegetation photosynthesis and respiration (and bacterial respiration). These latter mechanisms also contribute to variable dissolved oxygen conditions downstream of the dam.

Response to Comment ORG46-103

Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* text has been revised to specify algal and bacterial respiration and to indicate that the Iron Gate Dam monitoring site is 1,000 feet downstream of the dam. Please refer to Volume III Attachment 1 Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* for the revisions.

<u>Comment ORG46-104</u>

The DEIR should acknowledge that dissolved oxygen levels reach saturation in the Klamath River within a couple of miles downstream Iron Gate Dam (PacifiCorp 2018a), well above Seiad Valley, which is approximately 60 miles downstream.

Response to Comment ORG46-104

Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* has been revised in Volume III Attachment 1 to clarify that existing data indicate that in 2017 dissolved oxygen concentrations were reaerated to above the minimum Basin Plan saturation levels within approximately 2 to 3 miles downstream from Iron Gate Dam. Please refer to Volume III Attachment 1 Section 3.2.2.5 *Water Quality – Environmental Setting – Dissolved Oxygen* for the revisions.

Comment ORG46-105

The water quality impact assessment of reservoir drawdown on pH does not address sediment-related acidification. This is an important omission that affects the adequacy of this section. The substantial sediment load released by the Proposed Project to downstream reaches will include anoxic sediments. As stated elsewhere in the DEIR (Section 3.2.5.4), these sediments will exert a substantial oxygen demand in downstream reaches during reservoir drawdown. Section 3.2.5.4 states that part of the oxygen demand would be from ferrous iron content of anoxic sediments.

However, nowhere in the DEIR is the re consideration of the acid production potential in these oxidation reactions. Oxidation of sulfidic minerals will produce acid. With such a large sediment load and in such weakly buffered waters (Section 3.2.2.6), the DEIR must assess the potential for acidification in the river downstream of Iron Gate Dam.

Another potential source of acidification that is not acknowledged and assessed in the DEIR is drainage from residual sediments in reservoirs. These drained sediments are no different than dredge spoils in their potential for acidification with oxidation. Acid seeps can form on the exposed banks within the former reservoir areas. Low pH can also mobilize metals in the seeps at concentrations that could have adverse impacts on water quality.

It may be that acidification will not be severe; however, without any analysis, it is impossible to know. Typically, an acceptable analysis of acidification potential is based on analysis of sediment mineralogy and a pH mass balance model is created to assess potential acidification impacts. The DEIR is lacking any of this information.

Response to Comment ORG46-105

While the comment asserts that there is a potential for sediment-related acidification, the comment does not provide substantial evidence regarding this potential physical impact of the Proposed Project on the environment (CEQA Guidelines section 15384). The existing evidence supports the conclusion that sediment-related acidification is unlikely to occur as the result of the project and that further study is not necessary.

Section 3.2.2.6 *Water Quality – Environmental Setting – pH* summarizes the available literature and data on existing conditions. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*. Measurements of the potential for sediment-related acidification were not conducted as part of the previous reservoir sediment investigation (Shannon and Wilson 2006; USBR 2011) because the 2009 or 2018 Sediment Evaluation Framework (SEF) for the Pacific Northwest does not include assessment of the acid generation potential by sediments (RSET 2009, 2018). The 2018 SEF was prepared by Northwest Regional Sediment Evaluation Team Agencies (i.e., the U.S. Army Corps of

Engineers (Northwestern Division and Portland, Seattle, and Walla Walla Districts), U.S. Environmental Protection Agency, Region 10, National Oceanic and Atmospheric Administration, West Coast Region, U.S. Fish and Wildlife Service, Pacific Region, Oregon Department of Environmental Quality, Idaho Department of Environmental Quality, Washington Department of Ecology, and Washington Department of Natural Resources) and incorporates the best available science to evaluate discharges of dredged material. The acid generation potential discussed in the comment is typically evaluated for mining wastes that are extracted from underground anoxic environments (USEPA 1994) rather than anoxic reservoir sediments.

Measurements of pH in the elutriate sediment samples undertaken for the 2012 KHSA EIS/EIR and Secretarial Determination analyses indicate low acid generation potential from reservoir sediments during reservoir drawdown and downstream transport of the sediment deposits. The pH of the reservoir sediment cores ranged from 6.6 s.u. for J.C. Boyle Reservoir samples to 7.8 s.u. for Copco No. 1 Reservoir samples (USBR 2011). Klamath River Renewal Corporation (KRRC) collected measurements of soil pH during 2017 reservoir sediment core sampling and plant nutrient availability (PNA) laboratory analyses and these soil pH data indicate that the soil pH is slightly acidic. During the PNA lab analyses, which were undertaken to evaluate reservoir sediments as a growth medium, the pH ranged from 6.2 to 6.5 s.u. in sediment samples from J.C. Boyle, Copco No. 1, and Iron Gate reservoirs (Volume II Appendix B: *Definite Plan – Appendix H, Section 8.1.2 Reservoir Revegetation and Grow Tests* [pages 141 to 152]). In the reservoir sediment cores (USBR 2011) and the more recently collected PNA reservoir sediment samples, pH was measured after the sediment samples had been stored for several days to approximately five weeks. As a result, the available pH measurements likely represent a range of anoxic to slightly aerobic conditions in the sediments, but they are unlikely to characterize the pH under completely aerobic conditions.

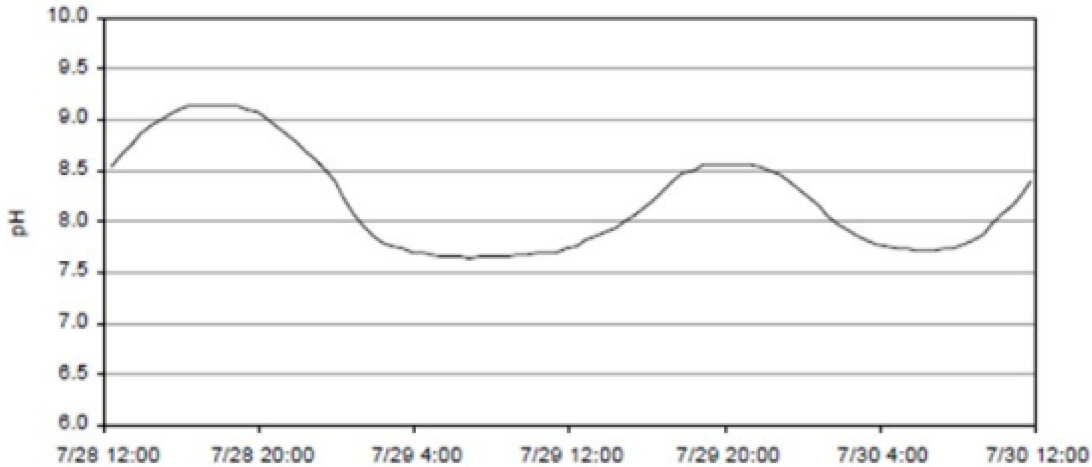
Measurements of elutriate sediment sample pH are potentially the most representative of pH under aerobic conditions. The elutriate sediment samples were prepared by vigorously mixing four parts reservoir sediment with one part native (i.e., reservoir) water for thirty minutes, letting the mixture settle for one hour, extracting the overlying solution, and centrifuging the solution to remove particles. The native water was collected from the surface of the reservoirs where dissolved oxygen levels were measured between approximately 6.5 milligram per liter (mg/L) to approximately 11 mg/L, so the mixing during preparation of the elutriate sediment samples would have exposed the reservoir sediment to an aerobic environment and would thus represent the acid generation potential from rapidly oxidizing iron or sulfide minerals in the sediments. The elutriate sediment sample pH ranged from 7.6 standard units (s.u.) in Iron Gate Reservoir to 8.0 s.u. in J.C. Boyle Reservoir (USBR 2011) suggesting there is a low acid generation potential for reservoir sediments as they are reaerated during sediment mobilization and transport downstream of the Hydroelectric Reach.

To date, no measurement or analysis results for the Lower Klamath Project reservoir sediments or elutriate test results, including acid volatile sulfide measurements in the reservoir sediments and sulfide measurements in the elutriate sediment samples, have identified a significant potential for acid generation during or following reservoir drawdown and no further testing along these lines has been recommended by the prior studies (Shannon and Wilson 2006; GEC 2006; USBR 2011; CDM 2011).

Overall, the multiple lines of evidence discussed above, including direct measurement of pH after reservoir sediments were exposed to an aerobic environment, indicate that the acid generation potential of reservoir sediments is low and a more detailed analysis of the acid generation potential of the reservoir sediments based on an analysis of sediment minerology and a pH mass balance model is not necessary.

Comment ORG46-106

The DEIR states that alkalinity "Levels below 10 mg/L indicate that the system is poorly buffered and very susceptible to changes in pH." The correct value indicative of a weakly buffered system is 100 mg/L, not 10 mg/L. The pH of water is an important parameter in aquatic systems because many reactions that control water quality are pH dependent. Typically, surface freshwater (rivers and lakes) contain both acids and bases, and biological processes tend to increase either acidity or basicity. The interactions among these opposing compounds and processes determine pH. Carbon dioxide ($CO_{2(aq)}$) is particularly influential in regulating pH in aquatic systems. $CO_{2(aq)}$ is acidic, and its concentration varies as a result of its utilization by aquatic plants in photosynthesis and release in respiration of aquatic organisms. The alkalinity of water results primarily from carbonate (CO_3^{-2}) and bicarbonate ions (HCO_3^-). And alkalinity tends to buffer water against excessive pH change (Boyd 2000; Stumm and Morgan 1996; Tchobanoglous and Schroeder 1987). Alkalinity in environmental waters is beneficial because it minimizes pH changes in response to various factors that include acidification (e.g., acid rain), pollutant inputs to aquatic systems, and primary production (Kalff 2002). Primary production in systems that have low to moderate alkalinity can experience increases in pH during periods of high photosynthesis. During these periods, algae deplete available $CO_{2(aq)}$ and utilize HCO_3^- as a secondary source of $CO_{2(aq)}$, excreting excess hydroxyl ions (OH^-) to the water, contributing the elevated pH conditions (Kirk 2011). Review of the 2009 through 2017 KHSA Interim Measure 15 water quality data indicates that alkalinity concentrations in the Klamath River system typically in the 40 to 70 mg/L (as $CaCO_3$) range in the upper basin (Link River Dam), 65 to 85 mg/L (as $CaCO_3$) range downstream of Iron Gate Dam, and SO to 100 mg/L (as $CaCO_3$) range in the lower basin (Orleans). Given the naturally productive nature of the Klamath River, alkalinity values below approximately 100 mg/L are subject to *seasonal pH deviations during periods of maximum photosynthetic activity. A 48-hour trace of pH is shown in the figure below for the Klamath River downstream of the Shasta River (June 28, 12:00 to June 29, 12:00, 1997; Deas 2000), indicating an increase of 1.5 pH units due to primary production. Elevated pH in the upper basin and throughout the river system in response to seasonal productivity has been identified through the KHSA Interim Measure 15 monitoring program as well as other monitoring efforts. Elevated pH can lead to short duration chronic, and in extreme cases acute ammonia toxicity (USEPA 2013).*



Response to Comment ORG46-106
Please refer to Volume III Attachment 1 Section 3.2.2.6 *pH* and Volume II Appendix C, Section C.5 *pH* (pages C-59 to C-68) for a discussion of pH and the variations in pH due to photosynthesis in the Klamath River. The second paragraph in Section 3.2.2.6 *pH* specifically states that the “Klamath River is a weakly buffered system (i.e., has typically low alkalinity less than 100 mg/L as calcium carbonate [CaCO3]; PacifiCorp [2004a], Karuk Tribe of California [2010a]), so it is susceptible to photosynthesis-driven daily and seasonal swings in pH.” While alkalinity levels less than 100 mg/L do indicate that the system is weakly buffered, it is also correct that alkalinity levels below 10 mg/L would indicate that the system is ***poorly*** buffered and very susceptible to changes in pH. Volume III Attachment 1 presents the final Section 3.2 *Water Quality*.

Volume II Appendix C, Section C.5.2.1 *Iron Gate Dam to Salmon River* (pages C-62 to C-65) also notes that observed exceedances of pH water quality objectives usually occur during later afternoon or early evening, following the period of maximum photosynthesis (North Coast Regional Board 2010, Asarian and Kann 2013).

Section 3.2.2.6 *pH* has been revised to clarify the range of pH variations measured in the Klamath River downstream of its confluence with the Shasta River during July 1997 (the comment incorrectly identified it as June 1997). Please refer to Volume III Attachment 1 Section 3.2.2.6 *pH* for the revisions.

Comment ORG46-107

The DEIR states "Historically, seasonal algal blooms and elevated chlorophyll-a concentrations have been observed in the Hydroelectric Reach, including a 1975 survey in Iron Gate Reservoir documenting algal blooms in March, July, and October, including diatoms and blue green algae (USEPA 1978)." It should be noted that of the three sample dates in USEPA (19 78), Microcystis sp. and Dolichospermum sp. are absent, and in only one of the three sample dates is a blue-green algae dominant (Oscillatoria sp.).

The "more contemporary data" discussion in this paragraph should be updated following a review of the data generated in the KHSA Interim Measure 15 monitoring program through 2017. The reference in the text to Figure 3.2-5 only includes data through 2007 (note that the DEIR text incorrectly refers to Figure 3.2-25). In addition, the DEIR states that "...chlorophyll-a levels in Copco No. 1 and Iron Gate reservoirs can be two to ten times higher than in the Klamath River..." without telling the reader where in the river the data are being compared. This is important because chlorophyll-a levels in Iron Gate Reservoir, for example, have been consistently lower than those in Keno reservoir. Since 2015, reductions in chlorophyll-a downstream of Iron Gate Dam when compared to Iron Gate Reservoir are at least partially attributable to operation of the intake barrier curtain in Iron Gate Reservoir (Watercourse 2016; PacifiCorp 2017b).

Response to Comment ORG46-107

Water quality data collected under Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM15) include chlorophyll-*a* data for summer through early fall (i.e., May to October) during the period 2000 to 2017 at monitoring locations in the Klamath River and the upper 10 meters of the Lower Klamath Project Reservoirs (Figure ORG46-107-1). The IM15 data include chlorophyll-*a* concentrations measured downstream of Iron Gate Dam during periods between 2014 and 2017 when an intake barrier/thermal curtain was used in Iron Gate Reservoir. The IM15 data and the chlorophyll-*a* data plotted in Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* Figure 3.2-5 exhibit generally similar chlorophyll-*a* trends, with the following exceptions: the range of chlorophyll-*a* concentrations in the IM15 2000 to 2017 dataset (Figure ORG46-107-1) is greater than the range of chlorophyll-*a* concentrations in the 2005 to 2007 dataset plotted in Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* Figure 3.2-5, and chlorophyll-*a* concentrations for locations downstream of Keno Dam to upstream of Copco No. 1 Reservoir are generally greater in J.C. Boyle Reservoir in the IM15 2000 to 2017 dataset (Figure ORG46- 107-1) than in the 2005 to 2007 dataset plotted in Figure 3.2-5. Maximum chlorophyll-*a* concentrations measured at multiple Klamath River stations and in Copco No. 1 and J.C. Boyle reservoirs in the IM15 2000 to 2017 dataset are higher than those plotted in Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* Figure 3.2-5, with maximum chlorophyll-*a* concentrations measured in

J.C. Boyle Reservoir (825 micrograms per liter [ug/L]) at two orders of magnitude greater than those measured in the 2005 to 2007 dataset (5 ug/L). Minimum chlorophyll-*a* concentrations measured in Iron Gate Reservoir in the IM15 2000 to 2017 dataset are lower than those plotted in Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* Figure 3.2-5.

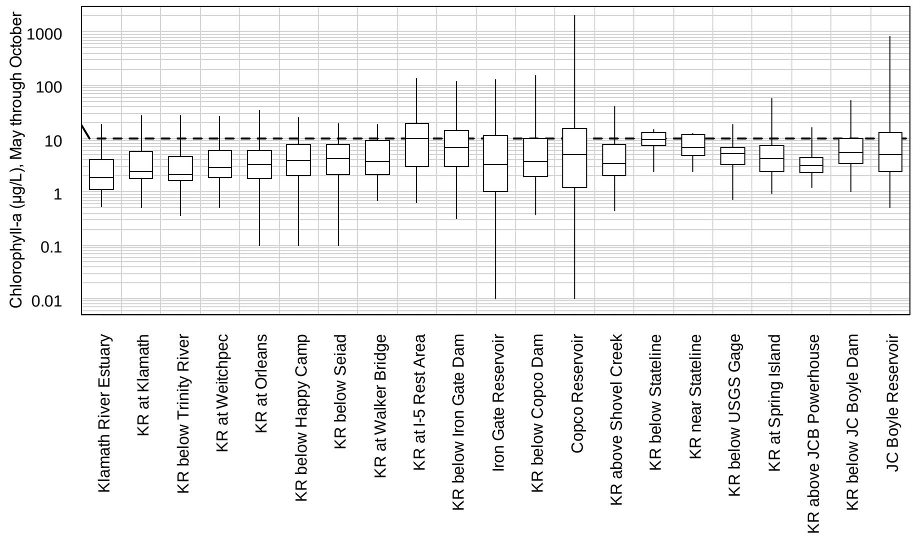


Figure ORG46-107-1. Longitudinal Analysis of Summer Through Fall (May to October) KHSA Interim Measure 15 (IM15) Chlorophyll-*a* Concentrations from 2000 to 2017 Along the Klamath River and in the Upper 10 Meters of the Reservoirs. Whiskers extend from minimum to maximum value, boxes extend from the first to the third quartile, and the horizontal line indicates the median of the dataset at each site. The Dashed Horizontal Line is the Chlorophyll-a Klamath River Total Maximum Daily Load (TMDL) Target (i.e., 10 ug/L). Note the Logarithmic Scale. Chlorophyll-*a* Data From Stations That Shifted Locations Between Years Are Plotted Together (e.g., KR at Walker Bridge). Source: PacifiCorp 2003a, 2004b, 2005b, 2007, 2008b, 2009, 2010, 2011, 2012, 2013, 2014c, 2015b, 2016b, 2017b.

It is appropriate to state "chlorophyll-*a* levels in Copco No. 1 and Iron Gate reservoirs can be two to ten times greater than those in the mainstem Klamath River" without specifying the exact comparison point in the mainstem Klamath River; Figure 3.2-5 provides the reader with the data to determine the multiple locations within the mainstem Klamath River where the statement is true, including the monitoring locations "Abv Shovel", "I-5", "Walker Bridge", "Seiad Valley", "Orleans", "Weitch", "Bel Weitch", "Turwar", and "Lower Est" in Figure 3.2-5.

Water quality measurements during 2015 and 2016 when the intake barrier/thermal curtain was in use in Iron Gate Reservoir indicate that the intake barrier/thermal curtain reduces entrainment of blue-green algae into the Iron

Gate Powerhouse intake and subsequent release downstream into the Klamath River. Chlorophyll-*a* concentrations downstream of Iron Gate Dam during 2015 and 2016 when the intake barrier/thermal curtain was in use also showed a decrease compared to chlorophyll-*a* concentrations in Iron Gate Reservoir, with chlorophyll-*a* concentrations consistently below 10 ug/L (i.e., Klamath TMDLs phytoplankton chlorophyll-*a* target) even when chlorophyll-*a* concentrations in the reservoir were greater than 10 ug/L (PacifiCorp 2016a, 2017a). However, water quality monitoring data from 2017 and 2018 downstream of Iron Gate Dam show multiple exceedances of the Klamath TMDLs phytoplankton chlorophyll-*a* target (i.e., 10 ug/L) (Watercourse Engineering, Inc. 2018, 2019). The intake barrier/thermal curtain was completely rolled up during portions of 2017 to maximize dissolved oxygen concentrations for aquatic life (PacifiCorp 2018a), so decreases in chlorophyll-*a* downstream of Iron Gate Dam from operation of the intake barrier/thermal curtain would be potentially limited by the need to access water with higher dissolved oxygen concentrations to comply with dissolved oxygen standards. An analysis of the intake barrier/thermal curtain performance during 2017 or 2018 has not been published and PacifiCorp continues to test and refine the intake barrier/thermal curtain design and operations, but available data do not indicate that this measure would prevent releases from Iron Gate Dam that exceed the Klamath TMDLs phytoplankton chlorophyll-*a* target of 10 ug/L for Iron Gate Reservoir during the May to October growth season (North Coast Regional Board 2010).

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to clarify the algal species present during the 1975 surveys of Iron Gate Reservoir and to clarify the influence of the intake barrier/thermal curtain on chlorophyll-*a*. Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* Figure 3.2-5 also has been revised by replacing it with Figure ORG46-107-1 above showing the measured KHSA IM 15 chlorophyll-*a* concentrations from 2000 to 2017. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Chlorophyll-a and Algal Toxins* for the revisions.

Comment ORG46-108

Algae toxins may be produced wherever conditions are suit able for associated blue-green algae growth (benthic or planktonic forms), and there are no data to support the conclusion that algal toxins in the lower river only occur because of the presence of Iron Gate and Copco reservoirs. The DEIR should be revised to acknowledge this. The DEIR indicates that Copco No. 1 and Iron Gate reservoirs are responsible for the production of algal toxins, such as microcystin, in the Klamath River downstream of Iron Gate Dam. This is not thoroughly correct and is somewhat misleading. Algal toxins (including microcystin) have been documented upstream of the hydroelectric projects in Agency Lake, Upper Klamath Lake, and Keno Reservoir.

The DEIR should be revised to accurately reflect the complexity of algal-toxin production in the Klamath River. For example, in addition to the citation of Otten et al. (2015), the DEIR should include more recent information on the causes and instances of algal toxins in the Klamath River such as presented by Otten (2017), Otten and Dreher (2017), and Paerl et al. (2018). This more recent information indicates that Microcystis blooms and microcystin concentrations have increased in magnitude and persistence in recent years in Upper Klamath Lake, and that microcystin concentrations are consistently elevated in the lake during the bloom season (Otten 2017b; Otten and Dreher 2017). Key message from Paerl et al. (2018) is that management of eutrophication and harmful algae blooms should recognize causes and interconnection across watershed gradients. Paerl et al. (2018) conclude that it makes little sense to attempt controls in the downstream reservoirs without first addressing the predominant sources coming from upstream. However, Paerl et al. (2018) indicate that in practice most management responses to eutrophication issues have involved interventions aimed at treating individual segments of the system and frequently focus on the problem rather than the underlying causes of the blooms that often take place upstream.

Response to Comment ORG46-108

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* does not claim that algal toxins occur in the Middle and Lower Klamath River only because of Copco No. 1 and Iron Gate reservoirs; instead, this section summarizes the available data characterizing microcystin (an algal toxin) from the Klamath River indicating that Iron Gate Reservoir is the principal source of *Microcystis aeruginosa* cells to the Klamath River downstream of Iron Gate Dam (Otten et al. 2015). The comment is correct that algal toxins potentially would be produced wherever there is suitable habitat for blue-green algae growth in the Klamath River. Blue-green algae growth has been observed in calm, slow-moving habitats along shorelines and protected coves and backwaters during low-flow periods in the Middle and Lower Klamath River under existing conditions (Fetcho 2008; Raymond 2008; Kann and Corum 2009; Kann et al. 2010a; Genzoli and Kann 2016, 2017), but Otten et al. (2015) found no evidence of endemic *Microcystis aeruginosa* populations in the flowing regions of the Klamath River upstream or downstream of Copco No. 1 and Iron Gate reservoirs and concluded that the river itself does not represent favorable cyanobacterial habitat. The longitudinal decrease in *Microcystis aeruginosa* cell density and microcystin concentrations in open-channel and shoreline samples from the Klamath River downstream of Iron Gate Dam to upstream of the Klamath River Estuary suggests that the water velocity and constant mixing in the river are not supportive of blue-green algae reproduction and algal toxin production (Otten et al. 2015; Genzoli and Kann 2017). However, the analysis in Volume I Section 3.4.5 *Phytoplankton and Periphyton – Potential Impacts and Mitigation* Potential Impact 3.4-2 (pages 3-428 to 3-433) specifically acknowledges that algae growth could occur in slow-moving habitats along the river margins after dam removal, stating: "Some phytoplankton growth may still occur after dam removal in calm, slow-moving habitats along shorelines and protected coves and backwaters during low-flow periods in the Middle and Lower Klamath River, but these habitats already support growth of blue-green algae, including *Microcystis aeruginosa*, that results in occasional exceedances of 2016 CCHAB secondary thresholds and World Health Organization (WHO) guidelines (Falconer et al. 1999; Kann et al. 2010a; State Water Board et al. 2010, updated 2016; Genzoli and Kann 2016, 2017)."

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised in Volume III Attachment 1 to clarify the potential for blue-green algae growth along the shoreline, as well as longitudinal trends in *Microcystis aeruginosa* cell density and microcystin concentrations in the Klamath River. Data from Volume II Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a* (pages C-68 to C-83) have also been brought forward into Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* to clarify microcystin trends in the Klamath River. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Please see Master Response PAP-1 for discussion of upstream sources of algae and associated algal toxins, including Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM15) monitoring data for the period 2008 to 2017 that characterize the existing conditions for microcystin (algal toxin) concentrations in the Klamath River upstream of J.C. Boyle Reservoir as consistently less than 4 micrograms per liter [ug/L] (i.e., the microcystin threshold of significance).

Please also refer to Volume I Section 3.4.2 *Phytoplankton and Periphyton – Environmental Setting* (pages 3-392 to 3-422) for further discussion of cyanobacteria [blue-green algae] growth dynamics and associated algal toxin production within the Klamath River, especially Volume I Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach* (pages 3-405 to 3-413) and Volume I Section 3.4.2.4 *Phytoplankton and Periphyton – Environmental Setting – Middle and Lower Klamath River* (pages 3-413 to 3-419) for a comparison of the suitability of habitat conditions in the river and reservoir reaches for toxigenic blue-green algae growth, and genetic analyses of *Microcystis aeruginosa* in Copco No. 1 Reservoir, Iron Gate Reservoir, and multiple Klamath River sites downstream of Iron Gate Dam that identify Iron Gate Reservoir as the principal source of *Microcystis aeruginosa* to the Klamath River downstream of Iron Gate Dam (Otten et al. 2015). Volume I Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach* (pages 3-405 to 3-413) already incorporates information on *Microcystis aeruginosa* growth dynamics in Copco No. 1 and Iron Gate Reservoirs from Otten and Dreher (2017).

Otten (2017) was not cited in the EIR since it is focused on comparing methodologies for estimating algal toxins and cell densities in the Klamath River (i.e., the effectiveness of molecular assays targeting the genes responsible for toxin production versus measurement of algal toxin concentrations or cell counts). However, Otten (2017) does contain algal toxin and *Microcystis aeruginosa* cell count data, and Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins – Chlorophyll-a and Algal Toxins* and Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach* have been revised to include data reported in Otten (2017). The algal toxin and cell count data presented in Otten (2017) support the current summary of existing conditions without additional text changes, so this citation has been added, as appropriate, to the references for the summary of existing conditions. Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* and Volume III Attachment 1 Section 3.4.2.3 *Phytoplankton and Periphyton – Environmental Setting – Hydroelectric Reach – Phytoplankton* for the revisions.

Volume I Section 3.4.2.1 *Phytoplankton – Environmental Setting – Phytoplankton* (pages 3-392 to 3-403) summarizes the general algal growth dynamics discussed in Paerl et al. (2018), including the influence of habitat suitability and nutrient availability on algal growth and toxin production. While Paerl et al. (2018) provides an overview of the longitudinal algal growth dynamics across a watershed and potential management strategies to influence algal growth dynamics, it does not provide new information on algal growth conditions in the Klamath Basin or specific recommendations for management activities to alter algal growth or algal toxins in the Klamath Basin. Additionally, Paerl et al. (2018) concludes that “it makes little sense to attempt ***nutrient*** [emphasis added] control in the downstream reservoirs without first addressing the predominant source” coming from upstream, but it does not address or make conclusions on the potential for dam removal and elimination of the slow-moving reservoir habitat to reduce blue-green algae growth in a watershed.

Comment ORG46-109

The DEIR states “In contrast, data from 2008 and 2009 did not show microcystin bioaccumulation in the tissue and liver samples from fish collected from Copco No. 1 and Iron Gate reservoirs (CH2M HILL 2009; PacifiCorp 2010).” This discussion is inadequate and incomplete. The DEIR needs to include all the results for fish sampled for microcystin in the Klamath River. In 2008, tissue was collected from a total of 272 resident fish (Yellow Perch, Crappie, and Rainbow Trout) and all laboratory analysis did not detect microcystin in these samples. In 2009, a total of 43 fish tissue and liver samples were collected from Yellow Perch, and again microcystin was not detected. These studies are posted on PacifiCorp's Klamath website (http://www.pacificorp.com/es/hydro/hl/kr.html). The data from the anadromous fish sampling for microcystin that was done in 2007 and 2010 should also be presented and discussed. In 2007, fish and liver samples were collected from 11 adult Chinook Salmon and 8 Steelhead and *microcystin was not detected in any of these samples (CH2M HILL 2009). In 2010, tissue and liver samples were collected from 25 Steelhead, 20 fall Chinook, and 3 Coho in the Klamath River. While microcystin was not detected in any of the fish tissues, four Chinook livers and a Steelhead liver had detectable amounts of microcystin present.*

The DEIR analysis needs to go beyond discussion of simple microcystin presence in these sampled tissues and discuss what the toxin quantities mean in terms of associated levels of potential human health risk. The DEIR also needs to distinguish where microcystin concentrations have been detected in fish tissue versus liver since it is toxin levels in the consumed tissue that pose a human health risk because fish livers are not consumed. To PacifiCorp's knowledge, no microcystin has been found in adult salmonid fish tissue in the Klamath River, yet the DEIR fails to mention this. The DEIR discusses the risk to fish but presents no evidence to show what harm, if any, occurs at the individual or population level from microcystin exposure. Any analysis related to microcystin effects on the fisheries must distinguish between resident and anadromous fish since most of the anadromous salmonids enter the river as adults to spawn and die.

Response to Comment ORG46-109

Section 3.3.2.3 *Aquatic Resources – Environmental Setting – Habitat Attributes Expected to the Affected by the Proposed Project – Algal Toxins* provides further discussion of microcystin bioaccumulation in fish and mussel tissue, including discussion of results from samples collected in 2007, 2008, 2009, and 2010.

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* also provides a comparison of the detected microcystin concentrations relative to public health guidelines. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Section 3.3 *Aquatic Resources*.

Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* has been revised to include the detailed microcystin bioaccumulation results for fish and mussel tissue samples collected in 2007, 2008, 2009, and 2010 and further elaborate on the comparison of detected microcystin concentrations in salmonids and public health guidelines. The additional data do not constitute significant new information (CEQA Guidelines section 15088.5(a)). Please refer to Volume III Attachment 1 Section 3.2.2.7 *Water Quality – Environmental Setting – Chlorophyll-a and Algal Toxins* for the revisions.

Comment ORG46-110

This section of the DEIR concludes that trace metals decline as water flows downstream, with the exception of nickel, magnesium, and calcium. The decline is attributed to binding and precipitation. However, the section does not provide a reason why such a decline was not observed for nickel, magnesium, and calcium. Please provide more detail to support the conclusions.

Response to Comment ORG46-110

The referenced sentence summarizes the conclusions of Flint et al. (2005), which documented that the concentration of trace elements in the Klamath River decreased as water flowed downstream (with the exception of nickel, magnesium, and calcium) during 2002 and 2003 at four United States Geological Survey (USGS) gage stations downstream of Iron Gate Dam. The authors did not provide data, hypothesis, or analysis to explain why there was no decline observed for nickel, magnesium, and calcium. As such, the reason why nickel, magnesium, and calcium concentrations did not decline in the downstream direction during measurements in 2002 and 2003 is unknown.

Comment ORG46-111

The DEIR indicates that acid volatile sulfides (AVS) were measured but does not indicate if simultaneously extracted metals (SEM) were measured. This is important because AVS measurements are meaningless without the companion SEM measurements. If SEM data were collected, a discussion of the potential for metals toxicity should be discussed using the USEPA's Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Metal Mixtures (Cadmium, Copper, Lead, Nickel, Silver and Zinc (USEPA 2005).

Response to Comment ORG46-111

Simultaneously extracted metals (SEM) data associated with the acid volatile sulfides (AVS) measurements are not reported by USBR (2011). However, the AVS measurements collected by United States Bureau of Reclamation (USBR) are not used to assess the potential for metals toxicity in the EIR analysis. Instead, as stated in Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants*, the potential sediment toxicity to benthic organisms, including metals toxicity, was directly assessed by bioassays of sediment and elutriate sediment samples using fish and invertebrate national benchmark toxicity species. Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* and Appendix C, Section C.7.1.1 *Inorganic and Organic Contaminants – Upper Klamath Basin – Hydroelectric Reach – Sediment Toxicity and Bioaccumulation Tests* contain a summary of the bioassay results. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality* and the final Appendix C *Water Quality Supporting Technical Information*.

Additionally, the dissolved metal concentrations in interstitial water are correlated with observed biological effects to sediment-dwelling (i.e., benthic) organisms (USEPA 2005), so the dissolved metal concentrations measured in the elutriate sediment samples would also quantify the potential metals toxicity.

Comment ORG46-112

The DEIR uses the term "dioxin" without defining it. The reader is left to assume that when using that term the authors are referring to the 17 dioxin and furan *congeners. The text further uses the term "toxic equivalency concentrations" without defining that for the reader. To fully inform the reader, the text should be rewritten to clarify the terminology.*

Response to Comment ORG46-112

Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* have been revised to clarify what is meant by dioxin and toxic equivalency concentrations. Please refer to Volume III Attachment 1 Section 3.2.2.8 *Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* for the revisions.

Comment ORG46-113

The DEIR compares "dioxin" concentrations to threshold values. We suspect that these are 2,3,7,8 2,3,7,8-tetrachlorodibenzodioxin (TCDD) toxicity equivalent quotients or toxic equivalents but the DEIR fails to indicate specifically what is being evaluated.

Response to Comment ORG46-113

Dioxin threshold values specified in Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* are toxic equivalent concentrations relative to 2,3,7,8-tetrachlorodibenzodioxin (2,3,7,8-TCDD). Toxic equivalent concentrations are equal to toxic equivalent quotients and abbreviated as TEQ.

Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* has been revised to clarify that dioxin threshold values are expressed as TEQs. Please refer to Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* for the revisions.

Comment ORG46-114

The DEIR discusses the results from whole sediment toxicity tests with the amphipod Hyalella azteca. The text states "Toxicity tests generally indicate a low potential for toxicity…." Additional text should be provided that describes the criteria for classifying toxicity as 'low' or 'moderate' potential and what this means for the Proposed Project.

Response to Comment ORG46-114

Section 3.2.2.8 *Inorganic and Organic Contaminants – Sediment Contaminants* has been revised in Volume III to clarify the meaning of "low" and "moderate" potential for sediment toxicity and correct the typo that indicated *Hyalella azteca* had the decreased survival. Please refer to Volume III Attachment 1 Potential Impact 3.2-14 for analysis of the freshwater and marine aquatic species exposure to inorganic and organic contaminants under the Proposed Project due to release of reservoir sediments, including the analysis of what the survival rates of benthic organisms in reservoir sediments means for the Proposed Project and how percent survival of the benchmark benthic indicator species was used in the determination of “low” and “moderate” potential for sediment toxicity. The analysis in Potential Impact 3.2-14 also correctly identifies the benthic midge *Chironomus dilutus* as having the decreased survival in J.C. Boyle Reservoir sediments. Please refer to Volume III Attachment 1 Section 3.2.2.8 *Inorganic and Organic Contaminants – Sediment Contaminants* for the revisions.

Comment ORG46-115

The DEIR presents comparisons of sediment chemical concentrations to risk-based screening values. The paragraph as written is confusing and hard to follow and it is impossible to differentiate between ecological and human health-based screening values. To increase readability, this paragraph should be split into two, with one devoted to ecological and one to human health.

Response to Comment ORG46-115

Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* has been revised to clarify the human health and ecological screening levels exceeded by the total arsenic, total copper, and total lead concentrations measured in reservoir and estuary sediment samples. Please refer to Volume III Attachment 1 Section 3.2.2.8 *Water Quality – Environmental Setting – Inorganic and Organic Contaminants – Sediment Contaminants* for the revisions.

Comment ORG46-116

The definition for “substantial” is not adequate. The DEIR states that “...substantial, as used in the significance criteria, means the effect on water quality and the support of beneficial uses (or human health or environmental receptors, as specified) is of considerable importance.” The connection to the beneficial uses is appropriate, but the term “of considerable importance” is not defined.

Response to Comment ORG46-116

To the extent that identified water quality significance criteria can be expressed quantitatively, Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance* does so explicitly, or the details are provided in Volume III Attachment 1 Section 3.2.5 *Water Quality – Potential Impacts and Mitigation*. If it is not possible to identify meaningful quantitative significance criteria, or if such criteria would otherwise be inappropriate for a particular analysis, then qualitative thresholds of significance are presented and discussed instead. The phrase “of considerable importance” does not require definition beyond the ordinary usage of the term. Together, the stated significance criteria and impact analysis approach subsections for water quality provide the necessary context regarding the phrase ‘of considerable importance’ in determining significance for the water quality effects analyzed in the Lower Klamath Project EIR. Volume III Attachment 1 presents the final Section 3.2 *Water Quality*.

Lastly, lacking any specific identification of a problem with an impact analysis in the EIR due to use of the phrase 'of considerable importance', the assertion that this phrase must be further defined in this section does not constitute substantial evidence regarding the potential physical impacts of the Proposed Project on the environment (CEQA Guidelines section 15384).

Please also refer to Master Response CEQ-3.

Comment ORG46-117

The discussion of turbidity references a lack of data but fails to acknowledge that turbidity data has been routinely collected with all KHSA Interim Measure 15 water quality samples since 2009. While this is spot data at a monthly or bimonthly time-step, it is certainly more precise than the approach taken in the DEIR.

The DEIR connects the criterion for turbidity to "natural conditions" but does not characterize or define natural. According to CEQA the comparison should be made for turbidity impacts relative to baseline conditions (those present at the time of the Notice of Preparation (NOP) for the DEIR.

Response to Comment ORG46-117

Please refer to Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* for an explanation for why sufficient turbidity data are not available for the Klamath Basin to use the Basin Plan turbidity water quality objective to analyze potential impacts under the Proposed Project in the manner anticipated by the Basin Plan (i.e., relative to natural conditions), as well as the rationale for using the specified suspended sediment concentration (SSC) threshold of significance (i.e., 100 milligram per liter [mg/L] for a continuous two week period).

Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* has been revised to further clarify what is meant by "natural conditions" in the turbidity water quality objective in the Basin Plan. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* for the revisions.

Turbidity is a measure of the collective optical properties of a water sample that cause light to be scattered and absorbed rather than transmitted in straight lines (Anderson 2004). Turbidity changes as suspended material increases and scatters or absorbs more light in a water sample, but the specific relationship between turbidity and suspended material may vary widely between samples from different monitoring sites and between different watersheds due to variations in the suspended material properties (e.g., the size, shape, and refractive index of particles having different light scattering properties). Flow variations in a river may result in turbidity naturally fluctuating several orders of magnitude, but turbidity has also been observed to fluctuate by an order of magnitude or more when flows are relatively constant due variations in the suspended material properties being transported during different times (Bash et al. 2001).

While monthly to bi-monthly turbidity data have been collected as part of Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM15) water quality samples, monthly to bi-monthly turbidity data represent the turbidity conditions only during the specific time of the measurements, and the IM15 turbidity data would not characterize the full range of turbidity conditions occurring under existing conditions. Turbidity measurements are infrequently collected during high winter flows (likely due to safety concerns of sampling at high flows), with no January, four February, and six March turbidity measurements downstream of Iron Gate Dam (river mile [RM] 193.1) in turbidity data from 2000 to 2017. As such, it is not possible to quantify the full range of turbidity under existing conditions (i.e., those present at the time of the Notice of Preparation [December 22, 2016]), especially during the main reservoir drawdown period between January and March. IM15 turbidity data would not provide a more precise approach to assessing turbidity under the Proposed Project since there is no turbidity data during one of the primary periods that needs to be analyzed.

The Basin Plan turbidity water quality objective (Basin Plan Section 3.3.17 *Turbidity* [page 3-6]) specifies that turbidity shall not be increased more than 20 percent above naturally occurring background levels. The Basin Plan defines natural conditions as conditions or circumstances affecting the physical, chemical, or biological integrity of water that are not influenced by past or present anthropogenic activities. Thus, naturally occurring background levels of turbidity would be those not influenced by past or present anthropogenic activities. However, there are not sufficient data to determine the turbidity under natural conditions or existing conditions, so the Basin Plan numeric turbidity water quality objective relative to natural conditions are not used as a threshold of significance in the EIR suspended sediment analysis. As explained in Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments*, narrative sediment water quality objectives were interpreted into a numeric SSC threshold of significant to assess potential impacts to the most sensitive beneficial use (COLD). As explained in Section 3.2.4.2 *Water Quality – Impact Analysis Approach – Suspended Sediments* and analyzed in Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments*, daily total SSCs were modeled for existing conditions representing WY 1961–2008 (“background”) and changes in SSCs under the Proposed Project are quantitatively compared to the modeled background SSC levels or qualitatively compared relative to existing conditions, as appropriate, to evaluate the potential impacts from suspended sediments.

Comment ORG46-118

The DEIR acknowledges that there are differences between suspended sediment concentrations and total suspended solids but fails to explain what these differences mean in terms of data interpretation and how this difference may affect the impact analysis. The assumption that they are equivalent as made in the DEIR needs to be justified.

Response to Comment ORG46-118

Please refer to Gray et al. (2000) cited in Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Suspended Sediments* for an in-depth comparison of suspended sediment concentration (SSC) and total suspended solids (TSS) data. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Footnote 39 in Section 3.2.3.1 *Thresholds of Significance – Suspended Sediments* also has been revised to clarify the justification for using TSS and SSC interchangeably. Please refer to Volume III Attachment 1 Section 3.2.3.1 *Thresholds of Significance – Suspended Sediments* for the revisions.

As detailed in Gray et al. (2000), an analysis of 3,235 paired SSC and TSS natural-water samples from eight states showed SSC and TSS values generally follow a line of equal value (i.e., 1:1 line), but SSC values tend to exceed their paired TSS values, particularly at larger values of SSC. The SSC values better represent the actual sediments in a sample because the TSS measurement methodology of using a pipette or pouring often results in underestimating the larger particles (i.e., sand-sized particles) that rapidly settle or may plug up the opening of a pipette. Further analysis of 860 paired SSC and TSS natural-water samples with known relative amounts of sand-size and finer material shows that SSC values tend to be larger than their paired TSS values when the percentage of sand-size material exceeds about 25 percent of the mass of sediment in the sample. SSC values are consistently larger than their paired TSS values when the percentage of sand-sized material exceeds a third of the mass of sediment in the sample. SSC and TSS data are more or less evenly distributed around the line of equal value when particle sizes are finer than 0.062 millimeters [mm](i.e.,1 silts or clays) and TSS is greater than approximately 5 milligram per liter (mg/L).

Overall, the implication of the Grey et al. (2000) results is that TSS measurements tend to underestimate overall suspended material concentrations, especially at higher flows that suspend a higher fraction of larger particles. Sediment transport modeling for the Lower Klamath Project analyses utilized SSCs, so the analysis of potential impacts due to the release of reservoir sediments under the Proposed Project (i.e., Potential Impact 3.2-3) would be unaffected by the differences between SSC and TSS measurements. The analyses in Potential Impact 3.2-4 and Potential Impact 3.2-5 did not rely on TSS measurements, so these analyses would be unaffected by the differences between SSC and TSS measurements. The analysis in Potential Impact 3.2-5 may underestimate the algal-derived (organic) suspended material occurring under existing conditions because the algal-derived (organic) suspended material were measured as TSS, but relative fraction of algal-derived (organic) suspended material that would be likely to settle during TSS measurements is unknown and TSS measurements may in fact accurately reflect actual suspended material. The analysis in Potential Impact 3.2-5 evaluated long-term changes in algal-derived (organic) suspended materials relative to existing conditions, so potential underestimates of algal-derived (organic) suspended material under existing conditions would shift the existing conditions and would not alter the overall conclusions of the analysis.

Comment ORG46-119

The discussion in this section indicates that certain aspects of water quality in the DEIR impact analysis relied on models developed for the Klamath River TMDL. The DEIR' s Thresholds of Significance for these aspects of water quality are tied to specific Klamath River TMDL-derived quantities (such as, for water temperature, dissolved oxygen, nutrients, chlorophyll-a, and algal toxins). The DEIR's analysis of long-term water quality impacts explicitly includes the Klamath River TMDLs and incorporates TMDL scenarios and results of modeling performed for development of the TMDLs. By doing so, the DEIR analysis incorporates the assumption that TMDLs will be fully achieved, despite unknowns and uncertainties regarding potential TMDL actions and their implementation.

The TMDL modeling results are not an appropriate basis for comparing alternatives. PacifiCorp has previously documented substantial technical flaws with the assumptions, modeling, and analyses used in development of the TMDLs. PacifiCorp has previously presented the flaws in the compliance scenarios and the technical analysis and modeling supporting the California Klamath River TMDL during the development of the TMDL and is contained in the Petition for Writ of Mandate filed to challenge the same (PacifiCorp v State Water Resources Control Board, 2011 , case 34-2011-80000769). PacifiCorp does not waive, and expressly preserves, its legal challenge to the TMDL and TMDL models, and preserves its rights to challenge TMDL implementation plan measures and conclusions regarding the Klamath Hydroelectric Project's effects on water quality in other proceedings.

PacifiCorp's position remains that the TMDLs will require nutrient loads in the Klamath River that are less than those that would occur naturally (that is, without anthropogenic effects). Independent assessments of conditions for anadromous fish in the Klamath Basin by the National Research Council (NRC 2004 , 2008) and the Klamath River Expert Panels (Dunne et al. 2011; Goodman et al. 2011), although not referring to the TMDLs specifically, indicate that very substantial water quality improvements in the Klamath Basin, such as assumed in the TMDLs, are unrealistic, unlikely, or at best highly uncertain. Therefore, the DEIR makes the flawed assumption of full attainment of TMDLs which in turn results in an analysis that unrealistically assumes dramatic long-term water quality *improvements in the basin. Disclosure and discussion of substantial uncertainties related to TMDL assumptions is absent in the DEIR. This represents a major flaw relative to the DEIR's ultimate accuracy in assessing the effects of the Proposed Project and utility for supporting decisions on the Proposed Project.*

Response to Comment ORG46-119

Please refer to Master Response WQ-5. Additionally, analysis in Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* specifically notes that the Klamath River Total Maximum Daily Load (TMDL) model scenarios include as a starting point assumption that there will be full implementation of the TMDLs and considers the implications of this assumption with respect to the use of TMDL model results in the analysis. Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 provides a discussion of the TMDL model results in the water temperature analysis, Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 provides a discussion of the TMDL model results in the nutrients analysis, Section 3.2.5.4 *Water Quality – Potential Impacts and Mitigation – Dissolved Oxygen* Potential Impact 3.2-10 provides a discussion of the TMDL model results in the dissolved oxygen analysis, and Section 3.2.5.5 *Water Quality – Potential Impacts and Mitigation – pH* Potential Impact 3.2-11 provides a discussion of the TMDL model results in the pH analysis. As discussed in Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Impact Analysis Approach – Chlorophyll-a and Algal Toxins*, the Klamath River TMDL model results were not used in the analysis of chlorophyll-a and algal toxins because the model appears to over-predict the chlorophyll-a under the “dams-out” scenario. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Please also refer to response to comment ORG46-124 for an additional discussion regarding Klamath River TMDL modeling.

Comment ORG46-120

The DEIR relies on the River Basin Model 10 (RBM10) for quantifying the sensitivity of water quality and related impacts to projected climate change. Specifically, the DEIR states that “The RBM10 model was developed as part of the Klamath Dam Removal Secretarial Determination studies and includes the effects of climate change and KBRA hydrology on water temperatures (Perry et al. 2011).” Given the limitations of the climate change projections and methodology used, the DEIR rightfully limits the use of RBM10-related results for significance determinations. “The climate change predictions are used to give additional context to the temperature discussion, but they are not relied on for significance determinations. Future climate changes are not part of the existing condition against which this EIR compares potential impacts under the Proposed Project.” This approach is appropriate because climate change would be expected to compound the errors previously raised regarding the flow modeling. However, in contrast to this statement, the approach used in the DEIR was to *integrate climate change predictions throughout the discussion and finding of impacts in the water quality and aquatic resources sections of the Proposed Project and to a lesser extent the alternatives. More than 20 statements throughout the impacts discussions highlight the climate change adaptation aspects/benefit of the Proposed Project and its benefit over other alternatives. For example, page 3-77 paragraph 4 states "In the long term, the beneficial effects would also help to offset the impacts of climate change on late summer/fall water temperatures." This style of presentation creates confusion in the impacts discussions. A better approach would be to present the climate change adaptation aspects/benefit of the Proposed Project and the other alternatives in a climate change adaptation section.*

Response to Comment ORG46-120

As explained in Section 3.2.4.1 Water *Quality – Impact Analysis Approach – Water Temperature* and quoted in the comment, the climate change projections are used to provide additional context for the water temperature discussion, but they are not relied on for significance determinations. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*. Referencing this context in the discussion of long-term potential impacts on water quality under the Proposed Project provides relevant information for understanding the potential impacts for particular water quality parameters over the long term, even as the analysis does not rely on climate change projections for the purpose of making significance determinations. Providing information in a separate section, as the commenter prefers, would require the reader to flip back and forth between the Proposed Project impact analysis for a particular parameter and a separate but corresponding climate change discussion elsewhere in the document. As such, the discussion of the long-term influence of climate change is retained in the analysis of long-term potential impacts under the Proposed Project.

Comment ORG46-121

In this paragraph, the DEIR describes the predicted short-term suspended sediment concentrations during Proposed Project reservoir drawdowns. These suspended sediment concentrations predictions are a major factor used in the DEIR's assessment of impacts, particularly on water quality and aquatic biota. However, these suspended sediment concentrations predictions rely on professional judgement and extrapolations of previous modeling work, rather than detailed quantitative analysis of the actual Proposed Project. In addition, the DEIR assessment makes the simplified and unsupported assumption that the predicted suspended sediment concentrations would be within the range of model-uncertainty. However, this type of extrapolation is inappropriate because it compounds the uncertainty that already exists in the model results. The prediction of suspended sediment concentrations during drawdown also neglects the effects from slump failure and sediment jetting, which would likely further increase suspended sediment concentrations. Given the importance of suspended sediment concentrations as a factor in the assessment of impacts, the DEIR needs a more thorough and rigorous analysis and discussion regarding *the factors that would contribute to predicted suspended sediment concentrations.*

Response to Comment ORG46-121

Section 3.2.4.2 *Water Quality – Impact Analysis Approach – Suspended Sediments* summarizes the impact analysis approach and the models used in the analysis of suspended sediments. The discussion referenced by the comment does not describe the predicted short-term suspended sediment concentrations (SSCs) during reservoir drawdown under the Proposed Project. Potential Impact 3.2-3 provides a discussion of the predicted SSCs during reservoir drawdown under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*, including Section 3.2.4.2 *Water Quality – Impact Analysis Approach – Suspended Sediments* and Potential Impact 3.2-3.

Contrary to the assertion in the comment, detailed quantitative analyses from two different sediment transport models (i.e., Sediment and River Hydraulics – One Dimension [SRH-1D] and Dam Removal Express Assessment Model – 1 [DREAM-1]) were utilized to estimate the SSCs that would result from dam removal and the release of reservoir sediments. As explained in Section 3.2.4.2 *Water Quality – Impact Analysis Approach – Suspended Sediments*, the SSCs under the Proposed Project are primarily estimated from the detailed quantitative SRH-1D USBR (2012a) modeling results. The maximum drawdown rate under the Proposed Project (i.e., 5 feet per day) is greater than modeled by USBR (2012a) (i.e., 2.25 to 3 feet per day). As such, the quantitative, peer-reviewed DREAM-1 sediment transport model results (Stillwater Sciences 2008) estimating the potential variation in SSCs when the drawdown rates during dam removal change between 3, 6, or 9 feet per day were used to quantify how the maximum drawdown rate under the Proposed Project would alter estimates of SSCs in USBR (2012a) model results. This provides a sufficient quantification of the potential variations in SSCs due to changes in the maximum drawdown rate between USBR (2012a) model results and the Proposed Project because a) the drawdown rates in the DREAM-1 results span the range of drawdown rates under the Proposed Project, and b) the change in the drawdown rate from 3 to 6 feet per day in the DREAM-1 results is similar to the expected change from 3 to 5 feet per day.

Additionally, potential slump failures are implicitly included in the DREAM-1 Stillwater Sciences (2008) sediment transport model results by limiting the stable bank slope to a relatively low slope (i.e., 1:10 V:H). Thus, the model's estimates of changes in SSCs under various drawdown rates would include any change in SSCs from potential slump failures. The processes and physics governing the production of SSCs from reservoir drawdown are similar in both the Stillwater Sciences (2008) DREAM-1 and USBR (2012a) SRH-1D models and thus it is reasonable to assume that the USBR (2012a) SSC model results would exhibit a similar response to changes in reservoir drawdown rates.

Increases in SSC uncertainty from changes to drawdown rates under the Proposed Project compared to those used in the USBR (2012a) SRH-1D model would not be expected to alter the overall analysis and significance determination for SSC. Model uncertainty cannot be directly evaluated since the modeled condition (i.e., dam removal) has not occurred and there are no measured SSCs available for comparison with modeled SSCs, but model uncertainty can be estimated from a sensitivity analysis of the model (Jung et al. 2018). As part of the USBR (2012a) SSC modeling, a sensitivity analysis was conducted to determine how the modeled SSCs would vary due to changes in multiple sediment transport modeling parameters and equations (see USBR [2012a] Section 9.2.1.3 *Concentrations during Dam Removal – Sensitivity Analysis* [pages 9-18 to 9-32]). Such a sensitivity analysis provides an estimate of the uncertainty associated with the modeled SSCs since it highlights how changes in the values of model parameters and equations would potentially alter the modeled SSCs. Comparison of the variations in SSCs with changes in model parameters and equations shows that SSCs remained similar regardless of changes in these parameters and equations during parts of the drawdown period, but SSCs also varied by up to an order of magnitude during other periods (see USBR [2012a] Figures 9.25 and 9.26 [pages 9-31 to 9-32]). Overall, the modeled SSCs would have the most uncertainty during peak SSCs (i.e., approximately 2 to 5 times the estimated SSCs) and when SSCs are declining following peak SSCs (i.e., approximately an order of magnitude). Thus, the potential increase in peak SSCs due to changes in the drawdown rates (i.e., approximately doubling) is generally within the range of the modeled uncertainty. As demonstrated by the sensitivity analysis, all parameters or representations of physical processes (i.e., equations) in the model have an associated uncertainty. The comment is correct that the uncertainty associated with the changes in drawdown rates would increase the overall uncertainty of the modeled SSCs, but it is not inherently inappropriate for the model uncertainty to increase when a model parameter varies (i.e., drawdown rate). Variations in any model parameter could theoretically introduce uncertainty. Accordingly, Section 3.2.4.2 *Water Quality – Impact Analysis Approach – Suspended Sediments* explains the uncertainty associated with the USBR (2012a) model and the additional uncertainty introduced by variations in the drawdown rates between the USBR (2012a) model results and the Proposed Project. Overall, the expected increase in uncertainty would not be expected to alter the overall analysis and significance determination, so it is appropriate to use the DREAM-1 drawdown results with the SRH-1D model results.

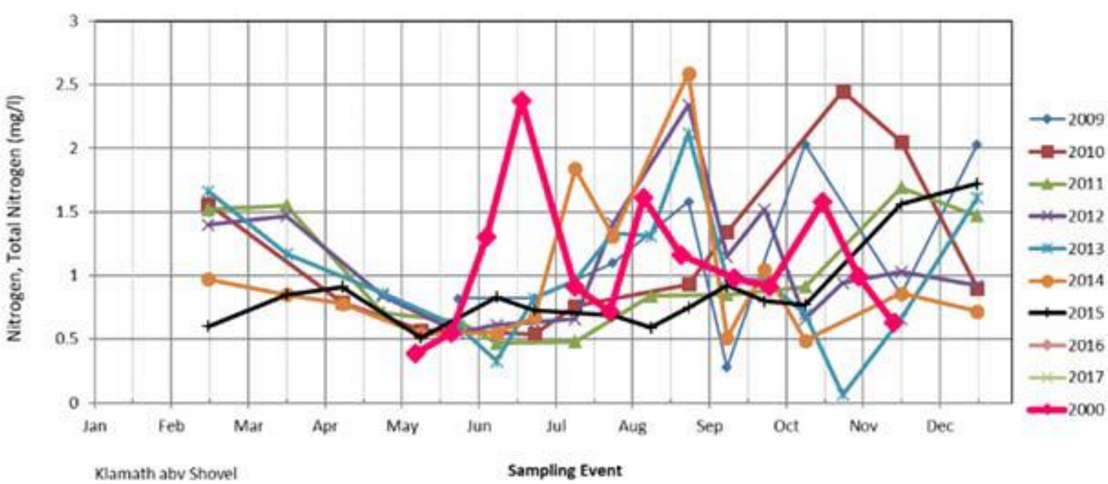
Section 3.2.5 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3 provides an estimate of the changes in the USBR (2012a) SSC model results due to sediment jetting during drawdown. Sediment jetting would be limited to the six areas where restoration actions are proposed within the Copco No. 1 Reservoir footprint (see Volume I Section 2.7.4.2 *Proposed Project – Proposed Project – Restoration Within the Reservoir Footprint – River Restoration Features* Figure 2.7-11 [page 2-75]) and three areas where restoration actions are proposed within the Iron Gate Reservoir footprint (see Volume I Figure 2.7-12 [page 2-76]). As further clarification of the discussion of sediment jetting under the Proposed Project in Potential Impact 3.2-3, sediment jetting would likely result in negligible to small increases in the total reservoir sediment estimated to erode by USBR (2012a) and associated increases in SSCs, because sediment jetting would be focused on supporting the natural movement of reservoir sediments in the areas where sediment jetting would occur. Additionally, areas with slopes greater than 0.1 to 0.2 are already anticipated to slump toward the river channel in USBR (2012a), so sediment jetting in these areas would not be anticipated to increase the total reservoir sediment estimated to erode by USBR (2012a) or the associated SSCs. Sediment jetting in areas with generally low slopes (less than 0.1 to 0.2) would potentially result in localized slope or bank failure, but this localized slope or bank failure would not be likely to propagate due to the surrounding low slopes. Thus, the analysis in Potential Impact 3.2-3 does consider the increase in SSCs during drawdown from sediment jetting and associated potential slumping.

Please also specifically refer to Potential Impact 3.2-3 for discussion of the potential changes in SSCs downstream of Copco No. 1 Dam due to sediment jetting within the Copco No. 1 Reservoir footprint, and of the potential changes in SSCs downstream of Iron Gate Dam due to sediment jetting within both the Copco No. 1 and Iron Gate reservoir footprints. Volume III Attachment 1 presents the final Section 3.2 *Water Quality*.

The best available information and quantitative modeling results are used to analyze the potential impacts from SSCs under the Proposed Project. There are no available data or other evidence to indicate that additional quantitative analysis, improvements in the precision of the modeling, or changes in the model uncertainty would meaningfully alter the sediment analysis provided or alter the conclusion that there would be a significant and unavoidable impact for SSCs under the Proposed Project (see Potential Impact 3.2-3).

Comment ORG46-122

Regarding the TMDL model assumptions for full TMDL implementation the DEIR states that "Despite this assumption, the Klamath River TMDL model results are still informative with respect to the analysis of potential nutrient impacts under the Proposed Project, particularly since nutrient models were not developed for the FERC relicensing process." Nutrient models as part of the Klamath River Water Quality Model (KRWQM) were developed by Watercourse Engineering for the FERC relicensing process (PacifiCorp 2004a). These models were subsequently used with modification by the North Coast Regional Water Board in the developing the Klamath River TMDL in California. The TMDL model included only a single simulation year based on the year 2000. Since the TMDL model was developed, the KRWQM models have incorporated additional years of data that have substantively improved model representation of water quality processes in the Klamath River (see PacifiCorp 2014). The TMDL's use of a *single year yields no information on natural annual variability. As an example of interannual variability, total nitrogen for the Klamath River upstream of Copco Reservoir (Klamath above Shovel Creek site) is plotted below using data from the KHSA Interim Measure 15 monitoring program in comparison to data from 2000 (Watercourse 2003a, 2003b). While the year 2000 may represent a proxy for an "average" condition, the year is not a conservative assumption because there are several years with notably higher total nitrogen concentrations. Similar results are apparent for other constituents, as well. Therefore, relying solely on the TMDL is a serious limitation of the DEIR, not only because a single year is insufficient to capture variability, but also because well over a decade of additional data have been collected since the year 2000 and the modeling upon which the TMDL is based has been substantially improved.*



Response to Comment ORG46-122

Contrary to the comment's assertion, and as discussed in Section 3.2.4.3 *Water Quality – Impact Analysis Approach – Nutrients*, the analysis of potential impacts to nutrients under the Proposed Project does not rely solely on results of Total Maximum Daily Load (TMDL) modeling efforts; rather the EIR uses both Klamath River TMDL model results and existing nutrient budget analysis results that compare existing conditions with those under dam removal conditions. While the comment asserts that more recent versions of the Klamath River Water Quality Model (KRWQM) incorporate additional years of data to improve model representation of water quality processes in the Klamath River, the more recent KRWQM results do not compare nutrients for existing conditions with dam removal conditions (PacifiCorp 2008a, 2014a). PacifiCorp (2014a) Section 4.2 *Current Conditions and Processes Affecting Water Quality* (pages 4-4 to 4-56), Section 4.3 *Project Contributions to Water Quality* (pages 4-56 to 4-57), and Section 5.2.11 *Biostimulatory Substances* (pages 5-125 to 5-134) specifically discuss the present conditions (i.e., existing conditions) and the [Lower Klamath] Project contribution to nutrients, but there is no discussion in PacifiCorp (2014a) of updated modeling results of potential nutrient conditions under dam removal conditions or a comparison of nutrients under existing conditions and under dam removal conditions. PacifiCorp (2014a) is focused on comparing existing conditions with continued operations of the measures to enhance water quality and beneficial uses (i.e., the Proposed Project in PacifiCorp [2014a]). Additionally, analysis of the Lower Klamath Project contributions to nutrient conditions under existing conditions in PacifiCorp (2014a) relies heavily on the nutrient analysis by Kann and Asarian (2005, 2007) and Asarian et al. (2009) that were used in the development of the nutrient budget analysis discussed in Section 3.2.4.3 *Water Quality – Impact Analysis Approach – Nutrients* and used in Potential Impact 3.2-8. PacifiCorp (2019a) documenting the most recent version of the KRWQM also does not compare nutrients under existing conditions and under dam removal conditions. Thus, the Klamath River TMDL model results are the most recent, publicly available nutrient model results comparing existing conditions and dam removal conditions.

The Klamath River TMDL model results are not presented as conservative representations of potential impacts in the EIR. While the Klamath River TMDL model results are only available for one year (i.e., 2000), other models and analysis results are used when available in the EIR to characterize interannual variability and to evaluate potential impacts to water quality parameters. For example, data from 2005 to 2008 were used to develop the nutrient retention rates and nutrient budget for the free-flowing reaches of the Klamath River (Asarian et al. 2010) and the results of this nutrient budget analysis were used in the comparison of nutrients under existing conditions and under dam removal conditions, as explained in Section 3.2.4.3 *Water Quality – Impact Analysis Approach – Nutrients*.

Please refer to Master Response WQ-4 for a discussion of nutrient interannual variability and how nutrient data from 2000 to 2017 were considered in the EIR analysis.

Please also refer to Master Response WQ-5 for further discussion of the appropriateness of using Klamath River TMDL model results in the EIR analysis.

Comment ORG46-123

The challenge with nutrient budgets is that they are generally calculated based on long averaging periods (e.g., annual budgets or monthly budgets) and occur at discrete locations in the reservoir-river system. Thus, they are spatially and temporally coarse. By their very nature, nutrient budgets are not mechanistic models meaning that relationships and processes among constituents are not represented. Overall, they represent a simplification of processes. By using the results of an up-to-date water quality model, a more accurate and effective assessment of potential outcomes associated with the various alternatives could have been conducted in the DEIR.

Response to Comment ORG46-123

Please refer to Section 3.2.4.3 *Water Quality – Impact Analysis Approach – Nutrients* for a summary of the mechanistic Klamath River Total Maximum Daily Load (TMDL) water quality model used in addition to nutrient budgets to analyze the potential impacts to nutrients under the Proposed Project. A nutrient budget approach is a well-accepted and technically appropriate method for estimating the total mass of nitrogen or phosphorus into and out of a river or reservoir reach. Nutrient budgets use a data-driven empirical approach and characterize the net nutrient results of all the processes occurring within the river or reservoir. This approach provides a useful complement to the mechanistic modeling approach used in the Klamath River TMDL model since nutrient budgets do not require numerous assumptions about individual processes (e.g., nutrient uptake rates by periphyton) and interactions between processes (e.g., oxidation of ammonia to nitrate and nutrient uptake by periphyton). Comparison of the results from the two different approaches provide a verification of the accuracy of the nutrient estimate from each approach and an overall more robust analysis of the potential impacts under the Proposed Project. Although the existing nutrient budget for the Klamath River (Asarian et al. 2009, 2010) is relatively spatially coarse as compared with the mechanistic KRWQM, the nutrient budget approach is based on measurements at the boundaries of each reach being modeled and thus is not inherently less accurate than a model that relies on assumptions about nutrient uptake and release mechanisms at a smaller spatial scale.

Please refer to Asarian et al. (2009, 2010) for more details on the nutrient budget approaches summarized in Section 3.2.4.3 *Water Quality – Impact Analysis Approach – Nutrients*, including the technical appropriateness of the nutrient budget approach, refinements to the nutrient budget approach used to address comments from PacifiCorp (2006) and others on an initial nutrient budget analysis, a quantification of the uncertainty associated with the approach, and a comparison of the estimated nutrient budget results with other literature studies. Contrary to the commenter’s assumption of an annual or monthly time-scale, daily nutrient concentrations and loads were estimated in the nutrient budget using multiple regression modeling methods along with the available nutrient and hydrologic measurements (Asarian et al. 2009, 2010). Volume III Attachment 1 presents the final Section 3.2 *Water Quality*.

Comment ORG46-124

The TMDL modeling results are not an appropriate basis for comparing alternatives (see comment 3.2-34).

Response to Comment ORG46-124

Aside from the concerns related to the use of the Klamath River Total Maximum Daily Load (TMDL) model in the EIR analysis that are discussed in Master Response WQ-5, the EIR states that both the Klamath River Water Quality Model (KRWQM) and the Klamath River TMDL model include a scenario that is similar to existing conditions (i.e., with the Lower Klamath Project dams in place) and scenarios with one or more dams removed that are similar to the Proposed Project and/or alternatives analyzed in Section 4 *Alternatives*. While the TMDL modeling results do not include scenarios that exactly reflect the Proposed Project and/or the alternatives, the TMDL model results are still informative with respect to the analyses of water quality parameters presented in the EIR. Section 4 *Alternatives* notes in several locations (i.e., pages 4-186, 4-194, 4-198, 4-250, 4-257, 4-261, 4-262) that the TMDL model results are still informative with respect to the analyses, even though the assumptions inherent to the TMDL models are necessarily different than the existing conditions baseline for the CEQA analysis of the Proposed Project and the alternatives.

Please also refer to responses to comments ORG46-422 and ORG46-424 for discussion of how the assumption of TMDL compliance is considered in the alternatives analysis.

Comment ORG46-125

Rather than explain why the State Water Board believes that the Klamath River TMDL model over-predicts chlorophyll-a for a dam removal scenario, the DEIR simply states "Instead, this EIR's chlorophyll-a impact analysis is based on a qualitative assessment of whether the Proposed Project would result in exceedances of the California 10 µg/L [sic] target for the Lower Klamath Project reservoirs and adversely affect beneficial uses with respect to water column concentrations of chlorophyll-a." The numerical endpoints analysis used in the DEIR is inadequate to assess a "without dams" condition because it does not address the conversion of inorganic nutrients to periphyton and macrophyte biomass in the Klamath River from J.C. Boyle Reservoir to Iron Gate Dam. Periphyton and macrophyte growth will be extensive in this reach due to nutrients from upstream reaches (Upper Klamath Lake and Keno reservoir). Senescence, reproductive processes, sloughing, grazing, and scour of the bed community (periphyton and macrophytes), coupled with phytoplankton release from Upper Klamath Lake and Keno reservoir, have not been addressed in the DEIR.

The assumed timeline to achievement of the TMDL is unclear in the DEIR. Upper Klamath Lake is not expected to achieve compliance with the Upper Klamath Lake TMDL for decades (ODEQ 2002, 2018). Further, even under a future TMDL compliance scenario, compliance at Upper Klamath Lake will not occur in every year. Specifically, very large fluxes of organic matter would still be periodically released into the river from Upper Klamath Lake. According to studies upon which the Upper Klamath Lake TMDL analysis was based, very large fluxes would still occur 2 out of every 8 years after the TMDL measures are achieved (OOEQ 2002). These large nutrient and organic matter fluxes from Upper Klamath Lake are not explicitly considered in the DEIR's analysis. Certainly, DEIR long-term impacts (3 years or more into the future) will occur simply as a result of the decades it will take to achieve TMDL compliance. This point is made in the DEIR (pg. 3-80, paragraph 1): "Note that the Klamath River TMDL model for both "dams-in" and "dams-out" scenarios assumes full *implementation of the TMDLs, a condition that is currently highly speculative with respect to the mechanisms and timing required to achieve future compliance."*

The DEIR should clarify the rationale for the use of chlorophyll-a as a surrogate to address toxin producing algae. As stated in the DEIR "chlorophyll-a target of 10 µu/L [sic] (i.e., reduction to) is a conservative estimate of mean summer chlorophyll-a concentrations required to move the system toward support of beneficial uses." These beneficial uses extend beyond toxin-producing algae.

Response to Comment ORG46-125

Comparison of the Klamath River Total Maximum Daily Load (TMDL) modeled and measured chlorophyll-*a* concentrations under existing conditions indicates that the Klamath River TMDL model over-predicts chlorophyll-*a* concentrations, including multiple peaks in modeled chlorophyll-*a* that are not observed in the measured chlorophyll-*a* data (Tetra Tech 2009).

Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins* has been revised to correct a typo for the citation to Tetra Tech (2009) that discusses the comparison of modeled and measured chlorophyll-*a* concentrations and to clarify that the Klamath River TMDL model would be likely to over-predict chlorophyll-*a* under the "dams-out" scenario since it over-predicted chlorophyll-*a* under existing conditions. Please refer to Volume III Attachment 1 Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins* for the revisions.

As discussed in Section 3.2.3.1 *Water Quality – Significance Criteria – Thresholds of Significance – Chlorophyll-a and Algal Toxins* and Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins*, the California Klamath River TMDL suspended algae (i.e., phytoplankton) chlorophyll-*a* target (10 micrograms per liter [ug/L]) used as the threshold of significance in the EIR is based on a previous nutrient numeric endpoints (NNE) analysis (Creager et al. 2006; Tetra Tech 2008). There is no direct application of the NNE approach in the EIR. The water quality analysis includes the NNE phytoplankton chlorophyll-*a* target because it is a surrogate measure of the phytoplankton biomass that could have a potential impact on water quality (i.e., algal toxins). Chlorophyll-*a* is considered a surrogate for phytoplankton [algal] biomass since phytoplankton cells contain chlorophyll-*a* and a greater amount of phytoplankton biomass would release a greater amount of chlorophyll-*a* when the cells break apart (i.e., lyse) and degrade. Higher phytoplankton biomass would also potentially correspond to higher algal toxin concentrations if the phytoplankton biomass includes a relatively large proportion of toxin-producing blue-green algae [cyanobacteria] cells. As presented in Appendix C, Section C.6 *Algal Toxins and Chlorophyll-a*, *Microcystis aeruginosa* cell density correlates significantly with microcystin concentrations measured in Copco No. 1 and Iron Gate reservoirs and Klamath River locations (Kann et al. 2010a). Thus, as explained in Section 3.2.4.6 *Water Quality – Impact Analysis Approach –*

Chlorophyll-a and Algal Toxins, in addition to chlorophyll-*a* concentrations, algal toxins are analyzed based on trends in the density of toxin-producing blue-green algae, including *Microcystis aeruginosa*, to algal toxin concentrations. Volume III Attachment 1 presents the final Section 3.2 *Water Quality.*

Please refer to Volume I Section 3.4.5 *Phytoplankton and Periphyton – Potential Impacts and Mitigation* (pages 3-426 to 3-440) for analysis of the potential changes in phytoplankton and periphyton abundance and extent in the Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary under the Proposed Project. Periphyton and macrophyte colonization and growth in the new free-flowing river portions of the Hydroelectric Reach would potentially contribute to chlorophyll-*a* concentrations, but there is not sufficient information or models available at this time to quantitively predict the changes in chlorophyll-*a* concentrations from potential periphyton and macrophyte growth under the Proposed Project. Accordingly, Volume I Section 3.4.5 *Phytoplankton and Periphyton – Potential Impacts and Mitigation* (pages 3-426 to 3-440) analyzes the potential changes in periphyton and macrophyte abundance directly rather than using chlorophyll-*a* as a surrogate for periphyton or macrophyte abundance. Please also refer to responses to comments ORG46-33, ORG46-34, ORG46-36, ORG46-89, ORG46-95, ORG46-97, ORG46-99, ORG46-108, ORG46-136, ORG46-137, ORG46-146, ORG46-147, ORG46-149 for further discussion of potential periphyton and macrophyte growth in the Klamath River under the Proposed Project.

Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins* have been revised to clarify that the chlorophyll-*a* target is based on phytoplankton chlorophyll-*a*. Please refer to Volume III Attachment 1 Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins* for the revisions.

As explained in Section 3.2.4.6 *Water Quality – Impact Analysis Approach – Chlorophyll-a and Algal Toxins*, the Klamath River TMDL model results are not used in the analysis of potential impacts to chlorophyll-*a* and algal toxins under the Proposed Project and the analysis in Potential Impact 3.2-12 does not rely on achieving TMDL compliance. Please refer to Master Response WQ-5 for discussion of the Klamath River TMDL model results for other water quality parameters.

Episodic large fluxes of organic matter and associated chlorophyll-*a* are part of existing conditions, so data from 2002 to 2010 analyzed in the EIR would characterize these large fluxes. Please also refer to response to comment ORG46-107 for additional summary of Klamath Hydropower Settlement Agreement (KHSA) Interim Measure 15 (IM 15) chlorophyll-*a* data from 2000 to 2017 that would characterize the episodic large fluxes from upstream of the Hydroelectric Reach. Chlorophyll-*a* concentrations measured upstream of J.C. Boyle Reservoir, including episodic large fluxes of chlorophyll-*a* associated with algae, are generally similar or less than chlorophyll-*a* concentrations in Copco No. 1 and Iron Gate reservoirs and downstream of Iron Gate Dam under existing conditions. The Proposed Project does not include any changes to Klamath River conditions upstream of J.C. Boyle Reservoir, so chlorophyll-*a* concentrations measured at the upstream extent of J.C. Boyle Reservoir would represent the maximum chlorophyll-*a* concentrations entering the Hydroelectric Reach under the Proposed Project. Turbulent-mixing conditions in the river are expected to continue to decrease chlorophyll-*a* concentrations in the Hydroelectric Reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir under the Proposed Project, as is the case under existing conditions. The conversion of the reservoirs to free-flowing, turbulent river reaches would likely result in a slight decrease in chlorophyll-*a* through the Hydroelectric Reach under the Proposed Project compared to under existing conditions. Thus, chlorophyll-*a* concentrations in the Hydroelectric Reach due to transport of chlorophyll-*a* into this reach from upstream sources, including episodic large fluxes, would be similar to or less than existing conditions under the Proposed Project.

Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* Potential Impact 3.2-12 has been revised to clarify that the chlorophyll-*a* concentrations in the Hydroelectric Reach due to transport of chlorophyll-*a* into this reach from upstream sources, including chlorophyll-*a* from Upper Klamath Lake and episodic large fluxes from the Lake Ewauna/Keno Impoundment, would be similar to or less than existing conditions under the Proposed Project. Please refer to Volume III Attachment 1 Section 3.2.5.6 *Water Quality – Potential Impacts and Mitigation – Chlorophyll-a and Algal Toxins* for the revisions.

With respect to the comment regarding organic matter and nutrients entering the Hydroelectric Reach from upstream sources, Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-6 provides an analysis of the algal-derived (organic) suspended material, including an explicit consideration of the episodic large fluxes of suspended material (i.e., organic matter) from upstream of the Hydroelectric Reach, including Upper Klamath Lake. Section 3.2.5.3 *Water Quality – Potential Impacts and Mitigation – Nutrients* Potential Impact 3.2-8 provides an analysis of long-term nutrient conditions in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean Nearshore Environment under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment ORG46-126

The DEIR states "The KRWQM did not model water temperatures within the Hydroelectric Reach." This statement is incorrect because the KRWQM did model water temperature in this reach. The KRWQM model was developed for the Klamath River system from Link River Dam, near Klamath Falls (RM 254) to

Turwar (RM 6), and includes existing Klamath Hydroelectric Project facilities, as well as a without dam representation (including alternatives with selected dams removed and others retained). However, the TMDL model that was adapted from the original KRWQM by the North Coast Regional Water Quality Control Board, has an error that under-predicts water temperature in riverine reaches.

Response to Comment ORG46-126

Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 – *Hydroelectric Reach* has been revised to clarify that documentation of Klamath River Water Quality Model (KRWQM) water temperature results within the Hydroelectric Reach is not available under conditions similar to the Proposed Project (i.e., removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams). Dam removal scenarios modeled by the PacifiCorp (2004a-1) KRWQM were different from the Proposed Project because the two dam removal scenarios removed Keno Dam in addition to J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams. In the PacifiCorp (2004a-1) KRWQM results, there is a difference between the water temperature upstream of J.C. Boyle Reservoir under existing conditions and under removal of Keno, J.C. Boyle, Copco No. 1, Copco No.2, and Iron Gate dams, indicating that removal of Keno Dam would alter the water temperature in the Hydroelectric Reach. There would be no difference in the water temperature upstream of J.C. Boyle Reservoir under existing conditions and under the Proposed Project since the Proposed Project would not alter conditions upstream of J.C. Boyle Reservoir, so the modeled water temperature difference upstream of J.C. Boyle Reservoir between existing conditions and dam removal scenarios demonstrates PacifiCorp (2004a-1) KRWQM results do not characterize water temperature conditions in the entire Hydroelectric Reach under the Proposed Project. PacifiCorp (2005) KRWQM included modeling of conditions similar to the Proposed Project with only the removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, but no model results for the Hydroelectric Reach were presented and the model results were only presented downstream of Iron Gate Dam. While PacifiCorp (2008, 2014) present California Temperature Objective KRWQM model results for locations in the Hydroelectric Reach (i.e., water temperature in the Klamath River under hypothetical removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams increased by 2.8°C), the California Temperature Objective KRWQM results are 7-day average of the maximum water temperatures and they do not describe the hourly or daily variations in water temperature under the Proposed Project. PacifiCorp (2019a) does not present KRWQM water temperature results in the Hydroelectric Reach under dam removal conditions. Please refer to Volume III Attachment 1 Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* for the revisions.

With respect to the comment's concern about how the Total Maximum Daily Load (TMDL) model predicts water temperature in riverine reaches, please refer to Response 10a in Appendix 10 of the Klamath River TMDLs (North Coast

Regional Board 2010), where the North Coast Regional Board explains, in response to a related comment by PacifiCorp, that the TMDL model applied a 20 percent reduction to short-wave solar radiation into riverine segments during model calibration because the solar radiation calculated in the model between J.C. Boyle and Copco No. 1 reservoirs from solar radiations equations that use latitude, longitude, and elevation was approximately 20 percent higher than observed solar radiation. This 20 percent reduction in estimated solar radiation into the riverine segments was justified since the modeled solar radiation equation was not measured data and the adjustment achieved consistency with observed data and more accurate water temperature predictions between J.C. Boyle Dam and Copco No. 1 Reservoir.

Comment ORG46-127

The DEIR erroneously states that "The KRWQM indicates that the overall water temperature influence of the Hydroelectric Reach is mostly attenuated by RM 66.3 at the confluence with the Salmon River (see Figure 3.2-10)." Regarding this statement, PacifiCorp model results (see PacifiCorp 2004a, 2008) show that the thermal effects of the Project reservoirs on water temperatures downstream of Iron Gate Dam (RM 190) progressively diminish until reaching a downstream location where effects are absent. From December through July, the effects are quite small or absent by the time the river reaches the confluence with the Scott River (RM 143.9). In August and November, the effects are small or absent by the time the river reaches Seiad Valley (RM 120), and in September and October, by the time the river reaches the confluence with Clear Creek (RM 95). In no cases does modeling indicate that thermal effects extend to the confluence with the Salmon River.

Response to Comment ORG46-127

Contrary to the comment's assertion, *Section 3.2.5.1 Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 correctly characterizes 2004/2005 Klamath River Water Quality Model (KRWQM) water temperature results, whereby the influence of Iron Gate Dam (river mile [RM] 193.1) releases on Klamath River water temperature are mostly attenuated by the confluence with the Salmon River (RM 66.3). As reported in PacifiCorp (2005), shown in Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Figure 3.2-10, and reproduced below, hourly water temperatures simulated by the 2004/2005 KRWQM and based on 2004 data in the Klamath River upstream of the Salmon River for existing conditions (i.e., with the dams) and without J.C. Boyle (JCB), Copco No. 1 and Copco No. 2 (Copco), and Iron Gate (IG) dams (i.e., the Proposed Project) are not identical. While the differences between modeled Klamath River water temperatures upstream of the Salmon River under existing conditions and without the dams are typically less than 1°C, there are visually obvious differences between these two conditions which supports the EIR statement that Iron Gate Dam releases influence Klamath River water temperature upstream of the confluence with the Salmon

River, especially during spring (i.e., March) and summer through fall (i.e., mid-June to early-November).

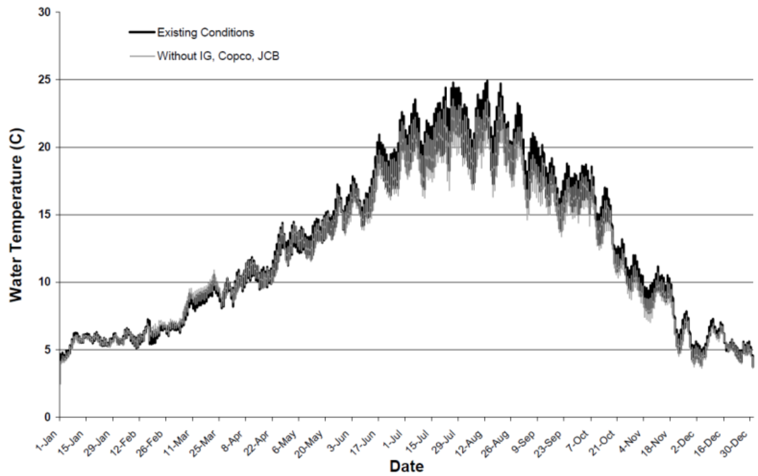


Figure 3.2-10 from Potential Impact 3.2-1. Simulated Hourly Water Temperature in the Klamath River Upstream from the Salmon River (≈RM 66.3) Based on Year 2004 for Existing Conditions Compared to Hypothetical Conditions without J.C. Boyle (JCB), Copco No. 1, Copco No. 2, and Iron Gate (IG) Dams. Source: PacifiCorp 2005.

While not shown in Potential Impact 3.2-1, water temperature results simulated by the 2004/2005 KRWQM in the Klamath River upstream of the Salmon River based on 2000 to 2003 data are also not identical between existing conditions and a dam removal condition (i.e., without Iron Gate, Copco No. 1, and J.C. Boyle dams), further indicating that Iron Gate Dam releases influence water temperature in the Klamath River downstream to the confluence of the Salmon River. For the 2000 to 2003 dataset, the differences between the 2004/2005 KRWQM water temperature results under existing conditions and a without-dams condition are typically less than 1ºC, such that the influence of Iron Gate Dam releases on Klamath River water temperature is mostly attenuated by this location. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

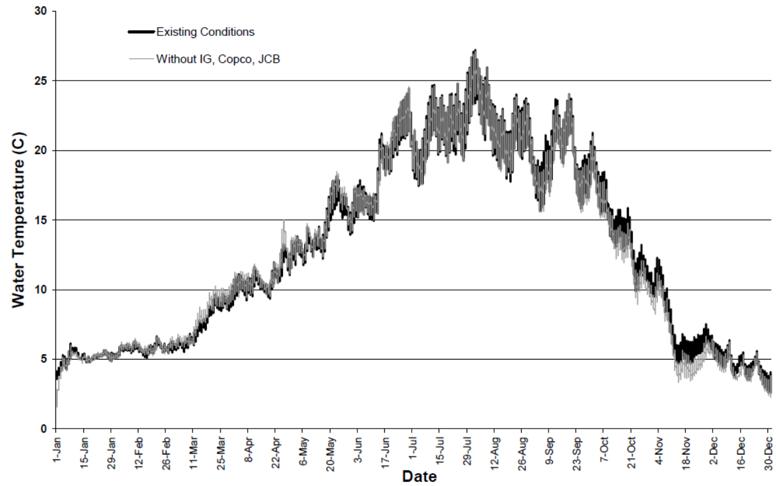

Figure 4-16 from PacifiCorp (2005), Appendix B. Simulated Hourly Water Temperature in the Klamath River Upstream from the Salmon River (≈RM 66.3) Based on Year 2000 for Existing Conditions Compared to Hypothetical Conditions without J.C. Boyle (JCB), Copco No. 1, Copco No. 2, and Iron Gate (IG) Dams.

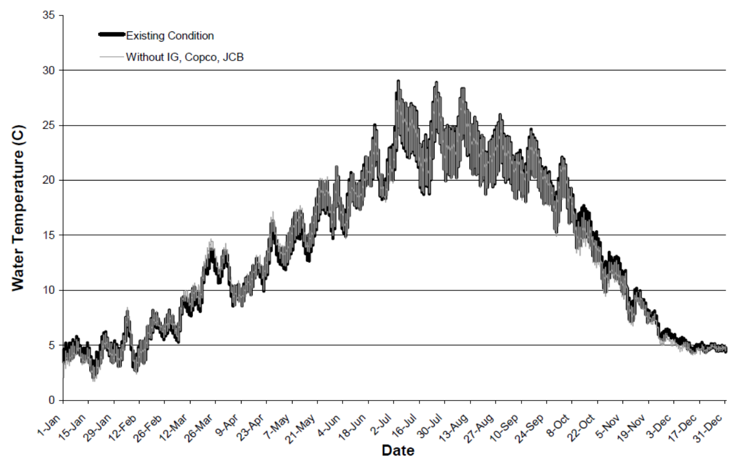

Figure 4-17 from PacifiCorp (2005), Appendix B. Simulated Hourly Water Temperature in the Klamath River Upstream from the Salmon River (≈RM 66.3) Based on Year 2001 for Existing Conditions Compared to Hypothetical Conditions without J.C. Boyle (JCB), Copco No. 1, Copco No. 2, and Iron Gate (IG) Dams.

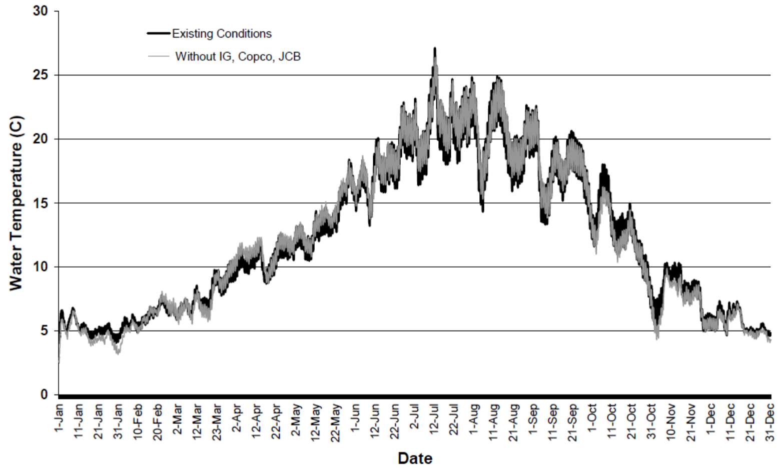

Figure 4-18 from PacifiCorp (2005), Appendix B. Simulated Hourly Water Temperature in the Klamath River Upstream from the Salmon River (≈RM 66.3) Based on Year 2002 for Existing Conditions Compared to Hypothetical Conditions without J.C. Boyle (JCB), Copco No. 1, Copco No. 2, and Iron Gate (IG) Dams.

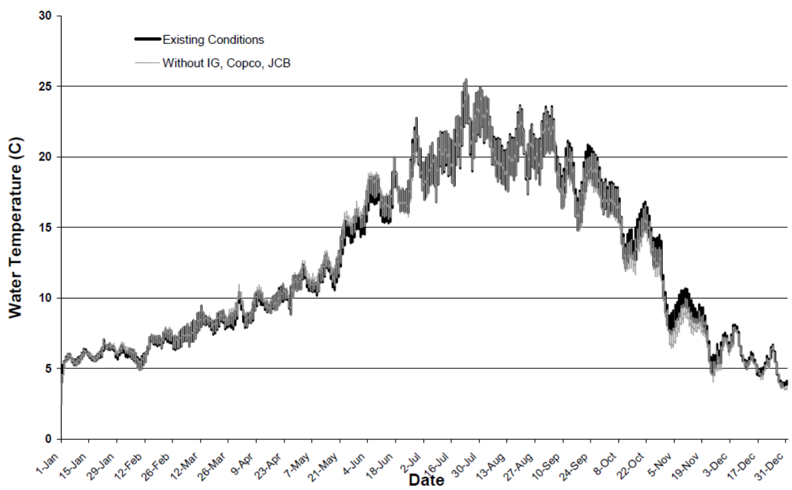

Figure 4-19 from PacifiCorp (2005), Appendix B. Simulated Hourly Water Temperature in the Klamath River Upstream from the Salmon River (≈RM 66.3) Based on Year 2003 for Existing Conditions Compared to Hypothetical Conditions without J.C. Boyle (JCB), Copco No. 1, Copco No. 2, and Iron Gate (IG) Dams.

Additionally, the comment is incorrect to assert “in no cases does modeling [PacifiCorp (2004a-1, 2008a) 2004/2005 KRWQM water temperature results] indicate that thermal effects of Iron Gate Dam releases extend to the confluence with the Salmon River” because KRWQM results from PacifiCorp (2004a-1, 2008a) show Iron Gate Dam releases influencing Klamath River water temperature to the confluence with the Salmon River. In PacifiCorp (2004a-1), the KRWQM was used to model existing conditions (EC), steady flow conditions (i.e., no peaking flows) with the dams remaining in place (Steady Flow [SF]), and without-Project (WOP) conditions that included the removal of Keno Dam in addition to removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams. While the WOP conditions modeled by the KRWQM in PacifiCorp (2004a-1) are different from the Proposed Project, the model results still highlight the influence of Iron Gate Dam releases on downstream water temperature in the Klamath River. As stated in PacifiCorp (2004a-1) Section 4.8.8.2 Temperature (pages 4-79 to 4-84), the "thermal lag effect [of Iron Gate Dam releases] is still evident in the Klamath River just above the Shasta River (RM 177.5) (Figure 4.8-64), but is greatly diminished by Seiad Valley (RM 129) (Figure 4.8-65) and generally absent by the Salmon River (RM 67) (Figure 4.8-66)." As shown in PacifiCorp (2004a-1) Figure 4.8-66 (reproduced below), water temperature differences between the without-Project (i.e., defined as removal of Keno, J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams in PacifiCorp [2004]) and existing conditions (i.e., WOP-EC) are typically less than 1ºC, but there are still differences between the 2004/2005 KRWQM without-Project and existing conditions water temperatures, especially during spring and fall when the differences approach or exceed 1ºC. These water temperature differences indicate releases from Iron Gate Dam are influencing Klamath River water temperature upstream of the Salmon River, although the influence of Iron Gate Dam releases is mostly attenuated.

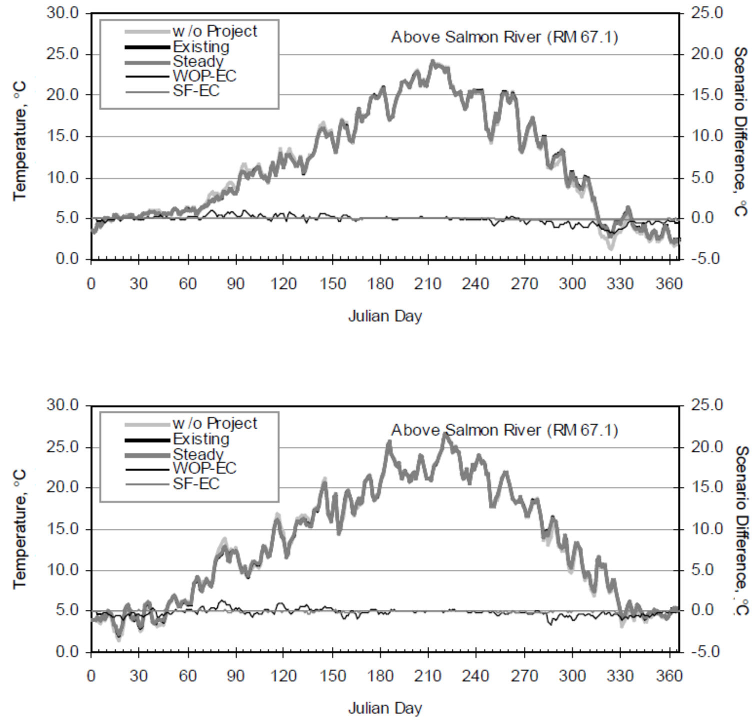

Figure 4.8-66 from PacifiCorp (2004a-1). EC [Existing Conditions] Versus SF [Steady Flow] and WOP [without-Project] Mean Daily Water Temperature in the Klamath River Above the Salmon River for 2000 (top) and 2001 (bottom). Please note that "Without-Project" in PacifiCorp (2004a-1) is defined as removal of Keno, J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams.

PacifiCorp (2008a) Section 5.2.3.3 *Project Contributions – Klamath River Farther Downstream of Iron Gate Dam* (pages 5-73 to 5-79) states that the annual maximum water temperature is generally similar at Seiad Valley and at the Salmon River, indicating that the releases from Iron Gate Dam do not significantly influence or control water temperatures in the Lower Klamath River during summer months, compared to the influence on water temperatures of climatological conditions and downstream inflows from various tributary rivers. However, the KRWQM water temperature results plotted in PacifiCorp (2008) Figure 5.2-24 (page 5-77) indicate that the Klamath River water temperatures at the Salmon River are different under existing conditions (i.e., with dams) and under a hypothetical without-Project condition (i.e., without J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams and powerhouse developments) during parts of the year (i.e., spring and fall), thus there is an influence of Iron Gate Dam releases on Klamath River water temperatures to the confluence with the Salmon River, as stated in Potential Impact 3.2-1. In PacifiCorp (2008) Figure 5.2-24 (reproduced below), KRWQM water temperature results are presented for the PacifiCorp (2008) Proposed Project (i.e., continued operations of the Lower Klamath Project dams with additional measures to enhance water quality and beneficial uses, whereby the PacifiCorp [2008] Proposed Project is different from the Lower Klamath Project), Existing Conditions, and a California Temperature Objective (i.e., no more than 5ºF [2.8ºC] increase in hypothetical without-Project water temperatures [based on model simulations]; labeled as “Objective” in the figure).

While PacifiCorp (2008) Figure 5.2-24 does not present a direct comparison of Klamath River water temperatures at the Salmon River under existing conditions with the dams in place and under hypothetical without-Project conditions (i.e., removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams and powerhouse developments), the “Objective” water temperatures shown in Figure 5.2-24 are the hypothetical without-Project conditions shifted up by 2.8ºC. Thus, a comparison of the PacifiCorp (2008) Figure 5.2-24 Klamath River water temperatures at the Salmon River under existing conditions and the “Objective” water temperatures shifted down by 2.8ºC would ascertain whether there is a difference between KRWQM Klamath River water temperatures at the Salmon River under existing conditions and under dam removal conditions. As shown in Figure ORG46-127-1, the modeled 7-day average of maximum daily water temperatures in the Klamath at the Salmon River under existing conditions, and the “Objective” water temperatures shifted down by 2.8ºC (i.e., the blue lower dashed line) representing the water temperature under dam removal conditions, are not identical, with differences between the water temperatures most evident during spring and fall. While the differences in the 7-day average of maximum daily water temperatures are typically less than 1ºC, there is a visually obvious water temperature difference during portions of the year that indicate Lower Klamath Project (i.e., Iron Gate Dam) releases are influencing Klamath River water temperatures to the confluence with the Salmon River.

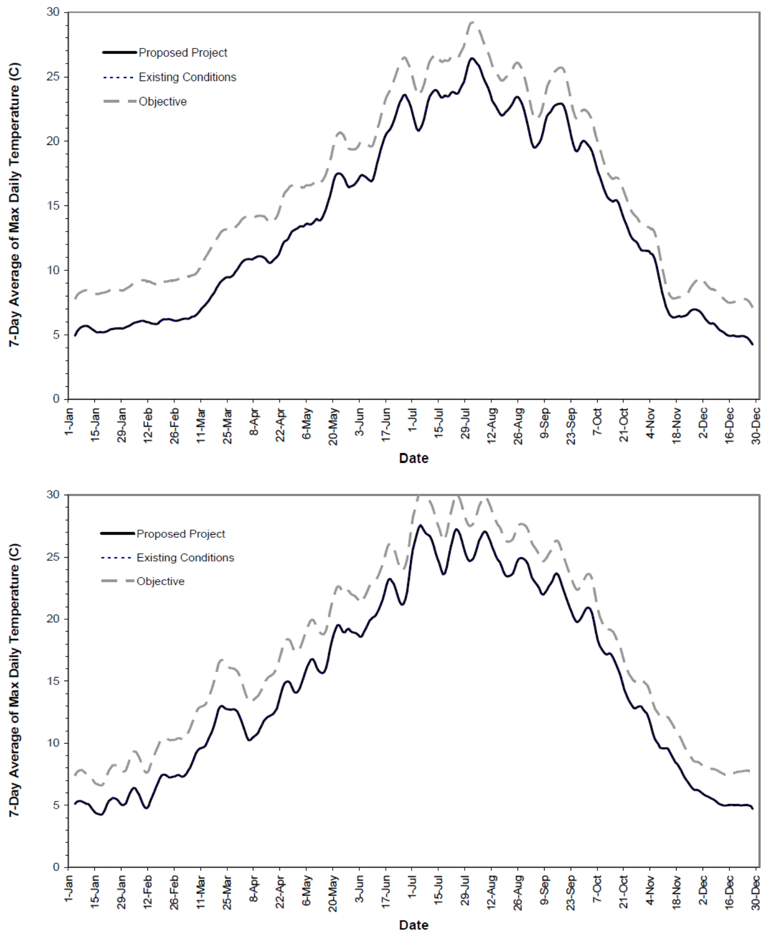

Figure 5.2-24 from PacifiCorp (2008). Time-Series of the 7-Day Average of Maximum Water Temperature (in Degrees C) for the Year 2000 (Top Plot) and 2001 (Bottom Plot) in the Klamath River at the Salmon River, Compared to the California Temperature Objective (i.e., No More Than 5ºF [2.8ºC] Increase Above Hypothetical Without-Project Water Temperatures [Based on Model Simulations]).

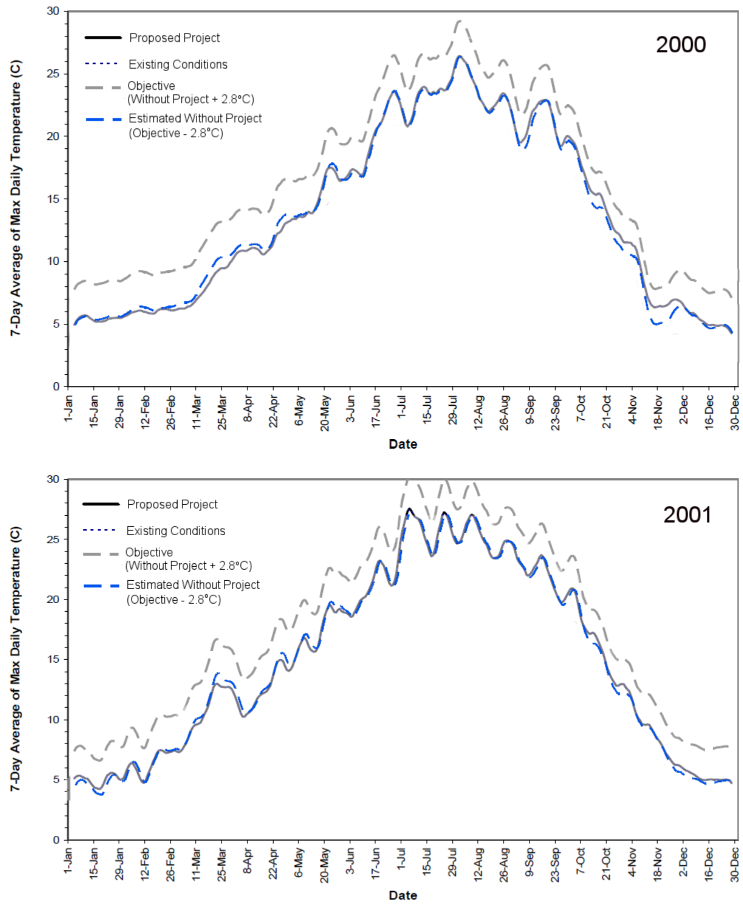

Figure ORG46-127-1 modified Figure 5.2-24 from PacifiCorp (2008). Time-Series of the 7-Day Average of Maximum Water Temperature (˚C) for the Year 2000 (Top Plot) and 2001 (Bottom Plot) in the Klamath River at the Salmon River, Compared to the California Temperature Objective (i.e., No More Than 5˚F [2.8˚C] Increase Above Hypothetical Without-Project Water Temperatures [Based on Model Simulations]) (grey upper dashed line) and the California Temperature Objective shifted 2.8˚C Down to Estimate the Hypothetical Without-Project Water Temperatures (blue lower dashed line).

Additionally, PacifiCorp (2014) presents Klamath River water temperature results at the confluence of the Salmon River from an updated version of the KRWQM in Figure 5.2-25 (reproduced below) for the PacifiCorp (2014) Proposed Project (i.e., continued operations of the Lower Klamath Project dams with additional measures to enhance water quality and beneficial uses, whereby the PacifiCorp [2014] Proposed Project is different from the Lower Klamath Project), Existing Conditions, and a California Temperature Objective (i.e., no more than 5˚F [2.8˚C] increase hypothetical without-Project water temperatures [based on model simulations] where the without-Project is defined as without the J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams and powerhouse developments; labeled as "Objective").

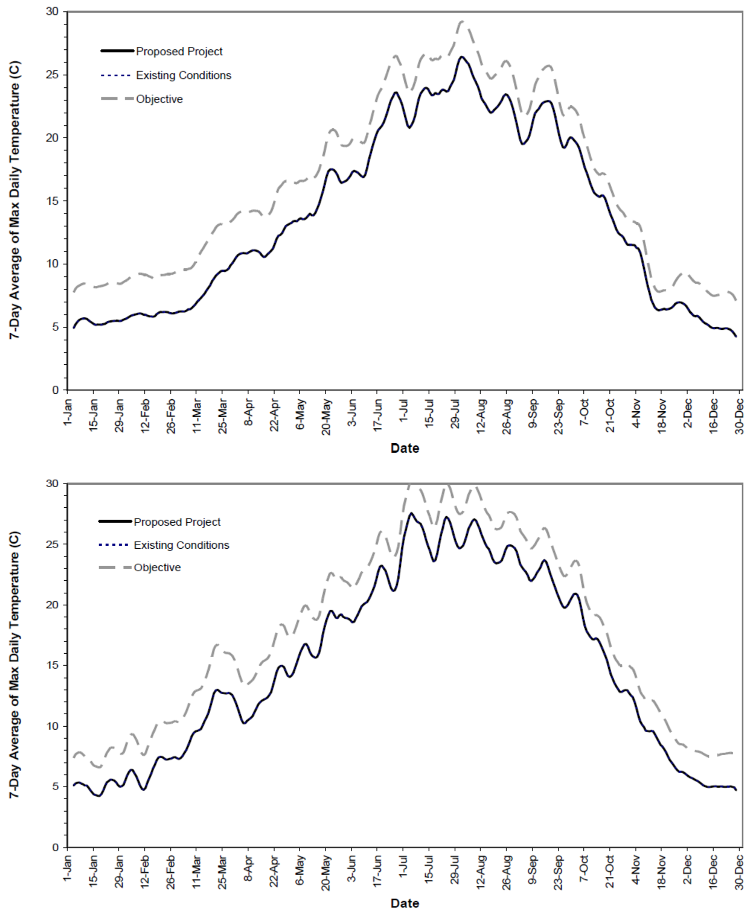

Figure 5.2-25 from PacifiCorp (2014). Time-Series of the 7-Day Average of Maximum Water Temperature (in Degrees C) for the Year 2000 (Top Plot) and 2001 (Bottom Plot) in the Klamath River at the Salmon River, Compared to the California Temperature Objective (i.e., No More Than 5°F [2.8°C] Increase Above Hypothetical Without-Project Water Temperatures [Based on Model Simulations]).

Similar to the previous comparison of PacifiCorp (2008) KRWQM results, a comparison of the PacifiCorp (2014) Figure 5.2-25 Klamath River water temperatures at the Salmon River under existing conditions and the "Objective" water temperatures shifted down by 2.8°C would demonstrate whether there is a difference between the updated 2014 KRWQM water temperature results at the Salmon River under existing conditions and under dam removal conditions. As shown in Figure ORG46-127-2, the PacifiCorp updated 2014 KRWQM 7-day average of maximum daily Klamath River water temperatures at the Salmon River under existing conditions and the "Objective" water temperatures shifted down by 2.8°C (i.e., the blue lower dashed line) are not identical, with differences between the water temperatures being most evident during spring and fall. The differences are typically less than 1°C but they do occur during portions of the year, especially November 2000, and these differences indicate that Lower

Klamath Project (i.e., Iron Gate Dam) releases would potentially influence Klamath River water temperatures to the confluence with the Salmon River.

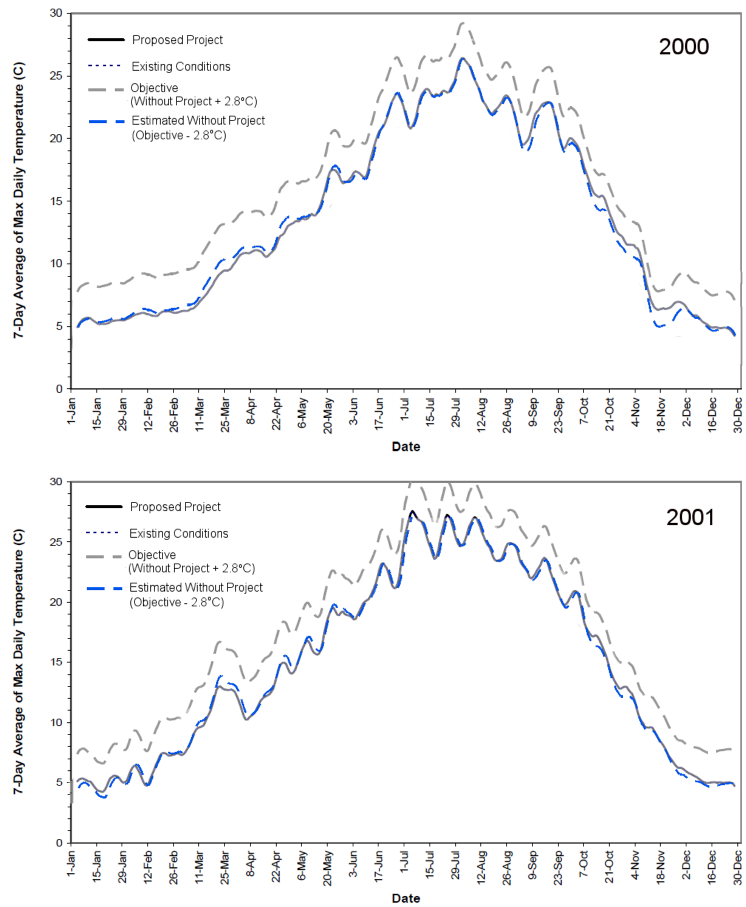

Figure ORG46-127-2 modified Figure 5.2-25 from PacifiCorp (2014). Time-Series of the 7-Day Average of Maximum Water Temperature (°C) for the Year 2000 (Top Plot) and 2001 (Bottom Plot) in the Klamath River at the Salmon River, Compared to the California Temperature Objective (i.e., No More Than 5°F [2.8°C] Increase Above Hypothetical Without-Project Water Temperatures [Based on Model Simulations]) (grey upper dashed line) and the California Temperature Objective shifted 2.8°C Down to Estimate the Hypothetical Without-Project Water Temperatures (blue lower dashed line).

Overall, KRWQM water temperature results from PacifiCorp 2004, 2005, 2008, and 2014 exhibit differences of approximately 1°C or less in Klamath River water temperatures at the confluence with the Salmon River under existing conditions and dam removal conditions during portions of the year. Water temperature differences in the Klamath River at the confluence with the Salmon River between existing conditions and dam removal conditions are most consistently evident across all KRWQM simulations during spring (i.e., March) and fall (i.e., October through November), although the specific time period where water temperature differences exist varies between years. While the differences are relatively small (i.e., approximately 1°C or less), they indicate that Iron Gate Dam releases do influence water temperature conditions to the confluence of the Salmon River during portions of the year (typically spring and fall months) and support the EIR statement that the water temperature influence of the Hydroelectric Reach is mostly attenuated by RM 66.3 at the confluence with the Salmon River. Differences of less than 1°C in KRWQM water temperatures typically in winter (i.e., December through February) and late spring to early fall (i.e., May through September) months suggest that the water temperature influence of Iron Gate Dam releases typically attenuates farther upstream in the Klamath River during these time periods, but interannual variations (i.e., PacifiCorp (2005) 2001 versus 2004/2005 KRWQM results) suggest the influence of Iron Gate Dam releases could extend to the confluence of Salmon River even during some summer to early fall months.

While the comment focused on KRWQM water temperature results, River Basin Model-10 (RBM-10) water temperature modeling results for a 50-year simulation period under existing conditions (i.e., “dams in”) and under removal of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams (i.e., “dams out”) also show a difference in the mean monthly water temperature of greater than 1°C extending downstream of Iron Gate Dam to upstream of the Salmon River during November (Risley et al. 2012).

The consistency of modeled water temperature differences between existing conditions and dam removal scenarios occurring in the Klamath River from Iron Gate Dam to the confluence of the Salmon River during fall conditions across multiple versions of the KRWQM (PacifiCorp 2004, 2005, 2008, 2014) and the RBM-10 model (Risley et al. 2012) provides evidence that the water temperature influence of the Hydroelectric Reach does extend to the confluence with the Salmon River (RM 66.3), and the relatively small magnitude of the water temperature differences (i.e., approximately 1ºC or less) provides evidence that the influence of the Hydroelectric Reach is mostly attenuated by the confluence with the Salmon River.

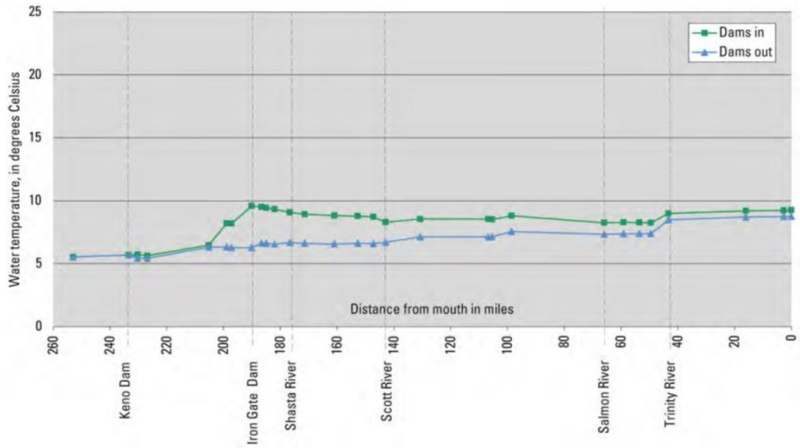

Figure 12 from Risley et al. (2012). Graph Showing Simulated Klamath River Mean November Water Temperatures Using National Marine Fisheries Service 2010 Biological Opinion Flow Requirements as Input Values.

<u>Comment ORG46-128</u>

The DEIR states that water temperatures would be "more favorable for salmonids in the mainstem" under the Proposed Project. This conclusion is not supported by available information either spatially or temporally. PacifiCorp (2008) concludes that the Klamath Hydroelectric Project-related effects on water temperature progressively diminish until reaching a downstream location where effects are absent (see comment 3.2-42). From a temporal perspective, Klamath Hydroelectric Project dams serve to cool water temperatures during the spring months, which may lessen Ceratonova shasta (C. shasta) severity in the reach of the river downstream of Iron Gate Dam. Klamath Hydroelectric Project dams also reduce summer peak water temperatures, which decreases stress on salmonids (see Figure 3.2-8).

The DEIR asserts that "...fall-run Chinook salmon spawning in the mainstem Klamath River during fall would no longer be delayed (reducing pre-spawn mortality), and adult migration would occur in more favorable water temperatures than under existing conditions." This assertion completely ignores the fact that, as discussed above, during fall migration (September-October) the existing Klamath Hydroelectric Project's effects on water temperature are not apparent downstream of the confluence with Clear Creek (RM 95). When fall-run Chinook migration is delayed by water temperatures, the fish are typically downstream of the confluence with the Trinity River (RM 40). Review of water temperature data for locations at Weitchpec and downstream of Iron Gate Dam in September and October illustrates that water temperatures are quite similar. That is, prior to reaching the spawning areas in the vicinity of Iron Gate Dam, fish must first migrate through warm water in the lower Klamath River where water temperature effects from dam removal would not occur (e.g., see "Significance" page 3-82 where it is stated: "No significant impact for the Middle Klamath River downstream from the Salmon River, Lower Klamath River, Klamath"). If *migrating fish are moving past the Trinity River under current conditions without delay, then there would be no additional delay upstream near Iron Gate Dam.*

Response to Comment ORG46-128

Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature* provides a comprehensive spatial assessment (i.e., the analysis is specific to locations within the watershed that relate to key aquatic species distribution and life history) and temporal assessment (i.e., the analysis considers specific seasons that relate to key aquatic resource life history events) of aspects of the Proposed Project that are predicted to provide more favorable water temperature conditions for salmonids, as well as those aspects of the Proposed Project that would not improve water temperature conditions for salmonids. As discussed in the section, cooler water temperatures in fall are predicted to result in earlier spawning by fall run Chinook salmon downstream of Iron Gate Dam. This relationship between water temperature and spawning timing is distinct from the relationship between water temperature and migration in the lower Klamath River that the commenter raises. Please refer to Volume III Attachment 1 for the final Section 3.3 *Aquatic Resources*.

Please also refer to response to comment ORG46-127, which affirms that the Lower Klamath Project effects on water temperature in the mainstem river are apparent to the confluence with the Salmon River (river mile [RM] 66.3).

Comment ORG46-129

The DEIR states "The return to a more natural thermal regime compared with existing conditions would align better with the California Thermal Plan's prohibition on increased temperature discharges above natural temperatures and would be beneficial." Natural temperatures in certain reaches could lead to elevated temperatures at critical times of the year. (e.g., spring outmigration). This is also a condition that could be exacerbated by climate change, as noted on page 3-81 (paragraph 2): "...water temperatures in the Upper Klamath Basin are expected to increase on the order of 2°F to 5°F between 2012 and 2061." The DEIR should explain the risk that the future thermal regime, even if more natural, might not support current (and desired) beneficial uses (e.g., salmon populations) under expected climate change conditions.

The DEIR should recognize the limitation of the TMDL assessment in that temperature criteria (as well as other constituents) are based on only a single year (2000). There is no hydrology or meteorology variability assessed in the TMDL. Year 2000 is neither a particularly wet nor a particularly dry hydrologic year. Under more variable dry or wet year conditions, it is unclear if temperature targets can be met. This is a serious limitation of the TMDL that is not addressed in the DEIR.

Response to Comment ORG46-129

Section 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* Potential Impact 3.2-1 has been revised in Volume III Attachment 1 to clarify the Chinook Salmon Expert Panel conclusion that removal of the Lower Klamath Project dams offers greater potential than the existing conditions for Chinook salmon to tolerate climate change even with River Basin Model-10 (RBM-10) modeled warming under the combined effects of the Proposed Project and climate change. Please refer to Volume III Attachment 1 3.2.5.1 *Water Quality – Potential Impacts and Mitigation – Water Temperature* for the revisions.

Comment ORG46-130

The DEIR states "Warmer springtime temperatures would result in fry emerging earlier, encountering favorable temperatures for growth sooner than under existing conditions, which could support higher growth rates and encourage earlier outmigration downstream, similar to what likely occurred under historical conditions, and reduce stress and disease." This statement regarding the effects of water temperatures on egg development and fry emergence is incorrect (see comment 3.3-55 and Major Issue 2.9.4). Additionally, elevated temperatures could exacerbate disease effects on fish. The DEIR should clarify the importance of the natural variability of thermal condition in the spring period. Water temperatures respond to meteorological conditions in a highly variable manner with spring period conditions experiencing both cool (e.g., high snowmelt runoff years) and warm (e.g., drought years) spells. Thus, fish may remain upriver later in cool to moderate spring weather conditions, only to be caught far from the ocean when warmer weather conditions occur later in the spring. The DEIR's qualitative assessment is overly simplistic to accurately represent the complexities of water temperature and fish movement.

Response to Comment ORG46-130

Section 3.3.5.4 *Aquatic Resources – Potential Impacts and Mitigation – Water Temperature* provides an analysis of the potential influence of warmer water on salmonids, including egg development and fry emergence under the Proposed Project. Please refer to Volume III Attachment 1 for the final Section 3.3. *Aquatic Resources*. Please also refer to response to comments ORG46-19 and ORG46-212 for additional discussion of how the EIR analyzes temperature-related impacts to salmonids.

Comment ORG46-131

The DEIR claims that the predicted suspended sediment concentrations during Proposed Project reservoir drawdowns are conservative, but this claim relies on extrapolation of model results and does not include the effects of bank slumping or sediment jetting. The realized short-term suspended sediment concentrations could be higher and extend for a longer period of time.

Response to Comment ORG46-131

Potential Impact 3.2-3 presents a conservative estimate of the *short-term impacts* of suspended sediment releases rather than a conservative estimate of the suspended sediment concentrations (SSCs) under the Proposed Project. As discussed in Section 3.2.4.2 *Water Quality – Impact Analysis and Approach – Suspended Sediments* and Section 3.2.5.2 *Water Quality – Potential Impacts and Mitigation – Suspended Sediments* Potential Impact 3.2-3, the analysis of the short-term impacts of suspended sediment releases under dam removal are conservative because variations between the drawdown rates and sediment jetting would likely result in a shorter duration of SSCs greater than the magnitude of the SSC threshold of significance (i.e., 100 mg/L) under the Proposed Project than estimated by USBR (2012a) modeling. The higher drawdown rates and sediment jetting proposed by Klamath River Renewal Corporation (KRRC) would result in relatively more erosion of the total reservoir sediment deposit during the drawdown period (i.e., November of dam removal year 1 to March 15 of dam removal year 2), rather after the drawdown period (i.e., after March 15 of drawdown year 2). Although peak SSCs during drawdown would increase compared to USBR (2012a) modeled SSCs given a higher drawdown rate and sediment jetting, the USBR (2012a) modeled SSCs during drawdown already exceed the magnitude of the SSC threshold of significance and the expected increase in SSCs with a higher drawdown rate and sediment jetting would not alter the overall impact from SSCs in the Klamath River. Additionally, the transport of a higher percentage of the total erodible reservoir sediments during drawdown would reduce the amount of reservoir sediments transported and SSCs in the Klamath River after drawdown. Thus, USBR (2012a) model estimates of SSCs with a lower drawdown rate and no sediment jetting are likely to represent an overestimate of the duration of SSCs greater than 100 mg/L and the duration of short-term impacts from SSCs due to dam removal compared to the Proposed Project.

Overall, Potential Impact 3.2-3 considers that a higher reservoir drawdown rate and sediment jetting would increase peak SSCs over those modeled in USBR (2012a), and it also considers that a higher reservoir drawdown rate and sediment jetting would decrease the duration of SSCs greater than the SSC threshold of significance (i.e., 100 milligram per liter [mg/L]) relative to that modeled by USBR (2012a); thus the analysis provides a conservative estimate of the *short-term impacts* due to elevated SSCs in the Klamath River. Additionally, USBR (2012a) model results do not include potential reductions in SSCs due to vegetation growth on reservoir sediments, so USBR (2012a) modeled SSCs potentially overestimate the actual SSCs under the Proposed Project during the winter following dam removal (i.e., late-dam removal year 2 through early post-dam removal year 1). As such, the analysis of USBR (2012a) modeled SSCs during the winter following dam removal also would result in a conservative estimate of short-term impacts from SSCs in the Klamath River. Please refer to Volume III Attachment 1 for the final Section 3.2 *Water Quality*.

Comment ORG46-132

The DEIR acknowledges that sediment jetting could potentially increase the amount of sediment discharged from the reservoirs but fails to specifically quantify this or discuss the effects of this in the DEIR. Because sediment jetting would occur during drawdown, reservoir sediments may not yet have dewatered or consolidated sufficiently for the sediments to be stable. Thus, sediment jetting, which the DEIR states could mobilize up to 34 and 41 percent of expected sediment erosion in Copco and Iron Gate reservoirs, respectively, could increase sediment delivery to the river if it induces slope and bank failures in areas of the reservoir that were anticipated by USBR (2011) to be stable following drawdown.

Response to Comment ORG46-132

Please refer to Section 3.2.5 *Water Quality – Potential Impacts and Mitigation* Potential Impact 3.2-3 for an estimate of the potential maximum and minimum sediment volume that could be transported by sediment jetting during reservoir drawdown and an estimate of the changes in suspended sediment concentrations (SSCs) due to sediment jetting. Table 3.2-12 in Potential Impact 3.2-3 presents estimates of the potential range of sediment volume that would be transported by sediment jetting during drawdown and compares this sediment volume with the potential range of total 2020 sediment volume anticipated to erode under dam removal. Sediment jetting would be undertaken to support the natural erosion of reservoir sediment during reservoir drawdown, at a time when potential water quality impacts from elevated SSCs would already be occurring under the Proposed Project, and would decrease the potential for erosion to occur after drawdown concludes. Sediment jetting would primarily transport reservoir sediment deposits that are already considered to be erodible during drawdown (USBR 2012a).
